The diagram above shows the default search direction, from the "left" (lower point numbers) of the wave toward the "right" (higher point numbers).

The *startLevel* and *endLevel* values define the base levels of the edge. You can explicitly set these levels with the */L=(startLevel,endLevel)* flag or you can let EdgeStats find the base levels for you by using the */A=avgPts* flag which averages points around *startX* and *endX*.

Given *startLevel* and *endLevel* and a *frac* value (see the */F=frac* flag) EdgeStats defines level1, level2 and level3 as shown in the diagram above. With the default *frac* value of 0.1, level1 is the 10% point, level2 is the 50% point and level3 is the 90% point.

With these levels defined, EdgeStats searches the wave from *startX* to *endX* looking for level2. Having found it, it then searches for level1 and level3. It returns results via variables described below.

EdgeStats sets the following variables:

|                |                                                                                                                            |
|----------------|----------------------------------------------------------------------------------------------------------------------------|
| V_flag         | 0: All three level crossings were found.<br>1: One or two level crossings were found.<br>2: No level crossings were found. |
| V_EdgeLoc1     | X location of level1.                                                                                                      |
| V_EdgeLoc2     | X location of level2.                                                                                                      |
| V_EdgeLoc3     | X location of level3.                                                                                                      |
| V_EdgeLv10     | <i>startLevel</i> value.                                                                                                   |
| V_EdgeLv11     | level1 value.                                                                                                              |
| V_EdgeLv12     | level2 value.                                                                                                              |
| V_EdgeLv13     | level3 value.                                                                                                              |
| V_EdgeLv14     | <i>endLevel</i> value.                                                                                                     |
| V_EdgeAmp4_0   | Edge amplitude ( <i>endLevel</i> - <i>startLevel</i> ).                                                                    |
| V_EdgeDLoc3_1  | Edge width (x distance between point 1 and point 3).                                                                       |
| V_EdgeSlope3_1 | Edge slope (straight line slope from point 1 and point 3).                                                                 |

These X locations and distances are in terms of the X scaling of the named wave unless you use the */P* flag, in which case they are in terms of point number.

The EdgeStats operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details.

## Edit

**Edit** [*flags*] [*columnSpec* [, *columnSpec*]...] [**as** *titleStr*]

The Edit operation creates a table window or subwindow containing the specified columns.

### Parameters

*columnSpec* is usually just the name of a wave. If no *columnSpecs* are given, Edit creates an empty table.

Column specifications are wave names optionally followed by one of the suffixes:

| Suffix | Meaning                           |
|--------|-----------------------------------|
| .i     | Index values.                     |
| .l     | Dimension labels.                 |
| .d     | Data values.                      |
| .id    | Index and data values.            |
| .ld    | Dimension labels and data values. |

If the wave is complex, the wave names may be followed by *.real* or *.imag* suffixes. However, as of Igor Pro 3.0, both the real and imaginary columns are added to the table together — you can not add one without the other — so using these suffixes is discouraged.

**Historical Note:** Prior to Igor Pro 3.0, only 1D waves were supported. We called index values “X values” and used the suffix “.x” instead of “.i”. We called data values “Y values” and used the suffix “.y” instead of “.d”. For backward compatibility, Igor accepts “.x” in place of “.i” and “.y” in place of “.d”.

*titleStr* is a string expression containing the table’s title. If not specified, Igor will provide one which identifies the columns displayed in the table.

### Flags

*/FG=(gLeft, gTop, gRight, gBottom)*

Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window.

The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use \* to specify a default guide name.

Guides may override the numeric positioning set by */W*.

*/HIDE=h* Hides (*h* = 1) or shows (*h* = 0, default) the window.

*/HOST=hcSpec* Embeds the new table in the host window or subwindow specified by *hcSpec*.

When identifying a subwindow with *hcSpec*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

*/I* Specifies that */W* coordinates are in inches.

*/K=k* Specifies window behavior when the user attempts to close it.

*k*=0: Normal with dialog (default).

*k*=1: Kills with no dialog.

*k*=2: Disables killing.

*k*=3: Hides the window.

If you use */K=2* or */K=3*, you can still kill the window using the **KillWindow** operation.

*/M* Specifies that */W* coordinates are in centimeters.

*/N=name* Requests that the created table have this name, if it is not in use. If it is in use, then *name0*, *name1*, etc. are tried until an unused window name is found. In a function or macro, *S\_name* is set to the chosen table name.

*/W=(left,top,right,bottom)*

Gives the table a specific location and size on the screen. Coordinates for */W* are in points unless */I* or */M* are specified before */W*.

When used with the */HOST* flag, the specified location coordinates of the sides can have one of two possible meanings:

When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.

When any value is greater than 1, coordinates are taken to be fixed locations measured in points, or **Control Panel Units** for control panel hosts, relative to the top left corner of the host frame.

### Details

You can not change dimension index values shown in a table. Use the Change Wave Scaling dialog or the **SetScale** operation.

If */N* is not used, Edit automatically assigns to the table window a name of the form "Table*n*", where *n* is some integer. In a function or macro, the assigned name is stored in the *S\_name* string. This is the name you can use to refer to the table from a procedure. Use the **RenameWindow** operation to rename the graph.

### Examples

These examples assume that the waves are 1D.

```
Edit myWave,otherWave // 2 columns: data values from each wave
Edit myWave.id // 2 columns: x and data values
Edit cmplxWave // 2 columns: real and imaginary data values
Edit cmplxWave.i // One column: x values
```

The following examples illustrates the use of column name suffixes in procedures when the name of the wave is in a string variable.

```
Macro TestEdit()
 String w = "wave0"
 Edit $w // edit data values
 Edit $w.i // show index values
 Edit $w.id // index and data values
End
```

Note that the suffix, if any, must not be stored in the string. In a user-defined function, the syntax would be slightly different:

```
Function TestEditFunction()
 Wave w = $"wave0"
 Edit w // no $, because w is name, not string
 Edit w.i // show index values
 Edit w.id // index and data values
End
```

The **DoWindow** operation. For a description of how tables are used, see Chapter II-12, **Tables**.

## ei

### ei(x)

The ei function returns the value of the exponential integral  $Ei(x)$ :

$$Ei(x) = P \int_{-\infty}^x \frac{e^t}{t} dt \quad (x > 0),$$

where  $P$  denotes the principal value of the integral.

**noise****noise(num [, RNG])**

The noise function returns a random value drawn from a uniform distribution having a range of  $[-num, num)$ .

noise returns a complex result if *num* is complex or if it is used in a complex expression. See **Use of noise With Complex Numbers** on page V-195.

The random number generator is initialized using a seed derived from the system clock when you start Igor. This almost guarantees that you will never get the same sequence twice. If you want repeatable “random” numbers, use **SetRandomSeed**.

The optional parameter *RNG* selects one of three pseudo-random number generators.

If you omit the *RNG* parameter, gnoise uses *RNG* number 3, named "Xoshiro256\*\*". This random number generator was added in Igor Pro 9.00 and is recommended for all new code. In earlier versions of Igor, the default was 1 (Linear Congruential Generator).

The available random number generators are:

| <i>RNG</i> | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1          | <p>Linear Congruential Generator by L'Ecuyer with added Bayes-Durham shuffle. The algorithm is described in <i>Numerical Recipes</i> as the function <code>ran2()</code>. This option has nearly <math>23^2</math> distinct values and the sequence of random numbers has a period in excess of <math>10^{18}</math>.</p> <p>This <i>RNG</i> is provided for backward compatibility only. New code should use <i>RNG</i>=3 (Xoshiro256**).</p>                                       |
| 2          | <p>Mersenne Twister by Matsumoto and Nishimura. It is claimed to have better distribution properties and period of <math>2^{19937}-1</math>.</p> <p>See Matsumoto, M., and T. Nishimura, Mersenne Twister: A 623-dimensionally equidistributed uniform pseudorandom number generator, <i>ACM Trans. on Modeling and Computer Simulation</i>, 8, 3-30, 1998.</p> <p>This <i>RNG</i> is provided for backward compatibility only. New code should use <i>RNG</i>=3 (Xoshiro256**).</p> |
| 3          | <p>Xoshiro256** by David Blackman and Sebastiano Vigna. It has a period of <math>2^{256}-1</math>, is 4 dimensionally equidistributed and passes all statistical tests at the time of writing.</p> <p>For technical details, see "Scrambled linear pseudorandom number generators", 2019 (<a href="http://vigna.di.unimi.it/ftp/papers/ScrambledLinear.pdf">http://vigna.di.unimi.it/ftp/papers/ScrambledLinear.pdf</a>).</p>                                                        |

**Use of noise With Complex Numbers**

noise returns a complex result if *num* is complex or if it is used in a complex expression.

```
Function DemoENoiseComplex()
 // noise(rv) in a complex expression returns a complex result
 // and is equivalent to cplx(noise(rv),noise(rv))
 Variable rv = 1 // A real variable
 SetRandomSeed 1
 Variable/C cv1 = noise(rv) // Real parameter, complex result
 SetRandomSeed 1
 Variable/C cv2 = cplx(noise(rv),noise(rv)) // Equivalent
 Print cv1, cv2
```

## EqualWaves

---

```
// enoise(cv) is equivalent to cmplx(enoise(real(cv)),enoise(imag(cv)))
Variable/C cv = cmplx(1,1) // A complex variable
SetRandomSeed 1
Variable/C cv3 = enoise(cv) // Complex parameter, complex result
SetRandomSeed 1
Variable/C cv4 = cmplx(enoise(real(cv)),enoise(imag(cv))) // Equivalent
Print cv3, cv4
End
```

### Example

```
// Generate uniformly-distributed integers on the interval [from,to] with from<to
Function RandomInt(from, to)
 Variable from, to
 Variable amp = to - from
 return floor(from + mod(abs(enoise(100*amp)), amp+1))
End
```

### See Also

## EqualWaves

**EqualWaves(waveA, waveB, selector [, tolerance])**

The *EqualWaves* function compares *waveA* to *waveB*. Each wave can be of any data type. It returns 1 for equality and zero otherwise.

Use the *selector* parameter to determine which aspects of the wave are compared. You can add *selector* values to test more than one field at a time or pass -1 to compare all aspects.

| <i>selector</i> | Field Compared   |
|-----------------|------------------|
| 1               | Wave data        |
| 2               | Wave data type   |
| 4               | Wave scaling     |
| 8               | Data units       |
| 16              | Dimension units  |
| 32              | Dimension labels |
| 64              | Wave note        |
| 128             | Wave lock state  |
| 256             | Data full scale  |
| 512             | Dimension sizes  |

If you use the selectors for wave data, wave scaling, dimension units, dimension labels or dimension sizes, *EqualWaves* will return zero if the waves have unequal dimension sizes. The other selectors do not require equal dimension sizes.

### Details

If you are testing for equality of wave data and if the *tolerance* is specified, it must be a positive number. The function returns 1 for equality if the data satisfies:

$$\sum_i (\text{waveA}[i] - \text{waveB}[i])^2 < \text{tolerance}.$$

If *tolerance* is not specified, it defaults to  $10^{-8}$ .

If *tolerance* is set to zero and *selector* is set to 1 then the data in the two waves undergo a binary comparison (byte-by-byte).

If *tolerance* is non-zero then the presence of NaNs at a given point in both waves does not contribute to the sum shown in the equation above when both waves contain NaNs at the same point. A NaN entry that is present in only one of the waves is sufficient to flag inequality. Similarly, INF entries are excluded from the tolerance calculation when they appear in both waves at the same position and have the same signs.

If you are comparing wave data (selector =1) and both waves contain zero points the function returns 1.

#### See Also

The **MatrixOp** operation equal keyword.

## erf

**erf(num [, accuracy])**

The erf function returns the error function of *num*.

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt.$$

Optionally, *accuracy* can be used to specify the desired fractional accuracy.

In complex expressions the error function is

$$\text{erf}(z) = \frac{2z}{\sqrt{\pi}} {}_1F_1\left(\frac{1}{2}; \frac{3}{2}; -z^2\right),$$

where

$${}_1F_1\left(\frac{1}{2}; \frac{3}{2}; -z^2\right)$$

is the confluent hypergeometric function of the first kind HyperG1F1. In this case the accuracy parameter is ignored.

#### Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to  $10^{-7}$ , that means that you wish that the absolute value of  $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$  be less than  $10^{-7}$ .

For backwards compatibility, in the absence of *accuracy* an alternate calculation method is used that achieves fractional accuracy better than about  $2 \times 10^{-7}$ .

If *accuracy* is present, erf can achieve fractional accuracy better than  $8 \times 10^{-16}$  for *num* as small as  $10^{-3}$ . For smaller *num* fractional accuracy is better than  $5 \times 10^{-15}$ .

Higher accuracy takes somewhat longer to calculate. With *accuracy* set to  $10^{-16}$  erf takes about 50% more time than with *accuracy* set to  $10^{-7}$ .

#### See Also

The **erfc**, **erfcw**, **dawson**, **inverseErf**, and **inverseErfc** functions.

## erfc

**erfc(num [, accuracy])**

The erfc function returns the complementary error function of *num* ( $\text{erfc}(x) = 1 - \text{erf}(x)$ ). Optionally, *accuracy* can be used to specify the desired fractional accuracy.

In complex expressions the complementary error function is

$$\text{erfc}(z) = 1 - \text{erf}(z) = 1 - \frac{2z}{\sqrt{\pi}} {}_1F_1\left(\frac{1}{2}; \frac{3}{2}; -z^2\right) \text{ where } {}_1F_1\left(\frac{1}{2}; \frac{3}{2}; -z^2\right)$$

is the confluent hypergeometric function of the first kind HyperG1F1. In this case the accuracy parameter is ignored.

**Details**

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to  $10^{-7}$ , that means that you wish that the absolute value of  $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$  be less than  $10^{-7}$ .

For backwards compatibility, in the absence of *accuracy* an alternate calculation method is used that achieves fractional accuracy better than  $2 \times 10^{-7}$ .

If *accuracy* is present, erfc can achieve fractional accuracy better than  $2 \times 10^{-16}$  for *num* up to 1. From *num* = 1 to 10 fractional accuracy is better than  $2 \times 10^{-15}$ .

Higher accuracy takes somewhat longer to calculate. With *accuracy* set to  $10^{-16}$  erfc takes about 50% more time than with *accuracy* set to  $10^{-7}$ .

**See Also**

The **erf**, **erfcw**, **inverseErfc**, and **dawson** functions.

**erfcw****erfcw(z)**

The erfcw is a complex form of the error function defined by

$$\text{erfcw}(z) = \exp[-z^2] \text{erfc}(-iz),$$

where

$$\text{erfc}(z) = \frac{2}{\sqrt{\pi}} \int_z^{\infty} \exp[-t^2] dt.$$

The function is computed with accuracy of 0.5e-10. It is particularly useful for large  $|z|$  where the computation of  $\text{erfc}(z)$  starts encountering numerical instability.

**See Also**

The **erf**, **erfc**, **inverseErfc**, and **dawson** functions.

**ErrorBars****ErrorBars** [*flags*] *traceName*, *mode* [*errorSpecification*]

The ErrorBars operation adds or removes error bars to or from the named trace in the specified graph and modifies error bar settings.

The "error bars" are lines that extend from each data point to "caps". The length of the line (or "bar") is usually used to bracket a measured value by the amount of uncertainty, or "error" in the measurement.

**Parameters**

*traceName* is the name of a trace on a graph (see **Trace Names** on page II-270).

A string containing *traceName* can be used with the \$ operator to specify *traceName*.

*mode* is one of the following keywords:

|     |                                     |
|-----|-------------------------------------|
| OFF | No error bars.                      |
| X   | Horizontal error bars only.         |
| Y   | Vertical error bars only.           |
| XY  | Horizontal and vertical error bars. |

**BOX** [=fillColor] Box error bars, optionally with fill color expressed as (r,g,b) or (r,g,b,a). If no color is specified, boxes are not filled. The *fillColor* parameter was added in Igor Pro 8.00.

**ELLIPSE**={mode, p, alpha}

Plots error ellipses.

You must provide error values via a three-column wave using the *ewave=ew* error specification described below.

*mode=0*: *ew* contains the standard deviation in X, the standard deviation in Y, and the correlation between X and Y.

*mode=1*: *ew* contains the variance in X, the variance in Y, and the covariance of X and Y.

*p* is the probability level represented by the error ellipses. *p=0.6837*, *p=0.95*, and *p=0.997* represent one, two, and three standard deviations respectively. Larger values of *p* result in larger ellipses corresponding to higher confidence levels.

*alpha* is an opacity value in the range of 0 (fully transparent) to 65535 (fully opaque). See **Error Ellipse Color** on page II-293 for details.

The ellipse mode was added in Igor Pro 9.00.

See **Error Ellipses** on page II-293 for further discussion.

**NOCHANGE** This mode allows you to programmatically change aspects of error bars using flags (see **Flags** below) without affecting the mode or error specification.

The NOCHANGE mode was added in Igor Pro 9.00.

**SHADE**={options, fillMode, fgColor, bkColor [, negFillMode, negFgColor, negBkColor ]}

SHADE was added in Igor Pro 7.00.

*options* is reserved for future use and must be zero.

*fillMode* sets the fill pattern.

*n=0*: No fill.

*n=1*: Erase.

*n=2*: Solid black.

*n=3*: 75% gray.

*n=4*: 50% gray.

*n=5*: 25% gray.

*n>=6*: See **Fill Patterns** on page III-500.

*fgColor* is (r,g,b) or (r,g,b,a). If all zeros including alpha, i.e., (0,0,0,0), then the actual color will be the trace color with an alpha of 20000.

*bkColor* is used for patterns only and can be simply (0,0,0) for solid fills.

*negFillMode* is the same as *fillMode* but for negative error shading.

*negFgColor* is the same as *fgColor* but for negative error shading.

*negBkColor* is the same as *bkColor* but for negative error shading.

The *errorSpecification*, described below, affects only the Y amplitude of error shading.

The X values of the trace to which shading is applied must be monotonic. Results with non-monotonic X values are undefined.

See **Error Shading** on page II-293 for more information and examples. See **Color Blending** on page III-500 for information on the alpha color parameter.

## ErrorBars

---

### Error Specification Parameters

For any mode other than OFF and NOCHANGE, you must provide an error specification which consists of a keyword followed by zero or more parameters:

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pct=value</code>    | <i>value</i> is the length of an error bar expressed as a percentage of the trace X or Y value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>sqrt</code>         | The error bar length is the square root of the trace X or Y value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>const=value</code>  | <i>value</i> is the length of an error bar independent of the trace X or Y value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>ewave=ew</code>     | <i>ew</i> is a three-column wave with error ellipse parameters. Each row represents information for one trace data point. The interpretation of the columns of <i>ew</i> depends on the mode parameter provided with the ELLIPSE keyword:<br><i>mode=0</i> : <i>ew</i> contains the standard deviation in X, the standard deviation in Y, and the correlation between X and Y.<br><i>mode=1</i> : <i>ew</i> contains the variance in X, the variance in Y, and the covariance of X and Y.<br><i>ew</i> may include a subrange specification as long as it results in effectively a 2D wave with three columns and a row for each trace data point. See <b>Subrange Display Syntax</b> on page II-309.<br>See <b>Error Ellipses</b> on page II-293 for further discussion. |
| <code>wave=(w1,w2)</code> | Each error bar length is obtained from the corresponding point of wave <i>w1</i> for negative bars and from wave <i>w2</i> for positive bars.<br>If you omit <i>w1</i> no negative bars are drawn. If you omit <i>w2</i> no positive bars are drawn.<br>You can use subrange syntax for <i>w1</i> and <i>w2</i> . See <b>Subrange Display Syntax</b> on page II-309.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>mulWave = ew</code> | Each error bar length is computed from a multiplier taken from the corresponding point of a wave <i>ew</i> . If your trace wave is <i>tw</i> , the error bar lengths are computed as:<br>positive error bar length = $tw * (ew - 1)$<br>negative error bar length = $tw * (1 - 1/ew)$<br>This is appropriate if you have computed geometric mean and standard deviation, as would be appropriate for errors with lognormal distribution. Such error bars appear symmetrical on a log axis.<br>The values in <i>e</i> must be greater than or equal to 1. Values less than 1 result in the error bar not be displayed for that data point. An error value of exactly 1 results in a zero-length error bar.<br>The <code>mulWave</code> keyword was added in Igor Pro 9.00. |
| <code>nochange</code>     | Don't change <i>errorSpecification</i> from existing values. <code>nochange</code> allows you to, for instance, change the fill color for the box mode without having to repeat <i>errorSpecification</i> for the X and Y errors. <code>nochange</code> was in Igor Pro 8.00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

See the *Examples* below for examples using *mode* and *errorSpecification*.

*mode* and *errorSpecification* control only the lengths of the horizontal and vertical lines (the "bars") to the "caps". All other sizes and thicknesses are controlled by the flags.

### XY mode Error Bars

#### Flags

- `/CLIP=clip` Sets a distance in points by which error bars are allowed to extend beyond the plot area. If you use the first form, the vertical and horizontal values are both set to *clip*. Use the second form to set horizontal and vertical clipping independently. *clipH* and *clipV* default to 2 points. Values may be negative to restrict error bar drawing to an area inside the plot area. `/CLIP` was added in Igor Pro 9.00.
- `/CLIP={clipH, clipV}`
- `/L=lineThick` Specifies the thickness of both the X and Y error bars drawn from the point on the wave to the caps. If you use the ELLIPSE keyword to draw error ellipses, *lineThick* sets the thickness of the ellipse outline.
- `/RGB=strokeColor` Sets the color of the lines used to draw the error bars. *strokeColor* is expressed as (r,g,b) or (r,g,b,a). The default color, used if you omit `/RGB`, is the same as the color of the trace to which the error bars are attached. `/RGB` was added in Igor Pro 8.00.
- If you use the ELLIPSE keyword, *strokeColor* sets the color of the ellipse outline.
- `/T=thick` Specifies the thickness of both the X and Y error bar “caps”. In box mode, `/T` sets the thickness of the box outline.
- `/W=winName` Changes error bars in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
- When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.
- `/X=xWidth` Specifies the width (height, actually) of the caps to the left or right of the point.
- `/Y=yWidth` Specifies the width of the caps above or below the point.

The thicknesses and widths are in units of points. The thickness parameters need not be integers. Although only integral thicknesses can be displayed exactly on a standard resolution screen, nonintegral thicknesses are produced properly on high resolution devices. Use `/T=0` to completely suppress the caps and `/L=0` to completely suppress the lines to the caps.

#### Details

If a wave specifying error values for *traceName* is shorter than the wave displayed by *traceName* then the last value of the error wave is used for the unavailable points. If a point in an error wave contains NaN (Not a Number) then the half-bar associated with that point is not shown.

#### Examples

```
// X 10% of wave1, Y is 5% of wave1
ErrorBars wave1, XY pct=10, pct=5

// X error bars only, square root of wave1
ErrorBars wave1, X sqrt
```

## EstimatePeakSizes

---

```
// Y error bars only, constant error value = 4.3
ErrorBars wavel,Y const=4.3

// Error box, 10% in horizontal direction, 5% in vertical direction
ErrorBars wavel,BOX pct=10,pct=5

// Error box filled with blue color having 50% alpha (transparency)
// 10% in horizontal direction, 5% in vertical direction
ErrorBars wavel,BOX=(0,0,65535,32767) pct=10,pct=5

// Change the error box fill to red color having 50% alpha
// without changing the way the errors are computed.
ErrorBars wavel,BOX=(65535,0,0,32767) nochange, nochange

// Y error bars only, wave w1 has errors for Y+ bars
// wave w2 has errors for Y- bars
ErrorBars wavel,Y wave=(w1,w2)

// Y error bars only, same wave for both Y+ and Y-.
// Overrides the trace color to make the error bars black.
ErrorBars/RGB=(0,0,0) wavel,Y wave=(w1,w1)

// Y error bars only, no Y+ error bars, wave w2 has errors for Y- bars
ErrorBars wavel,Y wave=(,w2)

// Turns error bars for wavel off
ErrorBars wavel,OFF
```

### Error Ellipse Example

See [Error Ellipse Example](#) on page II-294.

### See Also

[Error Bars](#) on page II-292, [Trace Names](#) on page II-270, [Programming With Trace Names](#) on page IV-87.

## EstimatePeakSizes

```
EstimatePeakSizes [/B=baseWave] [/X=xWave] [/E=bothEdgesWave] edgePct,
 maxWidth, box, npks, peakCentersWave, peakWave, peakAmplitudesWave,
 peakWidthsWave
```

The EstimatePeakSizes operation estimates the amplitudes and widths of peaks whose estimated centers are given.

The EstimatePeakSizes operation is used primarily by the Igor Technical Note #20 and its variants.

### Parameters

*edgePct* is the percentage of peak height at which the edge is detected, relative to the baseline. It must be between 1 and 99, and is usually 50.

*maxWidth* is the maximum width that will be returned in *peakWidthsWave*, in X coordinates.

*box* is the number of peak values included in the sliding average when smoothing *peakWave* and *baseWave*. If you specify an even number, the next-higher odd number is used.

*npks* is the number of peaks whose sizes are to be estimated. It must be at least 1.

*peakCentersWave* must contain the point numbers of the centers of the peaks and have a length of at least *npks*. The peak sizes are estimated by starting the search for the peak edges from these peak centers. The *i*-th peak center must be stored in *peakCentersWave*[*i*] where *i* ranges from 0 to *npks*-1. The peak center values in *peakCentersWave* must be monotonically increasing or decreasing.

*peakWave* is the input wave containing the peaks.

*peakAmplitudesWave* is an output wave that will contain the baseline-corrected peak amplitudes of the peaks. It must have a length of at least *npks*. The *i*-th peak amplitude is stored in *peakAmplitudesWave*[*i*].

*peakWidthsWave* is an output wave that will contain the widths of the peaks in X coordinates. It must have a length of at least *npks*. The *i*-th peak width is stored in *peakWidthsWave*[*i*].

### Flags

*/B=baseWave*      *baseWave* is subtracted from *peakWave* to compute the derived data which is searched for edges. It must be the same length as *peakWave*.

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/E=bothEdgesWave</code> | <i>bothEdgesWave</i> specifies an already-existing output wave. It must have a length of at least $npks*2$ . The point coordinates of the <i>i</i> -th peak edges are stored in <i>bothEdgesWave</i> [ <i>i</i> *2] and <i>bothEdgesWave</i> [ <i>i</i> *2+1].<br><br>If the X values increase with point number, <i>bothEdgesWave</i> [ <i>i</i> *2] will be greater than <i>bothEdgesWave</i> [ <i>i</i> *2+1], which may defy expectations. |
| <code>/X=xWave</code>         | <i>xWave</i> supplies the X coordinates for the corresponding points in <i>peakWave</i> and <i>baseWave</i> . It must be of the same length as <i>peakWave</i> and must be monotonically increasing or decreasing.                                                                                                                                                                                                                             |

## Execute

**Execute** [/Z] *cmdStr*

The Execute operation executes the contents of *cmdStr* as if it had been typed in the command line.

The most common use of Execute is to call a macro or an external operation from a user-defined function. This is necessary because Igor does not allow you to make such calls directly.

When the /Z flag is used, an error code is placed in V\_flag. The error code will be -1 if a missing parameter style macro is called and the user clicks Quit Macro, or zero if there was no error.

### Flags

/Z           Errors are not fatal and error dialogs are suppressed.

### Details

Because the command line and command buffer are limited to 2500 bytes on a single line, *cmdStr* is likewise limited to a maximum of 2500 executable bytes.

Do not reference local variables in *cmdStr*. The command is not executed in the local environment provided by a macro or user-defined function.

Execute can accept a string expression containing a macro. The string must start with Macro, Proc, or Window, and must follow the normal rules for macros. All lines must be terminated with carriage returns including the last line. The name of the macro is not important but must exist. Errors will be reported except when using the /Z flag, which will assign V\_Flag a nonzero number in an error condition.

### Examples

It is a good idea to compose the command to be executed in a local string variable and then pass that string to the Execute operation. This prints the string to the history for debugging:

```
String cmd
sprintf cmd, "GBLoadWave/P=%s/S=%d \"%s\"", pathName, skipCount, fileName
Print cmd // For debugging
Execute cmd

// Execute with a macro:
Execute "Macro junk(a,b)\rvariable a=1,b=2\r\rprint \"hello from macro\",a,b\rEnd\r"
```

### See Also

**The Execute Operation** on page IV-201 for other uses.

## Execute/P

**Execute/P** [/Q/Z] *cmdStr*

Execute/P is similar to Execute except the command string, *cmdStr*, is not immediately executed but rather is posted to an operation queue. Items in the operation queue execute only when nothing else is happening. Macros and functions must not be running and the command line must be empty.

## ExecuteScriptText

---

### Flags

- `/Q` Command is not printed in the command line or history area.
- `/Z` No error reporting.

### See Also

**Operation Queue** on page IV-276 for more details on using `Execute/P` with the operation queue.

## ExecuteScriptText

**ExecuteScriptText** [*flags*] *textStr*

The `ExecuteScriptText` operation passes your text to Apple's scripting subsystem for compilation and execution or to the Windows command line.

Text produced by the script, including error messages, is returned in the string output variable `S_value`. On Windows, `S_value` is set only if you include the `/B` (execute in background) flag.

### Parameters

*textStr* must contain a valid AppleScript program or Windows command line.

### Flags

- `/B` Execute the script in the background task, i.e., leaving Igor as the active application. If you omit `/B` on Windows, the program invoked by the script becomes the active program. If you include `/B`, Igor remains the active program. `/B` is ignored on Macintosh and the script is always executed in the background.
- `/W=waitTime` *waitTime* is the maximum time in seconds to wait before `ExecuteScriptText` returns. `/W` is accepted on any platform but is supported only on Windows.
- `/UNQ` Removes any leading and trailing double-quote characters from `S_value`. `/UNQ` is useful on Macintosh only and has no effect on Windows. The `/UNQ` flag was added in Igor Pro 7.00.
- `/Z` Include `/Z` if you want to handle errors in your code. Omit it if you want `ExecuteScriptText` to report errors to Igor. See *ExecuteScriptText Error Handling* below for details.

### ExecuteScriptText Error Handling

If you omit the `/Z` flag, if the script returns an error, `ExecuteScriptText` returns the error to Igor and procedure execution stops.

If you include the `/Z` flag then `ExecuteScriptText` sets the `V_flag` output variable to a nonzero value if the script returned an error or to zero if no error occurred. `ExecuteScriptText` does not report the error to Igor so procedure execution continues.

### ExecuteScriptText on Macintosh

Text generated by the script, including error messages, is returned in the `S_value` output string variable.

Prior to Igor Pro 8.00, `S_value` containing a text value was typically quoted. This does not appear to be the case starting with Igor Pro 8 which uses more up-to-date system calls. We recommend that you use the `/UNQ` flag with Igor 7 and later so that you can reliably expect `S_value` to be unquoted.

The `/B` flag (execute in background) is ignored.

The `/W` flag is ignored and `ExecuteScriptText` does not return until the script is finished.

Prior to Igor Pro 8.00, the current directory was always `/` and the `PATH` environment variable was the system default, not the user default (usually `PATH=/usr/bin:/bin:/usr/sbin:/sbin`). Now neither of these is guaranteed to be the case. You should not make any assumptions about the current directory or the value of any environment variable. Use full paths to files and programs whenever you need to provide a path.

## Macintosh Examples

```
// Macintosh: Convert file.PICT to file.GIF
String script = "tell application \"clip2gif\" \"
script += \"to save file \"HD:file.PICT\"\\r\"
ExecuteScriptText/Z script

// Macintosh: Execute a Unix shell command
Function/S DemoUnixShellCommand()
 // Paths must be POSIX paths (using /).
 // Paths containing spaces or other nonstandard characters
 // must be single-quoted. See Apple Technical Note TN2065 for
 // more on shell scripting via AppleScript.
 String unixCmd
 unixCmd = "ls '/Applications/Igor Pro 8 Folder'"

 String igorCmd

 sprintf igorCmd, "do shell script \"%s\"", unixCmd
 Print igorCmd // For debugging only

 ExecuteScriptText/UNQ igorCmd
 Print S_value // For debugging only
 return S_value
End
```

## ExecuteScriptText on Windows

textStr contains the full path to a batch file or the name of an executable file with optional Windows-style path and optional arguments:

```
[path]executableName [.exe] [arg1]...
```

If you omit path and executableName ends with ".exe" or with no extension, Igor locates the executable by searching first the registry and then along the PATH environment variable. If not found, then the Igor Pro Folder directory is assumed. Here is an example of a command consisting of just the name of an executable:

```
ExecuteScriptText "calc" // calc.exe, calculator
```

When calling a batch file or other non-\*.exe file, supply the full path. If the path (or file name) contains spaces, you must quote the path:

```
ExecuteScriptText "\"C:\\Program Files\\my.bat\""
```

The outer double-quotes are consumed by ExecuteScriptText. The inner double quotes, represented by the \" escape sequence, remain in the command passed to the operating system.

Use the /B flag to run the command in the background, keeping Igor as the active application. Omit /B to allow the program launched by the command to become the active program. When executing a batch file, /B prevents the DOS window from appearing.

If you include /B, output from the command is returned via the S\_value output string variable. If you omit /B, S\_value is set to "".

The /W=waitTime flag provides a way to time out if a command takes too long. It is useful when calling non-GUI programs only. For GUI programs, ExecuteScriptText returns as soon as the GUI program starts processing events, regardless of the value specified for waitTime.

For non-GUI programs, if you specify a positive value for waitTime, ExecuteScriptText waits up to that many seconds for the command to complete. If the command fails to complete within that period of time, ExecuteScriptText returns an error. If you omit the /W flag or if you pass zero for waitTime, ExecuteScriptText waits until the command completes no matter how long it takes. If the script being executed creates a command window, via cmd.exe, for example, the Windows process completes only when the command window closes, not after the script commands execute.

## Windows Examples

```
// Windows: Execute a DOS command in the background
ExecuteScriptText/B "hostname"; Print S_value

// Windows: Open MatLab in background
ExecuteScriptText/B "C:\\Matlab\\bin\\matlab.exe myFile.m"

// Windows: Pass a script to Windows Script Host
ExecuteScriptText/W=5 "WScript.exe \"C:\\Test Script.vbs\""
```

## exists

---

```
// Windows: Execute a batch file and leave the command window open
ExecuteScriptText "cmd.exe /K \"C:\\mybatch.bat\"

// Windows: Execute a DOS command and get output, if any
// ExecuteDOSCommand(command, maxSecondsToWait)
// Executes a DOS command and returns any output text as the function result.
// Returns "" if the DOS command returns no text.
// maxSecondsToWait is the maximum number of seconds to wait for DOS to finish
// the command. If it takes longer than that, an error is generated.
// This function creates files in the Igor Pro User Folder:
// IgorBatch.bat Holds command that DOS is to execute
// IgorBatchOutput.txt Holds output generated by DOS command, if any
// Example:
// Print ExecuteDOSCommand("echo %PATH%", 3)
Function/S ExecuteDOSCommand(command, maxSecondsToWait)
 String command // e.g., "echo %PATH%"
 Variable maxSecondsToWait // Error if DOS takes longer than this

 String quoteStr = "\""

 // Get path to batch file in "Igor Pro User Files"
 String dirPath = SpecialDirPath("Igor Pro User Files", 0, 0, 0)
 dirPath = ParseFilePath(5, dirPath, "\\", 0, 0) // Convert to Windows path
 String batchFilePath = dirPath + "IgorBatch.bat"
 String batchOutputFilePath = dirPath + "IgorBatchOutput.txt"

 DeleteFile/Z batchOutputFilePath

 // Write DOS command to batch file
 String dosCommand = command + " > " + quoteStr + batchOutputFilePath + quoteStr
 Variable refNum
 Open refNum as batchFilePath
 FBinWrite refNum, dosCommand
 Close refNum

 // Execute batch file
 // The DOS command must complete in the number of seconds specified via /W
 // /C means cmd.exe quits after executing the command
 String text
 sprintf text, "cmd.exe /C \"%s\"", batchFilePath
 ExecuteScriptText/W=(maxSecondsToWait) text

 // Get output
 String result = ""
 Open/R/Z refNum as batchOutputFilePath
 if (V_flag != 0)
 result = ""
 // result = "<No output was generated by batch file>" // For debugging
 else
 // Read contents of batch file into string
 FStatus refNum
 Variable numBytesInFile = V_logEOF
 result = PadString("", numBytesInFile, 0x20)
 FBinRead refNum, result
 Close refNum
 endif

 return result
End
```

### See Also

See **AppleScript** on page IV-261.

## exists

### **exists** (*objNameStr*)

The exists function returns a number which indicates if *objNameStr* contains the name of an Igor object, function or operation.

### Details

*objNameStr* can optionally include a full or partial path to the object. If the name does not include a path, exists checks for waves, strings and variables in the current data folder.

*objNameStr* can optionally include a module name or independent module name prefix such as "ProcGlobal#" to check for the existence of functions. This works for macros as well.

The return values are:

- 0: Name not in use, or does not conflict with a wave, numeric variable or string variable in the specified data folder.
- 1: Name of a wave in the specified data folder.
- 2: Name of a numeric or string variable in the specified data folder.
- 3: Function name.
- 4: Operation name.
- 5: Macro name.
- 6: User-defined function name.

exists is not aware of local variables or parameters in user-defined functions, however it is aware of local variables and parameters in macros.

*objNameStr* is a string or string expression, *not* a name.

### Examples

```
// Prints 2 if V_flag exists as a global variable in the current data folder:
Print exists("V_Flag")

// Prints 5 if a macro named Graph0 exists.
Print exists("ProcGlobal#Graph0")
```

### See Also

The **DataFolderExists** and **WaveExists** functions and the **WinType** operation.

## exp

**exp** (*num*)

The exp function returns  $e^{num}$ . In complex expressions, *num* is complex, and exp(*num*) returns a complex value.

## ExperimentInfo

**ExperimentInfo** [ /Q[=*quiet*] ] [ **keyword=value** [, **keyword=value** ...] ]

The ExperimentInfo operation returns information about the current Igor experiment. The information is returned in the output variable V\_Flag and the output string variable S\_Value, as described below.

ExperimentInfo was added in Igor Pro 8.00.

To get the name of the current experiment, use **IgorInfo**(1).

### Flags

- /Q[=*quiet*]* If you omit /Q or pass 0 for quiet, ExperimentInfo prints information to the history area of the command window.  
If you specify /Q or /Q=1, ExperimentInfo prints nothing to the history area. Information is still returned via V\_Flag and S\_Value.

### Keywords

- getRequiredIgorVersion Returns the version of Igor required to open the current experiment via V\_Flag. Returns a message explaining the requirement via S\_Value.  
See **Getting the Required Igor Version** on page V-209 for details.
- getLongNameUsage[={*dfRef*, *mask*, *options*, *length*}

Returns information about long object names used in the current experiment via *V\_Flag* and *S\_Value*. This may be of interest because experiments that use long object names (longer than 31 bytes) require Igor Pro 8.00 or later.

*V\_Flag* is set to the number of long names found.

*S\_Value* is set to a description of the long names found. If you omit */Q* or specify */Q=0*, the description is also printed to the history area of the command window.

All of the parameters are optional. However, if you specify any of them, you must specify all of them.

*dfRef* specifies the data folder to start from and defaults to root:. It is a full or partial path to the starting data folder. You can specify root: or \* for *dfRef* to get the default. You can specify : to get the current data folder.

*getLongNameUsage* reports on the contents of the data folder specified by *dfRef*. Consequently, the specified data folder itself is not reported even if its name is long.

*mask* specifies what types of long object names you want to know about. It is a bitwise parameter defined as follows:

- Bit 0: Wave names
- Bit 1: Variable names
- Bit 2: Data folder names
- Bit 3: Target window names
- Bit 4: Symbolic path names

*mask* defaults to 31 which specifies all of the above.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

*options* controls various aspects of the returned information. It is a bitwise parameter defined as follows:

- Bit 0: Produce text formatted for reading by humans
- Bit 1: Include headers if bit 0 is set
- Bit 2: Use full paths for waves, variables and data folders
- Bit 3: Use full paths for waves, variables and data folders

*options* defaults to 15.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

*length* specifies the length in bytes greater than which a name must be to be included in the output. It defaults to 31. If you specify 0 for *length* then waves are listed regardless of the length of their name.

See **Getting Long Name Usage Info** on page V-209 for details.

`getLongDimensionLabelUsage[={dfRef, mask, options, length}`

Returns information about waves with long dimension labels in the current experiment via *V\_Flag* and *S\_Value*. This may be of interest because such experiments require Igor Pro 8.00 or later.

*V\_Flag* is set to the number of waves with long dimension labels found.

*S\_Value* is set to a description of the waves found. If you omit */Q* or specify */Q=0*, the description is also printed to the history area of the command window.

All of the parameters are optional. However, if you specify any of them, you must specify all of them.

*dfRef* specifies the data folder to start from and defaults to root:. It is a full or partial path to the starting data folder. You can specify root: or \* for *dfRef* to get the default. You can specify : to get the current data folder.

*mask* determines if data folders are listed along with waves with long dimension labels to provide context. It is a bitwise parameter defined as follows:

Bit 2:      Include data folder names

All other bits are ignored.

*mask* defaults to 4 which means that bit 2 is set and data folders are listed, but they are listed only if bit 0 of the options parameter is also set.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

*options* controls various aspects of the returned information. It is a bitwise parameter defined as follows:

Bit 0:      Produce text formatted for reading by humans

Bit 1:      Include headers if bit 0 is set

Bit 2:      Use full paths for waves, variables and data folders

Bit 3:      Use full paths for waves, variables and data folders

*options* defaults to 15.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

*length* specifies the length in bytes greater than which a dimension label must be for the wave be included in the output. It defaults to 31. If you specify 0 for *length* then waves are listed regardless of the length of their dimension labels.

### Getting the Required Igor Version

The `getRequiredIgorVersion` keyword returns the version of Igor required to open the current experiment via `V_Flag`. If no particular version is required, it returns 0. If `V_Flag` is non-zero, `S_Value` contains an explanation of why a particular version of Igor is required.

As used here, the concept of the version of Igor required to open the current experiment is very narrow. If `getRequiredIgorVersion` returns a non-zero value via `V_Flag`, this means that the current experiment can not be opened at all in versions of Igor earlier than specified by `V_Flag`. Currently the only situation that `getRequiredIgorVersion` flags is the use of long object names, specifically long wave, variable, data folder, target window, and symbolic path names, or long wave dimension labels. If the experiment uses a long name or long dimension label, the experiment can not be opened in versions of Igor prior to 8.00, and `getRequiredIgorVersion` sets `V_Flag` to 8.00. See **Long Object Names** on page III-504 and **Long Dimension Labels** on page II-94 for background information.

If `getRequiredIgorVersion` returns zero, it means that the current experiment can be opened in earlier versions of Igor. However, it does not guarantee that the experiment will open without errors. For example, if you use a function or operation added in Igor Pro 8.00 in a procedure, you can open the experiment in earlier versions, but you will get a compile error when you do so. `getRequiredIgorVersion` does not flag the use of all Igor features that require a particular version. It flags only the specific situation explained in the previous paragraph.

### Getting Long Name Usage Info

For background information on long object names, see **Long Object Names** on page III-504.

Experiments that use long object names (longer than 31 bytes), require Igor Pro 8.00 or later. You can use the `ExperimentInfo` operation with the `getLongNameUsage` keyword to determine what long object names, if any, the current experiment uses. This will help if you want to modify the experiment so it can be opened in an earlier version of Igor.

The `getLongNameUsage` keyword reports information about long wave, variable, data folder, target window, and symbolic path names. It does not report information about long axis, annotation, control, special character, or XOP names or about long dimension labels.

## ExperimentInfo

---

getLongNameUsage returns information via the V\_Flag and S\_Value output variables and, if you omit /Q or specify /Q=0, it prints information to the history area of the command window.

In human-readable mode (bit 0 of options parameter set), if you include data folders in the output (bit 2 of mask parameter set), ExperimentInfo generates output for each data folder, whether its name is long or not, and uses indentation. This allows you to see any long names in the context of the entire data folder hierarchy.

If human-readable mode is off, ExperimentInfo generates output for a given data folder only if its name is long. This mode is intended for use by code rather than reading by humans. In this mode, the hierarchy (i.e., which data object exists in which data folder) is discernible only if you call for full paths.

If you specify a starting data folder using the *dfRef* parameter, and if human-readable mode is off, ExperimentInfo does not generate output for the starting data folder name, even if it is long. This is because ExperimentInfo generates output for the contents of the starting data folder.

Liberal names are quoted if you specify full paths (bit 1 of options parameter set) but unquoted if you request simple names only. The reason for not quoting simple names is explained under **Accessing Global Variables and Waves Using Liberal Names** on page IV-67.

### GetLongNameUsage Examples

```
// Display long names for all data objects (waves, variables, data folders)
// and for target windows an symbolic paths.
ExperimentInfo getLongNameUsage

// Print number of long names uses and nothing else
ExperimentInfo/Q getLongNameUsage; Print V_Flag

// More specialized tests - paste the following into the procedure window
// of an experiment that uses long names and execute DemoGetLongNamesUsage()

Constant kLongNamesLength = 31
Constant kHumanMask = 1 // Human mode
Constant kHeadersMask = 2 // Include headers
Constant kFullPathsMask = 4 // Use full paths
Constant kRecursiveMask = 8 // Recursive

Function DemoGetLongNamesUsage()
 Print "=== Data folders, human, names only ==="
 ExperimentInfo getLongNameUsage={*, 4, kHumanMask|kRecursiveMask, kLongNamesLength}
 Printf "\r"

 Print "=== Data folders, human, full paths ==="
 ExperimentInfo getLongNameUsage={*, 4, kHumanMask|kFullPathsMask | kRecursiveMask,
 kLongNamesLength}
 Printf "\r"

 Print "=== Data folders, non-human, names only ==="
 ExperimentInfo getLongNameUsage={*, 4, 0|kRecursiveMask, kLongNamesLength}
 Printf "\r"

 Print "=== Data folders, non-human, full paths ==="
 ExperimentInfo getLongNameUsage={*, 4, kFullPathsMask|kRecursiveMask,
 kLongNamesLength}
 Printf "\r"

 Print "=== All data objects, human, names only ==="
 ExperimentInfo getLongNameUsage={*, 7, kHumanMask|kRecursiveMask, kLongNamesLength}
 Printf "\r"

 Print "=== All data objects, human, full paths ==="
 ExperimentInfo getLongNameUsage={*, 7, kHumanMask|kFullPathsMask | kRecursiveMask,
 kLongNamesLength}
 Printf "\r"

 Print "=== All data objects, non-human, names only ==="
 ExperimentInfo getLongNameUsage={*, 7, 0|kRecursiveMask, kLongNamesLength}
 Printf "\r"

 Print "=== All data objects, non-human, full paths ==="
 ExperimentInfo getLongNameUsage={*, 7, kFullPathsMask|kRecursiveMask,
 kLongNamesLength}
 Printf "\r"
```

```

Print "=== All data objects, human, headers, names only ==="
int flags = kHumanMask | kHeadersMask | kRecursiveMask
ExperimentInfo getLongNameUsage={*, 7, flags, kLongNamesLength}
// Printf "\r" // Skip this because headers mode prints trailing blank line
End

```

**See Also**

**ExperimentModified, IgorInfo, Long Object Names** on page III-504

## ExperimentModified

**ExperimentModified** [*newModifiedState*]

The ExperimentModified operation gets and optionally sets the modified (save) state of the current experiment.

Use this command to prevent Igor from asking you to save the current experiment after you have made changes you do not need to save or, conversely, to force Igor to ask about saving the experiment even though Igor would not normally do so.

The variable V\_flag is always set to the experiment-modified state that was in effect before the ExperimentModified command executed: 1 for modified, 0 for not modified.

**Parameters**

If *newModifiedState* is present, it sets the experiment-modified state as follows:

- newModifiedState* = 0: Igor will not ask to save the experiment before quitting or opening another experiment, and the Save Experiment menu item will be disabled.
- newModifiedState* = 1: Igor will ask to save the experiment before quitting or opening another experiment, and the Save Experiment menu item will be enabled.

If *newModifiedState* is omitted, the state of experiment-modified state is not changed.

**Details**

Executing ExperimentModified 0 on the command line will not work because the command will be echoed to the history area, marking the experiment as modified. Use the command in a function or macro that does not echo text to the history area.

**Examples**

The /Q flag is vital: it suppresses printing into the history area which would mark the experiment as modified again.

```

Menu "File"
 "Mark Experiment Modified",/Q,ExperimentModified 1 // Enables "Save Experiment"
 "Mark Experiment Saved",/Q,ExperimentModified 0 // Disables "Save Experiment"
End

```

**See Also**

**SaveExperiment, ExperimentInfo, Menu Definition Syntax** on page IV-126.

## expInt

**expInt** (*n*, *x*)

The expInt function returns the value of the exponential integral  $E_n(x)$ :

$$E_n(x) = P \int_1^{\infty} \frac{e^{-xt}}{t^n} dt \quad (x > 0; n = 0, 1, 2 \dots).$$

**See Also**

**ei, ExpIntegralE1**

**References**

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

### ExpIntegralE1

#### **ExpIntegralE1 (z)**

The ExpIntegralE1(z) function returns the exponential integral of z.

If z is real, a real value is returned. If z is complex then a complex value is returned.

The ExpIntegralE1 function was added in Igor Pro 7.00.

#### **Details**

The exponential integral is defined by

$$E_1(z) = \int_z^{\infty} \frac{e^{-t}}{t} dt, \quad (|\arg(z)| < \pi).$$

#### **References**

Abramowitz, M., and I.A. Stegun, "Handbook of Mathematical Functions", Dover, New York, 1972. Chapter 5.

#### **See Also**

**expInt**, **CosIntegral**, **SinIntegral**, **hyperGPFQ**

### expnoise

#### **expnoise (b)**

The expnoise function returns a pseudo-random value from an exponential distribution whose average and standard deviation are *b* and the probability distribution function is

$$f(x) = \frac{1}{b} \exp\left(-\frac{x}{b}\right).$$

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable "random" numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

#### **See Also**

The **SetRandomSeed** operation.

**Noise Functions** on page III-390.

Chapter III-12, **Statistics** for a function and operation overview.

### ExportGizmo

#### **ExportGizmo [flags] keyword [=value]**

The ExportGizmo operation is obsolete but is still partially supported for partial backward compatibility.

You can export Gizmo graphics using File→Save Graphics which generates a **SavePICT** command. The ExportGizmo operation is only partially supported. It can export to the clipboard or to an Igor wave and it can print but it can no longer export to a file. Use SavePICT instead.

Documentation for the ExportGizmo operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "ExportGizmo"
```

### Extract

#### **Extract [type flags] [/INDX/O] srcWave, destWave, LogicalExpression**

The Extract operation finds data in *srcWave* wherever *LogicalExpression* evaluates to TRUE and stores the matching data sequentially in *destWave*, which will be created if it does not already exist.

#### **Parameters**

*srcWave* is the name of a wave.

*destWave* is the name of a new or existing wave that will contain the result.

*LogicalExpression* can use any comparison or logical operator in the expression.

### Flags

- `/FREE` Creates a free *destWave* (see **Free Waves** on page IV-90).  
`/FREE` is allowed only in functions and only if a simple name or wave reference structure field is specified for *destWave*.
- `/INDX` Stores the index in *destWave* instead of data from *srcWave*.
- `/O` Allows *destWave* to be the same as *srcWave* (overwrite source).

### Type Flags *(used only in functions)*

Extract also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-73 and **WAVE Reference Type Flags** on page IV-73 for a complete list of type flags and further details.

### Details

*srcWave* may be of any type including text.

*destWave* has the same type as *srcWave*, but it is always one dimensional. With `/INDX`, the *destWave* type is set to unsigned 32-bit integer and the values represent a linear index into *srcWave* regardless of its dimensionality.

### Example

```
Make/O source= x
Extract/O source,dest,source>10 && source<20
print dest
```

Prints the following to the history area:

```
dest [0]= {11,12,13,14,15,16,17,18,19}
```

### See Also

The **Duplicate** operation.

## factorial

### **factorial** (*n*)

The factorial function returns  $n!$ , where  $n$  is assumed to be a positive integer.

Note that while factorial is an integer-valued function, a double-precision number has 53 bits for the mantissa. This means that numbers over  $2^{52}$  will be accurate to about one part in about  $2 \times 10^{16}$ . Values of  $n$  greater than 170 result in overflow and return Inf.

If you encounter overflow you can use the **APMath** operation to obtain the result. For example:

- `Print factorial(1000)`  
inf
- `APMath/V result = factorial(1000)`  
4.02387260077093773543702433923003985719374864210715E+2567

## Faddeeva

### **Faddeeva** (*z*)

Faddeeva computes the Faddeeva function, also commonly denoted as "w", using an approximation that has, as described by the author, "accuracy is typically at at least 13 significant digits". Both the input and the output are complex numbers.

The Faddeeva function was added in Igor Pro 8.00.

The Faddeeva function is the basis of the Voigt function, implemented in Igor as **VoigtFunc**. `VoigtFunc(X, Y) = real(Faddeeva(cmplx(X, Y))`.

### References

The code used to compute the VoigtFunc was written by Steven G. Johnson of MIT. You can learn more about it at <http://ab-initio.mit.edu/Faddeeva>.

### See Also

**VoigtPeak, VoigtFunc, Built-in Curve Fitting Functions** on page III-206

## FakeData

### **FakeData** (*waveName*)

The FakeData function puts fake data in the named wave, which must be single-precision float. This is useful for testing things that require changing data before you have the source for the eventual real data. FakeData can be useful in a background task expression.

The FakeData function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details.

### Examples

```
Make/N=200 wave0; Display wave0
SetBackground FakeData(wave0) // define background task
CtrlBackground period=60, start // start background task
// observe the graph for a while
CtrlBackground stop // stop the background task
```

## FastGaussTransform

### **FastGaussTransform** [*flags*] *srcLocationsWave*, *srcWeightsWave*

The FastGaussTransform operation implements an efficient algorithm for evaluating the discrete Gauss transform, which is given by

$$G(y_j) = \sum_{i=0}^{N-1} q_i \exp\left(-\frac{\|y_j - x_i\|^2}{h}\right),$$

where  $G$  is an M-dimensional vector,  $y$  is an N-dimensional vector representing the observation position,  $\{q_i\}$  are the M-dimensional weights,  $\{x_i\}$  are N-dimensional vectors representing source locations, and  $h$  is the Gaussian width. The wave M\_FGT contains the output in the current data folder.

### Flags

|                                                        |                                                                                                                                                                                                                                                       |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/AERR=<i>aprxErr</i></code>                      | Sets the approximate error, which determines how many terms of the Taylor expansion of the Gaussian are used by the calculation. Default value is 1e-5.                                                                                               |
| <code>/WIDTH=<i>h</i></code>                           | Sets the Gaussian width. Default value is 1.                                                                                                                                                                                                          |
| <code>/OUTW=<i>locWave</i></code>                      | Specifies the locations at which the output is computed. <i>locWave</i> must have the same number of columns as <i>srcLocationsWave</i> . The other /OUT flags are mutually exclusive; you should use only one at any time.                           |
| <code>/OUT1={<i>x1,nx,x2</i>}</code>                   |                                                                                                                                                                                                                                                       |
| <code>/OUT2={<i>x1,nx,x2,y1,ny,y2</i>}</code>          |                                                                                                                                                                                                                                                       |
| <code>/OUT3={<i>x1,nx,x2,y1,ny,y2,z1,nz,z2</i>}</code> | Specifies gridded output of the required dimension. In each case you set the starting and ending values together with the number of intervals in that dimension. You cannot specify an output that does not match the dimensions of the input source. |
| <code>/Q</code>                                        | No results printed in the history area.                                                                                                                                                                                                               |
| <code>/RX=<i>rx</i></code>                             | Sets the maximum radius of any cluster. The clustering algorithm terminates when the maximum radius is less than <i>rx</i> . Without /RX, the maximum radius is the same as the maximum radius encountered.                                           |
| <code>/RY=<i>ry</i></code>                             | Sets the upper bound for the distance between an observation point and a cluster center for which the cluster contributes to the transform value. The default value for <i>ry</i> is 4 times the Gaussian width as specified by the /WIDTH flag.      |

|                                 |                                                                                                                                                                                                                       |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/TET=<i>nTerms</i></code> | Sets the number of terms in the Taylor expansion. Use <code>/TET</code> to set the number of terms and bypass the default error estimate, which is estimated from the approximate error value ( <code>/AERR</code> ). |
| <code>/Z</code>                 | No error reporting.                                                                                                                                                                                                   |

### Details

The discrete Gauss transform can be computed as a direct sum. An exact calculation is practical only for moderate number of sources and observation points and for low spatial dimensionality. With increasing dimensionality and increasing number of sources it is more efficient to take advantage of some properties of the Gaussian function. The `FastGaussianTransform` operation does so in two ways: It first arranges the sources in N-dimensional spatial clusters so that it is not necessary to compute the contributions of all source points that belong to remote clusters (see **FPClustering**). The second component of the algorithm is an approximation that factorizes the sum into a factor that depends only on source points and a factor that depends only on observation points. The factor that depends only on source points is computed only once while the factor that depends on observation points is evaluated once for each observation point.

The trade-off between computation efficiency and accuracy can be adjusted using multiple parameters. By default, the operation calculates the number of terms it needs to use in the Taylor expansion of the Gaussian. You can modify the default approximate error value using `/AERR` or you can directly set the number of terms in the expansion using `/TET`.

`FastGaussianTransform` supports calculations in dimensions that may exceed the maximum allowed wave dimensionality. `srcLocationsWave` must be a 2D, real-valued single- or double-precision wave in which each row corresponds to a single source position and columns represent the components in each dimension (e.g., a triplet wave would represent 3D source locations). `srcWeightsWave` must have the same number of rows as `srcLocationsWave` and it must be a real-valued single- or double-precision wave. In most applications `srcWeightsWave` will have a single column so that the output `G` will be scalar. However, if `srcWeightsWave` has multiple columns then `G` is a vector. This can be handy if you need to test multiple sets of coefficients at one time. If you specify observation points using `/OUTW` then `locWave` must have the same number of columns as `srcLocationsWave` (the number of rows in the output is arbitrary). The operation does not support wave scaling.

## FastOp

```
FastOp destWave = prod1 [± prod2 [± prod3]]
```

```
FastOp destWave += prod1 [± prod2]
```

The `FastOp` operation can be used to get improved speed out of certain wave assignment statements. The syntax was designed so that you can simply insert `FastOp` in front of any wave assignment statement that meets the syntax requirements. The `+=` syntax was added in Igor Pro 9.00.

### Parameters

*destWave* An existing destination wave for the assignment expression. An error will be reported at runtime if the waves are not all the same length or number type.

*prod1, prod2, prod3* Products with the following formats:

```
constexpr* wave1 * wave2
```

or

```
constexpr * wave1 / wave2
```

*constexpr* may be a literal numeric constant or a constant expression in parentheses. Such expressions are evaluated only once.

Any component in a prod expression may be omitted.

## Flags

*/C*

The */C* flag is obsolete in Igor Pro 9.00 and later and is ignored. For floating point waves, the type of expressions, real or complex, is determined by the type of the destination wave.

In Igor Pro 8 and before */C* is required when using a complex destination wave.

FastOp supports real and complex for floating point waves but only real for integer waves.

## Details

FastOp supports real and complex for floating point waves. It supports real only for integer waves.

If your waves are complex, make sure to use *WAVE/C* when declaring wave references in user-defined functions.

Certain combinations, listed in the following table, are evaluated using faster optimized code rather than more general but slower generic code. SP means "single-precision floating point" and DP means "double-precision floating point".

| Statement                        | Optimized Data Types             |
|----------------------------------|----------------------------------|
| <i>dest = 0</i>                  | All                              |
| <i>dest = waveA</i>              | All                              |
| <i>dest += C0 * waveA</i>        | SP and DP, real and complex      |
| <i>dest = dest + C0 * waveA</i>  | SP and DP, real and complex      |
| <i>dest = dest + waveA * C0</i>  | SP and DP, real and complex      |
| <i>dest = C0</i>                 | SP and DP and integer, real only |
| <i>dest = waveA + C1</i>         | SP and DP and integer, real only |
| <i>dest = C0 * waveA + C1</i>    | SP and DP, real only             |
| <i>dest = waveA + waveB + C2</i> | Integer only, real only          |

In the statements above, pluses may be minuses and the trailing constant (*C0*, *C1*, *C2*) may be omitted.

**Note:** Except for the optimized cases listed above which use integer calculations for integer waves, integer results are evaluated using double precision intermediate values. This limits precision for 64-bit integer waves to 53 bits.

Speedups generally range from 10 to 40 times faster than the equivalent statement with FastOp removed. The speedup is dependent on the computer and on the length of the waves with the greatest improvement occurring for waves with 1000 to 100,000 points.

## Examples

Valid expressions:

```
FastOp dest = 3
FastOp dest = waveA + waveB
FastOp dest = 0.5*waveA + 0.5*waveB
FastOp dest = waveA*waveB
FastOp dest = (2*3)*waveA + 6
FastOp dest = (locvar)*waveA
FastOp dest += waveA + waveB
```

Expressions that are **not** valid:

```
FastOp dest = 3*4
FastOp dest = (waveA + waveB)
FastOp dest = waveA*0.5 + 0.5*waveB
FastOp dest = waveA*waveB/2
FastOp dest = 2*3*waveA + 6
FastOp dest = locvar*waveA
FastOp dest += waveA + waveB + waveC
```

**See Also**

**MatrixOp**, **MatrixMultiply** and **MatrixMultiplyAdd** for additional efficient matrix operations.

**MultiThread****faverage**

**faverage**(*waveName* [, *x1*, *x2*])

The **faverage** function returns the trapezoidal average value of the named wave from  $x=x1$  to  $x=x2$ .

If your data are in the form of an XY pair of waves, see **faverageXY**.

**Details**

If *x1* and *x2* are not specified, they default to  $-\infty$  and  $+\infty$ , respectively.

If *x1* or *x2* are not within the X range of *waveName*, **faverage** limits them to the nearest X range limit of *waveName*.

**faverage** returns the area divided by  $(x2-x1)$ . In other words, the X scaling of *waveName* is eliminated when computing the average.

If any Y values in the specified X range are NaN, **faverage** returns NaN.

Unlike the **area** function, reversing the order of *x1* and *x2* does *not* change the sign of the returned value.

The **faverage** function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details.

The **faverage** function returns a complex result for a complex input wave. The real part of the result is the average of the real components in the input wave and the imaginary part of the result is the average of the imaginary components.

**Examples**

**Comparison of area, faverage and mean functions over interval (12.75,13.32)**

$$\begin{aligned} \text{area}(\text{wave}, 12.75, 13.32) &= 0.05 \cdot (43+55) / 2 && // \text{ first trapezoid} \\ &+ 0.20 \cdot (55+88) / 2 && // \text{ second trapezoid} \\ &+ 0.20 \cdot (88+100) / 2 && // \text{ third trapezoid} \\ &+ 0.12 \cdot (100+92.2) / 2 && // \text{ fourth trapezoid} \\ &= 47.082 \end{aligned}$$

$$\begin{aligned} \text{faverage}(\text{wave}, 12.75, 13.32) &= \text{area}(\text{wave}, 12.75, 13.32) / (13.32-12.75) \\ &= 47.082 / 0.57 = 82.6 \end{aligned}$$

$$\text{mean}(\text{wave}, 12.75, 13.32) = (55+88+100+87)/4 = 82.5$$

**See Also**

**Integrate**, **area**, **areaXY**, **faverageXY** and **Poly2D Example 3**

**faverageXY**

**faverageXY**(*XWaveName*, *YWaveName* [, *x1*, *x2*])

The **faverageXY** function returns the trapezoidal average value of *YWaveName* from  $x=x1$  to  $x=x2$ , using X values from *XWaveName*.

This function operates identically to **faverage**, except that it uses an XY pair of waves for X and Y values and it does not work with complex waves.

**Details**

If *x1* and *x2* are not specified, they default to  $-\infty$  and  $+\infty$ , respectively.

## FBinRead

---

If  $x1$  or  $x2$  are not within the X range of  $XWaveName$ , `faverageXY` limits them to the nearest X range limit of  $XWaveName$ .

`faverageXY` returns the area divided by  $(x2 - x1)$ .

If any values in the X range are NaN, `faverageXY` returns NaN.

Reversing the order of  $x1$  and  $x2$  does not change the sign of the returned value.

The values in  $XWaveName$  may be increasing or decreasing. `faverageXY` assumes that the values in  $XWaveName$  are monotonic. If they are not monotonic, Igor does not complain, but the result is not meaningful. If any X values are NaN, the result is NaN.

The `faverageXY` function is not multidimensional aware. See Chapter II-6, **Multidimensional Waves** for details on multidimensional waves, particularly **Analysis on Multidimensional Waves** on page II-95.

## FBinRead

**FBinRead** [*flags*] *refNum*, *objectName*

The FBinRead operation reads binary data from the file specified by *refNum* into the named object.

For simple applications of loading binary data into numeric waves you may find the `GBLoadWave` operation simpler to implement.

### Parameters

*refNum* is a file reference number from the Open operation used to open the file.

*objectName* is the name of a wave, numeric variable, string variable, or structure.

### Flags

`/B[=b]` Specifies file byte ordering.

*b*=0: Native (same as no `/B`).

*b*=1: Reversed (same as `/B`).

*b*=2: Big-endian (Motorola).

*b*=3: Little-endian (Intel).

`/F=f` Controls the number of bytes read and how the bytes are interpreted.

*f*=0: Native binary format of the object (default).

*f*=1: Signed byte; one byte.

*f*=2: Signed 16-bit word; two bytes.

*f*=3: Signed 32-bit word; four bytes.

*f*=4: 32-bit IEEE floating point; four bytes.

*f*=5: 64-bit IEEE floating point; eight bytes.

*f*=6: 64-bit integer; eight bytes. Requires Igor Pro 7.00 or later.

`/U` Integer formats (`/F=1, 2, or 3`) are unsigned. If `/U` is omitted, integers are signed.

### Details

If *objectName* is the name of a string variable then `/F` doesn't apply. The number of bytes read is the number of bytes in the string *before* the FBinRead operation is called. You can use the **PadString** function to set the size of a string.

The binary format that FBinRead uses for numeric variables or waves depends on the `/F` flag. If no `/F` flag is present, the native binary format of the named object is used.

Byte ordering refers to the order in which a multibyte datum is read from a file. For example, a 16-bit word (sometimes called a "short") consists of a high-order byte and a low-order byte. Under big-endian byte ordering the high-order byte is read from the file first. Under little-endian byte ordering the low-order byte is read from the file first.

FBinRead will read an entire structure from a disk file. The individual fields of the structure will be byte-swapped if the /B flag is designated.

The FBinRead operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details.

#### See Also

FBinWrite, Open, FGetPos, FSetPos, FStatus, GBLoadWave

## FBinWrite

**FBinWrite** [*flags*] *refNum*, *objectName*

The FBinWrite operation writes the named object in binary to a file.

#### Parameters

*refNum* is a file reference number from the **Open** operation used to open the file.

*objectName* is the name of a wave, numeric variable, string variable, or structure.

#### Flags

/B[=*b*] Specifies file byte ordering.

*b*=0: Native (same as no /B).

*b*=1: Reversed (same as /B).

*b*=2: Big-endian (Motorola).

*b*=3: Little-endian (Intel).

/F=*f* Controls the number of bytes written and how the bytes are formatted.

*f*=0: Native binary format of the object (default).

*f*=1: Signed byte; one byte.

*f*=2: Signed 16-bit word; two bytes.

*f*=3: Signed 32-bit word; four bytes.

*f*=4: 32-bit IEEE floating point; four bytes.

*f*=5: 64-bit IEEE floating point; eight bytes.

*f*=6: 64-bit integer; eight bytes. Requires Igor Pro 7.00 or later.

/P Adds an IgorBinPacket to the data. This is used for PPC or Apple event result packets (*refNum* = 0) and is not normally of use when writing to a file.

/U Integer formats (/F=1, 2, or 3) are unsigned. If /U is omitted, integers are signed.

#### Details

A zero value of *refNum* is used in conjunction with Program-to-Program Communication (PPC) or Apple events (*Macintosh*) or **ActiveX Automation** (*Windows*). The data that would normally be written to a file is appended to the PPC or Apple event or ActiveX Automation result packet.

If the object is a string variable then /F doesn't apply. The number of bytes written is the number of bytes in the string.

The binary format that FBinWrite uses for numeric variables or waves depends on the /F flag. If no /F flag is present, FBinWrite uses the native binary format of the named object.

Byte ordering refers to the order in which a multibyte datum is written to a file. For example, a 16-bit word (sometimes called a "short") consists of a high-order byte and a low-order byte. Under big-endian byte ordering, which is commonly used on Macintosh, the high-order byte is written to the file first. Under little-endian byte ordering, which is commonly used on Windows, the low-order byte is written to the file first.

FBinWrite will write an entire structure to a disk file. The individual fields of the structure will be byte-swapped if the /B flag is designated.

The FBinWrite operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details.

## FetchURL

---

### See Also

**FBinRead**, **Open**, **FGetPos**, **FSetPos**, **FStatus**, **GBLoadWave**

## FetchURL

### FetchURL(*urlStr*)

The FetchURL function returns a string containing the server's response to a request to get the contents of the URL specified by *urlStr*. If *urlStr* contains a URL that uses the file:// scheme, the contents of the local file is returned.

### Parameters

*urlStr* is a string containing the URL to retrieve. You can include a username, password, and server port number as part of the URL.

FetchURL expects that *urlStr* has been percent-encoded if it contains reserved characters. See **Percent Encoding** on page IV-266 for additional information on when percent-encoding is necessary and how to do it.

See **URLs** on page IV-265 for details about how to correctly specify the URL.

FetchURL supports only the http://, https://, ftp://, and file:// schemes. See **Supported Network Schemes** on page IV-266 for details.

There are two special values of *urlStr* that can be used to get information about the network library that Igor uses. The keyword=value pairs returned when *urlStr* is "curl\_version\_info" may be useful to programmers in that the features and protocols available in the library are specified.

```
FetchURL("curl_version")
FetchURL("curl_version_info")
```

### Details

If FetchURL encounters an error, it returns a NULL string. You should check for errors before using the returned string. In a user-defined function, use the **GetRTErr** function.

```
String urlStr = "http://www.badserver"
String response = FetchURL(urlStr)
Variable error = GetRTErr(1) // Check for error before using response
if (error != 0)
 // FetchURL produced an error
 // so don't try to use the response.
endif
```

### Limitations

It is possible for FetchURL to return a valid server response even though the URL you requested does not exist on the server or requires a username and password that you did not provide. In this situation, the response returned by the server will usually be a web page stating that the page was not found or another error message. You can check for this kind of error in your own code by examining the response.

FetchURL does not support advanced features such as network proxies, file or data uploads, setting the timeout period, or saving the server's response directly to a file. When using the http:// scheme, only the GET method is supported. This means that you cannot use FetchURL to submit form data to a web server that requires using the http POST method. Use the **URLRequest** operation if you need any of these features.

Igor Pro is not capable of displaying the contents of a URL in a rendered form like a web browser.

### Examples

```
// Retrieve the contents of the WaveMetrics home page.
String response
response = FetchURL("http://www.wavemetrics.com")

// Get a binary image file from a web server and then
// save the image to a file on the desktop.
String url = "http://www.wavemetrics.net/images/tbg.gif"
String imageBytes = FetchURL(url)
Variable error = GetRTErr(1)
if (error != 0)
 Print "Error downloading image."
else
 Variable refNum
 String localPath = SpecialDirPath("Desktop", 0, 0, 0) + "tbg.gif"
```

```

 Open/T=".gif" refNum as localPath
 FBinWrite refNum, imageBytes
 Close refNum
endif

```

### See Also

**FTPDownload, URLEncode, URLRequest**

**Network Communication** on page IV-265, **Network Connections From Multiple Threads** on page IV-269.

## FFT

**FFT** [*flags*] *srcWave*

The FFT operation computes the Discrete Fourier Transform of *srcWave* using a multidimensional prime factor decomposition algorithm. By default, *srcWave* is overwritten by the FFT.

### Output Wave Name

For compatibility with earlier versions of Igor, if you use FFT with no flags or with just the /Z flag, the operation overwrites *srcWave*.

If you use any flag other than /Z, FFT uses default output wave names: W\_FFT for a 1D FFT and M\_FFT for a multidimensional FFT.

We recommend that you use the /DEST flag to make the output wave explicit and to prevent overwriting *srcWave*.

### Flags

**/COLS** Computes the 1D FFT of 2D *srcWave* one column at a time, storing the results in the destination wave.

$$I[t_1][n] = \sum_{k=0}^{N-1} f[t_1][k] \exp(i2\pi kn / N).$$

You must specify a destination wave using the /DEST flag. No other flags are allowed with this flag. The number of rows must be even. If *srcWave* is a real (NxM) wave, the output matrix will be (1+N/2,M) in analogy with 1D FFT. To avoid changes in the number of points you can convert *srcWave* to complex data type. This flag applies only to 2D source waves. See also the /ROWS flag.

**/DEST=*destWave*** Specifies the output wave created by the FFT operation. It is an error to attempt specify the same wave as both *srcWave* and *destWave*. The default output wave name is W\_FFT for a 1D FFT and M\_FFT for a multidimensional FFT. When used in a function, the FFT operation by default creates a complex wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-71 for details.

**/FREE** Creates *destWave* as a free wave. /FREE is allowed only in functions and only if *destWave*, as specified by /DEST, is a simple name or wave reference structure field. See **Free Waves** on page IV-90 for more discussion. The /FREE flag was added in Igor Pro 7.00.

**/HCC** Hypercomplex transform (cosine). Computes the integral

$$I_c(\omega_1, \omega_2) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(t_1, t_2) \cos(t_1 \omega_1) \exp(it_2 \omega_2) dt_1 dt_2$$

using the 2D FFT (see **Details**).

`/HCS` Hypercomplex transform (sine). Computes the integral

$$I_s(\omega_1, \omega_2) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(t_1, t_2) \sin(t_1 \omega_1) \exp(it_2 \omega_2) dt_1 dt_2$$

using the 2D FFT (see **Details**).

`/MAG` Saves just the magnitude of the FFT in the output wave. See comments under `/OUT`.

`/MAGS` Saves the squared magnitude of the FFT in the output wave. See comments under `/OUT`.

`/OUT=mode` Sets the output wave format.

`mode=1:` Complex output (default)

`mode=2:` Real output

`mode=3:` Magnitude

`mode=4:` Magnitude square

`mode=5:` Phase

`mode=6:` Scaled magnitude

`mode=7:` Scaled magnitude squared

You can also identify modes 2-4 using the convenience flags `/REAL`, `/MAG`, and `/MAGS`. The convenience flags are mutually exclusive and are overridden by the `/OUT` flag.

The scaled quantities apply to transforms of real valued inputs where the output is normally folded in the first dimension (because of symmetry). The scaling applies a factor of 2 to the squared magnitude of all components except the DC. The scaled transforms should be used whenever Parseval's relation is expected to hold.

`/PAD={dim1 [, dim2, dim3, dim4]}`

Converts *srcWave* into a padded wave of dimensions *dim1, dim2,...* The padded wave contains the original data at the start of the dimension and adds zero entries to each dimension up to the specified dimension size. The *dim1...* values must be greater than or equal to the corresponding dimension size of *srcWave*. If you need to pad just the lowest dimension(s) you can omit the remaining dimensions; for example, `/PAD=dim1` will set *dim2* and above to match the dimensions in *srcWave*.

`/REAL` Saves just the real part of the transform in the output wave. See comments under `/OUT`.

`/ROWS` Calculates the FFT of only the first dimension of a 2D *srcWave*. It thus computes the 1D FFT of one row at a time, storing the results in the destination wave.

$$N[n][t_2] = \sum_{k=0}^{M-1} f[k][t_2] \exp(i2\pi kn / M)$$

You must specify a destination wave using the `/DEST` flag. No other flags are allowed with this flag. The number of columns must be even. If *srcWave* is a real (N×M) wave, the output matrix will be (N,1+M/2) in analogy with 1D FFT. To avoid changes in the number of points you can convert *srcWave* to complex data type. See also `/COLS` flag.

`/RP=[startPoint, endPoint]`

`/RX=(startX, endX)` Defines a segment of a 1D *srcWave* that will be transformed. By default the operation transforms the whole wave. It is sometimes useful to take advantage of this feature in order to transform just the defined interval, which includes both end points. You can define the interval using wave point indexing with the `/RP` flag or using the X-values with the `/RX` flag. The interval must include at least four data points and the total number of points must be an even number.

*/WINF=windowKind*

Premultiplies a 1D *srcWave* with the selected window function.

If you include the */PAD* flag, the window function is applied to the pre-padded data.

See **Window Functions** below for details.

*/Z*

Disables rotation of the FFT of a complex wave. Igor normally rotates the FFT result (which is also complex) by  $N/2$  so that  $x=0$  is at the center point ( $N/2$ ). When */Z* is specified, Igor does not perform this rotation and leaves  $x=0$  at the first point (0).

### Details

The data type of *srcWave* is arbitrary. The first dimension of *srcWave* must be an even number and the minimum length of *srcWave* is four points. When *srcWave* is a double precision wave, the FFT is computed in double precision. All other data types are transformed using single precision calculations. The result of the FFT operation is always a floating point number (single or double precision).

Depending on your choice of outputs, you may not be able to invert the transform in order to obtain the original *srcWave*.

*srcWave* or any of its intervals must have at least four data points and must not contain NaNs or INFs.

The FFT algorithm is based on prime number decomposition, which decomposes the number of points in each dimension of the wave into a product of prime numbers. The FFT is optimized for primes  $< 5$ . In time consuming applications it is frequently worthwhile to pad the data so that the total number of points factors into small prime numbers.

The hypercomplex transforms are computed by writing the sine and cosine as a sum of two exponentials. Let the 2D Fourier transform of the input signal be

$$F[n_1][n_2] = \sum_{k_1=0}^{N_1-1} \sum_{k_2=0}^{N_2-1} f[k_1][k_2] \exp\left(i2\pi k_1 \frac{n_1}{N_1}\right) \exp\left(i2\pi k_2 \frac{n_2}{N_2}\right)$$

then the two hypercomplex transforms are given by

$$I_c[n_1][n_2] = \frac{1}{2} (F[n_1][n_2] + F[-n_1][n_2])$$

and

$$I_s[n_1][n_2] = \frac{1}{2i} (F[n_1][n_2] - F[-n_1][n_2])$$

### Window Functions

The */F=windowKind* flag premultiplies a 1D *srcWave* with the selected window function.

In the following window definitions,  $w(n)$  is the value of the window function that multiplies the signal,  $N$  is the number of points in the signal wave (or range if */R* is specified), and  $n$  is the wave point index. With */R*,  $n=0$  for the first datum in the range.

Choices for *windowKind* are in bold.

#### **Bartlet:**

A synonym for Bartlett.

**Bartlett:**

$$w(n) = \begin{cases} \frac{2n}{N} & n = 0, 1, \dots, \frac{N}{2} \\ 2 - \frac{2n}{N} & n = \frac{N}{2}, \dots, N - 1 \end{cases}$$

**Blackman367, Blackman361, Blackman492, Blackman474:**

$$w(n) = a_0 - a_1 \cos\left(\frac{2\pi}{N} n\right) + a_2 \cos\left(\frac{2\pi}{N} 2n\right) - a_3 \cos\left(\frac{2\pi}{N} 3n\right).$$

$$n = 0, 1, 2, \dots, N - 1.$$

| <i>windowKind</i>  | $a_0$      | $a_1$      | $a_2$      | $a_3$   |
|--------------------|------------|------------|------------|---------|
| <b>Blackman367</b> | 0.42659071 | 0.49656062 | 0.07684867 | 0       |
| <b>Blackman361</b> | 0.44959    | 0.49364    | 0.05677    | 0       |
| <b>Blackman492</b> | 0.35875    | 0.48829    | 0.14128    | 0.01168 |
| <b>Blackman474</b> | 0.40217    | 0.49703    | 0.09392    | 0.00183 |

**Cos1, Cos2, Cos3, Cos4:**

$$w(n) = \cos\left(\frac{n}{N} \pi\right)^\alpha,$$

$$n = -\frac{N}{2}, \dots, -1, 0, 1, \dots, \frac{N}{2}.$$

| <i>windowKind</i> | $\alpha$     |
|-------------------|--------------|
| <b>Cos1:</b>      | $\alpha = 1$ |
| <b>Cos2:</b>      | $\alpha = 2$ |
| <b>Cos3:</b>      | $\alpha = 3$ |
| <b>Cos4:</b>      | $\alpha = 4$ |

**Hamming:**

$$w(n) = \begin{cases} 0.54 + 0.46 \cos\left(\frac{2\pi n}{N}\right) & n = -\frac{N}{2}, \dots, -1, 0, 1, \dots, \frac{N}{2} \\ 0.54 - 0.46 \cos\left(\frac{2\pi n}{N}\right) & n = 0, 1, 2, \dots, N - 1 \end{cases}$$

**Hanning:**

$$w(n) = \begin{cases} \frac{1}{2} \left[ 1 + \cos\left(\frac{2\pi n}{N}\right) \right] & n = -\frac{N}{2}, \dots, -1, 0, 1, \dots, \frac{N}{2} \\ \frac{1}{2} \left[ 1 - \cos\left(\frac{2\pi n}{N}\right) \right] & n = 0, 1, 2, \dots, N-1 \end{cases}$$

**KaiserBessel20, KaiserBessel25, KaiserBessel30:**

$$w(n) = \frac{I_0\left(\pi\alpha\sqrt{1-\left(\frac{2n}{N}\right)^2}\right)}{I_0(\pi\alpha)} \quad 0 \leq |n| \leq \frac{N}{2}.$$

where  $I_0$  is the zero-order modified Bessel function of the first kind.

| <i>windowKind</i>      | $\alpha$        |
|------------------------|-----------------|
| <b>KaiserBessel20:</b> | $\alpha = 2.$   |
| <b>KaiserBessel25:</b> | $\alpha = 2.5.$ |
| <b>KaiserBessel30:</b> | $\alpha = 3.$   |

**Parzen:**

$$w(n) = 1 - \left| \frac{2n}{N} \right|^2 \quad 0 \leq |n| \leq \frac{N}{2}.$$

**Poisson2, Poisson3, Poisson4:**

$$w(n) = \exp\left(-\alpha \frac{2|n|}{N}\right) \quad 0 \leq |n| \leq \frac{N}{2}.$$

| <i>windowKind</i> | $\alpha$      |
|-------------------|---------------|
| <b>Poisson2:</b>  | $\alpha = 2.$ |
| <b>Poisson3:</b>  | $\alpha = 3.$ |
| <b>Poisson4:</b>  | $\alpha = 4.$ |

**Riemann:**

$$w(n) = \frac{\sin\left(\frac{2\pi n}{N}\right)}{\left(\frac{2\pi n}{N}\right)} \quad 0 \leq |n| \leq \frac{N}{2}.$$

**Flat-Top:**

The flat-top windows are defined as a sum of cosine terms:

$$w(n) = \sum_{k=0}^m c_k \cos(kz), \quad z = \frac{2\pi j}{N}, \quad j = 0, 1, \dots, N-1.$$

Here are the supported flat-top window keywords for use as *windowKind* with the /WINF flag. These keywords require Igor Pro 8.00 or later:

| <i>windowKind</i> | Cosine Terms                                                                                                                                                                                                |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## FGetPos

**FGetPos** *refNum*

The FGetPos operation returns the file position for a file.

FGetPos is a faster alternative to FStatus if the only thing you are interested in is the file position.

The FGetPos operation was added in Igor Pro 7.00.

### Parameters

*refNum* is a file reference number obtained from the **Open** operation.

### Details

FGetPos supports very big files theoretically up to about 4.5E15 bytes in length.

FGetPos sets the following variables:

|                        |                                                             |
|------------------------|-------------------------------------------------------------|
| <code>v_flag</code>    | Nonzero (true) if <i>refNum</i> is valid.                   |
| <code>v_filePos</code> | Current file position for the file in bytes from the start. |

### See Also

**Open**, **FSetPos**, **FStatus**

## FIFO2Wave

**FIFO2Wave** [/R/S] *FIFOName*, *channelName*, *waveName*

The FIFO2Wave operation copies FIFO data from the specified channel of the named FIFO into the named wave. FIFOs are used for data acquisition.

### Flags

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                   |                |                   |                                                                                   |                   |                                                                  |                   |                                                        |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|----------------|-------------------|-----------------------------------------------------------------------------------|-------------------|------------------------------------------------------------------|-------------------|--------------------------------------------------------|
| <code>/R=[startPoint,endPoint]</code> | Dumps the specified FIFO points into the wave.                                                                                                                                                                                                                                                                                                                                                                                                                                      |                   |                |                   |                                                                                   |                   |                                                                  |                   |                                                        |

| <code>s=2:</code>                     | Changes the wave's number type to match the FIFO channel's type.                                                                                                                                                                                                                                                                                                                                                                                                                    |                   |                |                   |                                                                                   |                   |                                                                  |                   |                                                        |
| <code>s=3:</code>                     | Combination of <code>s=1</code> and <code>s=2</code> .                                                                                                                                                                                                                                                                                                                                                                                                                              |                   |                |                   |                                                                                   |                   |                                                                  |                   |                                                        |

### Details

The FIFO must be in the valid state for FIFO2Wave to work. When you create a FIFO, using NewFIFO, it is initially invalid. It becomes valid when you issue the start command via the CtrlFIFO operation. It remains valid until you change a FIFO parameter using CtrlFIFO.

If you specify a range of FIFO data points, using `/R=[startPoint,endPoint]` then FIFO2Wave dumps the specified FIFO points into the wave after clipping *startPoint* and *endPoint* to valid point numbers.

The valid point numbers depend on whether the FIFO is running and on whether or not it is attached to a file. If the FIFO is running then *startPoint* and *endPoint* are truncated to number of points in the FIFO. If the FIFO is buffering a file then the range can include the full extent of the file.

If you specify no range then FIFO2Wave transfers the most recently acquired FIFO data to the wave. The number of points transferred is the smaller of the number of points in the FIFO and number of points in the wave.

## FIFOStatus

---

FIFO2Wave may or may not change the wave's X scaling and number type, depending on the current X scaling and on the /S flag.

Think of the wave's X scaling as being controlled by two values,  $x_0$  and  $dx$ , where the X value of point  $p$  is  $x_0 + p * dx$ . FIFO2Wave always sets the wave's  $dx$  value equal to the FIFO's  $\Delta T$  value (as set by the CtrlFIFO operation). If you use no /S flag, FIFO2Wave does not set the wave's  $x_0$  value nor does it set the wave's number type.

If you are using FIFO2Wave to update a wave in a graph as quickly as possible, the /S=0 flag gives the highest update rate. The other /S values trigger more recalculation and slow down the updating.

If the wave's number type (possibly changed to match the FIFO channel) is a floating point type, FIFO2Wave scales the FIFO data before transferring it to the wave as follows:

$$\text{scaled\_value} = (\text{FIFO\_value} - \text{offset}) * \text{gain}$$

If the FIFO channel's gain is one and its offset is zero, the scaling would have no effect so FIFO2Wave skips it.

If the specified FIFO channel is an image strip channel (one defined using the optional vectPnts parameter to NewFIFOChan), then the resultant wave will be a matrix with the number of rows set by vectPnts and the number of columns set by the number of points described above for one-dimensional waves. To create an image plot that looks the same as the corresponding channel in a Chart, you will need to transpose the wave using **MatrixTranspose**.

## FIFOStatus

**FIFOStatus** [/Q] *FIFOName*

The FIFOStatus operation returns miscellaneous information about a FIFO and its channels. FIFOs are used for data acquisition.

### Flags

/Q                      Doesn't print in the history area.

### Details

FIFOStatus sets the variable  $V\_flag$  to nonzero if a FIFO of the given name exists. If the named FIFO does exist then FIFOStatus stores information about the FIFO in the following variables:

$V\_FIFORunning$     Nonzero if FIFO is running.  
 $V\_FIFOChunks$     Number of chunks of data placed in FIFO so far.  
 $V\_FIFONchans$     Number of channels in the FIFO.  
 $S\_Info$             Keyword-packed information string.

The keyword-packed information string consists of a sequence of sections with the following form: *keyword:value*;

You can pick a value out of a keyword-packed string using the **NumberByKey** and **StringByKey** functions. Here are the keywords for  $S\_Info$ :

| Keyword | Type   | Meaning                                                                                                                 |
|---------|--------|-------------------------------------------------------------------------------------------------------------------------|
| DATE    | Number | The date/time when start was issued via CtrlFIFO.                                                                       |
| DELTAT  | Number | The FIFO's $\Delta T$ value as set by CtrlFIFO.                                                                         |
| DISKTOT | Number | Current number of chunks written to the FIFO's file.                                                                    |
| FILENUM | Number | The output file refNum or review file refNum as set by CtrlFIFO. This will be zero if the FIFO is connected to no file. |

---

| Keyword  | Type   | Meaning                                                                                                                                        |
|----------|--------|------------------------------------------------------------------------------------------------------------------------------------------------|
| NOTE     | String | The FIFO's note string as set by CtrlFIFO.                                                                                                     |
| VALID    | Number | Zero if FIFO is not valid.                                                                                                                     |
| DATATYPE | Number | Channel's data type as if set by NewFIFOCHAN/Y=( <i>numType</i> ) where <i>numType</i> is a value as returned by the <b>WaveType</b> function. |

In addition, FIFOStatus writes fields to S\_Info for each channel in the FIFO. The keyword for the field is a combination of a name and a number that identify the field and the channel to which it refers. For example, if channel 4 is named "Pressure" then the following would appear in the S\_Info string: NAME4:Pressure.

In the following table, the channel's number is represented by "#".

| Keyword  | Type   | Meaning                                                 |
|----------|--------|---------------------------------------------------------|
| FSMINUS# | Number | Channel's minus full scale value as set by NewFIFOChan. |
| FSPLUS#  | Number | Channel's plus full scale value as set by NewFIFOChan.  |
| GAIN#    | Number | Channel's gain value as set by NewFIFOChan.             |
| NAME#    | String | Name of channel.                                        |
| OFFSET#  | Number | Channel's offset value as set by NewFIFOChan.           |
| UNITS#   | String | Channel's units as set by NewFIFOChan.                  |

## FilterFIR

**FilterFIR** [*flags*] *waveName* [, *waveName*]...

The FilterFIR operation convolves each *waveName* with automatically-designed filter coefficients or with *coefsWaveName* using time-domain methods.

The automatically-designed filter coefficients are simple lowpass and highpass window-based filters or a maximally-flat notch filter. Multiple filter designs are combined into a composite filter. The filter can be optionally placed into the first *waveName* or just used to filter the data in *waveName*.

FilterFIR filters data faster than **Convolve** when there are many fewer filter coefficient values than data points in *waveName*.

**Note:** FilterFIR replaces the obsolete **SmoothCustom** operation.

#### Parameters

*waveName* is a destination wave that is overwritten by the convolution of itself and the filter.

*waveName* may be multidimensional, but only one dimension selected by /DIM is filtered (for two-dimensional filtering, see **MatrixFilter**).

If *waveName* is complex, the real and imaginary parts are filtered independently.

#### Flags

/COEF [=coefsWaveName]

Replaces the first output *waveName* by the filter coefficients instead of the filtered results or, when *coefsWaveName* is specified, replaces the output wave(s) by the result of convolving *waveName* with coefficients in *coefsWaveName*.

*coefsWaveName* must not be one of the destination *waveNames*. It must be single- or double-precision numeric and one-dimensional.

To avoid shifting the output with respect to the input, *coefsWaveName* must have an odd length with the "center" coefficient in the middle of the wave.

The coefficients are usually symmetrical about the middle point, but FilterFIR does not enforce this.

*/DIM=d*

Specifies the wave dimension to filter.

*d=-1*: Treats entire wave as 1D (default).

*d=0*: Operates along rows.

*d=1*: Operates along columns.

*d=2*: Operates along layers.

*d=3*: Operates along chunks.

Use */DIM=0* to apply the filter to each individual column (each one a channel, say left and right) in a multidimensional *waveName* where each row comprises all of the sound samples at a particular time.

*/E=endEffect*

Determines how the ends of the wave (*w*) are handled when fabricating missing neighbor values. *endEffect* has values:

0: Bounce method (default). Uses  $w[i]$  in place of the missing  $w[-i]$  and  $w[n-i]$  in place of the missing  $w[n+i]$ .

1: Wrap method. Uses  $w[n-i]$  in place of the missing  $w[-i]$  and vice versa.

2: Fill with 0. Same as */ENDV={0}*.

3: Fill method. Uses  $w[0]$  in place of the missing  $w[-i]$  and  $w[n]$  in place of the missing  $w[n+i]$ .

*/ENDV={sv [, ev]}*

When fabricating missing neighbor values for each filtered wave, missing values before the start of data are replaced with *sv*.

Missing values after the end of data are replaced with *ev* if specified, or with *sv* if *ev* is omitted. */ENDV* implies */E=2*.

*/ENDV* was added in Igor Pro 9.00.

*/HI={f1, f2, n}*

Creates a high-pass filter based on the windowing method, using the Hanning window unless another window is specified by */WINF*.

*f1* and *f2* are filter design frequencies measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

*f1* is the end of the reject band, and *f2* is the start of the pass band:

$$0 < f1 < f2 < 0.5$$

*n* is the number of FIR filter coefficients to generate. A larger number gives better stop-band rejection. A good number to start with is 101.

Use both */HI* and */LO* to create a bandpass filter.

*/LO={f1, f2, n}*

Creates a low-pass filter. *f1* is the end of the pass band, *f2* is the start of the reject band, and *n* is the number of FIR filter coefficients. See */HI* for more details.

*/NMF={fc, fw [, eps, nMult]}*

Creates a maximally-flat notch filter centered at  $fc$  with a -3dB width of  $fw$ .  $fc$  and  $fw$  are filter design frequencies measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

The longest filter length allowed is 400,001 points, which requires  $fw \geq 0.000789$  (0.0789% of the sampling frequency).

Prior to Igor Pro 8.03 the longest filter length was 4,001 points, with  $fw \geq 0.00789$  (0.789% of the sampling frequency).

Coefficients at the ends that are smaller than the optional *eps* parameter are removed, making the filter shorter (and faster), though less accurate. The default is  $2^{-40}$ . Use 0 to retain all coefficients, no matter how small, even zero coefficients. Retaining all coefficients will substantially increase the execution time as  $fw$  is made smaller.

*nMult* specifies how much longer the filter may be to obtain the most accurate notch frequency. The default is 2 (potentially twice as many coefficients). Set *nMult*  $\leq 1$  to generate the shortest possible filter.

The maximally flat notch filter design is based on Zahradník and Vlcek, and uses arbitrary precision math (see **APMath**) to compute the coefficients.

*/WINF=windowKind*

Applies the named “window” to the filter coefficients. Windows alter the frequency response of the filter in obvious and subtle ways, enhancing the stop-band rejection or steepening the transition region between passed and rejected frequencies. They matter less when many filter coefficients are used.

If */WINF* is not specified, the Hanning window is used. For no coefficient filtering, use */WINF=None*.

Choices for *windowKind* are:

Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, and Riemann.

See **FFT** for window equations and details.

## Details

If *coefsWaveName* is specified, then */HI*, */LO*, and */NMF* are ignored.

If more than one of */HI*, */LO*, and */NMF* are specified, the filters are combined using linear convolution. The length of the combined filter is slightly less than the sum of the individual filter lengths.

A band pass or band reject filter results when both */LO* and */HI* are specified. A band pass filter results from */LO* frequencies greater than the */HI* frequencies (the pass bands of the low pass and high pass filters overlap). Beginning with Igor Pro 9.00, a band reject filter results when */LO* frequencies are less than the */HI* frequencies (the stop bands of the filters overlap).

The filtering convolution is performed in the time-domain. That is, the FFT is not employed to filter the data. For this reason the coefficients length should be small in comparison to the destination waves.

FilterFIR assumes that the middle point of *coefsWaveName* corresponds to the delay = 0 point. The “middle” point number =  $\text{trunc}(\text{numpts}(\text{coefsWaveName} - 1)/2)$ . *coefsWaveName* usually contains the two-sided impulse response of a filter, and usually contains an odd number of points. This is the kind of coefficients data generated by */HI*, */LO*, and */NMF*.

FilterFIR ignores the X scaling of all waves, except when */COEF* creates a coefficients wave, which preserves the X scale *deltax* and alters the *leftx* value so that the zero-phase (center) coefficient is located at  $x=0$ .

## Examples

```
// Make test sound from three sine waves
Variable/G fs= 44100 // Sampling frequency
Variable/G seconds= 0.5 // Duration
Variable/G n= 2*round(seconds*fs/2)
Make/O/W/N=(n) sound // 16-bit integer sound wave
SetScale/p x, 0, 1/fs, "s", sound
```

## FilterFIR

```
Variable/G f1= 200, f2= 1000, f3= 7000
Variable/G a1=100, a2=3000,a3=1500
sound= a1*sin(2*pi*f1*x)
sound += a2*sin(2*pi*f2*x)
sound += a3*sin(2*pi*f3*x)+gnoise(10) // Add a noise floor

// Compute the sound's spectrum in dB
FFT/MAG/WINF=Hanning/DEST=soundMag sound
soundMag= 20*log(soundMag)
SetScale d, 0, 0, "dB", soundMag

// Apply a 5 kHz low-pass filter to the sound wave
Duplicate/O sound, soundFiltered
FilterFIR/E=3/LO={4000/fs, 6000/fs, 101} soundFiltered

// Compute the filtered sound's spectrum in dB
FFT/MAG/WINF=Hanning/DEST=soundFilteredMag soundFiltered
soundFilteredMag= 20*log(soundFilteredMag)
SetScale d, 0, 0, "dB", soundFilteredMag

// Compute the filter's frequency response in dB
Make/O/D/N=0 coefs // Double precision is recommended
SetScale/p x, 0, 1/fs, "s", coefs
FilterFIR/COEF/LO={4000/fs, 6000/fs, 101} coefs
FFT/MAG/WINF=Hanning/PAD={(2*numpts(coefs))}/DEST=coefsMag coefs
coefsMag= 20*log(coefsMag)
SetScale d, 0, 0, "dB", coefsMag

// Graph the frequency responses
Display/R/T coefsMag as "FIR Lowpass Example";DelayUpdate
AppendToGraph soundMag, soundFilteredMag;DelayUpdate
ModifyGraph axisEnab(left)={0,0.6}, axisEnab(right)={0.65,1}
ModifyGraph rgb(soundFilteredMag)=(0,0,65535), rgb(coefsMag)=(0,0,0)
Legend
```

```
// Graph the unfiltered and filtered sound time responses
Display/L=leftSound sound as "FIR Filtered Sound";DelayUpdate
AppendToGraph/L=leftFiltered soundFiltered;DelayUpdate
ModifyGraph axisEnab(leftSound)={0,0.45}, axisEnab(leftFiltered)={0.55,1}
ModifyGraph rgb(soundFiltered)=(0,0,65535)

// Listen to the sounds
PlaySound sound // This has a very high frequency tone
PlaySound soundFiltered // This doesn't
```

## FilterIIR

**FilterIIR** [*flags*] [*waveName*, ...]

The FilterIIR operation applies to each *waveName* either the automatically-designed IIR filter coefficients or the IIR filter coefficients in *coefsWaveName*. Multiple filter designs are combined into a composite filter. The filter can be optionally placed into the first *waveName* or just used to filter the data in *waveName*.

The automatically-designed filter coefficients are bilinear transforms of the Butterworth analog prototype with an optional variable-width notch filter.

To design more advanced IIR filters, see **Designing the IIR Coefficients**.

### Parameters

*waveName* may be multidimensional, but only the one dimension selected by /DIM is filtered (for two-dimensional filtering, see **MatrixFilter**).

*waveName* may be omitted for the purpose of checking the format of *coefsWaveName*. If the format is detectably incorrect an error code will be returned in V\_flag. Use /Z to prevent command execution from stopping.

### Flags

- /CASC                    Specifies that *coefsWaveName* contains cascaded bi-quad filter coefficients. The cascade implementation is more stable and numerically accurate for high-order IIR filtering than Direct Form 1 filtering. See **Cascade Details**.
- /COEF [=coefsWaveName]
- Replaces the first output *waveName* by the filter coefficients instead of the filtered results or, when *coefsWaveName* is specified, replaces the output wave(s) by the result of filtering *waveName* with the IIR coefficients in *coefsWaveName*.
- coefsWaveName* must not be one of the destination *waveNames*. It must be single- or double-precision numeric and two-dimensional.
- When used with /CASC, *coefsWaveName* must have 6 columns, containing real-valued coefficients for a product of ratios of second-order polynomials (cascaded bi-quad sections).
- If /ZP is specified, it must be complex, otherwise it must be real.
- See **Details** for the format of the coefficients in *coefsWaveName*.
- /DIM=*d*                    Specifies the wave dimension to filter.
- d*=-1:                    Treats entire wave as 1D (default).
- d*=0:                    Operates along rows.
- d*=1:                    Operates along columns.
- d*=2:                    Operates along layers.
- d*=3:                    Operates along chunks.
- Use /DIM=0 to apply the filter to each individual column (each one a channel, say left and right) in a multidimensional *waveName* where each row comprises all of the sound samples at a particular time.
- /ENDV=*ev*                Values before the beginning of each filtered wave are replaced with *ev*. If you omit /ENDV they are replaced with zeros. To prevent filter startup artifacts set *ev* to the first value or a localized mean value at the start of the wave to be filtered.
- /ENDV was added in Igor Pro 9.00.
- /HI=*fHigh*                Creates a high-pass Butterworth filter with the -3dB corner at *fHigh*. The order of the filter is controlled by the /ORD flag.
- fHigh* is a filter design frequency measured in fractions of the sampling frequency, and may not exceed 0.5 (the normalized Nyquist frequency).

## FilterIIR

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### Details

FilterIIR sets *V\_flag* to 0 on success or to an error code if an error occurred. Command execution stops if an error occurs unless the */Z* flag is set. Omit */Z* and call **GetRTError** and **GetRTErrorMessage** under similar circumstances to see what the error code means.

### Direct Form 1 Details

Unless */CASC* or */ZP* are specified, the coefficients in *coefsWaveName* describe a ratio of two polynomials of the Z transform:

$$H(z) = \frac{Y(z)}{X(z)} = \frac{a_0 + a_1z^{-1} + a_2z^{-2} + \dots}{b_0 + b_1z^{-1} + b_2z^{-2} + \dots}$$

**Direct Form I Implementation**

$$y_i = \frac{a_0x_i + a_1x_{i-1} + a_2x_{i-2} + \dots - b_1y_{i-1} - b_2y_{i-2} + \dots}{b_0}$$

where *x* is the input wave *waveName* and *y* is the output wave (either *waveName* again or *destWaveName*). FilterIIR computes the filtered result using the Direct Form I implementation of *H(z)*.

The rational polynomial numerator ( $a_i$ ) coefficients in are column 0 and denominator ( $b_i$ ) coefficients in column 1 of *coefsWaveName*.

The coefficients in row 0 are the nondelayed coefficients  $a_0$  (in column 0) and  $b_0$  (in column 1).

The coefficients in row 1 are the  $z^{-1}$  coefficients,  $a_1$  and  $b_1$ .

The coefficients in row n are the  $z^{-n}$  coefficients,  $a_n$  and  $b_n$ .

The number of coefficients for the numerator can differ from the number of coefficients for the denominator. In this case, specify 0 for unused coefficients.

**Note:** If all the coefficients of the denominator are 0 ( $b_i=0$  except  $b_0=1$ ), then the filter is actually a causal FIR filter (Finite Impulse Response filter with delay of  $n-1$ ). In this sense, FilterIIR implements a superset of the FilterFIR operation.

**Alternate Direct Form 1 Notation**

The designation of  $a_i$ , etc. as the numerator is at odds with many textbooks such as *Digital Signal Processing*, which uses  $b$  for the numerator coefficients of the rational function,  $a$  for the denominator coefficients with an implicit  $a_0 = 1$ , in addition to reversing the signs of the remaining denominator coefficients so that they can write  $H(z)$  as:

$$H(z) = \frac{Y(z)}{X(z)} = \frac{\sum_{i=0}^n b_i z^{-i}}{1 - \sum_{i=1}^n a_i z^{-i}}$$

Coefficients derived using this notation need their denominator coefficients sign-reversed before putting them into rows 1 through n of column 1 (the second column), and the “missing” nondelayed denominator coefficient of 1.0 placed in row 0, column 1.

**Cascade Details**

When using /CASC, coefficients in *coefsWaveName* describe the product of one or more ratios of two quadratic polynomials of the Z transform:

$$H(z) = \frac{Y(z)}{X(z)} = \prod_{k=1}^K \frac{a_{0_k} + a_{1_k} z^{-1} + a_{2_k} z^{-2}}{b_{0_k} + b_{1_k} z^{-1} + b_{2_k} z^{-2}}$$

Each product term implements a “cascaded bi-quad section”, and  $H(z)$  can be realized by feeding the output of one section to the next one.

The cascade coefficients filter the data using a Direct Form II cascade implementation:

$$w_i = \frac{x_i - b_1 w_{i-1} - b_2 w_{i-2}}{b_0}$$

$$y_i = a_0 w_i + a_1 w_{i-1} + a_2 w_{i-2}$$

**Cascaded Bi-Quad Direct Form II Implementation**

## FilterIIR

The cascade implementation is more stable and numerically accurate for high-order IIR filtering than Direct Form I filtering. Cascade IIR filtering is recommended when the filter order exceeds 16 (a 16th-order Direct Form I filter has 17 numerator coefficients and 17 denominator coefficients).

*coefsWaveName* must be a six-column real-valued numeric wave. Each row describes one bi-quad section. The coefficients for the second term (or “section”) of the product ( $k=2$ ) are in the following row, etc.:

| <i>k</i> | Row | Col 0     | Col 1     | Col 2     | Col 3     | Col 4     | Col 5     |
|----------|-----|-----------|-----------|-----------|-----------|-----------|-----------|
| 1        | 0   | $a_{0_1}$ | $a_{1_1}$ | $a_{2_1}$ | $b_{0_1}$ | $b_{1_1}$ | $b_{2_1}$ |
| 2        | 1   | $a_{0_2}$ | $a_{1_2}$ | $a_{2_2}$ | $b_{0_2}$ | $b_{1_2}$ | $b_{2_2}$ |
| ...      |     |           |           |           |           |           |           |

The number of coefficients for the numerator ( $a$ 's) is allowed to differ from the number of coefficients for the denominator ( $b$ 's). In this case, specify 0 for unused coefficients.

For example, a third order filter (three poles and three zeros) cascade implementation is a single-order section combined with a second order section. The values for  $a_{2_k}$ ,  $b_{2_k}$  for that section ( $k$ ) would be 0. Here the second section is specified as the first-order section:

| <i>k</i> | Row | Col 0     | Col 1     | Col 2     | Col 3     | Col 4     | Col 5     |
|----------|-----|-----------|-----------|-----------|-----------|-----------|-----------|
| 1        | 0   | $a_{0_1}$ | $a_{1_1}$ | $a_{2_1}$ | $b_{0_1}$ | $b_{1_1}$ | $b_{2_1}$ |
| 2        | 1   | $a_{0_2}$ | $a_{1_2}$ | 0         | $b_{0_2}$ | $b_{1_2}$ | 0         |

### Alternate Cascade Notation

In the DSP literature, the  $b_{0_k}$  gain values are typically one and the  $H(z)$  expression contains an overall gain value, usually  $K$ . Here each product term (or “section”) has a user-settable gain value. Computing the correct gain values to control overflow in integer implementations is the responsibility of the user. For floating implementations, you might as well set all  $b_{0_k}$  values to one except, say,  $b_{0_1}$ , to control the overall gain.

### Zeros and Poles Details

When using /ZP, coefficients in *coefsWaveName* contains complex zeros and poles in the (also complex) Z transform domain:

$$H(z) = \frac{Y(z)}{X(z)} = \frac{(z - z_0)(z - z_1)(z - z_2)\dots}{(z - p_0)(z - p_1)(z - p_2)\dots}$$

*coefsWaveName* must be a two-column complex wave with zero0, zero1,... zeroN in the first column of N+1 rows, and pole0, pole1,... poleN in the second column of those same rows:

| <i>k</i> | Row | Col 0                  | Col 1                  |
|----------|-----|------------------------|------------------------|
| 1        | 0   | (zero0Real, zero0Imag) | (pole0Real, pole0Imag) |
| 2        | 1   | (zero1Real, zero1Imag) | (pole1Real, pole1Imag) |
| 3        | 2   | (zero2Real, zero2Imag) | (pole2Real, pole2Imag) |
| ...      |     |                        |                        |

If a zero or pole has a nonzero imaginary component, the conjugate zero or pole must be included in *coefsWaveName*. For example, if a zero is placed at (0.7, 0.5), the conjugate is (0.7, -0.5), and that value must also appear in column 0. These two zeros form what is known as a “conjugate pair”. The conjugate values must match within the greater of 1.0e-6 or 1.0e-6 \* |zeroOrPole|.

Use (0,0) for unused poles or zeros, as a zero or pole at  $z = (0,0)$  has no effect on the filter frequency response.

The /ZP format for the coefficients is internally converted into the Direct Form 1 implementation, or into the Cascade Direct Form 2 implementation if /CASC is specified. There is no option for returning these implementation-dependent coefficients in a wave.

### Designing the IIR Coefficients

Simple IIR filters can be used or created by specifying the /LO, /HI, /ORD, /N, /CASC, and /ZP flags. Use /COEF without *coefsWaveName* to put these simple IIR filter coefficients into the first *waveName*.

More advanced IIR filters (Bessel, Chebyshev) can be designed using the separate Igor Filter Design Laboratory (IFDL). IFDL is an Igor package that you use to design FIR (Finite Impulse Response) and IIR (Infinite Impulse Response) filters and to apply them to your data. The IIR design software creates IIR coefficients based on bilinear transforms of analog prototype filters such as Bessel, Butterworth, and Chebyshev.

Even without IFDL, you can create custom IIR filters by manually placing poles and zeros in the Z plane using the Pole and Zero Filter Design procedures. Copy the following line to your Procedure window and click the Compile button at the bottom of the procedure window:

```
#include <Pole And Zero Filter Design>
```

Then choose Pole and Zero Filter Design from the Analysis menu.

### Examples

```
// Make test sound from three sine waves
Variable/G fs= 44100 // Sampling frequency
Variable/G seconds= 0.5 // Duration
Variable/G n= 2*round(seconds*fs/2)
Make/O/W/N=(n) sound // 16-bit integer sound wave
SetScale/p x, 0, 1/fs, "s", sound
Variable/G f1= 200, f2= 1000, f3= 7000
Variable/G a1=100, a2=3000,a3=1500
sound= a1*sin(2*pi*f1*x)
sound += a2*sin(2*pi*f2*x)
sound += a3*sin(2*pi*f3*x)+gnoise(10) // Add a noise floor

// Compute the sound's spectrum in dB
FFT/MAG/WINF=Hanning/DEST=soundMag sound
soundMag= 20*log(soundMag)
SetScale d, 0, 0, "dB", soundMag

// Apply a 5 kHz, 6th order low-pass filter to the sound wave

## FindContour

**FindContour** [*flags*] *matrixWave*, *level*

The FindContour operation creates an XY pair of waves representing the locus of the solution to *matrixWave=level*.

The FindContour operation was added in Igor Pro 7.00.

**Flags**

|                          |                                                                                                                                 |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>/DSTX=destX</code> | Saves the output X data in the specified destination wave. The destination wave is created or overwritten if it already exists. |
| <code>/DSTY=destY</code> | Saves the output Y data in the specified destination wave. The destination wave is created or overwritten if it already exists. |

**Details**

FindContour uses a contour-following algorithm to generate a pair of waves describing the locus of the solution to *matrixWave=level*.

If you omit `/DSTX` the output X data is written to `W_XContour` in the current data folder.

If you omit `/DSTY` the output Y data is written to `W_YContour` in the current data folder.

The output waves are written as double-precision floating point. They use NaNs to separate different contiguous solution points.

**Example**

```
Make/N=(100,200) dataWave = 1e4*gauss(x,50,10,y,100,20)
FindContour dataWave,4 // Find solution to dataWave=4
NewImage dataWave
AppendToGraph/T W_YContour vs W_XContour
```

**See Also**

**AppendMatrixContour, ContourZ**

**FindDimLabel**

**FindDimLabel**(*waveName, dimNumber, labelString*)

Returns the index value corresponding to the label for the given dimension. Returns -1 if the label is for the entire dimension. Returns -2 if the label is not found.

Use *dimNumber* =0 for rows, 1 for columns, 2 for layers, or 3 for chunks.

**See Also**

**GetDimLabel, SetDimLabel, CopyDimLabels**

**FindDuplicates**

**FindDuplicates** [*flags*] *srcWave*

The FindDuplicates operation identifies duplicate values in a wave and optionally creates various output waves. *srcWave* can be either numeric or text.

When *srcWave* is numeric, the `/DN`, `/INDX`, `/RN` and `/SN` flags create output waves as described below. If you omit all of these flags then FindDuplicates does nothing.

When *srcWave* is text, the `/DT`, `/INDX`, `/RT` and `/ST` flags create output waves as described below. If you omit all of these flags then FindDuplicates does nothing.

The FindDuplicates operation was added in Igor Pro 7.00.

**Flags**

|                              |                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/FREE</code>           | Creates all output waves as free waves. The <code>/FREE</code> flag was added in Igor Pro 8.00. <code>/FREE</code> is permitted in user-defined functions only. If you use <code>/FREE</code> then all output wave parameters must be simple names, not paths or \$ expressions.<br><br>See <b>Free Waves</b> on page IV-90 for details on free waves. |
| <code>/INDX=indexWave</code> | Creates a numeric output wave containing the index of each encountered duplicate. The index is the point number in <i>srcWave</i> where a duplicate value was encountered. This flag applies to both numeric and text inputs.                                                                                                                          |
| <code>/Z</code>              | Do not report any errors.                                                                                                                                                                                                                                                                                                                              |

## FindDuplicates

---

### Flags for Numeric Source Wave

- /DN=dupsWave*      Creates a numeric output wave that contains the duplicates.
- /RN=dupsRemovedWave*  
Creates a numeric output wave that contains the source data with all duplicates removed.
- /SN=replacement*      Creates a numeric output wave with all duplicates replaced with *replacement*. *replacement* can be any numeric value including NaN or INF.  
The output wave is *W\_ReplacedDuplicates* in the current data folder unless you specify a different output wave using the */SNDS* flag.
- /SNDS=dupsReplacedWave*  
Specifies the output wave generated by */SN*. If you omit */SNDS* then the output wave created by */SN* is *W\_ReplacedDuplicates* in the current data folder. */SNDS* without */SN* has no effect.
- /TOL=tolerance*      Specifies the tolerance value for single-precision and double-precision numeric source waves.  
Two values are considered duplicates if  
 $\text{abs}(\text{value1} - \text{value2}) \leq \text{tolerance}$   
By default *tolerance* is zero.
- /UN=uniqueNumbersWave*  
Creates a numeric output wave that contains the unique numbers in *srcWave* sorted from small to large. When *srcWave* contains NaN entries they are sorted as the last point in *uniqueNumbersWave*.  
*/UN* is incompatible with */RN* which maintains the order of entries in *srcWave*.  
The */UN* flag was added in Igor Pro 9.00.
- /UNC=uniqueCounts*  
Creates a numeric output wave that contains the count of each entry in the *uniqueNumbersWave* created by the */UN* flag.  
The */UNC* flag was added in Igor Pro 9.00.

### Flags for Text Source Wave

- /CI*      Performs case-insensitive text comparisons on ASCII characters only. For example, "A" and "a" are considered duplicates.  
The */CI* flag was added in Igor Pro 9.00.
- /DT=dupsWave*      Creates a text output wave that contains the duplicates.
- /LOC*      Performs locale-aware text comparisons which take case into account for both ASCII and non-ASCII characters. For example, the non-ASCII characters "Å" and "å" are considered duplicates as well as the ASCII characters "A" and "a".  
*/LOC* is ignored unless you also include */CI*.  
The */LOC* flag was added in Igor Pro 9.00.
- /RT=dupsRemovedWave*  
Creates a text output wave that contains the source data with all duplicates removed.
- /ST=replacementStr*      Creates a text output wave with all duplicates replaced with *replacementStr*. *replacementStr* can be any text value including "".  
The output wave is *T\_ReplacedDuplicates* in the current data folder unless you specify a different output wave using the */STDS* flag.

*/STDS=dupsReplacedWave*

Specifies the output wave generated by */ST*. If you omit */STDS* then the output wave created by */ST* is *T\_ReplacedDuplications* in the current data folder. */STDS* without */ST* has no effect.

### Details

*FindDuplications* scans *srcWave* and identifies duplicate values. The first instance of any value is not considered a duplicate. Duplicates are either identical, as is the case with integer or text waves, or values that are within a specified tolerance in the case of single-precision or double-precision numeric waves.

Text comparison is case-sensitive unless you use */CI* or */CI/LOC*.

The operation creates wave references for the waves specified by the various flags above. See **Automatic Creation of WAVE References** on page IV-71 for details.

### Example

```
Function DemoFindDuplications(mode)
 int mode // 0=case sensitive; 1=/CI; 2=/CI/LOC

 Make/O/T sourceText={"A","a", "Å","å", "B","b"}
 switch(mode)
 case 0: // Case sensitive
 // Returns {"A","a","Å","å","B","b"}
 FindDuplications/FREE/RT=output sourceText
 break
 case 1: // Case insensitive for ASCII only
 // Returns {"A","Å","å","B"}
 FindDuplications/FREE/RT=output/CI sourceText
 break
 case 2: // Case insensitive, locale aware
 // Returns {"A","Å","B"}
 FindDuplications/FREE/RT=output/CI/LOC sourceText
 break
 endswitch

 Print sourceText
 Print output
End
```

### See Also

**FindLevels, FindValue, Sort, TextHistogram**

## FindLevel

**FindLevel** [*flags*] *waveName*, *level*

The *FindLevel* operation searches the named wave to find the X value at which the specified Y *level* is crossed.

### Flags

*/B=box* Sets box size for sliding average. If */B=box* is omitted or *box* equals 1, no averaging is done. If you specify an even box size then the next higher (odd) integer is used. If you use a box size greater than 1, *FindLevel* will be unable to find a level crossing that occurs in the first or last  $(box-1)/2$  points of the wave since these points don't have enough neighbors for computing the derived average wave values.

*/EDGE=e* Specifies searches for either increasing or decreasing level crossing.

- e=1*: Searches only for crossing where Y values are increasing as *level* is crossed from wave start towards wave end.
- e=2*: Searches only for crossing where the Y values are decreasing as *level* is crossed from wave start towards wave end.
- e=0*: Same as no */EDGE* flag (searches for either increasing and decreasing level crossing).

## FindLevel

---

|                               |                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/P</code>               | Computes the X crossing location in terms of point number. If <code>/P</code> is omitted, the level crossing location is computed in terms of X values.                                                                                                                                                                                                                                                |
| <code>/Q</code>               | Don't print results in history and don't report error if <i>level</i> is not found.                                                                                                                                                                                                                                                                                                                    |
| <code>/R=(startX,endX)</code> | Specifies an X range of the wave to search. You may exchange <i>startX</i> and <i>endX</i> to reverse the search direction.                                                                                                                                                                                                                                                                            |
| <code>/R=[startP,endP]</code> | Specifies a point range of the wave to search. You may exchange <i>startP</i> and <i>endP</i> to reverse the search direction. If you specify the range as <code>/R=[startP]</code> then the end of the range is taken as the end of the wave. If <code>/R</code> is omitted, the entire wave is searched.                                                                                             |
| <code>/T=dx</code>            | Search for two level crossings. <i>dx</i> must be less than <i>minWidthX</i> , so you must also specify <code>/M</code> if you use <code>/T</code> . (FindLevel limits <i>dx</i> so that second search start isn't beyond where the first search for next edge will be.)                                                                                                                               |
| <code>/T=dx</code>            | Performs a second search after finding the initial level crossing. The second search starts <i>dx</i> units beyond the initial level crossing and looks back in the direction of the initial crossing. If FindLevel finds a second level crossing, it sets <code>V_LevelX</code> to the average of the initial and second crossings. Otherwise, it sets <code>V_LevelX</code> to the initial crossing. |

### Details

FindLevel scans through the wave comparing *level* to values derived from the Y values of the wave. Each derived value is a sliding average of the Y values.

FindLevel searches for two derived wave values that straddle *level*. If it finds these values it computes the X value at which *level* is located by linearly interpolating between the straddling Y values.

FindLevel does not locate values exactly equal to *level*; it locates transitions through *level*. See **BinarySearch** for one method of locating exact values.

FindLevel reports its results by setting these variables:

|                       |                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>V_flag</code>   | 0: <i>level</i> was found.<br>1: <i>level</i> was not found.                                                                |
| <code>V_LevelX</code> | Interpolated X value at which <i>level</i> was found, or the corresponding point number if <code>/P</code> is specified.    |
| <code>V_rising</code> | 0: Y values at the crossing are decreasing from wave start towards wave end.<br>1: Y values at the crossing are increasing. |

If you omit the `/Q` flag then FindLevel also reports its results by printing them in the history area.

If *level* is not found, and if you omit the `/Q` flag, FindLevel generates an error which puts up an error alert and halts execution of any command line or macro that is in progress.

`V_LevelX` is returned in terms of the X scaling of the named wave unless you use the `/P` flag, in which case it is in terms of point number.

### FindLevel Handling of NaNs

In Igor Pro 8.00 and later, FindLevel handles NaN values differently than previous versions. Now if *level* falls between two non-NaN wave Y values with NaNs between them, those two Y values and their associated X scaling values are used to linearly interpolate the X location of the level crossing. Igor7 and earlier fail to find a crossing and set `V_LevelX` to NaN.

For example:

```
// Prints 2.5 in Igor8 or later, NaN in Igor7 or before
Make/O wave0 = {0, 1, NaN, NaN, 4, 5}
FindLevel/Q wave0, 2.5; Print V_levelX
```

You can revert to the pre-Igor 8 behavior by executing:

```
SetIgorOption UseIP6FindLevel = 1
```

**FindLevel and Multidimensional Waves**

The FindLevel operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details.

**See Also**

The **EdgeStats**, **FindLevels**, **FindValue**, and **PulseStats** operations and the **BinarySearch** and **BinarySearchInterp** functions.

**FindLevels**

**FindLevels** [*flags*] *waveName*, *level*

The FindLevels operation searches the named wave to find one or more X values at which the specified Y *level* is **crossed**.

To find where the wave is equal to a given value, use **FindValue** instead.

**Flags**

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/B=box</i>             | Sets box size for sliding average. See the <b>FindLevel</b> operation.                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>/D=destWaveName</i>    | Specifies wave into which FindLevels is to store the level crossing values. If <i>/D</i> and <i>/DEST</i> are omitted, FindLevels creates a wave named <i>W_FindLevels</i> to store the level crossing values in.                                                                                                                                                                                                                                       |
| <i>/DEST=destWaveName</i> | Same as <i>/D</i> . Both <i>/D</i> and <i>/DEST</i> create a real wave reference for the destination wave in a user function. See <b>Automatic Creation of WAVE References</b> on page IV-71 for details.                                                                                                                                                                                                                                               |
| <i>/EDGE=e</i>            | Specifies searches for either increasing or decreasing level crossing.<br><i>e=1:</i> Searches only for crossings where the Y values are increasing as level is crossed from wave start towards wave end.<br><i>e=2:</i> Searches only for crossings where the Y values are decreasing as level is crossed from wave start towards wave end.<br><i>e=0:</i> Same as no <i>/EDGE</i> flag (searches for both increasing and decreasing level crossings). |
| <i>/M=minWidthX</i>       | Sets the minimum X distance between level crossings. This determines where FindLevels searches for the next crossing after it has found a level crossing. The search starts <i>minWidthX</i> X units beyond the crossing. The default value for <i>minWidthX</i> is 0.                                                                                                                                                                                  |
| <i>/N=maxLevels</i>       | Sets a maximum number of crossings that FindLevels is to find. The default value for <i>maxLevels</i> is the number of points in the specified range of <i>waveName</i> .                                                                                                                                                                                                                                                                               |
| <i>/P</i>                 | Compute crossings in terms of points. See the <b>FindLevel</b> operation.                                                                                                                                                                                                                                                                                                                                                                               |
| <i>/Q</i>                 | Doesn't print to history and doesn't abort if no levels are found.                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>/R=(startX,endX)</i>   | Specifies X range. See the <b>FindLevel</b> operation.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>/R=[startP,endP]</i>   | Specifies point range. See the <b>FindLevel</b> operation.                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>/T=dx</i>              | Search for two level crossings. <i>dx</i> must be less than <i>minWidthX</i> , so you must also specify <i>/M</i> if you use <i>/T</i> . (FindLevels limits <i>dx</i> so that second search start isn't beyond where the first search for next edge will be.) See <b>FindLevel</b> for more about <i>/T</i> .                                                                                                                                           |

**Details**

The algorithm for finding a level crossing is the same one used by the **FindLevel** operation.

If FindLevels finds *maxLevels* crossings or can not find another level crossing, it stops searching.

## FindListItem

---

FindLevels sets the following variables:

V\_flag            0: *maxLevels* level crossings were found.  
                  1: At least one but less than *maxLevels* level crossings were found.  
                  2: No level crossings were found.

V\_LevelsFound    Number of level crossings found.

### Examples

```
Make/O/D/N=0 destWave
FindLevels/Q/D=destWave data, 5
if (V_LevelsFound)
 Print destWave[0] // First crossing X location

FindLevels/Q/D=destWave data, 5
if (V_LevelsFound)
 Print destWave[0] // First crossing X location
```

### See Also

The **FindLevel** operation for details about the level crossing detection algorithm and the /B, /P, /Q, /R, and /T flag values.

The FindLevels operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details.

## FindListItem

**FindListItem**(*itemStr*, *listStr* [, *listSepStr* [, *start* [, *matchCase* ]]])

The FindListItem function returns the byte offset into *listStr* where *itemStr* begins. *listStr* should contain items separated by the *listSepStr*.

Use FindListItem to locate the start of an item in a string containing a "wave0;wave1;" style list such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

Use WhichListItem to determine the index of an item in the list.

If *itemStr* is not found, if *listStr* is "", or if *start* is not within the range of 0 to strlen(*listStr*)-1, then -1 is returned.

*listSepStr*, *startIndex*, and *matchCase* are optional; their defaults are ";", 0, and 1 respectively.

### Details

*ItemStr* may have any length.

*listStr* is searched for the first instance of the item string bound by a *listSepStr* on the left and a *listSepStr* on the right. The returned number is the byte index where the first character of *itemStr* was found in *listSepStr*.

The search starts from the byte position in *listStr* specified by *start*. A value of 0 starts with the first character in *listStr*, which is the default if *start* is not specified.

*listString* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *listSepStr* are always case-sensitive. The comparison of *itemStr* to the contents of *listStr* is usually case-sensitive. Setting the optional *matchCase* parameter to 0 makes the comparison case insensitive.

In Igor6, only the first byte of *listSepStr* was used. In Igor7 and later, all bytes are used.

If *startIndex* is specified, then *listSepStr* must also be specified. If *matchCase* is specified, *startIndex* and *listSepStr* must be specified.

### Examples

```
Print FindListItem("w1", "w0;w1;w2,") // prints 3
Print FindListItem("v2", "v1,v2,v3,", ",") // prints 3
Print FindListItem("v2", "v0,v2,v2,", ",", 4) // prints 6
Print FindListItem("C", "a;c;C;") // prints 4
Print FindListItem("C", "a;c;C;", ";", 0, 0) // prints 2
```

## FindAPeak

**FindAPeak** [/B=*baseWaveName*] *minamp*, *pol*, *box*, *peakWave* [ (*startX*,*endX*) ]

FindAPeak locates the maximum or minimum of a peak by analyzing smoothed first and second derivatives.

The FindAPeak operation is used primarily by the Igor Technical Note #20 and its variants. For most purposes, use the more flexible **FindPeak** operation instead of FindAPeak.

### Parameters

*minamp* is minimum amplitude ("threshold") of a peak. Use it to reject small or spurious peaks.

*pol* is the expected peak polarity. Specify 1 to search for a positive-going peak or 2 to search for a negative-going peak.

*box* is the number of peak values to include in the sliding average when smoothing the derivatives. If you specify an even number, the next-higher odd number is used.

*peakWave* specifies the wave containing the peak.

[*startX*,*endX*] is an optional subrange to search in point numbers.

(*startX*,*endX*) is an optional subrange to search in X values.

If you omit the subrange, *startX* defaults to the first point in *peakWave* and *endX* defaults to the last point in *peakWave*.

The search always with *startX* and ends at *endX*, regardless of whether *startX* is less than or greater than *endX*. You can use this to control the direction of the search.

### Flags

/B=*baseWave*            Specifies a base wave containing values to subtract from *peakWave* to compute the derived data which FindAPeak searches for peaks.

### Details

FindAPeak creates a temporary smoothed version of *peakWave* and a temporary first derivative of the smoothed data. It scans through the first derivative for the first zero-crossing where the smoothed data exceeds the minimum amplitude as specified by *minamp*. The location of the zero-crossing is then more accurately determined by reverse linear interpolation. The smoothed second derivative is computed at that point to see if the peak is a positive-going or negative-going peak.

### Output Variables

FindAPeak reports results through these output variables:

|         |                                                              |
|---------|--------------------------------------------------------------|
| V_Flag  | 0 if a peak is found and to 1 if no peak is found.           |
| V_peakX | The interpolated X value of the peak center.                 |
| V_peakP | The interpolated fractional point number of the peak center. |

### See Also

**FindPeak**, **EstimatePeakSizes**

## FindPeak

**FindPeak** [*flags*] *waveName*

The FindPeak operation searches for a minimum or maximum by analyzing the smoothed first and second derivatives of the named wave. Information about the peak position, amplitude, and width are returned in the output variables.

### Flags

Some of the flags have the same meaning as for the FindLevel operation.

/B=*box*                Sets box size for sliding average.

## FindPeak

---

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/I</code>               | Modify the search criteria to accommodate impulses (peaks of one sample) by requiring only one value to exceed <i>minLevel</i> .<br>The default criteria requires that two successive values exceed <i>minLevel</i> for a peak to be found (or two successive values be less than the <code>/M</code> level when searching for negative peaks).<br>Impulses can also be found by omitting <i>minLevel</i> , in which case <code>/I</code> is superfluous. |
| <code>/M=minLevel</code>      | Defines minimum level of a peak. <code>/N</code> changes this to maximum level (see <b>Details</b> ).                                                                                                                                                                                                                                                                                                                                                     |
| <code>/N</code>               | Searches for a negative peak (minimum) rather than a positive peak (maximum).                                                                                                                                                                                                                                                                                                                                                                             |
| <code>/P</code>               | Location output variables (see <b>Details</b> ) are reported in terms of (floating point) point numbers. If <code>/P</code> is omitted, they are reported as X values.                                                                                                                                                                                                                                                                                    |
| <code>/Q</code>               | Doesn't print to history and doesn't abort if no peak is found.                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>/R=(startX,endX)</code> | Specifies X range and direction for search.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>/R=[startP,endP]</code> | Specifies point range and direction for search.                                                                                                                                                                                                                                                                                                                                                                                                           |

### Details

FindPeak sets the following variables:

|                                |                                                                                                                                                                                                                                                   |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>V_flag</code>            | Set only when using the <code>/Q</code> flag.<br>0: Peak was found.<br>Any nonzero value means the peak was not found.                                                                                                                            |
| <code>V_LeadingEdgeLoc</code>  | Interpolated location of the peak edge closest to <i>startX</i> or <i>startP</i> . If you use the <code>/P</code> flag, <code>V_LeadingEdgeLoc</code> is a point number rather than to an X value. If the edge was not found, this value is NaN.  |
| <code>V_PeakLoc</code>         | Interpolated X value at which the peak was found. If you use the <code>/P</code> flag, FindPeak sets <code>V_PeakLoc</code> to a point number rather than to an X value. Set to NaN if peak wasn't found.                                         |
| <code>V_PeakVal</code>         | The <i>approximate</i> Y value of the found peak. If the peak was not found, this value is NaN (Not a Number).                                                                                                                                    |
| <code>V_PeakWidth</code>       | Interpolated peak width. If you use the <code>/P</code> flag, <code>V_PeakWidth</code> is expressed in point numbers rather than as an X value. <code>V_PeakWidth</code> is never negative. If either peak edge was not found, this value is NaN. |
| <code>V_TrailingEdgeLoc</code> | Interpolated location of the peak edge closest to <i>endX</i> or <i>endP</i> . If you use the <code>/P</code> flag, <code>V_TrailingEdgeLoc</code> is a point number rather than to an X value. If the edge was not found, this value is NaN.     |

FindPeak computes the sliding average of the input wave using the BoxSmooth algorithm with the *box* parameter. The peak center is found where the derivative of this smoothed result crosses zero. The peak edges are found where the second derivative of the smoothed result crosses zero. Linear interpolation of the derivatives is used to more precisely locate the center and edges. The peak value is simply the greater of the two unsmoothed values surrounding the peak center (if `/N`, then the lesser value).

FindPeak is not a high-accuracy measurement routine; it is intended as a simple peak-finder. Use the **PulseStats** operation for more precise statistics.

Without `/M`, a peak is found where the derivative crosses zero, regardless of the peak height.

If you use the `/M=minLevel` flag, FindPeak ignores peaks that are lower than *minLevel* (i.e., the Y value of a found peak will exceed *minLevel*) in the box-smoothed input wave. If `/N` is also specified (search for minimum), FindPeak ignores peaks whose amplitude is greater than *minLevel* (i.e., the Y value of a found peak will be *less* than *minLevel*).

Without `/I`, a peak must have two successive values that exceed *minLevel*. Use `/I` when you are searching for peaks that may have only one value exceeding *minLevel*.

The search for the peak begins at *startX* (or the first point of the wave if /R is not specified), and ends at *endX* (or the last point of the wave if no /R). Searching backwards is permitted, and exchanges the values of *V\_LeadingEdgeLoc* and *V\_TrailingEdgeLoc*.

A simple automatic peak-finder is implemented in the "Peak Autofind.ipf" procedure file used in the Multipeak Fitting package. Execute `DisplayHelpTopic "Multipeak Fitting"` for details.

The FindPeak operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details.

## FindPointsInPoly

**FindPointsInPoly** *xWaveName*, *yWaveName*, *xPolyWaveName*, *yPolyWaveName*

The FindPointsInPoly operation determines if points fall within a certain polygon. It can be used to write procedures that operate on a subset of data identified graphically in a graph.

#### Details

FindPointsInPoly determines which points in *yWaveName* vs *xWaveName* fall within the polygon defined by *yPolyWaveName* vs *xPolyWaveName*.

*xWaveName* must have the same number of points as *yWaveName* and *xPolyWaveName* must have the same number of points as *yPolyWaveName*.

FindPointsInPoly creates an output wave named *W\_inPoly* with the same number of points as *xWaveName*. FindPointsInPoly indicates whether the point *yWaveName*[*p*] vs *xWaveName*[*p*] falls within the polygon by setting *W\_inPoly*[*p*] = 1 if it is within the polygon, or *W\_inPoly*[*p*] = 0 if it is not.

FindPointsInPoly uses integer arithmetic with a precision of about 1 part in 1000. This should be good enough for visually determined (hand-drawn) polygons but might not be sufficient for mathematically generated polygons.

The FindPointsInPoly operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details.

## FindRoots

**FindRoots** [*flags*] *funcspec*, *pWave* [, *funcspec*, *pwave* [, ...]]

**FindRoots** /P=*PolyCoefsWave*

The FindRoots operation determines roots or zeros of a specified nonlinear function or system of functions. The function or system of functions must be defined in the form of Igor user procedures.

Using the second form of the command, FindRoots finds all the complex roots of a polynomial with real coefficients. The polynomial coefficients are specified by *PolyCoefsWave*.

#### Flags for roots of nonlinear functions

|                                 |                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/B</i> [= <i>doBracket</i> ] | Specifies bracketing for roots of a single nonlinear function only.                                                                                                                                                                                                                                                                       |
| <i>doBracket</i> =0:            | Skips an initial check of the root bracketing values and the possible search for bracketing values. This means that you must provide good bracketing values via the /L and /H flags. See /L and /H flags for details on bracketing of roots. /B alone is the same as /B=0.                                                                |
| <i>doBracket</i> =1:            | Uses default root bracketing.                                                                                                                                                                                                                                                                                                             |
| <i>/F</i> = <i>trustRegion</i>  | Sets the expansion factor of the trust region for the search algorithm when finding roots of systems of functions. Smaller numbers will result in a more stable search, although for some functions larger values will allow the search to zero in on a root more rapidly. Default is 1.0; useful values are usually between 0.1 and 100. |

## FindRoots

---

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/I=maxIters</i>                         | Sets the maximum number of iterations in searching for a root to <i>maxIters</i> . Default is 100.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>/L=lowBracket</i>                       | <i>/L</i> and <i>/H</i> are used only when finding roots of a single nonlinear function. <i>lowBracket</i> and <i>highBracket</i> are X values that bracket a zero crossing of the function. A root is found between the bracketing values.<br><br>If <i>lowBracket</i> and <i>highBracket</i> are on the same side of zero, it will try to find a minimum or maximum between <i>lowBracket</i> and <i>highBracket</i> . If it is found, and it is on the other side of zero, Igor will find two roots.<br><br>If <i>lowBracket</i> and <i>highBracket</i> are on the same side of zero, but no suitable extreme point is found between, it will search outward from these values looking for a zero crossing. If it is found, Igor determines one root.<br><br>If <i>lowBracket</i> and <i>highBracket</i> are equal, it adds 1.0 to <i>highBracket</i> before looking for a zero crossing.<br><br>The default values for <i>lowBracket</i> and <i>highBracket</i> are zero. Thus, not using either <i>lowBracket</i> or <i>highBracket</i> is the same as <i>/L=0/H=1</i> . |
| <i>/H=highBracket</i>                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>/Q</i>                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>/T=tol</i>                              | Sets the acceptable accuracy to <i>tol</i> . That is, the reported root should be within $\pm tol$ of the real root.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>/X=xWave</i><br><i>/X={x1, x2, ...}</i> | Sets the starting point for searching for a root of a system of functions. There must be as many X values as functions. The starting point can be specified with a wave having as many points as there are functions, or you can write out a list of X values in braces. If you are finding roots of a single function, use <i>/L</i> and <i>/H</i> instead.<br><br>If you specify a wave, this wave is also used to receive the result of the root search.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>/Z=yValue</i>                           | Finds other solutions, that is, places where $f(x) = yValue$ . FindRoots usually finds zeroes — places where $f(x) = 0$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### Flag for roots of polynomials

|                         |                                                                                                                                                                                                                                                                                                              |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/P=PolyCoefsWave</i> | Specifies a wave containing real polynomial coefficients. With this flag, it finds polynomial roots and does not expect to find user function names on the command line.<br><br>The <i>/P</i> flag causes all other flags to be ignored.<br><br>Use of this flag is not permitted in a thread-safe function. |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Parameters

*func* specifies the name of a user-defined function.

*pwave* gives the name of a parameter wave that will be passed to your function as the first parameter. It is not modified. It is intended for your private use to pass adjustable constants to your function.

These parameters occur in pairs. For a one-dimensional problem, use a single *func*, *pwave* pair. An N-dimensional problem requires N pairs unless you use the combined function form (see **Combined Format for Systems of Functions**).

### Function Format for 1D Nonlinear Functions

Finding roots of a nonlinear function or system of functions requires that you realize the function in the form of an Igor user function of a certain form. In the FindRoots command you then specify the functions with one or more function names paired with parameter wave names. See **Finding Function Roots** on page III-338 for detailed examples.

The functions must have a particular form. If you are finding the roots of a single 1D function, it should look like this:

```
Function myFunc(w,x)
 Wave w
 Variable x
 return f(x) // an expression ...
End
```

Replace “f(x)” with an appropriate expression. The FindRoots command might then look like this:

```
FindRoots /L=0 /H=1 myFunc, cw // cw is a parameter wave for myFunc
```

### Function Format for Systems of Multivariate Functions

If you need to find the roots of a system of multidimensional functions, you can use either of two forms. In one form, you provide N functions with N independent variables. You must have a function for each independent variable. For instance, to find the roots of two 2D functions, the functions must have this form:

```
Function myFunc1(w, x1, x2)
 Wave w
 Variable x1, x2
 return f1(x1, x2) // an expression ...
End

Function myFunc2(w, x1, x2)
 Wave w
 Variable x1, x2
 return f2(x1, x2) // an expression ...
End
```

In this case, the FindRoots command might look like this (where cw1 and cw2 are parameter waves that must be made before executing FindRoots):

```
FindRoots /X={0,1} myFunc1, cw1, myFunc2, cw2
```

You can also use a wave to pass in the X values. Make sure you have the right number of points in the X wave — it must have N points for a system of N functions.

```
Function myFunc1(w, xW)
 Wave w, xW
 return f1(xW[0], xW[1]) // an expression ...
End

Function myFunc2(w, xW)
 Wave w, xW
 return f2(xW[0], xW[1]) // an expression ...
End
```

### Combined Format for Systems of Functions

For large systems of equations it may get tedious to write a separate function for each equation, and the FindRoots command line will get very long. Instead, you can write it all in one function that returns N Y values through a Y wave. The X values are passed to the function through a wave with N elements. The parameter wave for such a function must have N columns, one column for each equation. The parameters for equation N are stored in column N-1. FindRoots will complain if any of these waves has other than N rows.

Here is an template for such a function:

```
Function myCombinedFunc(w, xW, yW)
 Wave w, xW, yW
 yW[0] = f1(w[0][...], xW[0], xW[1], ..., xW[N-1])
 yW[1] = f2(w[1][...], xW[0], xW[1], ..., xW[N-1])
 ...
 yW[N-1] = fN(w[N-1][...], xW[0], xW[1], ..., xW[N-1])
End
```

When you use this form, you only have one function and parameter wave specification in the FindRoots command:

```
Make/N=(nrows, nequations) paramWave
fill in paramWave with values
Make/N=(number of equations) guessWave
guessWave = {x0, x1, ..., xN}
FindRoots /X=guessWave myCombinedFunc, paramWave
```

FindRoots has no idea how many actual equations you have in the function. If it doesn't match the number of rows in your waves, your results will not be what you expect!

### Coefficients for Polynomials

To find the roots of a polynomial, you first create a wave with the correct number of points. For a polynomial of degree N, create a wave with N+1 points. For instance, to find roots of a cubic equation you need a four-point wave.

## FindRoots

---

The first point (row zero) of the wave contains the constant coefficient, the second point contains the coefficient for  $X$ , the third for  $X^2$ , etc.

There is no hard limit on the maximum degree, but note that there are significant numerical problems associated with computations involving high-degree polynomials. Roundoff error most likely limits reasonably accurate results to polynomials with degree limited to 20 to 30.

Ultimately, if you are willing to accept very limited accuracy, the numerical problems will result in a failure to converge. In limited testing, we found no failures to converge with polynomials up to at least degree 100. At degree 150, we found occasional failures. At degree 200 the failures were frequent, and at degree 500 we found no successes.

Note that you really can't evaluate a polynomial with such high degree, and we have no idea if the computed roots for a degree-100 polynomial have any practical relationship to the actual roots.

While FindRoots is a thread-safe operation, finding polynomial roots is not. Using FindRoots/P=polyWave in a ThreadSafe function results in a compile error.

### Results for Nonlinear Functions and Systems of Functions

The FindRoots operation reports success or failure via the `V_flag` variable. A nonzero value of `V_flag` indicates the reason for failure.

|                        |                                                                                                                                                                                                                                                                                                                       |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>V_flag=0:</code> | Success, but check <code>V_YatRoot</code> , <code>V_YatRoot2</code> or <code>W_YatRoot</code> to make sure that the convergence point is sufficiently small to indicate a true root. It is very unlikely for the <code>Y</code> values to be exactly zero. "Sufficiently small" depends on the scale of your problem. |
| <code>V_flag=1:</code> | User abort.                                                                                                                                                                                                                                                                                                           |
| <code>V_flag=3:</code> | Exceeded maximum allowed iterations                                                                                                                                                                                                                                                                                   |
| <code>V_flag=4:</code> | <code>/T=tol</code> was too small. Reported by the root finder for systems of nonlinear functions.                                                                                                                                                                                                                    |
| <code>V_flag=5:</code> | The search algorithm wasn't making sufficient progress. It may mean that <code>/T=tol</code> was set to too low a value, or that the search algorithm has gotten trapped at a false root. Try restarting from a different starting point.                                                                             |
| <code>V_flag=6:</code> | Unable to bracket a root. Reported when finding roots of single nonlinear functions.                                                                                                                                                                                                                                  |
| <code>V_flag=7:</code> | Fewer roots than expected. Reported by the polynomial root finder. This may indicate that roots were successfully found, but some are doubled. Happens only rarely.                                                                                                                                                   |
| <code>V_flag=8:</code> | Decreased degree. Reported by the polynomial root finder. This indicates that one or more of the highest-order coefficients was zero, and a lower degree polynomial was solved.                                                                                                                                       |
| <code>V_flag=9:</code> | Convergence failure or other numerical problem. Reported by the polynomial root finder. This indicates that a numerical problem was detected during the computation. The results are not valid.                                                                                                                       |

The results of finding roots of a single 1D function are put into several variables:

|                         |                                                                                                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>V_numRoots</code> | The number of roots found. Either 1 or 2.                                                                                                                                                                                |
| <code>V_Root</code>     | The root.                                                                                                                                                                                                                |
| <code>V_YatRoot</code>  | The <code>Y</code> value of the function at the root. <i>Always</i> check this; some discontinuous functions may give an indication of success, but the <code>Y</code> value at the found root isn't even close to zero. |
| <code>V_Root2</code>    | Second root if FindRoots found two roots.                                                                                                                                                                                |
| <code>V_YatRoot2</code> | The <code>Y</code> value at the second root.                                                                                                                                                                             |

Results for roots of a system of nonlinear functions are reported in waves:

|                     |                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>W_Root</code> | <code>X</code> values of the root of a system of nonlinear functions. If you used <code>/X=xWave</code> , the root is reported in your wave instead. |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|

`W_YatRoot`      The Y values of the functions at the root of a system of nonlinear functions.  
Only one root is found during a single call to FindRoots.

Roots of a polynomial are reported in a wave:

`W_polyRoots`      A complex wave containing the roots of a polynomial. The number of roots should be equal to the degree of the polynomial, unless a root is doubled.

### See Also

**Finding Function Roots** on page III-338.

The FindRoots operation uses the Jenkins-Traub algorithm for finding roots of polynomials:

Jenkins, M.A., Algorithm 493, Zeros of a Real Polynomial, *ACM Transactions on Mathematical Software*, 1, 178-189, 1975. Used by permission of ACM (1998).

## FindSequence

**FindSequence** [*flags*] *srcWave*

The FindSequence operation finds the location of the specified sequence starting the search from the specified start point. The result of the search stored in `V_value` is the index of the entry in the wave where the first value is found or -1 if the sequence was not found.

### Flags

`/FNAN`      Specifies searching for a NaN value when *srcWave* is floating point.  
This flag was added in Igor Pro 7.00.

`/I=wave`      Specifies an integer sequence wave for integer search.

`/M=val`      If there are repeating entries in the match sequence, *val* is a tolerance value that specifies the maximum difference between the number of repeats. So, for example, if the match sequence is aaabbccc and the *srcWave* contains a sequence aabbcc then the sequence will not be considered a match if *val*=0 but will be considered a match if *val*=1.

`/R`      Searches in reverse from the point in *srcWave* specified by `/S` or, if you omit `/S`, from the end of *srcWave*. `/R` was added in Igor Pro 9.00.

`/S=start`      Sets starting point of the search.  
If you omit `/S`, the search starts from the start of *srcWave* or, if you include `/R`, from the end of *srcWave*.

`/T=tolerance`      Defines the tolerance (value  $\pm$  *tolerance* will be accepted) when comparing floating point numbers.

`/U=uValueWave`      Specifies the match sequence wave in case of unsigned long range.

`/V=rValueWave`      Specifies the match sequence wave in the case of single/double precision numbers.

`/Z`      No error reporting.

### Details

If the match sequence is specified via the `/V` flag, it is considered to be a floating point wave (i.e., single or double precision) in which case it is compared to data in the wave using a tolerance value. If the tolerance is not specified by the `/T` flag, the default value  $1.0^{-7}$ .

If the match sequence is specified via the `/I` flag, the sequence is assumed to be an integer wave (this includes both signed and unsigned char, signed and unsigned short as well as long). In this case *srcWave* must also be of integer type and the operation searches for the sequence based on exact equality between the match sequence and entries in the wave as signed long integers.

If the match sequence is unsigned long wave use the `/U` flag to specify the value for an integer comparison.

You can also use this operation on waves of two or more dimensions. In this case you can calculate the rows, columns, etc. For example, in the case of a 2D wave:

## FindValue

---

```
col=floor(V_value/rowsInWave)
row=V_value-col*rowsInWave
```

### See Also

The **FindValue** operation.

## FindValue

**FindValue** [*flags*] *srcWave*

**FindValue** [*flags*] *txtWave*

The FindValue operation finds the location of the specified value starting the search from the specified start point. The result of the search stored in V\_value is the index of the entry in the wave where the value is found or -1 if not found.

### Flags

- /FNAN** Specifies searching for a NaN value when *srcWave* is floating point.  
The /FNAN flag was added in Igor Pro 7.00.
- /I=*ival*** Specifies an integer value for integer search.
- /R** Reverses the order of the search.  
In the absence of /S and /RMD, the search starts from the end of the wave.  
/R is not compatible with /UOFV.  
The /R flag was added in Igor Pro 9.00.
- /RMD=[*firstRow,lastRow*][*firstColumn,lastColumn*][*firstLayer,lastlayer*][*firstChunk,lastChunk*]**  
Designates a contiguous range of data in the source wave to which the operation is to be applied. This flag was added in Igor Pro 8.00.  
You can include all higher dimensions by leaving off the corresponding brackets. For example:  
`/RMD= [firstRow, lastRow]`  
includes all available columns, layers and chunks.  
You can use empty brackets to include all of a given dimension. For example:  
`/RMD= [] [firstColumn, lastColumn]`  
means "all rows from column A to column B".  
You can use a \* to specify the end of any dimension. For example:  
`/RMD= [firstRow, *]`  
means "from firstRow through the last row".
- /S=*start*** Sets start of search in the wave. If /S is not specified, start is set to 0.
- /T=*tolerance*** Use this flag when comparing floating point numbers to define a non-negative tolerance such that the specified value  $\pm$  *tolerance* will be accepted.
- /TEXT=*templateString***  
Specifies a template string that will be searched for in *txtWave*.
- /TXOP=*txOptions*** Specifies the search options using a combination of binary values.  
1: Case sensitive  
2: Whole word  
4: Whole wave element
- /U=*uValue*** Specifies the match value in case of unsigned long range.

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/UOFV</code>     | The <code>/UOFV</code> (unordered find value) flag, which was added in Igor Pro 8.00, runs the search using multiple threads with each thread searching a different section of the wave. The search terminates when any thread finds a matching value.<br><br>Use <code>/UOFV</code> when you need the fastest result and you do not care if it finds the first matching value in the wave or a subsequent matching value.<br><br>By default <code>/UOFV</code> is ignored if <code>srcWave</code> contains fewer than 2,000 points. You can modify this value using <b>MultiThreadingControl</b> . <code>/UOFV</code> is also ignored if you use the <code>/RMD</code> flag. |
| <code>/V=rValue</code> | Specifies the match value in the case of single/double precision numbers. For most purposes you should also use <code>/T</code> to specify the tolerance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>/Z</code>        | No error reporting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### Details

If the match value is specified via the `/V` flag, it is considered to be a floating point value in which case it is compared to data in the wave using a tolerance value. If the tolerance is not specified by the `/T` flag, the value  $10^{-7}$  is used.

If the match value is specified via the `/I` flag, the value is assumed to be an integer. In this case `srcWave` must be of integer type and the operation searches for the value based on exact equality between the match value and entries in the wave as signed long integers.

If the match value is unsigned long use the `/U` flag to specify the value for an integer comparison.

You can also use this operation on waves of two or more dimensions. In this case you can calculate the rows, columns, etc. For example, in the case of a 2D wave:

```
col=floor(V_value/rowsInWave)
row=V_value-col*rowsInWave
```

When searching for text in a text wave the operation creates the variable `V_value` as above but it also creates the variable `V_startPos` to specify the position of *templateString* from the start of the particular wave element.

### Example

```
Make jack = sin(x/8) // Single-precision floating point
Display jack

// This prints -1 because 0.5 +/- 1.0E-7 does not occur in wave jack
FindValue /V=.5 jack; Print V_value

// This prints 21 because 0.5 +/- 0.01 does occur in wave jack
FindValue /V=.5 /T=.01 jack; Print V_value

// The value of jack(21), to 6 decimal digits of precision, is 0.493920
Print jack(21)
```

## FitFunc

### FitFunc

Marks a user function as a user-defined curve fit function. By default, only functions marked with this keyword are displayed in the Function menu in the Curve Fit dialog.

If you wish other functions to be displayed in the Function menu, you can select the checkbox labelled "Show old-style functions (missing FitFunc keyword)".

### See Also

**User-Defined Fitting Functions** on page III-250.

## floor

### floor (num)

The floor function returns the closest integer less than or equal to *num*.

The result for INF and NAN is undefined.

## FMaxFlat

---

### See Also

The **round**, **ceil**, and **trunc** functions.

## FMaxFlat

**FMaxFlat** [/SYM[=*sym*] /Z[=*z*]] *beta*, *gamma*, *coefsWave*

The FMaxFlat operation calculates the coefficients of Kaiser's maximally flat filter.

FMaxFlat is primarily used for the Kaiser maximally flat filter feature of the Igor Filter Design Laboratory (IFDL) package.

### Flags

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /SYM[= <i>sym</i> ] | Return symmetrical FIR filter coefficients without a leading length point (see <i>Details</i> below). The /SYM flag was added in Igor Pro 8.00.                                                                                                                                                                                                                                                                        |
| /Z[= <i>z</i> ]     | Prevents procedure execution from aborting if FMaxFlat generates an error. The /Z flag was added in Igor Pro 8.00.<br><br>V_Flag is set to a non-zero error code or zero if no error occurred.<br><br>Use /Z or the equivalent, /Z=1, if you want to handle errors in your procedures rather than having execution abort. Unlike some other operations /Z does suppress invalid beta and gamma value parameter errors. |

### Parameters

*beta* is the transition frequency ("cutoff") expressed as a fraction of the sampling frequency, more than 0 and less than 0.5.

*gamma* is the transition width in fraction of sampling frequency, a number more than 0 and less than 0.5, and less than both  $\beta^2$  and  $1-2\beta$ .

*coefsWave* is the 1D single- or double-precision floating point wave that receives the resulting coefficients. In Igor8 or later, FMaxFlat resizes *coefsWave* as necessary to fit the number of returned values. The upper bound on the number of coefficients can be computed as: `ceil(5/16/gamma/gamma)+1`

### Details

The operation is based on the "mxflat" program as found in Elliot and Kaiser (see references below).

Use the /SYM flag to return a *coefsWave* with symmetrical coefficients suitable for use with **FilterFIR**, in which case the number of points in *coefsWave* identifies the number of filter coefficients.

If you omit /SYM or specify /SYM=0, only half of the coefficients are computed by FMaxFlat. The rest can be obtained by symmetry, but the first point of *coefsWave* contains the number of computed coefficients in the designed filter. This unusual format is compatible with pre-Igor8 IFDL procedures.

### Example

```
// Make a maximally-flat low pass filter with cutoff at 1/4 sampling frequency
Make/O/D/N=0 coefs // coefs will be resized
FMaxFlat/SYM 0.25, 0.05, coefs // Make symmetrical FIR filter
Display coefs

// Analyze the filter's frequency response
FFT/OUT=3/PAD={256}/DEST=coefs_FFT coefs
Display coefs_FFT // Filter response for 1Hz sample rate

// Make sample data: a sweep from 0 to 20500 Hz
Make/O/N=1000 data= sin(p*p/1000*pi/2) // 0 to fs/2
SetScale/P x, 0, 1/41000, "s" data // 41000 Hz sample rate
Display data

// Analyze unfiltered data's frequency content
FFT/OUT=3/PAD={1000}/DEST=data_FFT data // Data frequency response
Display data_FFT

// Apply filter to copy of data
Duplicate/O data, filtered; DelayUpdate
FilterFIR/DIM=0/COEF=coefs filtered
Display filtered

// Analyse filtered data's frequency content
```

```
FFT/OUT=3/PAD={1000}/DEST=filtered_FFT filtered // Filtered data frequency response
Display filtered_FFT
TileWindows/O=1 // Tile Graphs
```

## FontList

**FontList**(*separatorStr* [, *options*])

The FontList function returns a list of the installed fonts, separated by the characters in *separatorStr*.

### Parameters

A maximum of 10 bytes from *separatorStr* are appended to each font name as the output string is generated. *separatorStr* is usually ";".

Use *options* to limit the returned font list according to font type. It is restricted to returning only scalable fonts (TrueType, PostScript, or OpenType), which you can do with *options* = 1.

To get a list of nonscalable fonts (bitmap or raster), use:

```
String bitmapFontList = RemoveFromList(FontList(";",1), FontList(";"))
```

(Most Mac OS X fonts are scalable, so bitmapFontList may be empty.)

### Examples

```
Function SetFont(fontName)
 String fontName
 Prompt fontName,"font name:",popup,FontList(";")+ "default;"
 DoPrompt "Pick a Font", fontName

 Print fontName

 Variable type= WinType("") // target window type
 String windowName= WinName(0,127)
 if((type==1) || (type==3) || (type==7)) // graph, panel, layout
 Print "Setting drawing font for "+windowName
 Execute "SetDrawEnv fname=\""+fontName+"\" "
 else
 if(type == 5) // notebook
 Print "Setting font for selection in "+windowName
 Notebook $windowName font=fontName
 endif
 endif
End
```

### See Also

The **FontSizeStringWidth**, **FontSizeHeight**, and **WinType** functions, and the **Execute**, **SetDrawEnv**, and **Notebook Operations**.

## FontSizeHeight

**FontSizeHeight**(*fontNameStr*, *fontSize*, *fontstyle* [, *appearanceStr*])

The FontSizeHeight function returns the line height in pixels of any string when rendered with the named font and the given font style and size.

### Parameters

*fontNameStr* is the name of the font, such as "Helvetica".

*fontSize* is the size (height) of the font in pixels.

## FontSizeStringWidth

---

*fontStyle* is text style (bold, italic, etc.). Use 0 for plain text.

### Details

The returned height is the sum of the font's ascent and descent heights. Variations in *fontStyle* and typeface design cause the actual font height to be different than *fontSize* would indicate. (Typically a font "height" refers to only the ascent height, so the total height will be slightly larger to accommodate letters that descend below the baseline, such as g, p, q, and y).

*FontSize* is in pixels. To obtain the height of a font specified in points, use the **ScreenResolution** function and the conversion factor of 72 points per inch (see Examples).

If the named font is not installed, **FontSizeHeight** returns NaN.

**FontSizeHeight** understands "default" to mean the current experiment's default font.

*fontStyle* is a binary coded integer with each bit controlling one aspect of the text style as follows:

|        |               |
|--------|---------------|
| Bit 0: | Bold          |
| Bit 1: | Italic        |
| Bit 2: | Underline     |
| Bit 4: | Strikethrough |

To set bit 0 and bit 2 (bold, underline), use  $2^0+2^2 = 1+4 = 5$  for *fontStyle*. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

The optional *appearanceStr* parameter has no effect on Windows.

On Macintosh, the *appearanceStr* parameter is used for determining the height of a string drawn by a control. Set *appearanceStr* to "native" if you are measuring the height of a string drawn by a "native GUI" control or to "os9" if not.

Set *appearanceStr* to "default" to use the appearance set by the user in the Miscellaneous Settings dialog. "os9" is the default value.

Usually you will want to set *appearanceStr* to the *S\_Value* output of **DefaultGUIControls/W=winName** when determining the height of a string drawn by a control.

### Examples

```
Variable pixels= 12 * ScreenResolution/72 // convert 12 points to pixels
Variable pixelHeight= FontSizeHeight("Helvetica",pixels,0)
Print "Height in points= ", pixelHeight * 72/ScreenResolution

Function FontIsInstalled(fontName)
 String fontName
 if(numtype(FontSizeHeight(fontName,10,0)) == 2)
 return 0 // NaN returned, font not installed
 else
 return 1
 endif
End
```

### See Also

The **FontList**, **FontSizeStringWidth**, **numtype**, **ScreenResolution**, and **DefaultGUIControls** functions.

## FontSizeStringWidth

**FontSizeStringWidth**(*fontNameStr*, *fontSize*, *fontstyle*, *theStr* [, *appearanceStr*])

The **FontSizeStringWidth** function returns the width of *theStr* in pixels, when rendered with the named font and the given font style and size.

### Parameters

*fontNameStr* is the name of the font, such as "Helvetica".

*fontSize* is the size (height) of the font in pixels.

*fontStyle* is text style (bold, italic, etc.). Use 0 for plain text.

*theStr* is the string whose width is being measured.

The optional *appearanceStr* parameter has no effect on Windows.

On Macintosh, the *appearanceStr* parameter is used for determining the width of a string drawn by a control. Set *appearanceStr* to "native" if you are measuring the width of a string drawn by a "native GUI" control or to "os9" if not.

Set *appearanceStr* to "default" to use the appearance set by the user in the Miscellaneous Settings dialog. "os9" is the default value.

Usually you will want to set *appearanceStr* to the *S\_Value* output of **DefaultGUIControls/W=winName** when determining the width of a string drawn by a control.

### Details

If the named font is not installed, *FontSizeStringWidth* returns NaN.

*FontSizeStringWidth* understands "default" to mean the current experiment's default font.

*FontSize* is in pixels. To obtain the width of a font specified in points, use the **ScreenResolution** function and the conversion factor of 72 points per inch (see Examples).

*fontStyle* is a binary coded integer with each bit controlling one aspect of the text style as follows:

|        |               |
|--------|---------------|
| Bit 0: | Bold          |
| Bit 1: | Italic        |
| Bit 2: | Underline     |
| Bit 4: | Strikethrough |

To set bit 0 and bit 2 (bold, underline), use  $2^0+2^2 = 1+4 = 5$  for *fontStyle*. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

### Examples

#### Example 1

```
Variable fsPix= 10 * ScreenResolution/72 // 10 point text in pixels
String text= "How long is this text?"
Variable WidthPix= FontSizeStringWidth("Helvetica",fsPix,0,text)
Print "width in inches= ", WidthPix / ScreenResolution
```

#### Example 2

```
Variable fsPix= 13 * ScreenResolution/72 // 13 point text in pixels
String text= "text for a control"
DefaultGUIControls/W=Panel0 // Sets S_Value
Variable WidthPix= FontSizeStringWidth("Helvetica",fsPix,0,text,S_Value)
Print "width in points= ", WidthPix / ScreenResolution * 72
```

## for-endfor

```
for(<initialization>;<continuation test>;<update>)
 <loop body>
endfor
```

A for-endfor loop executes the loop body code until the continuation test evaluates as false (zero) or until a break statement is executed in the body code. When the loop starts, the initialization expressions are evaluated once. For each iteration, the continuation test is evaluated at the beginning and the update expressions are evaluated at the end.

```
for(<type> varName : <wave>) // Range-based for loop added in Igor Pro 9.00
 <loop body>
endfor
```

A range-based for loop iterates over each element of a wave. The specified loop variable contains the value of the current wave element.

Range-Based For Loop, For Loop, break

## FPClustering

**FPClustering** [*flags*] *srcWave*

The FPClustering operation performs cluster analysis using the farthest-point clustering algorithm. The input for the operation *srcWave* defines M points in N-dimensional space. Outputs are the waves W\_FPCenterIndex and W\_FPClusterIndex.

### Flags

*/CAC* Computes all the clusters specified by */MAXC*.  
*/CM* Computes the center of mass for each cluster. The results are stored in the wave M\_clustersCM in the current data folder. Each row corresponds to a single cluster with columns providing the respective dimensional components.

*/DSO* Returns the distance map of *srcWave* in M\_DistanceMap. No other output is generated and all other flags are ignores.  
*/DSO* was added in Igor Pro 8.00.

The distance map is the Cartesian distance between any two rows in *srcWave*. The results are stored in the upper triangle of the double-precision output wave M\_DistanceMap. The lower triangle is set to zero (results can be obtained by symmetry).

Each element of the distance map is given by:

$$M\_DistanceMap_{rc} = \sqrt{\sum_{i=0}^{nCols-1} (srcWave[r][i] - srcWave[c][i])^2}$$

*/INCD* Computes the inter-cluster distances. The result is stored in the current data folder in the wave M\_InterClusterDistance, a 2D wave in which the [i][j] element contains the distance between cluster *i* and cluster *j*.

*/MAXC=nClusters* Terminates the calculation when the number of clusters reaches the specified value. Note that this termination condition is sufficient but not necessary, i.e., the operation can terminate earlier if the farthest distance of an element from a hub is less than the average distance.

*/MAXR=maxRad* Terminates the calculation when the maximum distance is less than or equal to *maxRad*.

*/NOR* Normalizes the data on a column by column basis. The normalization makes each columns of the input span the range [0,1] so that even when *srcWave* contains columns that may be different by several orders of magnitude, the algorithm is not biased by a larger implied cartesian distance.

*/Q* Don't print information to the history area.

*/SHUB=sHub* Specifies the row which is used as a starting hub number. By default the operation uses the first row in *srcWave*.

/Z No error reporting.

### Details

The input for FPClustering is a 2D wave *srcWave* which consists of M rows by N columns where each row represents a point in N-dimensional space. *srcWave* can contain only finite real numbers and must be of type SP or DP. The operation computes the clustering and produces the wave W\_FPCenterIndex which contains the centers or “hubs” of the clusters. The hubs are specified by the zero-based row number in *srcWave* which contains the cluster center. In addition, the operation creates the wave W\_FPClusterIndex where each entry maps the corresponding input point to a cluster index. By default, the operation continues to add clusters as long as the largest possible distance is greater than the average intercluster distance. You can also stop the processing when the operation has formed a specified number of clusters (see /MAXC).

The variable V\_max contains the maximum distance between any element and its cluster hub.

It is possible that in some circumstances you can get slightly different clustering depending on your starting point. The default starting hub is row zero of *srcWave* but you can use the /SHUB flag to specify a different starting point.

FPClustering computes the Cartesian distance between points. As a result, if the scale of any dimension is significantly larger than other dimensions it might bias the clustering towards that dimension. To avoid this situation you can use the /NOR flag which normalizes each column to the range [0,1] and hence equalizes the weight of each dimension in the clustering process.

## fprintf

**fprintf** *refNum*, *formatStr* [, *parameter*]...

The fprintf operation prints formatted output to a text file.

### Parameters

*refNum* is a file reference number from the **Open** operation used to open the file.

*formatStr* is the format string, as used by the **printf** operation.

*parameter* varies depending on *formatStr*.

### Details

If *refNum* is 1, fprintf will print to the history area instead of to a file, as if you used printf instead of fprintf. This useful for debugging purposes.

A zero value of *refNum* is used in conjunction with Program-to-Program Communication (PPC), Apple events (*Macintosh*) or **ActiveX Automation** (*Windows*). Data that would normally be written to a file is appended to the PPC, Apple event or ActiveX Automation result packet.

The fprintf operation supports numeric (real only) and string fields from structures. All other structures field types cause a compile error.

### Output to Standard Streams

If *refNum* is -1, Igor prints to the standard output stream (stdout).

If *refNum* is -2, Igor prints to the standard error stream (stderr).

This feature was added in Igor Pro 8.00. It is useful primarily when you launch Igor from a custom application. The application may be able to capture Igor's standard stream output.

On Macintosh, output printed to either of the standard streams is typically visible only if Igor is started from the Terminal. On Windows, stdout and stderr output is not visible even if Igor is started from the command line.

## FReadLine

---

### See Also

The **printf** operation for complete format and parameter descriptions. The **Open** operation and **Creating Formatted Text** on page IV-257.

## FReadLine

**FReadLine** [/N /ENCG=*textEncoding* /T] *refNum*, *stringVarName*

The FReadLine operation reads bytes from a file into the named string variable. The read starts at the current file position and continues until a terminator character is read, the end of the file is reached, or the maximum number of bytes is read.

### Parameters

*refNum* is a file reference number from the **Open** operation used to create the file.

### Flags

*/N=n* Specifies the maximum number of bytes to read.  
FReadLine can read lines text of length up to about 2 billion bytes.

*/ENCG=textEncoding*

*/ENCG={textEncoding, tecOptions [,mapErrorMode]}*

Specifies the text encoding of the plain text file being loaded.

This flag was added in Igor Pro 9.00.

See **Text Encoding Names and Codes** on page III-492 for a list of accepted values for *textEncoding*. The 32-bit Unicode text encodings UTF-32BE and UTF-32LE are currently not supported.

If you omit */ENCG*, *textEncoding* defaults to binary (255) and does no text encoding conversion but does look for and skip a UTF-8 byte order mark.

For most purposes the default values for *tecOptions* (3) and *mapErrorMode* (1) are fine and you can use */ENCG=textEncoding* instead of */ENCG={textEncoding, tecOptions [,mapErrorMode]}*.

*tecOptions* is an optional bitwise parameter that controls text encoding conversion. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

*tecOptions* is defined as follows:

- Bit 0: If cleared, the presence of null bytes causes FReadLine to consider the text invalid in all byte-oriented text encodings.  
If set (default), null bytes are allowed in byte-oriented text encodings.
- Bit 1: If cleared FReadLine does not validate text if the specified text encoding is UTF-8.  
If set (default), FReadLine validates text even if the text encoding is UTF-8.
- Bit 2: If cleared (default) FReadLine validates the text in the specified text encoding except that validation for UTF-8 is skipped if bit 1 is cleared.  
If set, FReadLine assumes that the text is valid in the specified text encoding and does not validate it. Setting this bit makes FReadLine slightly faster but it is usually inconsequential.

UTF-8 because it is not valid in the input text encoding. *mapErrorMode* is one of these values:

- 1: FReadLine generates an error.
- 2: Return a substitute character for the unmappable character. The substitute character for Unicode is the Unicode replacement character, U+FFFD. For most non-Unicode text encodings it is either control-Z or a question mark.
- 3: Skip unmappable input character.
- 4: Return an escape sequence representing the unmappable code point.

If *mapErrorMode* is 2, 3 or 4, FReadLine does not return an error in the event of an unmappable character.

See the discussion of *mapErrorMode* and the examples for **ConvertTextEncoding** for further discussion.

See **FReadLine and Byte Order Marks** on page V-262 below for further discussion.

*/T=termcharStr*

Specifies the terminator character.

*/T= (num2char (13) )* specifies carriage return (CR, ASCII code 13).

*/T= (num2char (10) )* specifies linefeed (LF, ASCII code 10).

*/T= " ; "* specifies the terminator as a semicolon.

*/T= " "* specifies the terminator as null (ASCII code 0).

See **Details** for default behavior regarding the terminator.

### Details

If */N* is omitted, there is no maximum number of bytes to read. When reading lines of text from a normal text file, you will not need to use */N*. It may be of use in specialized cases, such as reading text embedded in a binary file.

FReadLine can read lines text of length up to about 2 billion bytes.

If */T* is omitted, FReadLine will terminate on any of the following: CR, LF, CRLF, LFCR. (Most Macintosh files use CR. Most Windows files use CRLF. Most UNIX files use LF. LFCR is an invalid terminator but some buggy programs generate files that use it.) FReadLine reads whichever of these appears in the file, terminates the read, and returns just a CR in the output string. This default behavior transparently handles files that use CR, LF, CRLF, or LFCR as the terminator and will be suitable for most cases.

If you use the */T* flag, then FReadLine will terminate on the specified character only and will return the specified character in the output string.

Once you have read all of the bytes in the file, FReadLine will return zero bytes via *stringVarName*. The example below illustrates testing for this.

### FReadLine and Text Encodings

For background information on text encodings, see **Text Encodings** on page III-461.

In Igor Pro 9.00 and later, you can specify the text encoding of the file you are reading using the */ENCG* flag.

If you omit */ENCG*, FReadLine treats the data as binary and does no text encoding conversion. However, it does skip a UTF-8 byte order mark at the start of the file if present. Treating the data as binary works if the data you are loading is pure ASCII or is valid UTF-8 text.

If you specify a text encoding using */ENCG*, the FReadLine converts the text from the text encoding you specify into UTF-8 for internal storage. See **Text Encoding Names and Codes** on page III-492 for a list of accepted values for *textEncoding*. The 32-bit Unicode text encodings UTF-32BE and UTF-32LE are currently not supported.

In general it is not possible to accurately determine the text encoding of a plain text file programmatically so you need to know it *a priori*.

## fresnelCos

---

If the text is Unicode and includes a byte order mark then you can programmatically determine the text encoding by examining the byte order mark. You can do this using `FBinRead` to examine the first bytes of the file:

|                  |                                                   |
|------------------|---------------------------------------------------|
| 0xEF, 0xBB, 0xBF | UTF-8 byte order mark, <i>textEncoding=1</i>      |
| 0xFE, 0xFF       | UTF-16BE byte order mark, <i>textEncoding=100</i> |
| 0xFF, 0xFE       | UTF-16LE byte order mark, <i>textEncoding=101</i> |

If the file starts with a pattern other than these then you will need *a priori* knowledge or will need to make an assumption about the text encoding.

### FReadLine and Byte Order Marks

For background information on byte order marks, see **Byte Order Marks** on page III-473.

If you want to check for the presence of a byte order mark, use **FBinRead** instead of `FReadLine`.

The default text encoding, used if you omit `/ENCG`, is binary (255). In this case, `FReadLine` does no text encoding conversion. However, it does look for a UTF-8 byte order mark and skips it if present.

If you specify UTF-8 or UTF-16 as the text encoding using the `/ENCG` flag, and if the file data begins with a byte order mark, then `FReadLine` skips it.

### Example

```
Function PrintAllLinesInFile()
 Variable refNum
 Open/R refNum as "" // Display dialog
 if (refNum == 0) // User canceled
 return -1
 endif

 Variable lineNumber, len
 String buffer
 lineNumber = 0
 do
 FReadLine refNum, buffer
 len = strlen(buffer)
 if (len == 0)
 break // No more lines to be read
 endif
 Printf "Line number %d: %s", lineNumber, buffer
 if (CmpStr(buffer[len-1], "\r") != 0) // Last line has no CR ?
 Printf "\r"
 endif
 lineNumber += 1
 while (1)

 Close refNum
 return 0
End
```

### See Also

The **Open** and **FBinRead** operations.

## fresnelCos

### fresnelCos(x)

The `fresnelCos` function returns the Fresnel cosine function  $C(x)$ .

$$C(x) = \int_0^x \cos\left(\frac{\pi}{2}t^2\right) dt.$$

### See Also

The **fresnelSin** and **fresnelCS** functions.

**References**

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

**fresnelCS****fresnelCS (x)**

The `fresnelCS` function returns both the Fresnel cosine in the real part of the result and the Fresnel sine in the imaginary part of the result.

**See Also**

The `fresnelSin` and `fresnelCos` functions.

**fresnelSin****fresnelSin (x)**

The `fresnelSin` function returns the Fresnel sine function  $S(x)$ .

$$S(x) = \int_0^x \sin\left(\frac{\pi}{2}t^2\right) dt.$$

**See Also**

The `fresnelCos` and `fresnelCS` functions.

**References**

Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, 446 pp., Dover, New York, 1972.

**FSetPos****FSetPos refNum, filePos**

The `FSetPos` operation attempts to set the current file position to the given position.

**Parameters**

*refNum* is a file reference number obtained from the **Open** operation when the file was opened.

*filePos* is the desired position of the file in bytes from the start of the file.

**Details**

`FSetPos` generates an error if *filePos* is greater than the number of bytes in the file. You can ascertain this limit with the **FStatus** operation.

When a file that is open for writing is closed, any bytes past the end of the current file position are deleted by the operating system. Therefore, if you use `FSetPos`, make sure to set the current file position properly before closing the file.

`FSetPos` supports files of any length.

**See Also**

**Open**, **FGetPos**, **FStatus**

**FStatus****FStatus refNum**

The `FStatus` operation provides file status information for a file.

**Parameters**

*refNum* is a file reference number obtained from the **Open** operation.

**Details**

`FStatus` supports files of any length.

`FStatus` sets the following variables:

`v_flag`                      Nonzero (true) if *refNum* is valid, in which case `FStatus` sets the other variables as well.

## FTPCreateDirectory

---

|            |                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_filePos  | Current file position for the file in bytes from the start.<br>In Igor7 or later, if you only want to know the current file position, use <b>FGetPos</b> instead of FStatus, which is slower.                                                                                                                                                                                                                               |
| V_logEOF   | Total number of bytes in the file.                                                                                                                                                                                                                                                                                                                                                                                          |
| S_fileName | Name of the file.                                                                                                                                                                                                                                                                                                                                                                                                           |
| S_path     | Path from the volume to the folder containing the file. For example, "hd:Folder1:Folder2:". This is suitable for use as an input to the <b>NewPath</b> operation. Note that on the Windows operating system Igor uses a colon between folders instead of the Windows-standard backslash to avoid confusion with Igor's use of backslash to start an escape sequence (see <b>Escape Sequences in Strings</b> on page IV-14). |
| S_info     | Keyword-packed information string.                                                                                                                                                                                                                                                                                                                                                                                          |

The keyword-packed information string for S\_info consists of a sequence of sections with the following form: *keyword:value*; You can pick a value out of a keyword-packed string using the **NumberByKey** and **StringByKey** functions.

Here are the keywords for S\_info:

| Keyword   | Type   | Meaning                                                                                                       |
|-----------|--------|---------------------------------------------------------------------------------------------------------------|
| PATH      | string | Name of the symbolic path in which the file is located. This will be empty if there is no such symbolic path. |
| WRITEABLE | number | 1 if file can be written to, 0 if not.                                                                        |

## FTPCreateDirectory

**FTPCreateDirectory** [*flags*] *urlStr*

The FTPCreateDirectory operation creates a directory on an FTP server on the Internet.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-270.

FTPCreateDirectory sets V\_flag to zero if the operation succeeds or to a non-zero error code if it fails.

If the directory specified by *urlStr* already exists on the server, the server contents are not touched and V\_flag is set to -1. This is not treated as an error.

### Parameters

*urlStr* specifies the directory to create. It consists of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/test/newDirectory"). For example:

```
"ftp://ftp.wavemetrics.com/test/newDirectory"
```

*urlStr* must always end with a directory name, and must not end with a slash.

To indicate that *urlStr* contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

```
ftp://ftp.wavemetrics.com//pub/test/newDirectory
```

If you do not specify that the path in *urlStr* is absolute, it is interpreted as relative to the FTP user's base directory. Since pub is the base directory for an anonymous user at wavemetrics.com, these URLs reference the same directory for an anonymous user:

```
ftp://ftp.wavemetrics.com//pub/test/newDirectory // Absolute path
ftp://ftp.wavemetrics.com/test/newDirectory // Relative to base directory
```

Special characters, such as punctuation, that are used in *urlStr* may be incorrectly interpreted by the operation. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. See **Percent Encoding** on page IV-266 for additional information.

**Flags**

- /N=portNumber* Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, the default will be correct so you won't need to use the */N* flag.
- /U=userNameStr* Specifies the user name to be used when logging in to the FTP server. If */U* is omitted or if *userNameStr* is "", the login is done as an anonymous user. Use */U* if you have an account on the FTP server.
- /V=diagnosticMode* Determines what kind of diagnostic messages `FTPCreateDirectory` will display in the history area. *diagnosticMode* is a bitwise parameter, with the bits defined as follows:
- Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.
  - Bit 1: Show errors. This displays additional information when errors occur.
  - Bit 2: Show status. This displays commands sent to the server and the server's response.
- The default value for *diagnosticMode* is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.
- See **FTP Troubleshooting** on page IV-273 for other troubleshooting tips.
- /W=passwordStr* Specifies the password to be used when logging in to the FTP server. Use */W* if you have an account on the FTP server.
- If */W* is omitted, the login is done using a default password that will work with most anonymous FTP servers.
- See **Safe Handling of Passwords** on page IV-268 for information on handling sensitive passwords.
- /Z* Errors are not fatal. Will not abort procedure execution if an error occurs.
- Your procedure can inspect the `V_flag` variable to see if the transfer succeeded. `V_flag` will be zero if it succeeded, -1 if the specified directory already exists, or another nonzero value if an error occurred.

**Examples**

```
// Create a directory.
String url = "ftp://ftp.wavemetrics.com/pub/test/newDirectory"
FTPCreateDirectory url
```

**See Also**

**File Transfer Protocol (FTP)** on page IV-270.

**FTPDelete, FTPDownload, FTPUpload, URLEncode**

**FTPDelete**

**FTPDelete** [*flags*] *urlStr*

The `FTPDelete` operation deletes a file or a directory from an FTP server on the Internet.

**Warning:** If you delete a directory on an FTP server, all contents of that directory and any subdirectories are also deleted.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-270.

`FTPDelete` sets `V_flag` to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the `/Z` flag, can be used to allow procedures to continue to execute if an FTP error occurs.

**Parameters**

*urlStr* specifies the file or directory to delete. It consists of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/test/TestFile1.txt"). For example: "ftp://ftp.wavemetrics.com/test/TestFile1.txt"

## FTPDelete

---

*urlStr* must always end with a file name if you are deleting a file or with a directory name if you are deleting a directory. In the case of a directory, *urlStr* must not end with a slash.

To indicate that *urlStr* contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

```
ftp://ftp.wavemetrics.com//pub/test
```

If you do not specify that the path in *urlStr* is absolute, it is interpreted as relative to the FTP user's base directory. Since `pub` is the base directory for an anonymous user at `wavemetrics.com`, these URLs reference the same directory for an anonymous user:

```
ftp://ftp.wavemetrics.com//pub/test
```

```
ftp://ftp.wavemetrics.com/test
```

Special characters such as punctuation that are used in *urlStr* may be incorrectly interpreted by the operation. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. See **Percent Encoding** on page IV-266 for additional information

### Flags

- /D* Deletes a complete directory and all its contents. Omit */D* if you are deleting a file.
- /N=portNumber* Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, the default will be correct so you won't need to use the */N* flag.
- /U=usernameStr* Specifies the user name to be used when logging in to the FTP server. If */U* is omitted or if *usernameStr* is "", the login is done as an anonymous user. Use */U* if you have an account on the FTP server.
- /V=diagnosticMode* Determines what kind of diagnostic messages FTPDelete will display in the history area. *diagnosticMode* is a bitwise parameter, with the bits defined as follows:
- Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.
  - Bit 1: Show errors. This displays additional information when errors occur.
  - Bit 2: Show status. This displays commands sent to the server and the server's response.
- The default value for *diagnosticMode* is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.
- See **FTP Troubleshooting** on page IV-273 for other troubleshooting tips.
- /W=passwordStr* Specifies the password to be used when logging in to the FTP server. Use */W* if you have an account on the FTP server.
- If */W* is omitted, the login is done using a default password that will work with most anonymous FTP servers.
- See **Safe Handling of Passwords** on page IV-268 for information on handling sensitive passwords.
- /Z* Errors are not fatal. Will not abort procedure execution if an error occurs.
- Your procedure can inspect the *V\_flag* variable to see if the transfer succeeded. *V\_flag* will be zero if it succeeded, or a nonzero value if an error occurred.

### Examples

```
// Delete a file.
String url = "ftp://ftp.wavemetrics.com/test/TestFile1.txt"
FTPDelete url
```

```
// Delete a directory.
String url = "ftp://ftp.wavemetrics.com/test/TestDir1"
FTPDelete/D url
```

### See Also

**File Transfer Protocol (FTP)** on page IV-270.

FTPCreateDirectory, FTPDownload, FTPUpload, URLEncode

## FTPDownload

**FTPDownload** [*flags*] *urlStr*, *localPathStr*

The FTPDownload operation downloads a file or a directory from an FTP server on the Internet.

**Warning:** When you download a file or directory using the path and name of a file or directory that already exists on your local hard disk, all previous contents of the local file or directory are obliterated.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-270.

FTPDownload sets a variable named *V\_flag* to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the */Z* flag, can be used to allow procedures to continue to execute if a FTP error occurs.

If the operation succeeds, FTPDownload sets a string named *S\_Filename* to the full file path of the downloaded file or, if the */D* flag was used, the full path to the base directory that was downloaded. This is useful in conjunction with the */I* flag.

If the operation fails, *S\_Filename* is set to "".

### Parameters

*urlStr* specifies the file or directory to download. It consists of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/Test/TestFile1.txt"). For example: "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt".

*urlStr* must always end with a file name if you are downloading a file or with a directory name if you are downloading a directory. In the case of a directory, *urlStr* must not end with a slash.

To indicate that *urlStr* contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

```
ftp://ftp.wavemetrics.com//pub/test
```

If you do not specify that the path in *urlStr* is an absolute path, it is interpreted as a path relative to the FTP user's base directory. Since *pub* is the base directory for an anonymous user, this URL references the same directory:

```
ftp://ftp.wavemetrics.com/test
```

Special characters such as punctuation that are used in *urlStr* may be incorrectly interpreted by the operation. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. See **Percent Encoding** on page IV-266 for additional information.

*localPathStr* and *pathName* specify the name to use for the file or directory that will be created on your hard disk. If you use a full or partial path for *localPathStr*, see **Path Separators** on page III-453 for details on forming the path.

*localPathStr* must always end with a file name if you are downloading a file or with a directory name if you are downloading a directory. In the case of a directory, *localPathStr* must not end with a colon or backslash.

FTPDownload displays a dialog through which you can identify the local file or directory in the following cases:

1. You have used the */I* (interactive) flag.
2. You did not completely specify the location of the local file or directory via *pathName* and *localPathStr*.
3. There is an error in *localPathStr*. This can be either a syntactical error or a reference to a nonexistent file or directory.
4. The specified local file or directory exists and you have not used the */O* (overwrite) flag.

See **Examples** for examples of constructing a URL and local path.

### Flags

*/D* Downloads a complete directory. Omit it if you are downloading a file.

## FTPDownload

|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/I</i>                | Interactive mode which will prompt you to specify the name and location of the file or directory to be created on the local hard disk.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>/M=messageStr</i>     | Specifies the prompt message used by the dialog in which you specify the name and location of the file or directory to be created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>/N=portNumber</i>     | Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, this will be correct so you won't need to use the <i>/N</i> flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>/O[=mode]</i>         | Controls whether a local file or directory whose name is in conflict with the file or directory being downloaded is overwritten without prompting the user.<br><i>mode=0</i> : Prompts the user to allow the overwrite. This is the default behavior if <i>/O</i> is omitted.<br><i>mode=1</i> : Overwrites without prompting the user. If the <i>/D</i> flag is also used, all contents of the destination directory are deleted if it already exists. <i>/O=1</i> is the same as <i>/O</i> .<br><i>mode=2</i> : Merges files and subdirectories downloaded with the contents of the destination directory. Unlike <i>/O=1</i> , the contents of the destination directory are not deleted, however files and directories downloaded from the server will overwrite existing files and directories of the same name. When downloading a file this mode is accepted but has the same effect as <i>/O=1</i> . |
| <i>/P=pathName</i>       | Contributes to the specification of the file or directory to be created on your hard disk. <i>pathName</i> is the name of an existing symbolic path. See <b>Examples</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>/S=showProgress</i>   | Determines if a progress dialog is displayed.<br>0: No progress dialog.<br>1: Show a progress dialog (default).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>/T=transferType</i>   | Controls the FTP transfer type.<br>0: Image (binary) transfer (default).<br>1: ASCII transfer.<br><br>See <b>FTP Transfer Types</b> on page IV-273 for more discussion.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>/U=usernameStr</i>    | Specifies the user name to be used when logging in to the FTP server. If this flag is omitted or if <i>usernameStr</i> is "", you will be logged in as an anonymous user. Use this flag if you have an account on the FTP server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>/V=diagnosticMode</i> | Determines what kind of diagnostic messages FTPDownload will display in the history area. <i>diagnosticMode</i> is a bitwise parameter, with the bits defined as follows:<br>Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.<br>Bit 1: Show errors. This displays additional information when errors occur.<br>Bit 2: Show status. This displays commands sent to the server and the server's response.<br><br>The default value for <i>diagnosticMode</i> is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.<br><br>See <b>FTP Troubleshooting</b> on page IV-273 for other troubleshooting tips.                                                                                                                                                          |

- /W=passwordStr* Specifies the password to be used when logging in to the FTP server. Use this flag if you have an account on the FTP server.
- If this flag is omitted, "nopassword" will be used for the login password. This will work with most anonymous FTP servers. Some anonymous FTP servers request that you use your email address as a password. You can do this by including the */W="<your email address>"* flag.
- If */W* is omitted, the login is done using a default password that will work with most anonymous FTP servers.
- See **Safe Handling of Passwords** on page IV-268 for information on handling sensitive passwords.
- /Z* Errors are not fatal. Will not abort procedure execution if an error occurs.
- Your procedure can inspect the *V\_flag* variable to see if the transfer succeeded. *V\_flag* will be zero if it succeeded, -1 if the user canceled in an interactive dialog, or another nonzero value if an error occurred.

### Examples

Download a file using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test Folder:TestFile1.txt"
FTPDownload url, localPath
```

Download a file using a local symbolic path and file name:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String pathName = "Igor" // Igor is the name of a symbolic path.
String fileName = "TestFile1.txt"
FTPDownload/P=$pathName url, fileName
```

Download a directory using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test Folder:TestDir1"
FTPDownload/D url, localPath
```

## FTPUpload

**FTPUpload** [*flags*] *urlStr, localPathStr*

The FTPUpload operation uploads a file or a directory to an FTP server on the Internet.

**Warning:** When you upload a file or directory to an FTP server, all previous contents of the server file or directory are obliterated.

For background information on Igor's FTP capabilities and other important details, see **File Transfer Protocol (FTP)** on page IV-270.

FTPUpload sets a variable named *V\_flag* to zero if the operation succeeds and to nonzero if it fails. This, in conjunction with the */Z* flag, can be used to allow procedures to continue to execute if a FTP error occurs.

If the operation succeeds, FTPUpload sets a string named *S\_Filename* to the full file path of the uploaded file or, if the */D* flag was used, to the full path to the base directory that was uploaded. This is useful in conjunction with the */I* flag.

If the operation fails, *S\_Filename* is set to "".

### Parameters

*urlStr* specifies the file or directory to create. It consists of a naming scheme (always "ftp://"), a computer name (e.g., "ftp.wavemetrics.com" or "38.170.234.2"), and a path (e.g., "/Test/TestFile1.txt"). For example: "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt".

## FTPUpload

---

*urlStr* must always end with a file name if you are uploading a file or with a directory name if you are uploading a directory, in which case *urlStr* must not end with a slash.

To indicate that *urlStr* contains an absolute path, insert an extra '/' character between the computer name and the path. For example:

```
ftp://ftp.wavemetrics.com//pub/test
```

If you do not specify that the path in *urlStr* is an absolute path, it is interpreted as a path relative to the FTP user's base directory. Since *pub* is the base directory for an anonymous user, this URL references the same directory:

```
ftp://ftp.wavemetrics.com/test
```

Special characters such as punctuation that are used in *urlStr* may be incorrectly interpreted by the operation. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. If you get unexpected results and *urlStr* contains such characters, you can try percent-encoding the special characters. See **Percent Encoding** on page IV-266 for additional information.

*localPathStr* and *pathName* specify the name and location on your hard disk of the local file to be uploaded. If you use a full or partial path for *localPathStr*, see **Path Separators** on page III-453 for details on forming the path.

*localPathStr* must always end with a file name if you are uploading a file or with a directory name if you are uploading a directory. In the case of a directory, *localPathStr* must not end with a colon or backslash.

FTPUpload displays a dialog that you can use to identify the file or directory to be uploaded in the following cases:

1. You used the /I (interactive) flag.
2. You did not completely specify the location of the file or folder to be uploaded via *pathName* and *localPathStr*.
3. There is an error in *localPathStr*. This can be either a syntactical error or a reference to a nonexistent directory.

See **Examples** for examples of constructing a URL and local path.

### Flags

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /D                      | Uploads a complete directory. Omit it if you are uploading a file.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| /I                      | Interactive mode which displays a dialog for choosing the local file or directory to be uploaded.                                                                                                                                                                                                                                                                                                                                                                                             |
| /M= <i>messageStr</i>   | Specifies the prompt message used by the dialog in which you choose the local file or directory to be uploaded.                                                                                                                                                                                                                                                                                                                                                                               |
| /N= <i>portNumber</i>   | Specifies the server's TCP/IP port number to use (default is 21). In almost all cases, this will be correct so you won't need to use the /N flag.                                                                                                                                                                                                                                                                                                                                             |
| /O[= <i>mode</i> ]      | Overwrite. FTPUpload <i>always</i> overwrites the specified server file or directory, whether /O is used or not.<br><br>If /O=2 is <i>not</i> used, all files and subdirectories in the destination directory on the server are first deleted and then the local files and directories are uploaded to the server.<br><br>If /O=2 <i>is</i> used, the existing contents the contents of the local source directory are merged into the remote directory instead of completely overwriting it. |
| /P= <i>pathName</i>     | Contributes to the specification of the file or directory to be uploaded. <i>pathName</i> is the name of an existing symbolic path. See <b>Examples</b> .                                                                                                                                                                                                                                                                                                                                     |
| /S= <i>showProgress</i> | Determines if a progress dialog is displayed.<br>0: No progress dialog.<br>1: Show a progress dialog (default).                                                                                                                                                                                                                                                                                                                                                                               |

- /T=transferType* Controls the FTP transfer type.  
 0: Image (binary) transfer (default).  
 1: ASCII transfer.  
 See **FTP Transfer Types** on page IV-273 for more discussion.
- /U=userNameStr* Specifies the user name to be used when logging in to the FTP server. If this flag is omitted or if *userNameStr* is "", you will be logged in as an anonymous user. Use this flag if you have an account on the FTP server.
- /V=diagnosticMode* Determines what kind of diagnostic messages FTPUpload will display in the history area. *diagnosticMode* is a bitwise parameter, with the bits defined as follows:  
 Bit 0: Show basic diagnostics. Currently this just displays the URL in the history.  
 Bit 1: Show errors. This displays additional information when errors occur.  
 Bit 2: Show status. This displays commands sent to the server and the server's response.  
 The default value for *diagnosticMode* is 3 (show basic and error diagnostics). If you are having difficulties, you can try using 7 to show the commands sent to the server and the server's response.  
 See **FTP Troubleshooting** on page IV-273 for other troubleshooting tips.
- /W=passwordStr* Specifies the password used when logging in to the FTP server. Use this flag if you have an account on the FTP server.  
 If this flag is omitted, "nopassword" will be used for the login password. This will work with most anonymous FTP servers. Some anonymous FTP servers request that you use your email address as a password. You can do this by including the */W=<your email address>* flag.  
 If */W* is omitted, the login is done using a default password that will work with most anonymous FTP servers.  
 See **Safe Handling of Passwords** on page IV-268 for information on handling sensitive passwords.
- /Z* Errors are not fatal. Will not abort procedure execution if an error occurs.  
 Your procedure can inspect the *V\_flag* variable to see if the transfer succeeded. *V\_flag* will be zero if it succeeded, -1 if the user canceled in an interactive dialog, or another nonzero value if an error occurred.

### Examples

Upload a file using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String localPath = "hd:Test Folder:TestFile1.txt"
FTPUpload url, localPath
```

Upload a file using a local symbolic path and file name:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestFile1.txt"
String pathName = "Igor" // Igor is the name of a symbolic path.
String fileName = "TestFile1.txt"
FTPUpload/P=$pathName url, fileName
```

Upload a directory using a full local path:

```
String url = "ftp://ftp.wavemetrics.com/pub/test/TestDir1"
String localPath = "hd:Test Folder:TestDir1"
FTPUpload/D url, localPath
```

## FuncFit

**FuncFit** [*flags*] *fitFuncName*, *cwaveName*, *waveName* [*flag parameters*]

**FuncFit** [*flags*] {*fitFuncSpec*}, *waveName* [*flag parameters*]

The FuncFit operation performs a curve fit to a user defined function, or to a sum of fit functions using the second form (see **Fitting Sums of Fit Functions** on page V-273). Fitting can be done using any method that can be selected using the /ODR flag (see **CurveFit** for details).

FuncFit operation parameters are grouped in the following categories: flags, parameters (*fitFuncName*, *cwaveName*, *waveName* or {*fitFuncSpec*}, *waveName*), and flag parameters. The sections below correspond to these categories. Note that flags must precede the *fitFuncName* or *fitFuncSpec* and flag parameters must follow *waveName*.

In Igor Pro 9.00 and later, your fitting function can return complex values. The sections below indicate requirements for complex fitting functions. For details, see **Fitting with Complex-Valued Functions** on page III-248.

### Flags

See **CurveFit** for all available flags.

### Parameters

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>fitFuncName</i> | The user-defined function to fit to, which can be a function taking multiple independent variables (see also <b>FuncFitMD</b> ). Multivariate fitting with FuncFit <i>requires</i> /X= <i>xwaveSpec</i> . To fit complex data waves, your fitting function must be declared complex (Function/C).                                                                                                                                                                                                               |
| <i>cwaveName</i>   | Wave containing the fitting coefficients. If the fitting function is declared with a complex wave for the coefficient wave, then this wave must be complex.                                                                                                                                                                                                                                                                                                                                                     |
| <i>waveName</i>    | The wave containing the dependent variable data to be fit to the specified function. For functions of just one independent variable, the dependent variable data is often referred to as "Y data". You can fit to a subrange of the wave by supplying ( <i>startX,endX</i> ) or [ <i>startP,endP</i> ] after the wave name. See <b>Wave Subrange Details</b> below for more information on subranges of waves in curve fitting. If your fitting function returns complex values then this wave must be complex. |
| <i>fitFuncSpec</i> | List of fit functions and coefficient waves, with some optional information. Using this format fits a model consisting of the sum of the listed fit functions. Intended for fitting multiple peaks, but probably useful for other applications as well. See <b>Fitting Sums of Fit Functions</b> on page V-273. Does not support complex fitting functions.                                                                                                                                                     |

### Flag Parameters

These flag parameters must follow *waveName*.

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /E= <i>ewaveName</i>            | A wave containing the epsilon values for each parameter. Must be the same length as the coefficient wave. If your fitting function requires a complex coefficient wave then your epsilon wave must be complex. Not supported with complex fitting functions.                                                                                                                                                                                                                                                                                                  |
| /STRC= <i>structureInstance</i> | Used only with <b>Structure Fit Functions</b> on page III-261. When using a structure fit function, you must specify an instance of the structure to FuncFit. This will be an instance that has been initialized by a user-defined function that you write in order to invoke FuncFit.                                                                                                                                                                                                                                                                        |
| /X= <i>xwaveSpec</i>            | An optional wave containing X values for each of the input data values. If the fitting function has more than one independent variable, <i>xwaveSpec</i> is required and must be either a 2D wave with a column for each independent variable, or a list of waves, one for each independent variable. A list must be in braces: /X={ <i>xwave0</i> , <i>xwave1</i> , ...}. There must be exactly one column or wave for each independent variable in the fitting function. If your fitting function takes complex X values then your X waves must be complex. |

**/NWOK** Allowed in user-defined functions only. When present, certain waves may be set to null wave references. Passing a null wave reference to FuncFit is normally treated as an error. By using **/NWOK**, you are telling FuncFit that a null wave reference is not an error but rather signifies that the corresponding flag should be ignored. This makes it easier to write function code that calls FuncFit with optional waves.

The waves affected are the X wave or waves (**/X**), weight wave (**/W**), epsilon wave (**/E**) and mask wave (**/M**). The destination wave (**/D=wave**) and residual wave (**/R=wave**) are also affected, but the situation is more complicated because of the dual use of **/D** and **/R** to mean "do autodeestination" and "do autoresidual". See **/AR** and **/AD**.

If you don't need the choice, it is better not to include this flag, as it disables useful error messages when a mistake or run-time situation causes a wave to be missing unexpectedly.

**Note:** To work properly this flag must be the last one in the command.

Other parameters are used as for the **CurveFit** operation, with some exceptions for multivariate fits.

### Details for Multivariate Fits

The dependent variable data wave, *waveName*, must be a 1D wave even for multivariate fits. For fits to data in a multidimensional wave, see **FuncFitMD**.

For multivariate fits, the auto-residual (**/R** with no wave specified) is calculated and appended to the top graph if the dependent variable data wave is graphed in the top graph as a simple 1D trace. Auto residuals are calculated but not displayed if the data are displayed as a contour plot.

The autodest wave (**/D** with no wave specified) for multivariate fits has the same number of points as the data wave, with a model value calculated at the X values contained in the wave or waves specified with **/X=xwaveSpec**.

Confidence bands are not supported for multivariate fits.

### Wave Subrange Details

Almost any wave you specify to FuncFit can be a subrange of a wave. The syntax for wave subranges is the same as for the Display command (see **Subrange Display Syntax** on page II-309 for details). See **Wave Subrange Details** on page V-132 for a discussion of the use of subranges in curve fitting.

The backwards compatibility rules for CurveFit apply to FuncFit as well.

In addition to the waves discussed in the CurveFit documentation, it is possible to use subranges when specifying the coefficient wave and the epsilon wave. Since the coefficient wave and epsilon wave must have the same number of points, it might make sense to make them two columns from a single multicolumn wave. For instance, here is an example in which the first column is used as the coefficient wave, the second is used as the epsilon wave, and the third is used to save a copy of the initial guesses for future reference:

```
Make/D/N=(5, 3) myCoefs
myCoefs[] [0] = {1,2,3,4,5} // hypothetical initial guess
myCoefs[] [1] = 1e-6 // reasonable epsilon values
myCoefs[] [2] = myCoefs[p] [0] // save copy of initial guess
FuncFit myFitFunc, myCoefs[] [0] myData /E=myCoefs[] [1] ...
```

You might have a fit function that uses a subset of the coefficients that are used by another. It might be useful to use a single wave for both. Here is an example in which a function that takes four coefficients is used to fit a subset of the coefficients, and then that solution is used as the initial guess for a function that takes six coefficients:

```
Make/D/N=6 Coefs6={1,2,3,4,5,6}
FuncFit Fit4Coefs, Coefs6[0,3] fitfunc4Coefs ...
FuncFit Fit6Coefs, Coefs6 ...
```

Naturally, the two fit functions must be worked out carefully to allow this.

### Fitting Sums of Fit Functions

If Igor encounters a left brace at the beginning of the fit function name, it expects a list of fit functions to be summed during the fit. This is useful for, for instance, fitting several peaks in a data set to a sum of peak functions.

The fit function specification includes at least the name of the fitting function and an associated coefficient wave. A sum of fit functions requires multiple coefficient waves, one for each fit function. Any coefficient wave-related options must be specified in the fit function specification via keyword-value pairs.

The syntax of the sum-of-fit-functions specification is as follows:

```
{ {func1, coef1, keyword=value}, {func2, coef2, keyword=value}, ... }
```

or

```
{string=fitSpecStr}
```

Within outer braces, each fit function specification is enclosed within inner braces. You can use one or more fit function specifications, with no intrinsic limit on the number of fit functions.

The second format is available to overcome limitations on the length of a command line in Igor. This format is just like the first, but everything inside the outer braces is contained in a string expression (which may be just a single string variable).

You can use any fit function that can be used for ordinary fitting, including the built-in functions that are available using the CurveFit operation. If you should write a user-defined fitting function with the same name as a built-in fit function, the user-defined function will be used (this is strongly discouraged).

Every function specification must include an appropriate coefficient wave, pre-loaded with initial guesses.

The comma between each function specification is optional.

The keyword-value pairs are optional, and are used to communicate further options on a function-by-function basis. Available keywords are:

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>HOLD=holdstr</code>           | <p>Indicates that a fit coefficient should be held fixed during fitting. <i>holdstr</i> works just like the hold string specified via the /H flag for normal fitting, but applies only to the coefficient wave associated with the fit function it appears with.</p> <p>If you include HOLD in a string expression (the <code>{string=fitSpecStr}</code> syntax), you must escape the quotation marks around the hold string.</p> <p>If you use the command-line syntax <code>{ {func1, coef1, HOLD=holdStr}, . . . }</code>, <i>holdStr</i> may be a reference to a global variable acquired using SVAR, or it may be a quoted literal string.</p> <p>If you use <code>{string=fitSpecStr}</code>, <i>fitSpecStr</i> is parsed at run-time outside the context of any running function. Consequently, you cannot use a general string expression. You can use either <code>HOLD="quotedLiteralString"</code> or <code>HOLD=root:globalString</code>.</p> |
| <code>CONST={constants}</code>      | <p>Sets the values of constants in the fitting function. So far, only two built-in functions take constants: <code>exp_XOffset</code> and <code>dblexp_XOffset</code>. They each take just one constant (the X offset), so you will have a "list" of one number inside the braces.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>EPSW=epsilonWave</code>       | <p>Specifies a wave holding epsilon values. Use only with a user-defined fitting function to set the differencing interval used to calculate numerical estimates of derivatives of the fitting function.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>STRC=structureInstance</code> | <p>Specifies an instance of the structure to FuncFit when using a structure fit function. <i>structureInstance</i> is an instance that was initialized by a user-defined function that invokes FuncFit. This keyword (and structure fitting functions) can be used only when calling FuncFit from within a user-defined function. See <b>Structure Fit Functions</b> on page III-261 for more details.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

The **CurveFit** operation for parameter details. See also **FuncFitMD** for user-defined multivariate fits to data in a multidimensional wave.

The best way to create a user-defined fitting function is using the Curve Fitting dialog. See **Using the Curve Fitting Dialog** on page III-181, especially the section **Fitting to a User-Defined Function** on page III-190.

For details on the form of a user-defined function, see **User-Defined Fitting Functions** on page III-250.

## FuncFitMD

**FuncFitMD** [*flags*] *fitFuncName*, *cwaveName*, *waveName* [*flag parameters*]

The FuncFitMD operation performs a curve fit to the specified multivariate user defined *fitFuncSpec*. FuncFitMD handles gridded data sets in multidimensional waves. Most parameters and flags are the same as for the **CurveFit** and **FuncFit** operations; differences are noted below.

*cwaveName* is a 1D wave containing the fitting coefficients, and *functionName* is the user-defined fitting function, which has 2 to 4 independent variables.

FuncFitMD operation parameters are grouped in the following categories: flags, parameters (*fitFuncName*, *cwaveName*, *waveName*), and flag parameters. The sections below correspond to these categories. Note that flags must precede the *fitFuncName* and flag parameters must follow *waveName*.

### Flags

*/L=dimSize* Sets the dimension size of the wave created by the auto-trace feature, that is, */D* without destination wave. The wave *fit\_waveName* will be a multidimensional wave of the same dimensionality as *waveName* that has *dimSize* elements in each dimension. That is, if you are fitting to a matrix wave, *fit\_waveName* will be a square matrix that has dimensions *dimSize* *X* *dimSize*. **Beware:** *dimSize* = 100 requires 100 million points for a 4-dimensional wave!

### Parameters

*fitFuncName* User-defined function to fit to, which must be a function taking 2 to 4 independent variables.

*cwaveName* 1D wave containing the fitting coefficients.

*waveName* The wave containing the dependent variable data to be fit to the specified function. For functions of just one independent variable, the dependent variable data is often referred to as "Y data". You can fit to a subrange of the wave by supplying (*startX,endX*) or [*startP,endP*] for each dimension after the wave name. See **Wave Subrange Details** below for more information on subranges of waves in curve fitting.

### Flag Parameters

These flag parameters must follow *waveName*.

*/E=ewaveName* A wave containing the epsilon values for each parameter. Must be the same length as the coefficient wave.

*/T=twaveName* Like */X* except for the T independent variable. This is a 1D wave having as many elements as *waveName* has chunks.

*/X=xwaveName* The X independent variable values for the data to fit come from *xwaveName* instead of from the X scaling of *waveName*. This is a 1D wave having as many elements as *waveName* has rows.

*/Y=ywaveName* Like */X* except for the Y independent variable. This is a 1D wave having as many elements as *waveName* has columns.

*/Z=ywaveName* Like */X* except for the Z independent variable. This is a 1D wave having as many elements as *waveName* has layers.

**/NWOK** Allowed in user-defined functions only. When present, certain waves may be set to null wave references. Passing a null wave reference to FuncFitMD is normally treated as an error. By using **/NWOK**, you are telling FuncFitMD that a null wave reference is not an error but rather signifies that the corresponding flag should be ignored. This makes it easier to write function code that calls FuncFitMD with optional waves.

The waves affected are the X wave or waves (**/X**), the Y spacing wave (**/Y**), the Z spacing wave (**/Z**) the T spacing wave (**/T**), weight wave (**/W**), epsilon wave (**/E**) and mask wave (**/M**). The destination wave (**/D=wave**) and residual wave (**/R=wave**) are also affected, but the situation is more complicated because of the dual use of **/D** and **/R** to mean "do autodeestination" and "do autoresidual". See **/AR** and **/AD**.

If you don't need the choice, it is better not to include this flag, as it disables useful error messages when a mistake or run-time situation causes a wave to be missing unexpectedly.

**Note:** To work properly this flag must be the last one in the command.

**Details**

Auto-residual (**/R** with no wave specified) and auto-trace (**/D** with no wave specified) for functions having two independent variables are plotted in a separate graph window if *waveName* is plotted as a contour or image in the top graph. An attempt is made to plot the model values and residuals in the same way as the input data.

By default the auto-trace and auto-residual waves are 50x50 or 25x25x25 or 15x15x15x15. Use **/L=dimSize** for other sizes. Make your own wave and use **/D=waveName** or **/R=waveName** if you want a wave that isn't square. In this case, the wave dimensions must be the same as the dependent data wave.

Confidence bands are not available for multivariate fits.

**Wave Subrange Details**

Almost any wave you specify to FuncFitMD can be a subrange of a wave. The syntax for wave subranges is the same as for the Display command; see **Subrange Display Syntax** on page II-309 for details. Note that the dependent variable data (*waveName*) must be a multidimensional wave; this requires an extension of the subrange syntax to allow a multidimensional subrange. See **Wave Subrange Details** on page V-273 for a discussion of the use of subranges in curve fitting.

The backwards compatibility rules for **CurveFit** apply to FuncFitMD as well.

A subrange could be used to pick a plane from a 3D wave for fitting using a fit function taking two independent variables:

```
Make/N=(100,100,3) DepData
FuncFitMD fitfunc2D, myCoefs, DepData[] [] [0] ...
```

**See Also**

The **CurveFit** operation for parameter details.

The best way to create a user-defined fitting function is using the Curve Fitting dialog. See **Using the Curve Fitting Dialog** on page III-181, especially the section **Fitting to a User-Defined Function** on page III-190.

For details on the form of a user-defined function, see **User-Defined Fitting Functions** on page III-250.

**FUNCREF**

**FUNCREF protoFunc func [= funcSpec]**

Within a user function, FUNCREF is a reference that creates a local reference to a function or a variable containing a function reference.

When passing a function as an input parameter to a user function, the syntax is:

```
FUNCREF protoFunc func
```

In this FUNCREF reference, *protoFunc* is a function that specifies the format of the function that can be passed by the FUNCREF, and *func* is a function reference used as an input parameter.

When you declare a function reference variable within a user function, the syntax is:

```
FUNCREF protoFunc func = funcSpec
```

Here, the local FUNCREF variable, *func*, is assigned a *funcSpec*, which can be a literal function name, a \$ string expression that evaluates at runtime, or another FUNCREF variable.

**See Also**

**Function References** on page IV-106 for an example and further usage details.

**FuncRefInfo****FuncRefInfo** (*funcRef*)

The FuncRefInfo function returns information about a FUNCREF.

**Parameters**

*funcRef* is a function reference variable declared by a FUNCREF statement in a user-defined function.

**Details**

FuncRefInfo returns a semicolon-separated keyword/value string containing the following information:

| <b>Keyword</b> | <b>Information</b>                                                                                                                                         |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME           | The name of the reference function or "" if the FUNCREF variable has not been assigned to point to a function.                                             |
| ISPROTO        | 0 if the FUNCREF variable has been assigned to point to a function.<br>1 if it has not been assigned and therefore still points to the prototype function. |
| ISXFUNC        | 0 if it points to a user-defined function.<br>1 if the FUNCREF points to an external function.                                                             |

**See Also**

**Function References** on page IV-106 and **FUNCREF** on page V-276.

**Function****Function** [[/C /D /S /DF /WAVE] *functionName*( [*parameters* )

The Function keyword introduces a user-defined function in a procedure window.

The optional flags specify the return value type, if any, for the function.

**Flags**

|       |                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------|
| /C    | Returns a complex number.                                                                         |
| /D    | Returns a double-precision number. Obsolete, accepted for backward compatibility.                 |
| /S    | Returns a string.                                                                                 |
| /DF   | Returns a data folder reference. See <b>Data Folder Reference Function Results</b> on page IV-81. |
| /WAVE | Returns a wave reference. See <b>Wave Reference Function Results</b> on page IV-75.               |

**Details**

If you omit all flags, the result is a scalar double-precision number.

The /D flag is not needed because all numeric return values are double-precision.

**See Also**

Chapter IV-3, **User-Defined Functions** and **Function Syntax** on page IV-31 for further information.

**FunctionInfo****FunctionInfo**(*functionNameStr* [, *procedureWinTitleStr*])

The FunctionInfo function returns a keyword-value pair list of information about the user-defined or external function name in *functionNameStr*.

**Parameters**

*functionNameStr* a string expression containing the name or multipart name of a user-defined or external function. *functionNameStr* is usually just the name of a function.

## FunctionInfo

---

To return information about a static function, supply both the module name and the function name in `MyModule#MyFunction` format (see **Regular Modules** on page IV-234), or specify the function name and `procedureWinTitleStr` (see below).

To return information about a function in a different independent module, supply the independent module name in addition to any module name and function name (a double or triple name):

| Name                                                 | What It Refers To                                                                                                       |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>MyIndependentModule#MyFunction</code>          | Refers to a non-static function in an independent module.                                                               |
| <code>MyIndependentModule#MyModule#MyFunction</code> | Refers to a static function in a procedure file with <code>#pragma moduleName=MyModule</code> in an independent module. |

---

(See **Independent Modules** on page IV-236 for details on independent modules.)

The optional `procedureWinTitleStr` can be the title of a procedure window (such as "Procedure" or "File Name Utilities.ipf") in which to search for the named user-defined function. The information about the named function in the specified procedure window is returned.

The `procedureWinTitleStr` parameter makes it possible to select one of several static functions with identical names among different procedure windows, even if they do not contain a `#pragma moduleName=myModule` statement.

The `procedureWinTitleStr` parameter can also be a title followed by an independent module name in brackets to return information about the named function in the procedure window of the given title that belongs to named independent module. You can use this syntax in an independent module when inquiring about a function not in that independent module. For example, use "Procedure [ProcGlobal]" to return information about functions in the main procedure window.

`procedureWinTitleStr` can also be just an independent module name in brackets to return information about the named nonstatic function in any procedure window that belongs to named independent module.

### Details

The returned string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

#### User-Defined and External Functions

| Keyword      | Information Following Keyword                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME         | The name of the function. Same as contents of <code>functionNameStr</code> in most cases. Just the function name if you use the <code>module#function</code> format.                                                                                                                                                                                                                                                                                                                                                                                  |
| TYPE         | Value is "UserDefined" or "XFunc".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| THREADSAFE   | Either "yes" or "no". See <b>ThreadSafe Functions</b> on page IV-105.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| RETURNTYPE   | The return type or types of the function. See <b>Return Type and Parameter Type Codes</b> on page V-279.<br><br>For functions that return a single value, the return type is a simple number. For example, for a function that returns a single string:<br><code>RETURNTYPE: 8192;</code><br><br>For functions that return multiple values, the return types are listed in the order of their declaration in brackets separated by commas. For example, for a function that returns a number and a string:<br><code>RETURNTYPE: [4100, 12288];</code> |
| N_PARAMS     | Number of parameters for this function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| PARAM_n_TYPE | Number encoding the type of each parameter. There will be N of these keywords, one for each parameter. The part shown as <i>n</i> will be a number from 0 to N-1.                                                                                                                                                                                                                                                                                                                                                                                     |

---

See **Examples** for a method for decoding these keywords.

#### User-Defined Functions Only

| Keyword           | Information Following Keyword                                                                                                                                                                                                                                                                      |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PROCWIN           | Title of procedure window containing the function definition.                                                                                                                                                                                                                                      |
| MODULE            | Module containing function definition (see <b>Regular Modules</b> on page IV-234).                                                                                                                                                                                                                 |
| INDEPENDENTMODULE | Independent module containing function definition (see <b>Independent Modules</b> on page IV-236).                                                                                                                                                                                                 |
| SPECIAL           | The value part has one of three values:<br>no: Not a "special" function (not static or override).<br>static: Is a static function. Use the module#function format to get info about static functions.<br>override: Function is an override function. See <b>Function Overrides</b> on page IV-106. |
| SUBTYPE           | The function subtype, for instance <b>FitFunc</b> . See <b>Procedure Subtypes</b> on page V-13 for others.                                                                                                                                                                                         |
| PROCLINE          | Line number within the procedure window of the function definition.                                                                                                                                                                                                                                |
| VISIBLE           | Either "yes" or "no". Set to "no" in the unlikely event that the function is defined in an invisible file.                                                                                                                                                                                         |
| N_OPT_PARAMS      | Number of optional parameters. Usually zero.                                                                                                                                                                                                                                                       |

#### External Functions Only

| Keyword | Information Following Keyword                   |
|---------|-------------------------------------------------|
| XOP     | Name of the XOP module containing the function. |

#### Return Type and Parameter Type Codes

| Type                        | Code | Code in Hex |
|-----------------------------|------|-------------|
| Complex                     | 1    | 0x1         |
| Single Precision            | 2    | 0x2         |
| Variable                    | 4    | 0x4         |
| Double Precision            | 4    | 0x4         |
| Byte                        | 8    | 0x8         |
| 16-bit Integer              | 16   | 0x10        |
| 32-bit Integer              | 32   | 0x20        |
| Unsigned                    | 64   | 0x40        |
| /WAVE                       | 128  | 0x80        |
| Data folder reference       | 256  | 0x100       |
| Structure                   | 512  | 0x200       |
| Function reference          | 1024 | 0x400       |
| Pass by reference parameter | 4096 | 0x1000      |

### Return Type and Parameter Type Codes

| Type   | Code  | Code in Hex |
|--------|-------|-------------|
| String | 8192  | 0x2000      |
| Wave   | 16384 | 0x4000      |
| /Z     | 32768 | 0x8000      |

Igor functions can return a numeric value, a string value, a wave reference, or a data folder reference.

A returned numeric value is always double precision and may be complex. The return type for a normal numeric function is 4, for a complex function (Function/C) is 5 (4 for number +1 for complex).

A string function (Function/S) is 8192 (string). A Function/WAVE has a return type of 16384.

The return and parameter codes may be combined to indicate combinations of attributes. For instance, the code for a variable is 4 and the code for complex is 1. Consequently, the code for a complex variable parameter is 5. The code for a complex variable parameter passed by reference is  $(4+1+4096) = 4101$ .

Variables are always double-precision, hence the code of 4.

Waves may have a variety of codes. Numeric waves will combine with one of the number type codes such as 2 or 16. This does not reflect the numeric type of any actual wave, but rather any flag you may have used in the Wave reference. Thus, if the beginning of your function looks like

```
Function myFunc(w)
 Wave w
```

the code for the parameter `w` will be 16386 (16384 + 2) indicating a single-precision wave. You can use a numeric type flag with the Wave reference:

```
Function myFunc(w)
 Wave/I w
```

In this case, the code will be 16416 (16384 + 32).

Such codes are not very useful, as it is very rare to use a numeric type flag because the numeric type will be resolved correctly at runtime regardless of the flag.

A text wave has no numeric type, so its code is exactly 16384 or 49152 if /Z is also specified. Thus, the numeric type part of the code for a numeric wave serves to distinguish a numeric wave from a text wave. And a Wave/WAVE (a wave that contains references to other waves) has a code of 16512 (16384 + 128), unless /Z is also specified, which adds 32768, resulting in a code of 49280.

When a function uses the multi-valued return syntax, the return value types indicate that they are passed by reference. For example, the type code for a string returned this way is  $0x2000 + 0x1000 = 0x3000$  (12288 decimal).

### Examples

This function formats function information nicely and prints it in the history area in an organized fashion. You can copy it into the Procedure window to try it out. It uses the function `InterpretType()` below to print a human-readable version of the parameter and return types. To try `PrintFuncInfo()`, you will need to copy the code for `InterpretType()` as well.

```
Function PrintFuncInfo(functionName)
 String functionName

 String infostr = FunctionInfo(functionName)
 if (strlen(infostr) == 0)
 print "The function \""+functionName+"\" does not exist."
 return -1
 endif

 print "Name: ", StringByKey("NAME", infostr)

 String typeStr = StringByKey("TYPE", infostr)
 print "Function type: ", typeStr
 Variable IsUserDefined = CmpStr(typeStr, "UserDefined")==0

 // It's not really necessary to use an IF statement here;
 // it simply prevents lines with blank information being
```

```

// printed for an XFUNC.

if (IsUserDefined)
 print "Module: ", StringByKey("MODULE", infostr)
 print "Procedure window: ", StringByKey("PROCWIN", infostr)
 print "Subtype: ", StringByKey("SUBTYPE", infostr)
 print "Special? ", StringByKey("SPECIAL", infostr)

 // Note use of NumberByKey to get a numeric key value
 print "Line number: ", NumberByKey("PROCLINE", infostr)
endif

// See function InterpretType() below for example of
// interpreting type information.

Variable returnType = NumberByKey("RETURNSTYPE", infostr)

String returnTypeStr = InterpretType(returnType, 1)
printf "Return type: %d (0x%X) %s\r", returnType, returnType, returnTypeStr

Variable nparams = NumberByKey("N_PARAMS", infostr)
print "Number of Parameters: ", nparams

Variable nOptParams = 0
if (IsUserDefined)
 nOptParams = NumberByKey("N_OPT_PARAMS", infostr)
 print "Optional Parameters: ", nOptParams
endif

Variable i
for (i = 0; i < nparams; i += 1)
 // Note how the PARAM_n_TYPE keyword string is constructed here:
 String paramKeyStr = "PARAM_" + num2istr(i) + "_TYPE"
 Variable ptype = NumberByKey(paramKeyStr, infostr)

 String ptypeStr = InterpretType(ptype, 0)
 String format = "Parameter %d; type as number: %g (0x%X); type as string: %s"
 String output
 sprintf output, format, i, ptype, ptype, ptypeStr
 print output
endfor

return 0
End

```

Function that creates a human-readable string with information about parameter and return types. Note that various attributes of the type info is tested using the bitwise AND operator (&) to test for individual bits. The constants are expressed as hexadecimal values (prefixed with "0x") to make them more readable (at least to a programmer). Otherwise, 0x4000 would be 16384; at least, 0x4000 is clearly a single-bit constant.

```

Function/S InterpretType(type, isReturnType)
Variable type
Variable isReturnType // 0: type is parameter type; 1: type is return type.

String typeStr = ""

// limit type to unsigned 16-bit values (remove sign extensions caused by 0x8000)
type = type & 0xFFFF

// isNumeric is flag to tell whether to print out "complex" and "real";
// we don't want that information on strings, text waves or wave of wave references.
Variable isNumeric = 1

if (type & 0x4000) // test for WAVE bit set
 typeStr += "Wave"

 if(!isReturnType)
 if (type & 0x80) // test for WAVE/WAVE bit set
 typeStr += "/WAVE"
 // don't print "real" or "complex" for wave waves
 isNumeric = 0
 endif
 if (type & 0x8000) // test for WAVE/Z bit set
 typeStr += "/Z"

```

## FunctionList

---

```
 endif
 endif
 typeStr += " "

 if((type == 0x4000) || (type == (0x4000 | 0x8000))) // WAVE/T or WAVE/Z/T
 if(!isReturnType)
 // For parameter types, if no numeric bits are set, it is a text wave.
 // A numeric wave has some other bits set causing the value
 // to be different from 0x4000 or 0xC000.
 typeStr += "text "
 endif
 // Function/WAVE doesn't (cannot) specify whether the returned wave
 // is text or numeric.
 // Don't print "real" or "complex" for text or unknown wave types.
 isNumeric = 0
 endif
 elseif (type & 0x2000) // test for STRING bit set
 typeStr += "String "
 isNumeric = 0
 elseif (type & 4) // test for VARIABLE bit
 typeStr += "Variable "
 elseif (type & 0x100) // test for DFREF bit
 typeStr += "Data folder reference "
 isNumeric = 0
 elseif (type & 0x200) // test for STRUCTURE bit
 typeStr += "Struct "
 isNumeric = 0
 elseif (type & 0x400) // test for FUNCREF bit
 typeStr += "FuncRef "
 isNumeric = 0
 endif

 // print "real" or "complex" for numeric objects only
 if (isNumeric)
 if (type & 1) // test for COMPLEX bit
 typeStr += "cmplx "
 else
 typeStr += "real "
 endif
 endif

 if(!isReturnType && (type & 0x1000)) // test for PASS BY REFERENCE bit
 typeStr += "reference "
 endif

 return typeStr
End
```

The **StringByKey** and **NumberByKey** functions.

**StringByKey**, **NumberByKey**, and **FunctionList** functions.

**Regular Modules** on page IV-234 and **Independent Modules** on page IV-236.

## FunctionList

**FunctionList**(*matchStr*, *separatorStr*, *optionsStr*)

The **FunctionList** function returns a string containing a list of built-in or user-defined function names satisfying certain criteria. This is useful for making a string to list functions in a pop-up menu control. Note that if the procedures need to be compiled, then **FunctionList** will not list user-defined functions.

### Parameters

Only functions having names that match *matchStr* string are listed. Use "\*" to match all names. See **WaveList** for examples.

*separatorStr* is appended to each function name as the output string is generated. *separatorStr* is usually ";" for list processing (See **Processing Lists of Waves** on page IV-198 for details on list processing).

Use *optionsStr* to further qualify the list of functions. *optionsStr* is a string containing keyword-value pairs separated by commas. Available options are:

- KIND:***nk* Controls the kinds of functions returned.
- nk=1:* List built-in functions.
  - nk=2:* List normal and override user-defined functions.
  - nk=4:* List external functions (defined by an XOP).
  - nk=8:* List only curve fitting functions; must be summed with 1, 2, 4, or 16. For example, use 10 to list user-defined fitting functions.
  - nk=16:* Include static user-defined functions; requires WIN: option, must be summed with 1, 2, or 8. To list only static functions, subtract the non-static functions using RemoveFromList.
- SUBTYPE:***typeName*
- Lists functions that have the type *typeName*. That is, you could use ButtonControl as *typeName* to list only functions that are action procedures for buttons.
- VALTYPE:***nv* Restricts list to functions whose return type is a certain kind.
- nv=1:* Real-valued functions.
  - nv=2:* Complex-valued functions.
  - nv=4:* String functions.
  - nv=8:* WAVE functions
  - nv=16:* DFREF functions.
- Use a sum of these values to include more than one type. The return type is not restricted if this option is omitted.
- NPARAMS:***np* Restricts the list to functions having exactly *np* parameters. Omitting this option lists functions having any number of parameters.
- NINDVARS:***ni* Restricts the list to fitting functions for exactly *ni* independent variables. NINDVARS is ignored if you have not elected to list curve fitting functions using the KIND option. Functions for any number of independent variables are listed if the NINDVARS option is omitted.
- NRETURN:***nRet* Restricts list to user-defined functions that use the **Multiple Return Syntax** on page IV-36 to return *nRet* values.
- NRETURN is ignored if KIND:8 is specified.
- NRETURN was added in Igor Pro 9.00.
- PARAM\_n\_TYPE:***pType*
- Restricts list to functions whose nth input parameter type is a certain kind as described by *pType*.
- PARAM\_n\_TYPE is ignored if KIND:8 is specified.
- PARAM\_n\_TYPE was added in Igor Pro 9.00.
- Use PARAM\_0\_TYPE for the first parameter, PARAM\_1\_TYPE for the second parameter, and so on. You can use any number of PARAM\_n\_TYPE keyword=value pairs in a given FunctionList call.
- For each parameter, set *pType* to a parameter type code as described under **Return Type and Parameter Type Codes** on page V-284 below.
- See also **Return Type and Parameter Type Code Examples** on page V-285 below.
- RETURN\_n\_TYPE:***rType*

Restricts list to user-defined functions whose nth Multiple Return Syntax return type is a certain kind described by *rType*.

RETURN\_n\_TYPE is ignored if KIND:8 is specified.

RETURN\_n\_TYPE was added in Igor Pro 9.00.

Use RETURN\_0\_TYPE for the first return value, RETURN\_1\_TYPE for the second return value, and so on. You can use any number of RETURN\_n\_TYPE keyword=value pairs in a given FunctionList call.

For each return value, set *rType* to a return type code as described under **Return Type and Parameter Type Codes** on page V-284 below.

See also **Return Type and Parameter Type Code Examples** on page V-285 below.

WIN:*windowTitle* Lists functions that are defined in the procedure window with the given title. "Procedure" is the title of the built-in procedure window.

**Note:** Because the *optionsStr* keyword-value pairs are comma separated and procedure window names can have commas in them, the WIN:keyword must be the last one specified.

WIN:*windowTitle* [*independentModuleName*]

Lists functions that are defined in the named procedure window that belongs to the independent module *independentModuleName*. See **Independent Modules** on page IV-236 for details. Requires SetIgorOption IndependentModuleDev=1, otherwise no functions are listed.

Requires *independentModuleName*=ProcGlobal or SetIgorOption independentModuleDev=1, otherwise no functions are listed.

**Note:** The syntax is literal and strict: the window title must be followed by one space and a left bracket, followed directly by the independent module name and a closing right bracket.

WIN:[*independentModuleName*]

Lists functions that are defined in any procedure file that belongs to the named independent module.

Requires *independentModuleName*=ProcGlobal or SetIgorOption independentModuleDev=1, otherwise no functions are listed.

**Note:** The syntax is literal and strict: 'WIN:' must be followed by a left bracket, followed directly by the independent module name and a closing right bracket, like this:

```
FunctionList (... , "WIN: [myIndependentModuleName] ")
```

### Return Type and Parameter Type Codes

These codes are used with the PARAM\_N\_TYPE and RETURN\_N\_TYPE keywords:

| Type             | Code | Code in Hex |
|------------------|------|-------------|
| Complex          | 1    | 0x1         |
| Single Precision | 2    | 0x2         |
| Variable         | 4    | 0x4         |
| Double Precision | 4    | 0x4         |
| Byte             | 8    | 0x8         |
| 16-bit Integer   | 16   | 0x10        |
| 32-bit Integer   | 32   | 0x20        |
| Unsigned         | 64   | 0x40        |

| Type                        | Code  | Code in Hex |
|-----------------------------|-------|-------------|
| /WAVE                       | 128   | 0x80        |
| Data folder reference       | 256   | 0x100       |
| Structure                   | 512   | 0x200       |
| Function reference          | 1024  | 0x400       |
| Pass by reference parameter | 4096  | 0x1000      |
| String                      | 8192  | 0x2000      |
| Wave                        | 16384 | 0x4000      |
| /Z                          | 32768 | 0x8000      |

### Special Return Type and Parameter Type Codes

These special codes are used with the PARAM\_N\_TYPE and RETURN\_N\_TYPE keywords:

|                                 |    |
|---------------------------------|----|
| Any real-valued numeric wave    | -2 |
| Any complex-valued numeric wave | -3 |
| Any text wave                   | -4 |
| Any WAVE/WAVE                   | -5 |
| Any WAVE/DF                     | -6 |

### Return Type and Parameter Type Code Examples

This section shows common values used with the PARAM\_N\_TYPE and RETURN\_N\_TYPE keywords:

|                              |       |                |
|------------------------------|-------|----------------|
| Any real-valued numeric wave | -2    |                |
| Any complex numeric wave     | -3    |                |
| Any text wave                | -4    |                |
| Wave/S                       | 16386 | 0x4000 + 2     |
| Wave or Wave/D               | 16388 | 0x4000 + 4     |
| Wave/C or Wave/D/C           | 16389 | 0x4000 + 4 + 1 |
| Wave/T                       | 16384 | 0x4000 + 0     |

If /Z is used, add 32768 or 0x8000.

For pass-by-reference parameters, add 4096 or 0x1000.

To list user-defined functions in the main procedure window that have either a Wave or Wave/D first parameter, with or without /Z:

```
Print FunctionList("*", ";", "KIND:2,PARAM_0_TYPE:-2,WIN:Procedure") // WIN must be last
```

### Examples

To list user-defined fitting functions for two independent variables:

```
Print FunctionList("*", ";", "KIND:10,NINDVARS:2")
```

To list button-control functions that start with the letter *b* (note that button-control functions are user-defined):

```
Print FunctionList("b*", ";", "KIND:2,SUBTYPE:ButtonControl")
```

### See Also

**FunctionInfo**, **FuncRefInfo**, **MacroList**, **OperationList**, **StringFromList**, **WinList**, **DisplayProcedure**

### FunctionPath

#### **FunctionPath** (*functionNameStr*)

The FunctionPath function returns a path to the file containing the named function. This is useful in certain specialized cases, such as if a function needs access to a lookup table of a large number of values.

The most likely use for this is to find the path to the file containing the currently running function. This is done by passing "" for *functionNameStr*, as illustrated in the example below.

The returned path uses Macintosh syntax regardless of the current platform. See **Path Separators** on page III-453 for details.

If the procedure file is a normal standalone procedure file, the returned path will be a full path to the file.

If the function resides in the built-in procedure window the returned path will be ":Procedure". If the function resides in a packed procedure file, the returned path will be "<packed procedure window title>".

If FunctionPath is called when procedures are in an uncompiled state, it returns ":",.

#### **Parameters**

If *functionNameStr* is "", FunctionPath returns the path to the currently executing function or "" if no function is executing.

Otherwise FunctionPath returns the path to the named function or "" if no function by that name exists.

#### **Examples**

This example loads a lookup table into memory. The lookup table is stored as a wave in an Igor binary wave file.

```
Function LoadMyLookupTable()
 String path

 path = FunctionPath("") // Path to file containing this function.
 if (CmpStr(path[0],":") == 0)
 // This is the built-in procedure window or a packed procedure
 // file, not a standalone file. Or procedures are not compiled.
 return -1
 endif

 // Create path to the lookup table file.
 path = ParseFilePath(1, path, ":", 1, 0) + "MyTable.ibw"

 DFREF dfSave = GetDataFolderDFR()
 // A previously-created place to store my private data.
 SetDataFolder root:Packages:MyData

 // Load the lookup table.
 LoadWave/O path

 SetDataFolder dfSave
 return 0
End
```

#### **See Also**

The **FunctionList** function.

### GalleryGlobal

#### **GalleryGlobal**#*pictureName*

The GalleryGlobal keyword is used in an independent module to reference a picture in the global picture gallery which you can view by choosing Misc→Pictures.

#### **See Also**

See **Independent Modules and Pictures** on page IV-242.

### gamma

#### **gamma** (*num*)

The gamma function returns the value of the gamma function of *num*. If *num* is complex, it returns a complex result. Note that the return value for *num* close to negative integers is NaN, not ±Inf.

**See Also**

The **gammln** function.

**gammaEuler****gammaEuler**

The gammaEuler function returns the Euler-Mascheroni constant 0.5772156649015328606065.

The gammaEuler function was added in Igor Pro 7.00.

**gammaInc****gammaInc(a, x [, upperTail])**

The gammaInc function returns the value of the incomplete gamma function, defined by the integral

$$\Gamma(a, x) = \int_x^{\infty} e^{-t} t^{a-1} dt.$$

If *upperTail* is zero, the limits of integration are 0 to x. If *upperTail* is absent, it defaults to 1, and the limits of integration are x to infinity, as shown. Note that  $\text{gammaInc}(a, x) = \text{gamma}(a) - \text{gammaInc}(a, x, 0)$ .

Defined for  $x > 0$ ,  $a \geq 0$  (*upperTail* = zero or absent) or  $a > 0$  (*upperTail* = 0).

**See Also**

The **gamma**, **gammp**, and **gammq** functions.

**gammaNoise****gammaNoise(a [, b])**

The gammaNoise function returns a pseudo-random value from the gamma distribution

$$f(x) = \frac{x^{a-1} \exp\left(-\frac{x}{b}\right)}{b^a \Gamma(a)}, \quad x > 0, a > 0, b > 0,$$

whose mean is  $ab$  and variance is  $ab^2$ . For backward compatibility you can omit the parameter  $b$  in which case its value is set to 1. When  $a \rightarrow 1$  gammaNoise reduces to **expnoise**.

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

**See Also**

The **SetRandomSeed** operation.

**Noise Functions** on page III-390.

Chapter III-12, **Statistics** for a function and operation overview.

**gammln****gammln(num [, accuracy])**

The gammln function returns the natural log of the gamma function of  $num$ , where  $num > 0$ . If  $num$  is complex, it returns a complex result. Optionally, *accuracy* can be used to specify the desired fractional accuracy. If  $num$  is complex, it returns a complex result. In this case, *accuracy* is ignored.

**Details**

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to  $10^{-7}$ , that means that you wish that the absolute value of  $(f_{\text{actual}} - f_{\text{returned}})/f_{\text{actual}}$  be less than  $10^{-7}$ .

## gammp

---

For backward compatibility, if you don't include *accuracy*, `gammln` uses older code that achieves an accuracy of about  $2 \times 10^{-10}$ .

With *accuracy*, newer code is used that is both faster and more accurate. The output has fractional accuracy better than  $1 \times 10^{-15}$  except for values near zero, where the absolute accuracy ( $f_{\text{actual}} - f_{\text{returned}}$ ) is better than  $2 \times 10^{-16}$ .

The speed of calculation depends only weakly on accuracy. Higher accuracy is significantly slower than lower accuracy only for *num* between 6 and about 10.

### See Also

The `gamma` function.

## gammp

`gammp(a, x [, accuracy])`

The `gammp` function returns the regularized incomplete gamma function  $P(a,x)$ , where  $a > 0, x \geq 0$ . Optionally, *accuracy* can be used to specify the desired fractional accuracy. Same as `gammaInc(a, x, 0) / gamma(a)`.

### Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to  $10^{-7}$ , that means that you wish that the absolute value of  $(f_{\text{actual}} - f_{\text{returned}}) / f_{\text{actual}}$  be less than  $10^{-7}$ .

For backward compatibility, if you don't include *accuracy*, `gammp` uses older code that is slower for an equivalent accuracy, and cannot achieve as high accuracy.

The ability of `gammp` to return a value having full fractional accuracy is limited by double-precision calculations. This means that it will mostly have fractional accuracy better than about  $10^{-15}$ , but this is not guaranteed, especially for extreme values of *a* and *x*.

### See Also

The `gammaInc` and `gammq` functions.

## gammq

`gammq(a, x [, accuracy])`

The `gammq` function returns the regularized incomplete gamma function  $1 - P(a,x)$ , where  $a > 0, x \geq 0$ . Optionally, *accuracy* can be used to specify the desired fractional accuracy. Same as `gammaInc(a, x) / gamma(a)`.

### Details

The *accuracy* parameter specifies the fractional accuracy that you desire. That is, if you set *accuracy* to  $10^{-7}$ , that means that you wish that the absolute value of  $(f_{\text{actual}} - f_{\text{returned}}) / f_{\text{actual}}$  be less than  $10^{-7}$ .

For backward compatibility, if you don't include *accuracy*, `gammq` uses older code that is slower for an equivalent accuracy, and cannot achieve as high accuracy.

The ability of `gammq` to return a value having full fractional accuracy is limited by double-precision calculations. This means that it will mostly have fractional accuracy better than about  $10^{-15}$ , but this is not guaranteed, especially for extreme values of *a* and *x*.

### See Also

The `gammaInc` and `gammp` functions.

## Gauss

`Gauss(x,xc,wx [,y,yc,wy [,z,zc,wz [,t,tc,wt]])`

The `Gauss` function returns a normalized Gaussian for the specified dimension.

$$Gauss(\mathbf{r}, \mathbf{c}, \mathbf{w}) = \prod_{i=1}^n \frac{1}{w_i \sqrt{2\pi}} \exp \left[ -\frac{1}{2} \left( \frac{r_i - c_i}{w_i} \right)^2 \right],$$

where *n* is the number of dimensions.

**Parameters**

$x_c$ ,  $y_c$ ,  $z_c$ , and  $t_c$  are the centers of the Gaussian in the X, Y, Z, and T directions, respectively.

$w_x$ ,  $w_y$ ,  $w_z$ , and  $w_t$  are the widths of the Gaussian in the X, Y, Z, and T directions, respectively.

Note that  $w_i$  here is the standard deviation of the Gaussian. This is different from the width parameter in the gauss curve fitting function, which is  $\text{sqrt}(2)$  times the standard deviation.

Note also that the Gauss function lacks the cross-correlation parameter that is included in the Gauss2D curve fitting function.

**Examples**

```
Make/N=100 eee=gauss(x,50,10)
Print area(eee,-inf,inf)
0.999999
```

```
Make/N=(100,100) ddd=gauss(x,50,10,y,50,15)
Print area(ddd,-inf,inf)
0.999137
```

**See Also**

**Gauss1D** (duplicates the Gauss built-in curve fitting function)

**Gauss2D** (duplicates the Gauss2D built-in curve fitting function)

**Gauss1D****Gauss1D(w, x)**

The Gauss1D function returns the value of a Gaussian peak defined by the coefficients in the wave  $w$ . The equation is the same as the Gauss curve fit:

$$w[0] + w[1] \exp \left[ - \left( \frac{x - w[2]}{w[3]} \right)^2 \right].$$

**Examples**

Do a fit to a Gaussian peak in a portion of a wave, then extend the model trace to the rest of the X range:

```
Make/O/N=100 junkg // fake data wave
Setscale/I x -1,1,junkg
Display junkg
junkg = 1+2.5*exp(-((x-.5)/.3)^2)+gnoise(.1)
Duplicate/O junkg, junkgfit
junkgfit = NaN
AppendToGraph junkgfit
CurveFit gauss junkg[50,99] /D=junkgfit
// now extend the model trace
junkgfit = Gauss1D(w_coef, x)
```

**See Also**

The **CurveFit** operation.

**Gauss2D****Gauss2D(w, x, y)**

The Gauss2D function returns the value of a two-dimensional Gaussian peak defined by the coefficients in the wave  $w$ . The equation is the same as the Gauss2D curve fit:

$$w[0] + w[1] \exp \left\{ \frac{-1}{2(1-w[6]^2)} \left[ \left( \frac{x-w[2]}{w[3]} \right)^2 + \left( \frac{y-w[4]}{w[5]} \right)^2 - \left( \frac{2w[6](x-w[2])(y-w[4])}{w[3]w[5]} \right) \right] \right\}.$$

**Examples**

Do a fit to a Gaussian peak in a portion of a wave, then extend the model trace to the rest of the X range (watch out for the very long wave assignment to junkg2D):

## GBLoadWave

---

```
Make/O/N=(100,100) junkg2D // fake data wave
Setscale/I x -1,1,junkg2D
Setscale/I y -1,1,junkg2D
Display; AppendImage junkg2D
//Caution! Next command wrapped to fit page:
junkg2D = -1 + 2.5*exp((-1/(2*(1-.4^2)))*((x-.1)/.2)^2+((y+.2)/.35)^2+2*.4*
((x-.1)/.2)*((y+.2)/.35))
junkg2D += gnoise(.01)
Duplicate/O junkg2D, junkg2Dfit
junkg2Dfit = NaN
AppendMatrixContour junkg2Dfit
CurveFit gauss2D junkg2D[20,80][10,70] /D=junkg2Dfit[20,80][10,70]
// now extend the model trace
junkg2Dfit = Gauss2D(w_coef, x, y)
```

### See Also

The **CurveFit** operation.

## GBLoadWave

**GBLoadWave** [*flags*] [*fileNameStr*]

The GBLoadWave operation loads data from a binary file into waves.

For more complex applications such as loading structured data into Igor structures see the **FBinRead** operation.

### Parameters

If *fileNameStr* is omitted or is "", or if the /I flag is used, GBLoadWave presents an Open File dialog from which you can choose the file to load.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

### Flags

|                                                      |                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /A                                                   | Automatically assigns arbitrary wave names using "wave" as the base name. Skips names already in use.                                                                                                                                                                                                                    |
| /A= <i>baseName</i>                                  | Same as /A but it automatically assigns wave names of the form <i>baseName0</i> , <i>baseName1</i> .                                                                                                                                                                                                                     |
| /D= <i>d</i>                                         | New programming should use the /I flag instead of the /D, /L and /F flags.<br><i>d</i> =0: Creates single-precision waves.<br><i>d</i> =1: Creates double-precision waves.<br><br>/D by itself is equivalent to /D=1.                                                                                                    |
| /F= <i>f</i>                                         | New programming should use the /I flag instead of the /D, /L and /F flags.<br><i>f</i> specifies the data format of the file:<br><i>f</i> =1: Signed integer (8, 16, 32 bits allowed)<br><i>f</i> =2: Creates double-precision waves<br><i>f</i> =3: Floating point (default, 32, 64 bits allowed)                       |
| /FILT= <i>fileFilterStr</i>                          | Provides control over the file filter menu in the Open File dialog. This flag was added in Igor Pro 7.00.<br><br>The construction of the <i>fileFilterStr</i> parameter is the same as for the /F= <i>fileFilterStr</i> flag of the Open operation. See <b>Open File Dialog File Filters</b> on page IV-149 for details. |
| /I [= { <i>macFilterStr</i> , <i>winFilterStr</i> }] | Specifies interactive mode which displays the Open File dialog.<br><br>In Igor7 and later, the <i>macFilterStr</i> and <i>winFilterStr</i> parameters are ignored. Use the /FILT flag instead.                                                                                                                           |

---

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/J=j</code>             | Specifies how input floating point data is interpreted.<br><i>j=0</i> : IEEE floating point (default)<br><i>j=1</i> : VAX floating point                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>/L=length</code>        | New programming should use the <code>/T</code> flag instead of the <code>/D</code> , <code>/L</code> and <code>/F</code> flags.<br><i>length</i> specifies the data length of the data in the file in bits (default = 32). Allowable data lengths are 8, 16, 32, 64.                                                                                                                                                                                                                                                                                                                   |
| <code>/N</code>               | Same as <code>/A</code> except that, instead of choosing names that are not in use, it overwrites existing waves.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>/N=baseName</code>      | Same as <code>/N</code> except that it automatically assigns wave names of the form <i>baseName0</i> , <i>baseName1</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>/O=o</code>             | Controls overwriting of waves in case of a name conflict.<br><i>o=0</i> : Use unique wave names.<br><i>o=1</i> : Overwrite existing waves.<br><code>/O</code> by itself is equivalent to <code>/O=1</code> .                                                                                                                                                                                                                                                                                                                                                                           |
| <code>/P=pathName</code>      | Specifies the folder to look in for <i>fileNameStr</i> . <i>pathName</i> is the name of an existing symbolic path.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>/Q=q</code>             | Controls messages written to the history area of the command window.<br><i>q=0</i> : Write messages.<br><i>q=1</i> : Suppress messages.<br><code>/Q</code> by itself is equivalent to <code>/Q=1</code> .                                                                                                                                                                                                                                                                                                                                                                              |
| <code>/S=s</code>             | <i>s</i> is the number of bytes at the start of the file to skip. It defaults to 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>/T={fType,wType}</code> | Specifies the data type of the file ( <i>fType</i> ) and the data type of the wave or waves to be created ( <i>wType</i> ). The allowed codes for both <i>fType</i> and <i>wType</i> are:<br>2: Single-precision floating point<br>4: Double-precision floating point<br>8: 8-bit signed integer<br>16: 16-bit signed integer<br>32: 32-bit signed integer<br>128: 64-bit signed integer (Igor7 or later)<br>72: 8-bit unsigned integer (8+64)<br>80: 16-bit unsigned integer (16+64)<br>96: 32-bit unsigned integer (32+64)<br>192: 64-bit unsigned integer (128+64) (Igor7 or later) |
| <code>/U=u</code>             | Specifies the number of points of data per array in the file.<br>The default is 0 which means "auto". In this case GBLoadWave calculate the number of data pointers per array based on the number of bytes in the file, the number of bytes to be skipped at the start of the file ( <code>/S</code> flag), and the number of arrays in the file ( <code>/W</code> flag).                                                                                                                                                                                                              |
| <code>/V=v</code>             | Specifies interleaving of data in the file.<br><i>v=0</i> : Data in file is not interleaved (default)<br><i>v=1</i> : Data in file is interleaved<br><code>/V</code> by itself is equivalent to <code>/V=1</code> .                                                                                                                                                                                                                                                                                                                                                                    |

*/W=w* Specifies the number of arrays in the file. The default is 1.  
If you omit */W* but specify the number of points per data array in the file via */U* then GBLoadWave calculates the number of waves to be loaded based on the number of bytes in the file, the number of bytes to be skipped at the start of the file (*/S* flag), and the specified number of points per data array in the file (*/U* flag). Therefore, if you specify */U* and want to load just one wave you must also specify */W=1*.

*/Y={offset, mult}* Data loaded into waves is scaled using offset and mult:  
$$\text{output data} = (\text{input data} + \text{offset}) * \text{multiplier}$$
  
This is useful to convert integer data into scaled, real numbers.

### Details

The */N* flag instructs Igor to automatically name new waves "wave" (or *baseName* if */N=baseName* is used) plus a number. The number starts from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten.

The */A* flag is like */N* except that Igor skips names already in use.

The */T* flag allows you to specify a data type for both the input (data in the file) and the output (data in the waves). You should use the */T* flag instead of the */D*, */L* and */F* flags. These flags are obsolete but are still supported.

### GBLoadWave Open File Dialog

If you include the */I* flag, or if the */P=pathName* and *fileNameStr* parameters do not fully specify the file to be loaded, GBLoadWave displays the Open File dialog.

The */FILT=fileFilterStr* flag provides control over the file filter menu in the Open File dialog. This flag was added in Igor Pro 7.00. The construction of the *fileFilterStr* parameter is the same as for the */F=fileFilterStr* flag of the Open operation. See **Open File Dialog File Filters** on page IV-149 for details.

In Igor7 and later, the *macFilterStr* and *winFilterStr* parameters of the */I* flag are ignored. Use the */FILT* flag instead.

### Output Variables

GBLoadWave sets the following output variables:

|                    |                                                                       |
|--------------------|-----------------------------------------------------------------------|
| <i>V_flag</i>      | Number of waves loaded or -1 if an error occurs during the file load. |
| <i>S_fileName</i>  | Name of the file being loaded.                                        |
| <i>S_path</i>      | File system path to the folder containing the file.                   |
| <i>S_waveNames</i> | Semicolon-separated list of the names of loaded waves.                |

*S\_path* uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon.

When GBLoadWave presents an Open File dialog and the user cancels, *V\_flag* is set to 0 and *S\_fileName* is set to "".

### Example

```
// Load 128 point single precision version 2 Igor binary wave file
GBLoadWave/S=126/U=128 "fileName"

// Load 8 256 point arrays of 16 bit signed integers into single-precision waves
// after skipping 128 byte header
GBLoadWave/S=128/T={16,2}/W=8/U=256 "fileName"

// Load n 100 point arrays of double-precision floating point numbers
// into double-precision Igor waves with names like temp0, temp1, etc,
// overwriting existing waves. n is determined by the number of bytes
// in the file.
GBLoadWave/O/N=temp/T={4,4}/U=100 "fileName"

// Load a file containing a 1024 byte header followed by a 512 row
// by 384 column array of unsigned bytes into an unsigned byte matrix
```

```
// wave and display it as an image
GBLoadWave/S=1024/T={8+64,8+64}/N=temp "fileName"
Rename temp0, image
Redimension/N=(512,384) image
if (<file uses row-major order>)
 MatrixTranspose image
endif
Display; AppendImage image
```

"Row-major order" relates to how a 2D array is stored in memory. In row-major order, all data for a given row is stored contiguously in memory. In column-major order, all data for a given column is stored contiguously in memory. Igor uses column-major order but row-major is more common.

**FBinRead** operation for more complex applications such as loading structured data into Igor structures.

## gcd

**gcd(A, B)**

The gcd function calculates the greatest common divisor of *A* and *B*, which are both assumed to be integers.

#### Examples

Compute least common multiple (LCM) of two integers:

```
Function LCM(a,b)
 Variable a, b
 return((a*b)/gcd(a,b))
End
```

## GeometricMean

**GeometricMean(a, b)**

The GeometricMean function returns the arithmetic-geometric mean of two positive real numbers *a* and *b*. The mean is computed by creating two sequences {*a<sub>i</sub>*} and {*b<sub>i</sub>*} initialized to the input values: *a*<sub>0</sub>=*a* and *b*<sub>0</sub>=*b* with

$$a_{n+1} = \frac{1}{2}(a_n + b_n),$$

$$b_{n+1} = \sqrt{a_n b_n}.$$

The two sequences converge in a few iterations to a single value which is the arithmetic-geometric mean.

## GetAxis

**GetAxis** [/W=*winName* /Q] *axisName*

The GetAxis operation determines the axis range and sets the variables *V\_min* and *V\_max* to the minimum and maximum values of the named axis.

#### Parameters

*axisName* is usually "left", "right", "top" or "bottom", though it may also be the name of a free axis such as "VertCrossing".

## GetBrowserLine

---

### Flags

- /Q* Prevents values of *V\_flag*, *V\_min*, and *V\_max* from being printed in the history area. The results are still stored in the variables.
- /W=winName* Retrieves axis info from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
- When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Details

GetAxis sets *V\_min* according to the bottom of vertical axes or left of horizontal axes and *V\_max* according to the top of vertical axes or right of horizontal axes. It also sets the variable *V\_flag* to 0 if the specified axis is actually used in the graph, or to 1 if it is not.

Axis ranges and other graph properties are computed when the graph is redrawn. Since automatic screen updates are suppressed while a user-defined function is running, if the graph was recently created or modified, you must call DoUpdate to redraw the graph so you get accurate axis information.

The **AxisInfo** function.

## GetBrowserLine

**GetBrowserLine**(*fullPathStr* [, *mode*])

The GetBrowserLine function returns the zero-based line number of the data folder referenced by *fullPathStr*.

Documentation for the GetBrowserLine function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "GetBrowserLine"
```

## GetBrowserSelection

**GetBrowserSelection**(*index* [, *mode*])

The GetBrowserSelection function returns a string containing the full path, quoted if necessary, to a selected Data Browser item.

Documentation for the GetBrowserSelection function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "GetBrowserSelection"
```

## GetCamera

**GetCamera** [*flags*] [*keywords*]

The GetCamera operation provides information about a camera window.

Documentation for the GetCamera operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "GetCamera"
```

## GetDataFolder

**GetDataFolder**(*mode* [, *dfr*])

The GetDataFolder function returns a string containing the name of or full path to the current data folder or, if *dfr* is present, the specified data folder.

**GetDataFolderDFR** is preferred.

### Parameters

If *mode*=0, it returns just the name of the data folder.

If *mode*=1, GetDataFolder returns a string containing the full path to the data folder.

*dfr*, if present, specifies the data folder of interest.

**Details**

GetDataFolder can be used to save and restore the current data folder in a procedure. However GetDataFolderDFR is preferred for that purpose.

**Examples**

```
String savedDataFolder = GetDataFolder(1) // Save
SetDataFolder root:
Variable/G gGlobalRootVar
SetDataFolder savedDataFolder // and restore
```

**See Also**

Chapter II-8, **Data Folders**.

The **SetDataFolder** operation and **GetDataFolderDFR** function.

## GetDataFolderDFR

**GetDataFolderDFR()**

The GetDataFolderDFR function returns the data folder reference for the current data folder.

**Details**

GetDataFolderDFR can be used to save and restore the current data folder in a procedure. It is like GetDataFolder but returns a data folder reference rather than a string.

**Example**

```
DFREF saveDFR = GetDataFolderDFR() // Save
SetDataFolder root:
Variable/G gGlobalRootVar
SetDataFolder saveDFR // and restore
```

The **SetDataFolder** operation.

## GetDefaultFont

**GetDefaultFont(winName)**

The GetDefaultFont function returns a string containing the name of the default font for the named window or subwindow.

**Parameters**

If *winName* is null (that is, "") returns the default font for the experiment.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Details**

Only graph windows and the experiment as a whole have default fonts. If *winName* is the name of a window other than a graph (e.g., a layout), or if *winName* is not the name of any window, GetDefaultFont returns the experiment default font.

In user-defined functions, font names are usually evaluated at compile time. To use the output of GetDefaultFont in a user-defined function, you will usually need to build a command as a string expression and execute it with the **Execute** operation.

**Examples**

```
String fontName = GetDefaultFont("Graph0")
String command= "SetDrawEnv fname=\"\" + fontName + "\", save"
Execute command
```

**See Also**

The **GetDefaultFontSize**, **GetDefaultFontStyle**, **FontSizeHeight**, and **FontSizeStringWidth** functions.

### GetDefaultFontSize

**GetDefaultFontSize**(*graphNameStr*, *axisNameStr*)

The **GetDefaultFontSize** function returns the default font size of the graph or of the graph's axis (in points) in the specified window or subwindow.

#### Details

If *graphNameStr* is "" the top graph is examined.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

If *axisNameStr* is "", the font size of the default font for the graph is returned.

If named axis exists, the default font size for the named axis in the graph is returned.

If named axis does not exist, NaN is returned.

#### See Also

The **GetDefaultFont**, **GetDefaultFontStyle**, **FontSizeHeight**, and **FontSizeStringWidth** functions.

### GetDefaultFontStyle

**GetDefaultFontStyle**(*graphNameStr*, *axisNameStr*)

The **GetDefaultFontStyle** function returns the default font style of the graph or of the graph's axis in the specified window or subwindow.

#### Details

If *graphNameStr* is "" the top graph is examined.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

If *axisNameStr* is "", the font style of the default font for the graph is returned.

If named axis exists, the default font style for the named axis in the graph is returned.

If named axis does not exist, NaN is returned.

The function result is a bitwise value with each bit identifying one aspect of the font style as follows:

|        |               |
|--------|---------------|
| Bit 0: | Bold          |
| Bit 1: | Italic        |
| Bit 2: | Underline     |
| Bit 4: | Strikethrough |

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

#### See Also

The **GetDefaultFont**, **GetDefaultFontSize**, **FontSizeHeight**, and **FontSizeStringWidth** functions.

### GetDimLabel

**GetDimLabel**(*waveName*, *dimNumber*, *dimIndex*)

The **GetDimLabel** function returns a string containing the label for the given dimension or dimension element.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers and 3 for chunks.

If *dimIndex* is -1, it returns the label for the entire dimension. If *dimIndex* is  $\geq 0$ , it returns the dimension label for that element of the dimension.

#### See Also

**SetDimLabel**, **FindDimLabel**, **CopyDimLabels**

**Dimension Labels** on page II-93 for further usage details and examples.

## GetEnvironmentVariable

### GetEnvironmentVariable (*varName*)

The GetEnvironmentVariable function returns a string containing the current value of the specified environment variable for the currently running Igor process. If the variable does not exist, an empty string ("") is returned.

The GetEnvironmentVariable function was added in Igor Pro 7.00.

### Parameters

*varName*                      The name of an environment variable which may or may not exist. It must not be an empty string and may not contain an equals sign (=).  
As a special case, if a single equals sign ("=") is passed for *varName*, a carriage return (\r) separated list of all current key=value environment variable pairs is returned.

### Details

The environment of Igor's process is composed of a set of key=value pairs that are known as environment variables.

Any child process created by calling ExecuteScriptText inherits the environment variables of Igor's process.

On Windows, environment variable names are case-insensitive. On other platforms, they are case-sensitive.

GetEnvironmentVariable returns an empty string if *varName* does not exist or if it does exist but its value is empty. If you need to know whether or not the environment variable itself actually exists, you can use the following function:

```
Function EnvironmentVariableExists(varName)
 String varName
 String varList = GetEnvironmentVariable("=")

 // Replace \r with \n because GrepString treats \n only as line separator, not \r.
 varList = ReplaceString("\r", varList, "\n")
 String regExp = "(?m)^\s*" + varName + "\s*"
 return GrepString(varList, regExp)
End
```

### Examples

```
String currentUser = GetEnvironmentVariable("USER")
String varList = GetEnvironmentVariable("=")
```

## GetErrorMessage

### GetErrorMessage (*errorCode* [, *substitutionOption*])

GetErrorMessage returns a string containing an explanation of the error associated with *errorCode*. It is most useful for programmers providing custom error handling in user-defined functions.

The [GetRTErrorMessage](#) provides a simpler way to get a description of an error in a user-defined function.

For an overview of error handling, see [Flow Control for Aborts](#) on page IV-48.

### Details

*errorCode* is an Igor error code. Usually you obtain the error code during execution of a user-defined function via the [GetRTError](#) function or from the `V_Flag` variable created by many Igor operations.

If multiple errors occur in a user-defined function, this may result in GetErrorMessage returning an incomplete error message. See the [MultipleErrors](#) example below. You can achieve more reliable error reporting by calling [GetRTErrorMessage](#) from a [try-catch-endtry](#) block.

### Substitution

For a few error codes, the corresponding error message is designed to be combined with "substituted" information available only immediately after the error occurs. An example is the "parameter out of range" error which produces an error message such as "expected number between x and y". The optional *substitutionOption* parameter gives you control over substitution.

## GetFileFolderInfo

---

To get the correct error message, you must call `GetErrMsg` immediately after calling the function or operation that generated the error and you must pass the appropriate value for *substitutionOption*.

Igor maintains two contexts which store the substitution information: one for user-defined functions and one for all other contexts (command line execution, macros, and the Execute operation).

Set *substitutionOption* to one of these values:

| <i>substitutionOption</i> | <code>GetErrMsg</code> Action                                                                                                                                                                                                                                                                                    |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                         | Substitution values are filled in with "_Not Available_". This is the default when <i>substitutionOption</i> is not specified.                                                                                                                                                                                   |
| 1                         | Substitution values are blank.                                                                                                                                                                                                                                                                                   |
| 2                         | Substitution is performed based on the assumption that the error was received while executing a macro or a command using Igor's command line. This includes a command executed via the Execute operation even from a user-defined function because such commands are executed as if entered in the command line. |
| 3                         | Substitution is performed based on the assumption that the error was received while executing a user-defined function.                                                                                                                                                                                           |

For most purposes you should pass 3 for *substitutionOption* when the error was generated in a user-defined function other than through the Execute operation and pass 2 otherwise.

### Examples

```
// Macro, Execute or command line example
Execute/Q/Z "Duplicate/O nonexistentWave, dup"
Print GetErrMsg(V_Flag,2)
// Prints "expected wave name"

// Function example
Function Test()
 Make/O/N=(2,2) data= 0
 FilterIIR/COEF=data/LO=999/Z data // Purposely wrong /LO value
 Print GetErrMsg(V_Flag,3) // Substitution assuming user-defined function
End
// Executing Test() prints: "expected /LO frequency between 0 and 0.5"

// Multiple error example
// Because of the first error, an assignment to a null wave reference,
// the substitution information for the FilterIIR operation is not available.
Function MultipleErrors()
 Make/O/N=(2,2) data= 0
 WAVE ww = $"

 // Generates error because ww is not valid
 ww = 0

 // Generates another error because of purposely wrong /LO value
 FilterIIR/COEF=data/LO=999/Z data

 Print GetErrMsg(V_Flag,3) // Substitution assuming user-defined function
End
// Executing MultipleErrors() prints:
// "expected between and " // Wave error masks /LO error reporting
```

## GetFileFolderInfo

`GetFileFolderInfo` [*flags*] [*fileOrFolderNameStr*]

The `GetFileFolderInfo` operation returns information about a file or folder.

### Parameters

*fileOrFolderNameStr* specifies the file (or folder) for which information is returned. It is optional if */P=pathName* and */D* are specified, in which case information about the directory associated with *pathName* is returned.

If you use a full or partial path for *fileOrFolderNameStr*, see **Path Separators** on page III-453 for details on forming the path.

Folder paths should not end with single Path Separators. See the **MoveFolder Details** section.

If Igor can not determine the location of the file from *fileOrFolderNameStr* and *pathName*, it displays a dialog allowing you to specify the file to be examined. Use /D to select a folder.

### Flags

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /D                  | Uses the Select Folder dialog rather than Open File dialog when <i>pathName</i> and <i>fileOrFolderNameStr</i> do not specify an existing file or folder.                                                                                                                                                                                                                                                                                                                                            |
| /P= <i>pathName</i> | Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.                                                                                                                                                                                                                                                                                                                                                                                              |
| /Q                  | No information printed to the history area.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| /UTC[= <i>u</i> ]   | If you include /UTC or /UTC=1, GetFileFolderInfo returns creation and modification dates in UTC (coordinated universal time). If you omit /UTC or specify /UTC=0, GetFileFolderInfo returns creation and modification dates in local time.<br>The default, used if you omit /UTC, is local time.<br>The /UTC flag was added in Igor Pro 9.00.                                                                                                                                                        |
| /Z[= <i>z</i> ]     | Prevents procedure execution from aborting if GetFileFolderInfo tries to get information about a file or folder that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.<br>/Z=0: Same as no /Z.<br>/Z=1: Used for getting information for a file or folder only if it exists. /Z alone has the same effect as /Z=1.<br>/Z=2: Used for getting information for a file or folder if it exists and displaying a dialog if it does not exist. |

### Output Variables

GetFileFolderInfo returns information in the following output variables:

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_flag        | 0: File or folder was found.<br>-1: User cancelled the Open File dialog.<br>Other: An error occurred, such as the specified file or folder does not exist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| S_path        | Full file system path to the specified file or folder using Macintosh path syntax.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| V_isFile      | 1: <i>fileOrFolderNameStr</i> is a file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| V_isFolder    | 1: <i>fileOrFolderNameStr</i> is a folder.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| V_isInvisible | 1: File is invisible ( <i>Macintosh</i> ) or Hidden ( <i>Windows</i> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| V_isReadOnly  | Set if the file is locked ( <i>Macintosh</i> ) or is read-only ( <i>Windows</i> ).<br><br>On Macintosh, V_isReadOnly is either 0 (unlocked) or 1 (locked). To set this manually, display the Finder Info window for the file and then check or uncheck the "Locked" checkbox.<br><br>On Windows, V_isReadOnly is either 0 (unlocked) or 1 (locked). To set this manually, display the Properties window for the file and then check or uncheck the "Read-only" checkbox.<br><br>On both Macintosh and Windows, V_isReadOnly tells you only about the property set in the Finder or Windows desktop. It does not tell you if you have write permission for the file or for the folder containing the file. If your goal is to determine if you can write to the file, the only way to do that is to try to write to it and catch any resulting error. |

## GetFileFolderInfo

---

|                    |                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_creationDate     | Number of seconds since midnight on January 1, 1904 when the file or folder was first created in local time or UTC depending on the /UTC flag. Use <b>Secs2Date</b> to format the date as text. |
| V_modificationDate | Number of seconds since midnight on January 1, 1904 when the file or folder was last modified in local time or UTC depending on the /UTC flag. Use <b>Secs2Date</b> to format the date as text. |
| V_isAliasShortcut  | 1: File is an alias ( <i>Macintosh</i> ) or a shortcut ( <i>Windows</i> ) and S_aliasPath is also set.                                                                                          |

If *fileOrFolderNameStr* refers to a file (not a folder), GetFileFolderInfo returns additional information in the following variables:

|                |                                                                                                                                                                                                                                                                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| S_aliasPath    | If the specified file is an alias or shortcut, S_aliasPath is the full path to the target of the specified file. Otherwise it is "".<br><br>S_aliasPath uses Macintosh path syntax. When the source is a folder, it ends with a ":" character.                                                                                                                 |
| V_isStationery | 1: The stationery bit is set ( <i>Macintosh</i> ) or ( <i>Windows</i> ) the file type is one of the stationery file types (.pxt, .uxt, .ift).                                                                                                                                                                                                                  |
| S_fileType     | Four-character file type code, such as 'TEXT' or 'IGsU' (packed experiment). On Windows, these codes are fabricated by translating from the equivalent file name extensions, such as .txt and .pxp.                                                                                                                                                            |
| S_creator      | Four-character creator code, such as 'IGRO' (Igor Pro creator code).<br><br>On Windows, S_creator is set to 'IGRO' if the file name extensions is one of those registered to Igor Pro, such as .pxp or .bwav (but not .txt). For other registered extensions, S_creator is set to the full file path of the registered application. Otherwise it is set to "". |
| V_logEOF       | Number of bytes in the file data fork. For other forks, use <b>Open/F</b> and <b>FStatus</b> .                                                                                                                                                                                                                                                                 |
| V_version      | Version number of the file. On Macintosh, this is the value in the vers(1) resource. On Windows, a file version such as 3.10.2.1 is returned as 4.021: use S_fileVersion to avoid the problem of the second digit overflowing into the first digit.<br><br>"0": File version can't be determined, or the file can't be examined because it is already open.    |
| S_fileVersion  | The file version as a string.<br><br>On Macintosh, this is just a string representation of V_Version. On Windows, a file version such as 3.10.2.1 is returned as "3.10.2.1".<br><br>"0": ( <i>Macintosh</i> ) file version can't be determined.<br><br>"0.0.0.0": ( <i>Windows</i> ) file version can't be determined.                                         |

### Details

You can change some of the file information by using **SetFileFolderInfo**.

On Windows shortcuts have ".lnk" file name extensions that are hidden on the desktop. Prior to Igor Pro 9, *fileOrFolderNameStr* was required to include the ".lnk" extension. For consistency with operations such as NewPath and OpenNotebook, in Igor Pro 9.00 and later, it is optional. When *fileOrFolderNameStr* refers to a shortcut, the S\_path output variable includes the ".lnk" extension.

### Examples

Print the modification date of a file:

```
GetFileFolderInfo/Z "Macintosh HD:folder:afile.txt"
if(V_Flag == 0 && V_isFile) // file exists
 Print Secs2Date(V_modificationDate,0), Secs2Time(V_modificationDate,0)
endif
```

Determine if a folder exists (easier than creating a path with NewPath and then using PathInfo):

```
GetFileFolderInfo/Z "Macintosh HD:folder:subfolder"
if(V_Flag && V_isFolder)
 Print "Folder Exists!"
endif
```

Find the source for a shortcut or alias:

```
GetFileFolderInfo/Z "Macintosh HD:fileThatIsAlias"
if(V_Flag && V_isAliasShortcut)
 Print S_aliasPath
endif
```

#### See Also

The **SetFileFolderInfo**, **PathInfo**, and **FStatus** operations. The **IndexedFile**, **Secs2Date**, and **ParseFilePath** functions.

## GetFormula

### GetFormula (*objName*)

The GetFormula function returns a string containing the named object's dependency formula. The named object must be a wave, numeric variable or string variable.

#### Details

Normally an object will have an empty dependency formula and GetFormula will return an empty string (" "). If you assign an expression to an object using the := operator or the SetFormula operation, the text on the right side of the := or the parameter to SetFormula is the object's dependency formula and this is what GetFormula will return.

#### Examples

```
Variable/G dependsOnIt
Make/O wave0 := dependsOnIt*2 //wave0 changes when dependsOnIt does
Print GetFormula(wave0)
```

Prints the following in the history area:

```
dependsOnIt*2
```

#### See Also

See **Dependency Formulas** on page IV-228, and the **SetFormula** operation.

## GetGizmo

### GetGizmo [*flags*] *keyword* [=*value*]

The GetGizmo operation provides information about a Gizmo display window.

Documentation for the GetGizmo operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "GetGizmo"
```

## GetIndependentModuleName

### GetIndependentModuleName ()

The GetIndependentModuleName function returns the name of the currently running Independent Module. If no independent module is running, it returns "ProcGlobal".

#### See Also

**Independent Modules** on page IV-236.

**IndependentModuleList**.

### GetIndexedObjName

**GetIndexedObjName**(*sourceFolderStr*, *objectType*, *index*)

The GetIndexedObjName function returns a string containing the name of the indexth object of the specified type in the data folder specified by the string expression.

GetIndexedObjNameDFR is preferred.

#### Parameters

*sourceFolderStr* can be either ":" or "" to specify the current data folder. You can also use a full or partial data folder path. *index* starts from zero. If no such object exists a zero length string (" ") is returned. *objectType* is one of the following values:

| <i>objectType</i> | What You Get      |
|-------------------|-------------------|
| 1                 | Waves             |
| 2                 | Numeric variables |
| 3                 | String variables  |
| 4                 | Data folders      |

#### Examples

```
Function PrintAllWaveNames()
 String objName
 Variable index = 0
 do
 objName = GetIndexedObjName(":", 1, index)
 if (strlen(objName) == 0)
 break
 endif
 Print objName
 index += 1
 while(1)
End
```

#### See Also

The **CountObjects** function, and Chapter II-8, **Data Folders**.

### GetIndexedObjNameDFR

**GetIndexedObjNameDFR**(*dfr*, *objectType*, *index*)

The GetIndexedObjNameDFR function returns a string containing the name of the indexth object of the specified type in the data folder referenced by *dfr*.

GetIndexedObjNameDFR is the same as GetIndexedObjName except the first parameter, *dfr*, is a data folder reference instead of a string containing a path.

#### Parameters

*index* starts from zero. If no such object exists a zero length string (" ") is returned.

*objectType* is one of the following values:

| <i>objectType</i> | What You Get      |
|-------------------|-------------------|
| 1                 | Waves             |
| 2                 | Numeric variables |
| 3                 | String variables  |
| 4                 | Data folders      |

#### Examples

```
Function PrintAllWaveNames()
 String objName
 Variable index = 0
 DFRREF dfr = GetDataFolderDFR() // Reference to current data folder
```

```

do
 objName = GetIndexedObjNameDFR(dfr, 1, index)
 if (strlen(objName) == 0)
 break
 endif
 Print objName
 index += 1
while(1)
End

```

## GetKeyState

**GetKeyState (flags)**

The GetKeyState function returns a bitwise numeric value that indicates the state of certain keyboard keys.

To detect keyboard events directed toward a window that you have created, such as a panel window, use the window hook function instead of GetKeyState. See **Window Hook Functions** on page IV-291 for details.

GetKeyState is normally called from a procedure that is invoked directly through a user-defined button or user-defined menu item. The procedure tests the state of one or more modifier keys and adjusts its behavior accordingly.

Another use for GetKeyState is to determine if Escape is pressed. This can be used to detect that the user wants to stop a procedure.

GetKeyState tests the keyboard at the time it is called. It does not tell you if keys were pressed between calls to the function. Consequently, when a procedure uses the escape key to break a loop, the user must press Escape until the running procedure gets around to calling the function.

**Parameters**

*flags* is a bitwise parameter interpreted as follows:

|        |                                                                                                                                                           |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bit 0: | If set, GetKeyState reports keys even if Igor is not the active application. If cleared, GetKeyState reports keys only if Igor is the active application. |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|

All other bits are reserved and must be zero.

**Details**

When set, the return value is interpreted bitwise as follows:

|        |                                                                  |
|--------|------------------------------------------------------------------|
| Bit 0: | Command ( <i>Macintosh</i> ) or Ctrl ( <i>Windows</i> ) pressed. |
| Bit 1: | Option ( <i>Macintosh</i> ) or Alt ( <i>Windows</i> ) pressed.   |
| Bit 2: | Shift pressed.                                                   |
| Bit 3: | Caps Lock pressed.                                               |
| Bit 4: | Control pressed ( <i>Macintosh only</i> ).                       |
| Bit 5: | Escape pressed.                                                  |
| Bit 6: | Left arrow key pressed. Supported in Igor Pro 7.00 or later.     |
| Bit 7: | Right arrow key pressed. Supported in Igor Pro 7.00 or later.    |
| Bit 8: | Up arrow key pressed. Supported in Igor Pro 7.00 or later.       |
| Bit 9: | Down arrow key pressed. Supported in Igor Pro 7.00 or later.     |

To test if a particular key is pressed, do a bitwise AND of the return value with the mask value 1, 2, 4, 8, 16, 32, 64, 128, 256 and 512 for bits 0 through 9 respectively. To test if a particular key and only that key is pressed compare the return value with the mask value.

On Macintosh, it is currently possible to define a keyboard shortcut for a user-defined menu item and then, in the procedure invoked by the keyboard shortcut, to use GetKeyState to test for modifier keys. This is not

## GetLastUserMenuInfo

---

possible on Windows because the keyboard shortcut will not be activated if a modifier key not specified in the keyboard shortcut is pressed. It is also possible that this ability on Macintosh will be compromised by future operating system changes. On both operating systems, however, you can test for a modifier key when the user chooses a user-defined menu item or clicks a user-defined button using the mouse.

### Examples

```
Function ShiftKeyExample()
 Variable keys = GetKeyState(0)
 if (keys == 0)
 Print "No modifier keys are pressed."
 endif

 if (keys & 4)
 if (keys == 4)
 Print "The Shift key and only the Shift key is pressed."
 else
 Print "The Shift key is pressed."
 endif
 endif
End

Function EscapeKeyExample()
 Variable keys
 do
 keys = GetKeyState(0)
 if ((keys & 32) != 0) // User is pressing escape?
 break
 endif
 while(1)
End
```

## GetLastUserMenuInfo

### GetLastUserMenuInfo

The GetLastUserMenuInfo operation sets variables in the local scope to indicate the value of the last selected user-defined menu item.

### Details

GetLastUserMenuInfo creates and sets these special variables:

V\_flag    The kind of menu that was selected:

| V_flag | Menu Kind                                                                                                                       |
|--------|---------------------------------------------------------------------------------------------------------------------------------|
| 0      | Normal text menu item, including <b>Optional Menu Items</b> (see page IV-130) and <b>Multiple Menu Items</b> (see page IV-131). |
| 3      | "*FONT*"                                                                                                                        |
| 6      | "*LINESTYLEPOP*"                                                                                                                |
| 7      | "*PATTERNPOP*"                                                                                                                  |
| 8      | "*MARKERPOP*"                                                                                                                   |
| 9      | "*CHARACTER*"                                                                                                                   |
| 10     | "*COLORPOP*"                                                                                                                    |
| 13     | "*COLORTABLEPOP*"                                                                                                               |

---

See **Specialized Menu Item Definitions** on page IV-132 for details about these special user-defined menus.

V\_value Which menu item was selected. The value also depends on the kind of menu the item was selected from:

| V_flag | V_value meaning                                                    |
|--------|--------------------------------------------------------------------|
| 0      | Text menu item number (the first menu item is number 1).           |
| 3      | Font menu item number (use S_Value, instead).                      |
| 6      | Line style number (0 is solid line)                                |
| 7      | Pattern number (1 is the first selection, a SW-NE light diagonal). |
| 8      | Marker number (1 is the first selection, the X marker).            |
| 9      | Character as an integer, = char2num(S_Value). Use S_Value instead. |
| 10     | Color menu item (use V_Red, V_Green, V_Blue, and V_Alpha instead). |
| 13     | Color table list menu item (use S_Value instead).                  |

S\_value The menu item text, depending on the kind of menu it was selected from:

| V_flag | S_value meaning                         |
|--------|-----------------------------------------|
| 0      | Text menu item text.                    |
| 3      | Font name or "default".                 |
| 6      | Name of the line style menu or submenu. |
| 7      | Name of the pattern menu or submenu.    |
| 8      | Name of the marker menu or submenu.     |
| 9      | Character as string.                    |
| 10     | Name of the color menu or submenu.      |
| 13     | Color table name.                       |

In the case of **Specialized Menu Item Definitions** (see page IV-132), S\_value will be the title of the menu or submenu, etc.

V\_Red, V\_Green, V\_Blue, V\_Alpha

If a user-defined color menu ("\*COLORPOP\*" menu item) was chosen then these values hold the red, green, and blue values of the selected color. The values range from 0 to 65535 - see **RGBA Values**.

These outputs are set to 0 if the last user-defined menu selection was not a color menu selection.

S\_graphName, S\_traceName, V\_mouseX, V\_mouseY

These variables are set only when the user chooses a user-defined menu item from the TracePopup, AllTracesPopup, or GraphPopup contextual menu.

S\_graphName and S\_traceName are initially "" until a user-defined menu selection is made from one of these contextual menus, and are not reset for each user-defined menu selection.

S\_graphName is the full host-child specification for the graph. If the graph is embedded into a host window, S\_graphName might be something like "Panel0#G0". See **Subwindow Syntax** on page III-92.

S\_traceName is name of the trace that was selected by the trace contextual menu, or "" if the AllTracesPopup or GraphPopup menu was chosen. See **Trace Names** on page II-270.

V\_mouseX and V\_mouseY, added in Igor Pro 8.00, are the mouse location of the click that invoked the contextual menu. The location is in pixels; use **AxisValFromPixel** to determine the X and Y axis values that correspond to the pixel location.

## GetLastUserMenuInfo

---

S\_tableName, S\_firstColumnPath, S\_columnName, V\_mouseX, V\_mouseY

Added in Igor Pro 9.00.

These variables are set only when the user chooses a user-defined menu item from the TablePopup contextual menu.

S\_tableName, S\_firstColumnPath and S\_columnName are initially "" until a user-defined menu selection is made from a TablePopup contextual menus, and are not reset for each user-defined menu selection.

S\_tableName is the full host-child specification for the table. If the table is embedded into a host window, S\_tableName might be something like "Panel0#T0". See **Subwindow Syntax** on page III-92.

S\_firstColumnPath is full path to the wave selected by the table contextual menu, or "" if multiple columns from different waves were chosen. The full path is identical to **GetWavesDataFolder**(wave,2).

S\_columnName is name of the selected column as used in the **ModifyTable** command, or "" if multiple columns from different waves were selected.

You can obtain additional information about the selected cells in the table using the **GetSelection** operation.

V\_mouseX and V\_mouseY are the mouse location of the click that invoked the contextual menu. The location is in pixels relative to the top-left corner of the table.

### Examples

A Multiple Menu Items menu definition:

```
Menu "Wave List", dynamic
 "Menu Item 1", <some command>
 "Menu Item 2", <some command>
 WaveList("*,",",",""), DoSomethingWithWave()
End
```

The last item can create multiple menu items - one for each wave name returned by WaveList. If the user selects one of these items, the DoSomethingWithWave user function can call GetLastUserMenuInfo to determine which wave was selected:

```
Function DoSomethingWithWave()
 GetLastUserMenuInfo
 WAVE/Z selectedWave = $S_value
 // Use selectedWave for something
End
```

A trivial user-defined color menu definition:

```
Menu "Color"
 "*COLORPOP*", DoSomethingWithColor()
End

Function DoSomethingWithColor()
 GetLastUserMenuInfo
 ... do something with V_Red, V_Green, V_Blue, V_Alpha ...
End
```

See **Specialized Menu Item Definitions** on page IV-132 for another color menu example.

A Trace contextual menu Items menu definition:

```
Menu "TracePopup", dynamic // menu when a trace is right-clicked
 "-" // separator divides this from built-in menu items
 ExportTraceName(), ExportSelectedTrace()
 "Draw XY Here", DrawXYHere()
End

Function/S ExportTraceName()
 GetLastUserMenuInfo // Sets S_graphName, S_traceName, V_mouseX, V_mouseY
 if (strlen(S_traceName) > 0)
 String item = "Export "+S_traceName
 return item
 endif
```

```

 return "" // No item is added to the menu
End
Function ExportSelectedTrace()
 GetLastUserMenuInfo
 // Do something with S_graphName, S_traceName
End
Function DrawXYHere()
 GetLastUserMenuInfo

 // Figure out mouse position within graph (requires Igor 8)
 String info = traceinfo(S_graphName, S_traceName, 0)
 String xaxis = stringbykey("XAXIS", info)
 String yaxis = stringbykey("YAXIS", info)
 Variable x_pos = AxisValFromPixel(S_graphName, xaxis, V_mouseX)
 Variable y_pos = AxisValFromPixel(S_graphName, yaxis, V_mouseY)

 // Draw
 GetAxis/W=$S_graphName/Q $yaxis
 Variable miny=V_min, maxy=V_max
 GetAxis/W=$S_graphName/Q $xaxis
 Variable minx=V_min, maxx=V_max
 SetDrawLayer/W=$S_graphName/K userFront
 SetDrawEnv/W=$S_graphName push
 SetDrawEnv/W=$S_graphName xcoord= $xaxis, ycoord=$yaxis, save
 DrawLine/W=$S_graphName minx, y_pos, maxx, y_pos // horizontal line
 DrawLine/W=$S_graphName x_pos, miny, x_pos, maxy // vertical line
 SetDrawEnv/W=$S_graphName pop
End

```

## GetMarquee

**GetMarquee** [/K/W=*winName*/Z] [*axisName* [, *axisName*]]

The GetMarquee operation provides a way for you to use the marquee as an input mechanism in graphs and page layout windows. It puts information about the marquee into variables.

**Parameters**

If you specify *axisName* (allowed only for graphs) the coordinates are in axis units. If you specify an axis that does not exist, Igor generates an error.

If you specify only one axis then Igor sets only the variables appropriate to that axis. For example, if you execute "GetMarquee left" then Igor sets the V\_bottom and V\_top variables but does *not* set V\_left and V\_right.

**Flags**

- |                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /K                 | Kills the marquee. Usually you will want to kill the marquee when you call GetMarquee, so you should use the /K flag. This is modeled after what happens when you create a marquee in a graph and then choose Expand from the Marquee menu. There may be some situations in which you want the marquee to persist. Igor also automatically kills the marquee anytime the window containing the marquee is deactivated, including when a dialog is summoned. |
| /W= <i>winName</i> | Specifies the named window or subwindow. When omitted, action will affect the active window or subwindow.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.                                                                                                                                                                                                 |
| /Z                 | No runtime error generated if the target window isn't a graph or layout, but V_flag will be zero. /Z does not prevent other kinds of problems from generating a runtime error.                                                                                                                                                                                                                                                                              |

## GetMarquee

---

### Details

GetMarquee is intended to be used in procedures invoked through user menu items added to the graph Marquee menu and the layout Marquee menu.

GetMarquee sets the following variables and strings:

|              |                                                                                                             |
|--------------|-------------------------------------------------------------------------------------------------------------|
| V_flag       | 0: There was no marquee when GetMarquee was invoked.<br>1: There was a marquee when GetMarquee was invoked. |
| V_left       | Marquee left coordinate.                                                                                    |
| V_right      | Marquee right coordinate.                                                                                   |
| V_top        | Marquee top coordinate.                                                                                     |
| V_bottom     | Marquee bottom coordinate.                                                                                  |
| S_marqueeWin | Name of window containing the marquee, or "" if no marquee. If subwindow, subwindow syntax will be used.    |

When called from the command line, GetMarquee sets global variables and strings in the current data folder. When called from a procedure, it sets local variables and strings.

In addition, creating, adjusting, or removing a marquee may set additional marquee global variables (see the **Marquee Globals** section, below).

The target window must be a layout or a graph. Use /Z to avoid generating a runtime-error (V\_flag will be 0 if the target window was not a layout or graph).

If the target is a layout then Igor sets the variables in units of points relative to the top/left corner of the paper.

If the target is a graph then Igor sets V\_left and V\_right based on the specified horizontal axis. If no horizontal axis was specified, V\_left and V\_right are set relative to the left edge of the base window in points.

If the target is a graph then Igor sets V\_bottom and V\_top based on the specified vertical axis. If no vertical axis was specified, V\_top and V\_bottom are set relative to the top edge of the base window in points.

If there is no marquee when you invoke GetMarquee then Igor sets V\_left, V\_top, V\_right, V\_bottom based on the last time the marquee was active.

### GetMarquee Example

```
Menu "GraphMarquee"
 "Print Marquee Coordinates", PrintMarqueeCoords()
End

Function PrintMarqueeCoords()
 GetMarquee left, bottom
 if (V_flag == 0)
 Print "There is no marquee"
 else
 printf "marquee left in bottom axis terms: %g\r", V_left
 printf "marquee right in bottom axis terms: %g\r", V_right
 printf "marquee top in left axis terms: %g\r", V_top
 printf "marquee bottom in left axis terms: %g\r", V_bottom
 endif
End
```

You can run this procedure by putting it into the procedure window, making a marquee in a graph, clicking in the marquee and choosing Print Marquee Coordinates:

The procedure calls GetMarquee to set the local marquee variables and then prints their values in the history area:

```
PrintMarqueeCoords()
 marquee left in bottom axis terms: 32.1149
 marquee right in bottom axis terms: 64.7165
 marquee top in left axis terms: 0.724075
 marquee bottom in left axis terms: -0.131061
```

### Marquee Globals

You can cause Igor to update global marquee variables whenever the user adjusts the marquee (without the need for you to invoke GetMarquee) by creating a global variable named V\_marquee in the root data folder:

```
Variable/G root:V_marquee = 1 //Creates V_marquee and sets bit 0 only
```

When the user adjusts the marquee Igor checks to see if root:V\_marquee exists and which bits are set, and updates (and creates if necessary) these globals:

|                            |                                                                                                                   |
|----------------------------|-------------------------------------------------------------------------------------------------------------------|
| Variable/G root:V_left     | Marquee left coordinate.                                                                                          |
| Variable/G root:V_right    | Marquee right coordinate.                                                                                         |
| Variable/G root:V_top      | Marquee top coordinate.                                                                                           |
| Variable/G root:V_bottom   | Marquee bottom coordinate.                                                                                        |
| String/G root:S_marqueeWin | Name of window that contains marquee, or "" if no marquee.<br>Set only if root:V_Marquee has bit 15 (0x8000) set. |

Unlike the local variables, for graphs these global variables are never in points. Root:V\_left and V\_right will be axis coordinates based on the first bottom axis created for the graph (if none, then for the first top axis). The axis creation order is the same as is returned by **AxisList**. Similarly, root:V\_top and root:V\_bottom will be axis coordinates based on the first left axis or the first right axis.

Igor examines the global root:V\_marquee for bitwise flags to decide which globals to update, and when:

| root:V_marquee Bit Meaning                         | Bit Number | Bit Value |
|----------------------------------------------------|------------|-----------|
| Update global variables for graph marquees         | 0          | 1         |
| Update global variables for layout marquees        | 2          | 4         |
| Update S_marqueeWin when updating global variables | 15         | 0x8000    |

### Marquee Globals Example

By creating the global variable root:V\_marquee this way:

```
Variable/G root:V_marquee = 1 + 4 + 0x8000
```

whenever the user creates, adjusts, or removes a marquee in any graph or layout Igor will create and update the global root:V\_left, etc. coordinate variables and set the global string root:S\_marqueeWin to the name of the window which has the marquee in it. When the marquee is removed, root:S\_marqueeWin will be set to "".

This mechanism does neat things by making a **ValDisplay** or **SetVariable** control depend on any of the globals. See the Marquee Demo experiment in the Examples:Feature Demos folder for an example.

You can also cause a function to run whenever the user creates, adjusts, or removes a marquee by setting up a dependency formula using **SetFormula** to bind one of the marquee globals to one of the function's input arguments:

```
Variable/G root:dependencyTarget
SetFormula root:dependencyTarget, "MyMarqueeFunction(root:S_marqueeWin)"
Function MyMarqueeFunction(marqueeWindow)
 String marqueeWindow // this will be root:S_marqueeWin
 if(strlen(marqueeWindow))
 NVAR V_left= root:V_left, V_right= root:V_right
 NVAR V_top= root:V_top, V_bottom= root:V_bottom
 Printf marqueeWindow + " has a marquee at: "
 Printf "%d, %d, %d, %d\r", V_left, V_right, V_top, V_bottom
 else
```

## GetMouse

---

```
 Print "The marquee has disappeared."
 endif
 return 0 // return value doesn't really matter
End
```

### See Also

The **SetMarquee** and **SetFormula** operations. **Setting Bit Parameters** on page IV-12 for information about bit settings.

## GetMouse

**GetMouse** [/W=*winName*]

The GetMouse operation returns information about the position of the input mouse, and the state of the mouse buttons.

GetMouse is useful in situations such as background tasks where the mouse position and state aren't available as they are in control procedures and window hook functions.

### Flags

|                      |                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /W= <i>winName</i>   | Returns the mouse position relative to the named window or subwindow. When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92. |
| /W= <i>kwTopWin</i>  | Returns the mouse position relative to the currently frontmost non-floating window.                                                                                  |
| /W= <i>kwCmdHist</i> | Returns the mouse position relative to the command window.                                                                                                           |
| /W= <i>Procedure</i> | Returns the mouse position relative to the main Procedure window.                                                                                                    |

### Details

GetMouse returns the mouse position in local coordinates relative to the specified window unless /W is omitted in which case the returned coordinates are global.

On Windows, global coordinates are actually relative to the frame window. See **GetWindow** *wsizeDC* *kwFrameInner*.

Information is returned via the following string and numeric variables:

|        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_left | Horizontal mouse position, in pixels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| V_top  | Vertical mouse position, in pixels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| V_flag | Mouse button state. V_flag is a bitwise value with each bit reporting the mouse button states:<br><br>Bit 0: 1 if the primary mouse button (usually the left) is down, 0 if it is up.<br>Bit 1: 1 if the secondary mouse button (usually the right) is down, 0 if it is up.<br><br>On Macintosh, the secondary mouse button can be invoked by pressing the control key while clicking the primary (often the only) mouse button, but GetMouse does not report this with bit 1 set. Use <b>GetKeyState</b> 's bit 4 to test if the control key is pressed.<br><br>See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings. |
| S_name | Name of the window or subwindow which the position is relative to, or "" if not a nameable window or if /W was omitted. Most useful with /W= <i>kwTopWin</i> . The result can be <i>kwCmdHist</i> or <i>Procedure</i> , or the name of a target window.                                                                                                                                                                                                                                                                                                                                                                                          |

## GetRTError

**GetRTError** (*flag*)

The GetRTError function returns information about the error state of Igor's user-defined function runtime execution environment.

If *flag* is 0, GetRTError returns an error code if an error has occurred or 0 if no error has occurred.

If *flag* is 1, GetRTError returns an error code if an error has occurred or 0 if no error has occurred and it clears the error state of Igor's runtime execution environment. Use this if you want to detect and handle runtime errors yourself.

If *flag* is 2, GetRTError returns the state of Igor's internal abort flag but does not clear it.

For *flag*=0 and *flag*=1, you can call **GetErrorMessage** to obtain the error message associated with the returned error code, if any.

In Igor Pro 7.00 or later, using GetRTError(1) on the same line as a command that causes an error overrides the debugger "debug on error" setting and prevents the debugger from activating for that error.

### Example

```
// This illustrates how to detect and handle a runtime error
// rather than allowing it to cause Igor to abort execution.
Function Demo()
 <Call an Igor operation or a user-defined function>
 Variable err = GetRTError(0)
 if (err != 0)
 String message = GetErrorMessage(err,3)
 Printf "Error in Demo: %s\r", message
 err = GetRTError(1) // Clear error state
 Print "Continuing execution"
 endif
 <Call an Igor operation or a user-defined function>
End
```

### See also

The **GetErrorMessage** and **GetRTErrorMessage** functions.

## GetRTErrorMessage

### GetRTErrorMessage ()

In a user function, GetRTErrorMessage returns a string containing the name of the operation that caused the error, a semicolon, and an error message explaining the cause of the error. This is the same information that appears in the alert dialog displayed. If no error has occurred, the string will be of zero length. GetRTErrorMessage must be called before the error is cleared by calling GetRTError with a nonzero argument.

For an overview of error handling, see **Flow Control for Aborts** on page IV-48.

### See also

**Flow Control for Aborts** on page IV-48, **GetRTError**, **GetErrorMessage**

## GetRTLLocation

### GetRTLLocation (*sleepMS*)

GetRTLLocation is used for profiling Igor procedures.

You will typically not call GetRTLLocation directly but instead will use it through FunctionProfiling.ipf which you can access using this include statement:

```
#include <FunctionProfiling>
```

GetRTLLocation is called from an Igor preemptive thread to monitor the main thread. It returns a code that identifies the current location in the procedure files corresponding to the procedure line that is executing in the main thread.

### Parameters

*sleepMs* is the number of milliseconds to sleep the preemptive thread after fetching a value. *sleepMs* must be between 0.001 and 100.

### Details

The result from GetRTLLocation is passed to **GetRTLInfo** to determine the location in the procedures. This samples the main thread only and the location becomes meaningless after any procedure editing.

### See Also

**GetRTLInfo**

### GetRTLInfo

#### **GetRTLInfo (code)**

GetRTLInfo is used for profiling Igor procedures.

You will typically not call GetRTLInfo directly but instead will use it through FunctionProfiling.ipf which you can access using this include statement:

```
#include <FunctionProfiling>
```

GetRTLInfo is called from an Igor preemptive thread to monitor the main thread. It returns a key/value string containing information about the procedure location associated with code or "" if the location could not be found.

#### **Parameters**

*code* is the result from a very recent call to **GetRTLInfo**.

#### **Details**

The format of the result string is:

```
"PROCNAME:name;LINE:line;FUNNAME:name;"
```

As of Igor Pro 7.03, if the code is in an independent module other than ProcGlobal then this appears at the beginning of the result string:

```
IMNAME:inName;
```

The line number is padded with zeros to facilitate sorting.

#### **See Also**

**GetRTLInfo**

### GetRTStackInfo

#### **GetRTStackInfo (selector)**

The GetRTStackInfo function returns information about "runtime stack" (the chain of macros and functions that are executing).

#### **Details**

If *selector* is 0, GetRTStackInfo returns a semicolon-separated list of the macros and procedures that are executing. This list is the same you would see in the debugger's stack list.

The currently executing macro or function is the last item in the list, the macro or function that started execution is the first item in the list.

If *selector* is 1, it returns the name of the currently executing function or macro.

If *selector* is 2, it returns the name of the calling function or macro.

If *selector* is 3, GetRTStackInfo returns a semicolon-separated list of routine names, procedure file names and line numbers. This is intended for advanced debugging by advanced programmers only.

For example, if RoutineA in procedure file ProcA.ipf calls RoutineB in procedure file ProcB.ipf, and RoutineB calls GetRTStackInfo(3), it will return:

```
RoutineA, ProcA.ipf, 7; RoutineB, ProcB.ipf, 12;
```

The numbers 7 and 12 would be the actual numbers of the lines that were executing in each routine. Line numbers are zero-based.

When called from a function started by **MultiThread** or **ThreadStart** the runtime stack information begins with the function that started threaded execution.

In future versions of Igor, *selector* may request other kinds of information.

#### **Main Thread Example**

```
Function Called()
 Print "Called by " + GetRTStackInfo(2) + "()"
 Print "Routines in calling chain: " + GetRTStackInfo(0)
End
```

```

Function Calling()
 Called()
End

Macro StartItUp()
 Calling()
End

// Executing StartItUp() prints:
 Called by Calling()
 Routines in calling chain: StartItUp;Calling;Called;

```

### MultiThread Example

```

Macro BeginMultiThread(code)
 Variable code=3
 BeginMultiThreadFunc (code)
End

Function BeginMultiThreadFunc (Variable code)
 Make/O/N=4/T/FREE textWave
 MultiThread textWave = tsworker (code)
 Print textWave[0]
End

ThreadSafe Function/S tsworker (Variable code)
 String str= tssubr (code)
 return str
End

ThreadSafe Function/S tssubr (Variable code)
 String str= GetRTStackInfo (code)
 return str
End

// Executing BeginMultiThread(3) prints details for only the two threaded routines:
 tsworker, TSEExample, 16; tssubr, TSEExample, 21;

```

### See Also

The Stack and Variables Lists, ThreadSafe Functions and Multitasking, GetRTError

## GetScrapText

### GetScrapText ()

The GetScrapText function returns a string containing any plain text on the Clipboard (aka “scrap”). This is the text that would be pasted into a text document if you used Paste in the Edit menu.

### See Also

The PutScrapText and LoadPICT operations.

## GetSelection

### GetSelection *winType*, *winName*, *bitflags*

The GetSelection operation returns information about the current selection in the specified window.

### Parameters

*winType* is one of the following keywords:

graph, panel, table, layout, notebook, procedure

*winName* is the name of a window of the specified type.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

If *winType* is procedure then *winName* is actually a procedure window title inside a "\$" wrapper, such as:

```
GetSelection procedure $"DemoLoader.ipf", 3
```

*bitflags* is a bitwise parameter that is used in different ways for different window types, as described in **Details**. You should use 0 for undefined bits. **Setting Bit Parameters** on page IV-12 for further details about bit settings.

## GetUserData

---

### Details

For all window types, GetSelection sets V\_flag:

|        |                                                         |
|--------|---------------------------------------------------------|
| V_flag | 0: No selection when GetSelection was invoked.          |
|        | 1: There was a selection when GetSelection was invoked. |

Here is a description of what GetSelection does for each window type:

| <i>winType</i> | <i>bitFlags</i> | <b>Action</b>                                                                                                                                                                                                                                                                                         |
|----------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| graph          |                 | Does nothing.                                                                                                                                                                                                                                                                                         |
| panel          |                 | Does nothing.                                                                                                                                                                                                                                                                                         |
| table          | 1               | Sets V_startRow, V_startCol, V_endRow, and V_endCol based on the selected cells in the table. The top/left cell, not including the Point column, is (0, 0).                                                                                                                                           |
|                | 2               | Sets S_selection to a semicolon-separated list of column names.                                                                                                                                                                                                                                       |
|                | 4               | Sets S_dataFolder to a semicolon-separated list of data folders, one for each column.                                                                                                                                                                                                                 |
| layout         | 2               | Sets S_selection to a semicolon separated list of selected objects in the layout layer (not any drawing layers). S_selection will be " " if no objects are selected.                                                                                                                                  |
| notebook       | 1               | Sets V_startParagraph, V_startPos, V_endParagraph, and V_endPos based on the selected text in the notebook.                                                                                                                                                                                           |
|                | 2               | Sets S_selection to the selected text.                                                                                                                                                                                                                                                                |
|                | 4               | Requires Igor Pro 8.05 or later.                                                                                                                                                                                                                                                                      |
|                |                 | Sets V_startParagraph and V_endParagraph to the left margin and right margin respectively of the current ruler in points relative to the ruler 0 position.<br>Sets V_startPos, and V_endPos to the left edge and right edge respectively of the selection in points relative to the ruler 0 position. |
| procedure      | 1               | Sets V_startParagraph, V_startPos, V_endParagraph, V_endPos based on the selected text in the procedure window.                                                                                                                                                                                       |
|                | 2               | Sets S_selection to the selected text.                                                                                                                                                                                                                                                                |

---

### Examples

In a new experiment, make a table named "Table0" with some columns, and select some combination of rows and columns:

```
Make wave0 = p
Make wave1 = p + 1
Edit wave0, wave1
ModifyTable selection = (3,0,8,1,3,0)
```

Now execute these commands in a procedure or in the command line:

```
GetSelection table, Table0, 3
Print V_flag, V_startRow, V_startCol, V_endRow, V_endCol
Print S_selection
```

This will print the following in the history area:

```
1 3 0 8 1
wave0.d;wave1.d;
```

## GetUserData

**GetUserData(winName, objID, userdataName)**

The GetUserData function returns a string containing the user data for a window, subwindow graph trace or control. The return string will be empty if no user data exists.

You set user data on a window or subwindow using the `userData` keyword of the `SetWindow` operation. You set it on a graph trace using the `userData` keyword of the `ModifyGraph` operation. You set it on a control using the `userData` keyword of the various control operations.

#### Parameters

*winName* may specify a window or subwindow name. Use "" for the top window.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

*objID* is a string specifying the name of a control or graph trace. Use "" for a window or subwindow.

*userdataName* is the name of the user data or "" for the default unnamed user data.

#### See Also

The **ControlInfo**, **GetWindow**, and **SetWindow** operations.

## GetWavesDataFolder

### GetWavesDataFolder(*waveName*, *kind*)

The `GetWavesDataFolder` function returns a string containing the name of a data folder containing the wave named by *waveName*. Variations on the theme are selected by *kind*.

The most common use for this is in a procedure, when you want to create a wave or a global variable in the data folder containing a wave passed as a parameter.

`GetWavesDataFolderDFR` is preferred.

#### Details

| <i>kind</i> | GetWavesDataFolder Returns                                                                 |
|-------------|--------------------------------------------------------------------------------------------|
| 0           | Only the name of the data folder containing <i>waveName</i> .                              |
| 1           | Full path of data folder containing <i>waveName</i> , without wave name.                   |
| 2           | Full path of data folder containing <i>waveName</i> , including possibly quoted wave name. |
| 3           | Partial path from current data folder to the data folder containing <i>waveName</i> .      |
| 4           | Partial path including possibly quoted wave name.                                          |

Kinds 2 and 4 are especially useful in creating command strings to be passed to **Execute**.

#### Examples

```
Function DuplicateWaveInDataFolder(w)
 Wave w
 DFREF dfSav = GetDataFolderDFR()
 SetDataFolder GetWavesDataFolder(w,1)
 Duplicate/O w, $(NameOfWave(w) + "_2")
 SetDataFolder dfSav
End
```

#### See Also

Chapter II-8, **Data Folders**.

## GetWavesDataFolderDFR

### GetWavesDataFolderDFR(*waveName*)

The `GetWavesDataFolderDFR` function returns a data folder reference for the data folder containing the specified wave.

`GetWavesDataFolderDFR` is the same as `GetWavesDataFolder` except that it returns a data folder reference instead of a string containing a path.

#### See Also

**Data Folders** on page II-107, **Data Folder References** on page IV-78, **Built-in DFREF Functions** on page IV-80.

### GetWindow

**GetWindow** [/Z] *winName*, *keyword*

The GetWindow operation provides information about the named window or subwindow. Information is returned in variables, strings, and waves.

#### Parameters

*winName* can be the name of any target window (graph, table, page layout, notebook, control panel, Gizmo, camera, or XOP target window) or subwindow. It can also be the title of a procedure window or one of these four special keywords:

|              |                                                                                                                                                   |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| kwTopWin     | Specifies the topmost target window.                                                                                                              |
| kwCmdHist    | Specifies the command history area.                                                                                                               |
| kwFrameOuter | Specifies the “frame” or “application” window that Igor Pro has only under Windows. This is the window that contains Igor’s menus and status bar. |
| kwFrameInner | Specifies the inside of the same “frame” window under Windows. This is the window that all other Igor windows are inside.                         |

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Only one of the following keywords may follow *winName*. The keyword chosen determines the information stored in the output variables:

|          |                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| active   | Sets V_Value to 1 if the window is active or to 0 otherwise. Active usually means the window is the frontmost window.                                                                                                                                                                                                                                                                                        |
| activeSW | Stores the window “path” of currently active subwindow in S_Value. See <b>Subwindow Syntax</b> on page III-92 for details on the window hierarchy.                                                                                                                                                                                                                                                           |
| axsize   | Reads graph axis area dimensions (where the traces are, including axis standoff) into V_left, V_right, V_top, and V_bottom in local coordinates. Dimensions are in points.                                                                                                                                                                                                                                   |
| axsizeDC | Same as axSize but dimensions are in device coordinates (pixels).                                                                                                                                                                                                                                                                                                                                            |
| backRGB  | Sets V_Red, V_Green, V_Blue, and V_Alpha as <b>RGBA Values</b> to the background color of the window. The background color is set with <b>ModifyGraph (colors)</b> wbRGB, <b>ModifyLayout</b> bgRGB, and <b>Notebook</b> backRGB. Also returns the background color of procedure windows and the command/history windows. Other windows set these values to 65535 (opaque white).<br>Added in Igor Pro 7.00. |
| exterior | Sets V_value to 1 if the window is an exterior panel window or to 0 otherwise. Useful for window hook functions that must work for both regular windows and exterior panel windows, since exterior panels use their own hook function.                                                                                                                                                                       |
| bgRGB    | Another name for backRGB.<br>Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                         |
| cbRGB    | Sets V_Red, V_Green, V_Blue, and V_Alpha as <b>RGBA Values</b> to the control panel area background color of the window in graphs and panel windows, as set by <b>ModifyGraph (colors)</b> cbRGB and <b>ModifyPanel</b> cbRGB. Other windows set these values to 65535 (opaque white).<br>Added in Igor Pro 7.00.                                                                                            |

---

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| doScroll  | <p>If the window is a graph or panel window with scroll bars added by SetWindow doScroll, the variable V_value is set to 1.</p> <p>If the window is a graph or panel window without scroll bars added by SetWindow doScroll, the variable V_value is set to 0.</p> <p>If the window is other than a graph or panel window, an error is generated.</p> <p>Added in Igor Pro 9.00.</p>                                                                                                                                                                      |
| drawLayer | <p>If the specified window is a graph, layout, or panel window then the window's current drawing layer is returned in S_value. S_value is set to "" for other windows. See <b>Drawing Layers</b> on page III-68.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                                                       |
| expand    | <p>For graph windows, sets V_Value to the expand value set by <b>ModifyGraph (general)</b> expand=value, a value normally 0 or 1, where 1.5 means 150%.</p> <p>For notebook, procedure and command windows, sets V_Value to the magnification, normally 100. See the <b>Notebook</b> magnification=m documentation for details.</p> <p>For layout windows, sets V_Value to the <b>ModifyLayout</b> mag=m value, usually 0.5 (50%).</p> <p>Table windows set V_Value to 0, panels and other unsupported windows to NaN.</p> <p>Added in Igor Pro 7.00.</p> |
| file      | <p>Works for notebook and procedure windows only.</p> <p>Returns via S_value a semicolon-separated list containing:</p> <ul style="list-style-type: none"> <li>- the file name</li> <li>- the Mac path to the folder containing the file with a colon at the end</li> <li>- the name of a symbolic path pointing to that folder, if any</li> </ul> <p>If the window was never saved to a standalone file then "" is returned in S_value. If the specified window is not a notebook or procedure window then "" is returned in S_value.</p>                |
| gbRGB     | <p>Sets V_Red, V_Green, V_Blue, and V_Alpha as <b>RGBA Values</b> to the plot area background color of the window in graph windows, as set by <b>ModifyGraph (colors)</b> gbRGB. Other windows set these values to 65535 (opaque white).</p> <p>Use wbRGB to get the color of window background (the area outside of the axes).</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                        |
| gsize     | <p>Reads graph outer dimensions into V_left, V_right, V_top, and V_bottom in local coordinates. This includes axes but not the tool palette, control bar, or info panel. Dimensions are in points.</p>                                                                                                                                                                                                                                                                                                                                                    |
| gsizeDC   | <p>Same as gsize but dimensions are in device coordinates (pixels).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| hide      | <p>Sets V_Value bit 0 if the window or subwindow is hidden.</p> <p>Sets bit 1 if the host window is minimized.</p> <p>Sets bit 2 if the subwindow is hidden only because an ancestor window or subwindow is hidden. Added in Igor Pro 7.00.</p> <p>On Macintosh, if you execute MoveWindow 0, 0, 0, 0 to minimize a window to the dock, and then you immediately call GetWindow hide, bit 1 may not be correctly set because of the delay caused by the animation of the window sliding into the dock.</p>                                                |
| hook      | <p>Copies name of window hook function to S_value. See <b>Unnamed Window Hook Functions</b> on page IV-303.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## GetWindow

---

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hook( <i>hName</i> ) | For the given named hook <i>hName</i> , copies name of window hook function to <i>S_value</i> . See <b>Named Window Hook Functions</b> on page IV-293.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| logicalpapersize     | Returns logical paper size of the page setup associated with the named window into <i>V_left</i> , <i>V_right</i> , <i>V_top</i> , and <i>V_bottom</i> . Dimensions are in points.<br><br>If the Page Setup dialog uses 100% scaling, these are also the physical dimensions of the page. <i>V_left</i> and <i>V_top</i> are 0 and correspond to the left top corner of the physical page.<br><br>On the Macintosh, using a Scale of 50% multiplies all of these dimensions by 2.                                                                                                                                                                                                                                                                                                                                                                     |
| logicalprintablesize | Returns logical printable size of the page setup associated with the named window into <i>V_left</i> , <i>V_right</i> , <i>V_top</i> , and <i>V_bottom</i> . Dimensions are in points.<br><br>If the Page Setup dialog uses 100% scaling, these are also the physical dimensions of the page minus the margins. <i>V_left</i> and <i>V_top</i> are the number of points from the left top corner of the physical page to the left top corner of the printable area of page.<br><br>On the Macintosh, using a page setup scale of 50% multiplies all of these dimensions by 2.                                                                                                                                                                                                                                                                         |
| magnification        | Sets <i>V_Value</i> exactly the same way that expand does.<br><br>Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| maximize             | Sets <i>V_Value</i> to 1 if the window is maximized, 0 otherwise. On Macintosh, <i>V_Value</i> is always 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| needUpdate           | Sets <i>V_Value</i> to 1 if window or subwindow is marked as needing an update.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| note                 | Copies window note to <i>S_value</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| psize                | Reads graph plot area dimensions (where the traces are) into <i>V_left</i> , <i>V_right</i> , <i>V_top</i> , and <i>V_bottom</i> in local coordinates. Dimensions are in points.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| psizeDC              | Same as <i>psize</i> but dimensions are in device coordinates (pixels).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| sizeLimit            | Returns the size limits imposed on a window via <code>SetWindow sizeLimit</code> in the <i>V_minWidth</i> , <i>V_minHeight</i> , <i>V_maxWidth</i> and <i>V_maxHeight</i> . The values are scaled for screen resolution to the same units as <code>GetWindow wsize</code> , which is points. Very large limits are returned as INF.<br><br>The <i>sizeLimit</i> keyword was added in Igor Pro 7.00.<br><br>Also returns a <i>sizeLimit</i> status value in <i>V_Value</i> . 0 means no <code>SetWindow sizeLimit</code> command will appear in the window's recreation macro, usually because no <code>SetWindow sizeLimit</code> command was applied to the window. 1 means a <code>SetWindow sizeLimit</code> command will appear in the window's recreation macro. -1 means it won't appear because of conflicts with graph absolute sizing modes. |
| title                | Gets the title (set by as <i>titleStr</i> with <code>NewPanel</code> , <code>Display</code> , etc., or by the Window Control dialog) and puts it into <i>S_value</i> . <i>S_value</i> is set to "" if <i>winName</i> specifies a subwindow. See also the <i>wtitle</i> keyword, below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| userdata             | Returns the primary (unnamed) user data for a window in <i>S_value</i> . Use <b>GetUserData</b> to obtain any named user data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| wavelist             | Creates a 3 column text wave called <i>W_WaveList</i> containing a list of waves used in the graph in <i>winName</i> . Each wave occupies one row in <i>W_WaveList</i> . This list includes all waves that can be in a graph, including the data waves for contour plots and images.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| wbRGB                | Another name for <code>backRGB</code> .<br><br>Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>wsize</code>            | <p>Reads window dimensions into <code>V_left</code>, <code>V_right</code>, <code>V_top</code>, and <code>V_bottom</code> in points from the top left of the screen. For subwindows, values are local coordinates in the host.</p> <p>If the window is a graph or panel window with scroll mode turned on using <code>SetWindow doScroll</code>, then <code>V_left</code> and <code>V_top</code> are set to zero, and <code>V_right</code> and <code>V_bottom</code> are set to the width and height in points of the window content area.</p>                                                                                                            |
| <code>wsizeDC</code>          | <p>Same as <code>wsize</code> but dimensions are in local device coordinates (pixels). The origin is the top left corner of the host window's active rectangle.</p> <p>If the window is a graph or panel window with scroll mode turned on using <code>SetWindow doScroll</code>, then <code>V_left</code> and <code>V_top</code> are set to zero, and <code>V_right</code> and <code>V_bottom</code> are set to the width and height in pixels of the window content area.</p>                                                                                                                                                                          |
| <code>wsizeForControls</code> | <p>Reads window width into <code>V_right</code> and the window height into <code>V_bottom</code> in panel units. "Panel units" are scaled so that a control having the dimensions of <code>V_right</code> and <code>V_bottom</code> exactly fills the window.</p> <p>The <code>wsizeForControls</code> keyword was added in Igor Pro 9.00. See <i>Examples</i> below for an example.</p>                                                                                                                                                                                                                                                                 |
| <code>wsizeOuter</code>       | <p>Reads window dimensions into <code>V_left</code>, <code>V_right</code>, <code>V_top</code>, and <code>V_bottom</code> in points from the top left of the screen. Dimensions are for the entire window including any frame and title bar. For subwindows, values are for the host window.</p>                                                                                                                                                                                                                                                                                                                                                          |
| <code>wsizeOuterDC</code>     | <p>Same as <code>wsizeOuter</code> but dimensions are in local device coordinates (pixels). The origin is the top left corner of the host window's active rectangle, so <code>V_top</code> will be negative for a window with a title bar. <code>V_left</code> will be negative for windows with a frame; windows on Macintosh OS X have no frame, so <code>V_left</code> will be zero.</p>                                                                                                                                                                                                                                                              |
| <code>wsizeRM</code>          | <p>Generally the same as <code>wsize</code>, but these are the coordinates that would actually be used by a recreation macro except that the coordinates are in points even if the window is a panel. Also, if the window is minimized or maximized, the coordinates represent the window's restored location.</p> <p>On Windows, <code>GetWindow kwFrameOuter wsizeRM</code> returns the pixel coordinates of the MDI frame even when the frame is maximized. <code>wsizeDC</code> returns 2,2,2,2 in this case.</p>                                                                                                                                    |
| <code>wtitle</code>           | <p>Gets the actual window title displayed in the window's title bar, regardless of whether it was set by the user (see the title keyword above) or is the default title created by Igor, and puts it into <code>S_value</code>.</p> <p><code>S_value</code> is set to "" if <code>winName</code> specifies a subwindow.</p> <p>If <code>winName</code> is <code>kwFrameOuter</code> or <code>kwFrameInner</code>, on Macintosh <code>S_value</code> is set to the name of the Igor application. On Windows it is set to the full title of the application as seen on the frame's window, which can be altered using <code>DoWindow/T kwFrame</code>.</p> |

## Flags

|                 |                                                                                                                                                                                      |

|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Details

`winName` can be the title of a procedure window. If the title contains spaces, use:

```
GetWindow $"Title With Spaces" wsize
```

However, if another window has a name which matches the given procedure window title, that window's properties are returned instead of the procedure window.

The `wsize` parameter is appropriate for all windows.

The `gsize`, `psize`, `gbRGB`, and `wavelist` parameters are appropriate only for graph windows.

The logicalpapersize, logicalprintablesize and expand/magnification parameters are appropriate for all printable windows except for control panels and Gizmo plots.

### Local Coordinates

"Local coordinates" are relative to the top left of the graph area, regardless of where that is on the screen or within the graph window. All dimensions are reported in units of points (1/72 inch) regardless of screen resolution. On the Macintosh, this is the same as screen pixels.

### Frame Window Coordinates

kwCmdHist, kwFrameInner, and kwFrameOuter may be used with only the wsize keyword.

On Windows computers, kwFrameInner and kwFrameOuter return coordinates into V\_left, V\_right, V\_top, and V\_bottom. On the Macintosh, they always return 0, because Igor has no frame on the Macintosh.

kwFrameOuter coordinates are the location of the outer edges of Igor's application window, expressed in screen (pixel) coordinates suitable for use with MoveWindow/F to restore, minimize, or maximize the Igor application window.

If Igor is currently minimized, kwFrameOuter returns 0 for all values. If maximized, it returns 2 for all values. Otherwise, the screen (pixel) coordinates of the frame are returned in V\_left, V\_right, V\_top, and V\_bottom. This is consistent with MoveWindow/F.

kwFrameInner coordinates, however, are the location of the inner edges of the application window, expressed in Igor window coordinates (points) suitable for positioning graphs and other windows with **MoveWindow**.

If Igor is currently minimized, kwFrameInner returns the inner frame coordinates Igor would have if Igor were "restored" with MoveWindow/F 1, 1, 1, 1.

V\_left and V\_top will always both be 0, and V\_Bottom and V\_Right will be the maximum visible (or potentially visible) window (not screen) coordinates in points.

### The Wavelist Keyword

The format of W\_WaveList, created with the wavelist keyword, is as follows:

| Column 1  | Column 2                 | Column 3          |
|-----------|--------------------------|-------------------|
| Wave name | partial path to the wave | special ID number |

The wave name in column 1 is simply the name of the wave with no path. It may be the same as other waves in the list, if there are waves from different data folders.

The partial path in column 2 includes the wave name and can be used with the \$ operator to get access to the wave.

The special ID number in column 3 has the format ##<number>##. A version of the recreation macro for the graph can be generated that uses these ID numbers instead of wave names (see the **WinRecreation** function). This makes it relatively easy to find every occurrence of a particular wave using a function like **strsearch**.

### Examples

```
// These commands draw a red foreground rectangle framing
// the printable area of a page layout window.
GetWindow Layout0 logicalpapersize
DoWindow/F Layout0
SetDrawLayer/K userFront
SetDrawEnv linefgc=(65535,0,0), fillpat=0 // Transparent fill
DrawRect V_left+1, V_top+1, V_right-1, V_bottom-1

// These commands demonstrate the difference between title and wtitle.
Make/O data=x
Display/N=MyGraph data
GetWindow MyGraph title;Print S_Value // Prints nothing (S_Value = "")
GetWindow MyGraph wtitle;Print S_Value // Prints "MyGraph:data"
DoWindow/T MyGraph, "My Title for My Graph"
GetWindow MyGraph title;Print S_Value // Prints "My Title for My Graph"
GetWindow MyGraph wtitle;Print S_Value // Prints "My Title for My Graph"

// Create a panel expanded at 200% with a ListBox that fills the entire panel.
String list = CTabList() // List of color tables
Make/O/T/N=(ItemsInList(list)) tw = StringFromList(p,list)
NewPanel/EXP=2/N=DemoPanel
GetWindow DemoPanel wsizeForControls
```

```
ListBox list0, win=DemoPanel, pos={0,0}, size={V_right, V_Bottom}, listWave=tw
```

**See Also**

The **SetWindow**, **GetUserData**, **MoveWindow** and **DoWindow** operations.

The **IgorInfo** function.

## GetWindowBrowserSelection

**GetWindowBrowserSelection** (*mode*)

The GetWindowBrowserSelection function returns a semicolon separated string that represents the selection in the Window Browser.

GetWindowBrowserSelection was added in Igor Pro 9.00.

**Parameters**

*mode* specifies which selection should be returned:

*mode*=0: Returns the window names of the selected windows in the main window list.  
Other values for *mode* are reserved for possible future use.

If there is no selection, GetWindowBrowserSelection returns an empty string.

If the Window Browser is not open, GetWindowBrowserSelection returns an empty string and generates an error.

The order in which the selection is returned is undefined. If the order matters to you, you must sort the list yourself.

**See Also**

The **Window Browser** on page II-49, **SortList**

## GizmoInfo

**GizmoInfo** (*nameStr*, *key*)

The GizmoInfo function is used to determine if a particular name is valid and unique as a Gizmo item names.

Documentation for the GizmoInfo function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "GizmoInfo"
```

## GizmoPlot

**GizmoPlot**

GizmoPlot is a procedure subtype keyword that identifies a macro as being a Gizmo recreation macro. It is automatically used when Igor creates a window recreation macro for a Gizmo plot. See **Procedure Subtypes** on page IV-204 and **Saving and Recreating Graphs** on page II-338 for details.

## GizmoScale

**GizmoScale** (*dataValue*, *dimNumber* [, *gizmoNameStr*] )

The GizmoScale function returns a scaled *dataValue* for the specified dimension. The scaled values are used to position non-data drawing objects in the Gizmo window.

Documentation for the GizmoScale function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "GizmoScale"
```

## gnoise

**gnoise** (*num* [, *RNG*])

The gnoise function returns a random value drawn from a Gaussian distribution such that the standard deviation of an infinite number of such values would be *num*.

gnoise returns a complex result if *num* is complex or if it is used in a complex expression. See **Use of gnoise With Complex Numbers** on page V-322.

The random number generator is initialized using a seed derived from the system clock when you start Igor. This almost guarantees that you will never get the same sequence twice. If you want repeatable "random" numbers, use **SetRandomSeed**.

The Gaussian distribution is achieved using a Box-Muller transformation of uniform random numbers.

The optional parameter RNG selects one of three pseudo-random number generators used to create the uniformly-distributed random numbers providing the input to the Box-Muller transformation.

If you omit the RNG parameter, gnoise uses RNG number 3, named "Xoshiro256\*\*". This random number generator was added in Igor Pro 9.00 and is recommended for all new code. In earlier versions of Igor, the default was 1 (Linear Congruential Generator).

The available random number generators are:

| RNG | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | <p>Linear Congruential Generator by L'Ecuyer with added Bayes-Durham shuffle. The algorithm is described in <i>Numerical Recipes</i> as the function <code>ran2 ( )</code>. This option has nearly <math>23^2</math> distinct values and the sequence of random numbers has a period in excess of <math>10^{18}</math>.</p> <p>This RNG is provided for backward compatibility only. New code should use RNG=3 (Xoshiro256**).</p>                                     |
| 2   | <p>Mersenne Twister by Matsumoto and Nishimura. It is claimed to have better distribution properties and period of <math>2^{19937}-1</math>.</p> <p>See Matsumoto, M., and T. Nishimura, Mersenne Twister: A 623-dimensionally equidistributed uniform pseudorandom number generator, <i>ACM Trans. on Modeling and Computer Simulation</i>, 8, 3-30, 1998.</p> <p>This RNG is provided for backward compatibility only. New code should use RNG=3 (Xoshiro256**).</p> |
| 3   | <p>Xoshiro256** by David Blackman and Sebastiano Vigna. It has a period of <math>2^{256}-1</math>, is 4 dimensionally equidistributed and passes all statistical tests at the time of writing.</p> <p>For technical details, see "Scrambled linear pseudorandom number generators", 2019 (<a href="http://vigna.di.unimi.it/ftp/papers/ScrambledLinear.pdf">http://vigna.di.unimi.it/ftp/papers/ScrambledLinear.pdf</a>).</p>                                          |

### Use of gnoise With Complex Numbers

gnoise returns a complex result if *num* is complex or if it is used in a complex expression.

```
Function DemoGNoiseComplex()
 // gnoise(rv) in a complex expression returns a complex result
 // and is equivalent to cmplx(gnoise(rv),gnoise(rv))
 Variable rv = 1 // A real variable
 SetRandomSeed 1
 Variable/C cv1 = gnoise(rv) // Real parameter, complex result
 SetRandomSeed 1
 Variable/C cv2 = cmplx(gnoise(rv),gnoise(rv)) // Equivalent
 Print cv1, cv2

 // gnoise(cv) is equivalent to cmplx(gnoise(real(cv)),gnoise(imag(cv)))
 Variable/C cv = cmplx(1,1) // A complex variable
 SetRandomSeed 1
 Variable/C cv3 = gnoise(cv) // Complex parameter, complex result
 SetRandomSeed 1
 Variable/C cv4 = cmplx(gnoise(real(cv)),gnoise(imag(cv))) // Equivalent
 Print cv3, cv4
End
```

## Graph

### Graph

Graph is a procedure subtype keyword that identifies a macro as being a graph recreation macro. It is automatically used when Igor creates a window recreation macro for a graph. See **Procedure Subtypes** on page IV-204 and **Saving and Recreating Graphs** on page II-338 for details.

## GraphMarquee

### GraphMarquee

GraphMarquee is a procedure subtype keyword that puts the name of the procedure in the graph Marquee menu. See **Marquee Menu as Input Device** on page IV-163 for details.

## GraphNormal

### GraphNormal [/W=*winName*]

The GraphNormal operation returns the target or named graph to the normal mode, exiting any drawing mode that it may be in.

You would usually enter normal mode by choosing ShowTools from the Graph menu and clicking the crosshair tool.

### Flags

*/W=winName*           Reverts the named graph window. This must be the first flag specified when used in a Proc or Macro or on the command line.

### See Also

The **GraphWaveDraw** and **GraphWaveEdit** operations.

## GraphStyle

### GraphStyle

GraphStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Graph dialog and in the Graph Macros menu. See **Graph Style Macros** on page II-338 for details.

## GraphWaveDraw

### GraphWaveDraw [*flags*] [*yWave*, *xWave*]

The GraphWaveDraw operation initiates drawing a curve composed of *yWave* vs *xWave* in the target or named graph. The user draws the curve using the mouse, and the values are stored in a pair of waves as XY data.

The user can manually initiate drawing by choosing ShowTools from the Graph menu and clicking in the appropriate tool.

### Parameters

*yWave* and *xWave* can be simple names of waves in the current data folder or partial or full data folder paths to waves. If the waves already exist, GraphWaveDraw overwrites them. *yWave* and *xWave* can also be wave references pointing to existing waves in which case GraphWaveDraw overwrites them. Prior to Igor Pro 9.00, only simple names were accepted.

If *yWave* and *xWave* already exist, an error is generated unless you include the */O* flag.

If you omit *yWave* and *xWave* then waves named *W\_YPolyn* and *W\_XPolyn* are created in the current data folder. *n* is an integer used to make the output wave names unique in their data folder, so Igor might create waves named *W\_XPoly0* and *W\_YPoly0*, for example.

If there is no *yWave* vs *xWave* trace in the graph, GraphWaveDraw appends it.

### Flags

*/F[=f]*                   Initiates freehand drawing. In normal drawing, you click where you want a data point. In freehand drawing, you click once and then draw with the mouse button held down. If present, *f* specifies the smoothing factor. Max value is 8 (which is really slow), min value is 0 (default). The drawing tools use a value of 3 which is the recommended value.

## GraphWaveEdit

---

|                         |                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/L/R/B/T</code>   | Specifies which axes to use (Left, Right, Bottom, Top). Bottom and Left axes are used by default. Can specify free axes using <code>/L=axis name</code> type notation. See <b>AppendToGraph</b> for details. If necessary, the specified axes will be created. If an axis is created its range is set to -1 to 1.                                                 |
| <code>/M</code>         | Specifies that the curve being edited must be monotonic in the X dimension. The user is not allowed drag points so that they cross horizontally.                                                                                                                                                                                                                  |
| <code>/O</code>         | Overwrites <code>yWave</code> and <code>xWave</code> if they already exist.                                                                                                                                                                                                                                                                                       |
| <code>/W=winName</code> | Draws in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.<br><br>When identifying a subwindow with <code>winName</code> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |

### Details

Once drawing starts no other user actions are allowed.

In normal mode, drawing stops when you double-click or when you click the first point (in which case the last point is set equal to the first point). When drawing finishes, the edit mode is entered.

In freehand mode, drawing stops when the mouse is released or when 10000 points have been drawn.

If you include `/O` and the waves are already on the graph then the first trace instance on the graph displaying them is used even if the trace uses a different pair of axes than specified by `/L`, `/R`, `/B`, and `/T`.

### Output Variables

|                      |                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------|
| <code>S_xWave</code> | Path to the X wave relative to the current data folder. <code>S_xWave</code> is create in Igor Pro 9.00 and later. |
| <code>S_yWave</code> | Path to the X wave relative to the current data folder. <code>S_yWave</code> is create in Igor Pro 9.00 and later. |

The **GraphNormal**, **GraphWaveEdit** and **DrawAction** operations.

## GraphWaveEdit

**GraphWaveEdit** [*flags*] *traceName*

The **GraphWaveEdit** operation initiates editing a wave trace in a graph. The wave trace must already be in the graph.

Normally, you would initiate editing by choosing ShowTools from the Graph menu and clicking in the appropriate tool rather than using **GraphWaveEdit**.

### Parameters

*traceName* is a wave name, optionally followed by the # character and an instance number: "myWave#1" is the *second* instance of myWave appended to the graph ("myWave" is the first).

If *traceName* is omitted then you get to pick the wave trace to edit by clicking it.

### Flags

|                  |                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/M</code>  | Specifies that the edited trace must be monotonic in the X dimension. You cannot drag points so that they cross horizontally.            |
| <code>/ND</code> | Suppresses deletion of a data point when the user presses Option ( <i>Macintosh</i> ) or Alt ( <i>Windows</i> ) and clicks on the point. |
| <code>/NI</code> | Suppresses insertion of a new data point when the user clicks between points.                                                            |

|                         |                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/T=t</code>       | Sets the trace mode.<br><code>t=0</code> : Lines and small square markers (default).<br><code>t=1</code> : User settings unchanged.                                                                                                                                                                                                                                |
| <code>/W=winName</code> | Edits traces in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |

**Details**

The GraphWaveEdit operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details.

## Grep

```
Grep [flags] [srcFileStr] [srcTextWaveName] [as [destFileOrFolderStr]
 [destTextWaveName]]
```

The Grep operation copies lines matching a search expression from a file on disk, the Clipboard, or rows from a text wave to a new or existing file, an existing text wave, the History area, the Clipboard, or to S\_value as a string list.

**Source Parameters**

The optional *srcFileStr* can be

- The full path to the file to copy lines from (in which case */P* is not needed).
- The partial path relative to the folder associated with *pathName*.
- The name of a file in the folder associated with *pathName*.
- “Clipboard” to read lines of text from the Clipboard (in which case */P* is ignored).

If Igor can not determine the location of the source file from *srcFileStr* and *pathName*, it displays a dialog allowing you to specify the source file.

The optional *srcTextWaveName* is the name or path to a text wave.

Only one of *srcFileStr* or *srcTextWaveName* may be specified. If neither is specified then an Open File dialog is presented allowing you to specify a source file.

**Destination Parameters**

The optional *destFileOrFolderStr* can be

- The name of (or path to) an existing folder when */D* is specified.
- The name of (or path to) a possibly existing file.
- “Clipboard”, in which case the matching lines are copied to the Clipboard (and */P* and */D* are ignored). The text can be retrieved with the **GetScrapText** function.

If *destFileOrFolderStr* is a partial path, it is relative to the folder associated with *pathName*.

If */D* is specified, the source file is created inside the folder using the source file name.

If Igor can not determine the location of the destination file from *pathName*, *srcFileStr*, and *destFileOrFolderStr*, it displays a Save File dialog allowing you to specify the destination file (and folder).

The optional *destTextWaveName* is the name or path to an existing text wave. It may be the same wave as *srcTextWaveName*.

Only one of *destFileOrFolderStr* or *destTextWaveName* may be specified.

If no destination file or text wave is specified then matching lines are printed in the history area, unless the `/Q` flag is specified, in which case the matching lines aren't printed or copied anywhere (though the output variables are still set).

Use `/LIST` to set `S_value` to a string list containing the matching lines or rows.

Use `/INDX` to create a wave `W_index` containing the zero-based row or line number where matches were found.

### Parameter Details

If you use a full or partial path for either `srcFileStr` or `destFileOrFolderStr`, see **Path Separators** on page III-453 for details on forming the path.

Folder paths should not end with single path separators. See **MoveFolder's** Details section.

### Flags

- `/A` Appends matching lines to the destination file, creating it if necessary, appends text to the Clipboard if the `destFileOrFolderStr` is "Clipboard", or appends rows to the destination text wave. Has no effect on output to the History area.
- `/D` Interprets `destFileOrFolderStr` as the name of (or path to) an existing folder (or directory). Without `/D`, `destFileOrFolderStr` is the name of (or path to) a file. It is ignored if the destination is a text wave, the Clipboard, or the History area.  
If `destFileOrFolderStr` is not a full path to a folder, it is relative to the folder associated with `pathName`.
- `/DCOL={colNum}` Useful only when the destination is `destTextWaveName`.  
Copies matching lines of text from the source file, Clipboard, or `srcTextWaveName` to column `colNum` of `destTextWaveName`, with any terminator characters removed.  
The default when the source is a file or the Clipboard is `/DCOL={ 0 }`, which copies matching lines into the first column of `destTextWaveName`.  
The default when the source is `srcTextWaveName` is to copy each column of a matched row to the corresponding column in `destTextWaveName`.  
`/DCOL` must be used with the `/A` flag, otherwise the destination wave will have only 1 column.
- `/DCOL=[{colNum} [, delimStr], ...]`  
Useful only when the source is `srcTextWaveName` and the destination is a file, the Clipboard, History area, or `S_value`.  
Copies multiple columns in any order from matching rows of `srcTextWaveName` to the destination file, Clipboard, History area, or `S_value`.  
Construct the line by appending the contents of the numbered column and the `delimStr` parameters in the order specified. The output line is terminated as described in **Line Termination**.
- `/E=regExprStr` Specifies the Perl-compatible regular expression string. A line must match the regular expression to be copied to the output file. See **Regular Expressions**.  
*Multiple `/E` flags may be specified*, in which case a line is copied only if it matches every regular expression.
- `/E={regExprStr, reverse}`  
Specifies the Perl-compatible regular expression string, `regExprStr`, for which the sense of the match can be changed by `reverse`.  
`reverse=1`: Matching expressions are taken to **not** match, and vice versa. For example, use `/E={ "CheckBox" , 1 }` to list all lines that do not contain "CheckBox".  
`reverse=0`: Same as `/E=regExprStr`.
- `/ENCG=textEncoding`

---

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             | Specifies the text encoding of named text file. This flag applies if the source is a file and is ignored if the source is the clipboard or a text wave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                             | See <b>Text Encoding Names and Codes</b> on page III-492 for a list of accepted values for <i>textEncoding</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                             | If you omit /ENCG, Grep uses the default text encoding as specified by the Misc→Text Encoding→Default Text Encoding menu.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                             | Passing 0 for <i>textEncoding</i> acts as if /ENCG were omitted. Passing 255 (binary) for <i>textEncoding</i> is treated as an error because the source text must be internally converted to UTF-8 and there is no valid conversion from binary to UTF-8.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| /GCOL= <i>grepCol</i>       | Greps the specified column of <i>srcTextWaveName</i> , which is a two-dimensional text wave. The default search is on the first column ( <i>grepCol</i> =0). Use <i>grepCol</i> =-1 to match against any column of <i>srcTextWaveName</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                             | Does not apply if the source is a file or Clipboard.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| /I                          | Requires interactive searching even if <i>srcFileStr</i> and <i>destFileOrFolderStr</i> are specified and if the source file exists. Same as /I=3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| /I= <i>i</i>                | Specifies the degree of file search interactivity with the user. <ul style="list-style-type: none"> <li><i>i</i>=0: Default; interactive only if <i>srcFileStr</i> is not specified or if the source file is missing. Same as if /I were not specified.</li> <li><b>Note:</b> This is different behavior than other commands such as <b>CopyFile</b>.</li> <li><i>i</i>=1: Interactive even if <i>srcFileStr</i> is specified and the source file exists.</li> <li><i>i</i>=2: Interactive even if <i>destFileOrFolderStr</i> is specified.</li> <li><i>i</i>=3: Interactive even if <i>srcFileStr</i> is specified, the source file exists, and <i>destFileOrFolderStr</i> is specified.</li> </ul> |
| /INDX                       | Creates in the current data folder an output wave <i>W_Index</i> containing the line numbers (or row numbers) where matching lines were found. If this is the only output you need, also use the /Q flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| /LIST[= <i>listSepStr</i> ] | Creates an output string variable <i>S_value</i> containing a semicolon-separated list of the matching lines. If <i>listSepStr</i> is specified, then it is used to separate the list items. See <b>StringFromList</b> for details on string lists. If this is the only output you need, also use the /Q flag.                                                                                                                                                                                                                                                                                                                                                                                       |
| /M= <i>messageStr</i>       | Specifies the prompt message in any Open File dialog. If /S is not specified, then <i>messageStr</i> will be used for both the Open File and Save File dialogs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| /O                          | Overwrites any existing destination file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| /P= <i>pathName</i>         | Specifies the folder containing the source file or the folder into which the file is copied. <i>pathName</i> is the name of an existing symbolic path.<br>Both <i>srcFileStr</i> and <i>destFileOrFolderStr</i> must be either simple file or folder names, or paths relative to the folder specified by <i>pathName</i> .                                                                                                                                                                                                                                                                                                                                                                           |
| /Q                          | Prevents printing results to an output file, text wave, History, or Clipboard. Use /Q to check for a match to <i>regExprStr</i> by testing the value of <i>V_flag</i> , <i>V_value</i> , <i>S_value</i> (/LIST), or <i>W_Index</i> (/INDX) without generating any other matching line output.<br><b>Note:</b> When using /Q neither <i>destFileOrFolderStr</i> nor <i>destTextWaveName</i> may be specified.                                                                                                                                                                                                                                                                                         |
| /S= <i>saveMessageStr</i>   | Specifies the prompt message in any Save File dialog.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                             |                                      |
|-----------------------------|--------------------------------------|
| <i>/T=termCharStr</i>       | Specifies the terminator character.  |
| <i>/T= (num2char (13) )</i> | Carriage return (CR, ASCII code 13). |
| <i>/T= (num2char (10) )</i> | Linefeed (LF, ASCII code 10).        |
| <i>/T=" ; "</i>             | Semicolon.                           |
| <i>/T=" "</i>               | Null (ASCII code 0).                 |

See **Line Termination** for the default behavior of the terminator character.

|               |                                                                                                                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/Z[=z]</i> | Prevents aborting of procedure execution when attempting to open a nonexistent file for searching. Use <i>/Z</i> if you want to handle this case in your procedures rather than having execution abort. |
| <i>z=0:</i>   | Same as no <i>/Z</i> at all.                                                                                                                                                                            |
| <i>z=1:</i>   | Open file only if it exists. <i>/Z</i> alone is the same as <i>/Z=1</i> .                                                                                                                               |
| <i>z=2:</i>   | Open file if it exists and display a dialog if it does not exist.                                                                                                                                       |

### Line Termination

Line termination applies mostly to source and destination files. (The Clipboard and history area delimit lines with CR, and text waves have no line terminators.)

If */T* is omitted, Grep will break file lines on any of the following: CR, LF, CRLF, LFCR. (Most Macintosh files use CR. Most Windows files use CRLF. Most UNIX files use LF. LFCR is an invalid terminator but some buggy programs generate files that use it.)

Grep reads whichever of these terminator(s) appear in the source file and use them to write lines to any output file.

The terminator(s) are removed before the line is matched against the regular expression.

For lines that match *regExprStr*, terminator(s) in the input file are transferred to the output file unless the output is the Clipboard or history area, in which case the output terminator is always only CR (like **LoadWave**). This means you can transparently handle files that use CR, LF, CRLF, or LFCR as the terminator, and omitting */T* will be suitable for most cases.

If you use the */T* flag, then Grep will terminate line-from-file reads on the specified character only and will output the specified character into any output file.

### “Lines” in One-dimensional Text Waves

Grep considers each row of *srcTextWaveName* or *destTextWaveName* to be a “line” of input or output.

When the destination is a file, the Clipboard, or the History area, Grep copies all of the text in a matching row of *srcTextWaveName* to the file and terminates the line. See **Line Termination** for the rules on line terminators.

When the destination is a *destTextWaveName*, Grep simply copies all the text in a matching row to a row in *destTextWaveName*, without adding or omitting any terminators.

### “Lines” and Columns in Two-Dimensional Text Waves

Grep by default *matches* against only the first column (column 0) of each row of *srcTextWaveName*. You can use the */GCOL=grepCol* flag to specify a different column to match against. Use */GCOL=-1* to match against any column of *srcTextWaveName*.

When the source is a text wave and the destination is a file, the Clipboard, or the History area, Grep by default *copies* only the first column (column 0) to the destination.

Use the */DCOL={colNum1, delimStr1, colNum2, delimStr2, ... colNumN}* to print multiple columns (in any order) with delimiters after each column (the last column number need not be followed by a delimiter string). The output line is terminated with CR or *termcharStr* as described in **Line Termination**.

When both the source and destination are text waves and append (*/A*) is *not* specified, the destination text wave is redimensioned to have the same number of columns as the source text wave, and all columns of matching rows of *srcTextWaveName* are copied to *destTextWaveName*.

When both the source and destination are text waves and append */A* is specified, then the number of columns in *destTextWaveName* is left unchanged, and each column of *srcTextWaveName* is copied to the corresponding column of *destTextWaveName*.

If the destination is a text wave and the source is a file or the Clipboard, each line (without the terminator) is copied to the first column of the destination text wave, or use `/DCOL={destColNum}` to put the text into a different column.

### Output Variables

The Grep operation returns information in the following variables. When running in a user-defined function these are created as local variables. Otherwise they are created as global variables in the current data folder.

|                               |                                                                                                                                                                                                                                                                                                        |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>V_flag</code>           | 0: Output successfully generated.<br>-1: User cancelled either the Open File or Save File dialogs.<br>Other: An error occurred, such as the specified file does not exist.                                                                                                                             |
| <code>V_value</code>          | The number of input lines that matched the regular expression.                                                                                                                                                                                                                                         |
| <code>V_startParagraph</code> | Zero-based line number into the file or Clipboard (or the row number of a source text wave) where the first regular expression was matched. Also see the <code>/INDEX</code> flag.                                                                                                                     |
| <code>S_fileName</code>       | Full path to the source file, the source text wave, or "Clipboard". If an error occurred or if the user cancelled, it is an empty string.                                                                                                                                                              |
| <code>S_path</code>           | Full path to the destination file or destination text wave.<br>"Clipboard": If <code>destFileOrFolderStr</code> was the Clipboard.<br>"History": If the output was printed to the history area of the window.<br>"": If an error occurred, if the user cancelled, or if <code>/Q</code> was specified. |
| <code>S_value</code>          | Contains matching lines as a string list only if <code>/LIST</code> is specified.                                                                                                                                                                                                                      |

### Regular Expressions

A regular expression is a pattern that is matched against a subject string from left to right. Most characters stand for themselves in a pattern, and match the corresponding characters in the "subject".

In the case of Grep, the "subject" is each line of the source file or Clipboard, or each row in the source text wave.

The regular expression syntax supported by Grep, **GrepList**, and **GrepString** is based on the "Perl-Compatible Regular Expression" (PCRE) library.

The syntax is similar to regular expressions supported by various UNIX and POSIX `egrep(1)` commands. See **Regular Expressions** on page IV-175 for more details.

As a trivial example, the pattern "Fred" as specified here:

```
Grep/P=myPath/E="Fred" "afile.txt" as "FredFile.txt"
matches lines that contain the string "Fred" anywhere on the line.
```

Character matching is *case-sensitive* by default, similar to `strsearch`. Prepend the Perl 5 modifier `(?i)` to match upper and lower-case versions of "Fred":

```
// Copy lines that contain "Fred", "fred", "FRED", "fRED", etc
Grep/P=myPath/E="(?)fred" "afile.txt" as "AnyFredFile.txt"
```

To copy lines that do *not* match the regular expression, set the `/E` flag's reverse parameter:

```
// Copy lines that do NOT contain "Fred", "fred", "fRED", etc.
Grep/P=myPath/E="{(?)fred",1} "afile.txt" as "NotFredFile.txt"
```

**Note:** Igor doesn't use the opening and closing regular expression delimiters that UNIX `grep` or Perl use: they would have used `"/Fred/"` and `"/(?)fred/"`.

Regular expressions in Igor support the expected metacharacters and character classes that make the whole `grep` paradigm so useful. For example:

```
// Copy lines that START with a space or tab character
Grep/P=myPath/E="^[\\t]" "afile.txt" as "LeadingTabsFile.txt"
```

For a complete description of regular expressions, see **Regular Expressions** on page IV-175, especially for a description of the many uses of the regular expression backslash character (see **Backslash in Regular Expressions** on page IV-178).

**Note:** Because Igor Pro also has special uses for backslash (see **Escape Sequences in Strings** on page IV-14), you must double the number of backslashes you would normally use for a Perl or grep pattern. Each pair of backslashes identifies a single backslash for the Grep command.

For example, to copy lines that contain “\z”, the Perl pattern would be `\\z`, but the equivalent Grep expression would be `/E="\\z"`.

See **Backslash in Regular Expressions** on page IV-178 for a more complete description of backslash behavior in Igor Pro.

### Examples

```
// Copy lines in afile.txt containing "Fred" (case sensitive)
// to an output file named "AnyFredFile.txt" in the same directory.
Grep/P=myPath/E="Fred" "afile.txt" as "AnyFredFile.txt"

// Copy lines in afile.txt containing "Fred" and "Wilma" (case-insensitive)

```

## References

The regular expression syntax supported by Grep, **GrepString**, and **GrepList** is based on the *PCRE — Perl-Compatible Regular Expression Library* by Philip Hazel, University of Cambridge, Cambridge, England. The PCRE library is a set of functions that implement regular expression pattern matching using the same syntax and semantics as Perl 5.

Visit <http://pcre.org/> for more information about the PCRE library.

A good book on regular expressions is: Friedl, Jeffrey E. F., *Mastering Regular Expressions*, 2nd ed., 492 pp., O'Reilly Media, 2002.

A helpful web site is: <http://www.regular-expressions.info>

## See Also

**Regular Expressions** on page IV-175 and **Symbolic Paths** on page II-22.

**Demo, CopyFile, PutScrapText, LoadWave** operations. The **GrepString**, **GrepList**, **StringMatch**, and **CmpStr** functions.

## GrepList

**GrepList**(*listStr*, *regExprStr* [, *reverse* [, *listSepStr*]])

The GrepList function returns each list item in *listStr* that matches the regular expression *regExprStr*.

*listStr* should contain items separated by *listSepStr* which typically is ";".

*regExprStr* is a regular expression such as is used by the UNIX `grep(1)` command. It is much more powerful than the wildcard syntax used for **ListMatch**. See **Regular Expressions** on page IV-175 for *regExprStr* details.

## GrepString

---

*reverse* is optional. If missing, it is taken to be 0. If *reverse* is nonzero then the sense of the match is reversed. For example, if *regExprStr* is "^abc" and *reverse* is 1, then all list items that do not start with "abc" are returned.

*listSepStr* is optional; the default is "; ". In order to specify *listSepStr*, you must precede it with *reverse*.

### Examples

To list ColorTables containing "Red", "red", or "RED" (etc.):

```
Print GrepList(CTabList(), "(?i)red") // case-insensitive matching
```

To list window recreation commands starting with "\tCursor":

```
Print GrepList(WinRecreation("Graph0", 0), "^\\tCursor", 0, "\\r")
```

### See Also

**Regular Expressions** on page IV-175.

**ListMatch**, **StringFromList**, and **WhichListItem** functions and the **Grep** operation.

## GrepString

**GrepString**(*string*, *regExprStr*)

The GrepString function tests *string* for a match to the regular expression *regExprStr*. Returns 1 to indicate a match, or 0 for no match.

### Details

*regExprStr* is a regular expression such as is used by the UNIX grep(1) command. It is much more powerful than the wildcard syntax used for **StringMatch**. See **Regular Expressions** on page IV-175 for *regExprStr* details.

Character matching is case-sensitive by default, similar to **strsearch**. Prepend the Perl 5 modifier "(?i)" to match upper and lower-case text

### Examples

Test for truth that the string contains at least one digit:

```
if(GrepString(str, "[0-9]+"))
```

Test for truth that the string contains at least one "abc", "Abc", "ABC", etc.:

```
if(GrepString(str, "(?i)abc")) // case-insensitive test
```

### See Also

**Regular Expressions** on page IV-175.

The **StringMatch**, **CmpStr**, **strsearch**, **ListMatch**, and **ReplaceString** functions and the **Demo** and **sscanf** operations.

## GridStyle

**GridStyle**

GridStyle is a procedure subtype keyword that puts the name of the procedure in the Grid->Style Function submenu of the mover pop-up menu in the drawing tool palette. You can have Igor automatically create a grid style function for you by choosing Save Style Function from that submenu.

## GroupBox

**GroupBox** [/Z] *ctrlName* [*keyword* = *value* [, *keyword* = *value* ...]]

The GroupBox operation creates a box to surround and group related controls.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*ctrlName* is the name of the GroupBox control to be created or changed.

The following keyword=value parameters are supported:

|                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| align= <i>alignment</i>                        | <p>Sets the alignment mode of the control. The alignment mode controls the interpretation of the <i>leftOrRight</i> parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.</p> <p>If <i>alignment=0</i> (default), <i>leftOrRight</i> specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.</p> <p>If <i>alignment=1</i>, <i>leftOrRight</i> specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.</p> |
| appearance={ <i>kind</i> [, <i>platform</i> ]} | <p>Sets the appearance of the control. <i>platform</i> is optional. Both parameters are names, not strings.</p> <p><i>kind</i> can be one of <code>default</code>, <code>native</code>, or <code>os9</code>.</p> <p><i>platform</i> can be one of <code>Mac</code>, <code>Win</code>, or <code>All</code>.</p> <p>See <b>DefaultGUIControls Default Fonts and Sizes</b> for how enclosed controls are affected by native groupbox appearance.</p> <p>See <b>Button</b> for more appearance details.</p>                                                                       |
| disable= <i>d</i>                              | <p>Sets user editability of the control.</p> <p><i>d=0</i>: Normal.</p> <p><i>d=1</i>: Hide.</p> <p><i>d=2</i>: Draw in gray state.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| fColor=( <i>r,g,b[,a]</i> )                    | <p>Sets color of the title text. <i>r</i>, <i>g</i>, <i>b</i>, and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| font=" <i>fontName</i> "                       | <p>Sets font used for the box title, e.g., <code>font="Helvetica"</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| frame= <i>f</i>                                | <p>Sets frame mode. If 1 (default), the frame has a 3D look. If 0, then a simple gray line is used. Generally, you should not use <code>frame=0</code> with a title if you want to be in accordance with human interface guidelines.</p>                                                                                                                                                                                                                                                                                                                                      |

|                                      |                                                                                                                                                                                                                                                                                                  |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pos={leftOrRight,top}</code>   | Sets the position in <b>Control Panel Units</b> of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.                                                                     |
| <code>pos+={dx,dy}</code>            | Offsets the position of the box in <b>Control Panel Units</b> .                                                                                                                                                                                                                                  |
| <code>size={width,height}</code>     | Sets box size in <b>Control Panel Units</b> .                                                                                                                                                                                                                                                    |
| <code>userdata(UDName)=UDStr</code>  | Sets the unnamed user data to <i>UDStr</i> . Use the optional ( <i>UDName</i> ) to specify a named user data to create.                                                                                                                                                                          |
| <code>userdata(UDName)+=UDStr</code> | Appends <i>UDStr</i> to the current unnamed user data. Use the optional ( <i>UDName</i> ) to append to the named <i>UDStr</i> .                                                                                                                                                                  |
| <code>title=titleStr</code>          | Sets title to <i>titleStr</i> . Use "" for no title.                                                                                                                                                                                                                                             |
| <code>win=winName</code>             | Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |

### Flags

`/Z` No error reporting.

### Details

If no title is given and the width is less than 11 or height is specified as less than 6, then a vertical or horizontal separator line will be drawn rather than a box.

**Note:** Like TabControls, you need to click near the top of a GroupBox to select it.

### See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

**Control Panel Units** on page III-444 for a discussion of the units used for controls.

The **GetUserData** function for retrieving named user data.

The **ControlInfo** operation for information about the control.

## GuideInfo

### **GuideInfo**(winNameStr, guideNameStr)

The GuideInfo function returns a string containing a semicolon-separated list of information about the named guide line in the named host window or subwindow.

### Parameters

*winNameStr* can be "" to refer to the top host window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

*guideNameStr* is the name of the guide line for which you want information.

### Details

The returned string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

The following keywords will be present only for user-defined guides:

### See Also

The **GuideNameList**, **StringByKey** and **NumberByKey** functions; the **DefineGuide** operation.

| Keyword    | Information Following Keyword                                                                                                                                                                                      |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME       | Name of the guide.                                                                                                                                                                                                 |
| WIN        | Name of the window or subwindow containing the guide.                                                                                                                                                              |
| TYPE       | The value associated with this keyword is either <i>User</i> or <i>Builtin</i> . A <i>User</i> type denotes a guide created by the DefineGuide operation, equivalent to dragging a new guide from an existing one. |
| HORIZONTAL | Either 0 for a vertical guide, or 1 for a horizontal guide.                                                                                                                                                        |
| POSITION   | The position of the guide in points. This is the actual position relative to the left or top edge of the window, not the relative position specified to DefineGuide.                                               |

| Keyword     | Information Following Keyword                                                                                                                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GUIDE1      | The guide is positioned relative to GUIDE1.                                                                                                                                                                                                         |
| GUIDE2      | In some cases, the guide is positioned at a fractional position between GUIDE1 and GUIDE2. If the guide does not use GUIDE2, the value will be "".                                                                                                  |
| RELPOSITION | The position relative to GUIDE1 (and GUIDE2 if applicable). This is the same as the <i>val</i> parameter in DefineGuide. The returned value is in units of points if only GUIDE1 is used, or a fractional value if both GUIDE1 and GUIDE2 are used. |

## GuideNameList

**GuideNameList**(winNameStr, optionsStr)

The GuideNameList function returns a string containing a semicolon-separated list of guide names from the named host window or subwindow.

### Parameters

*winNameStr* can be "" to refer to the top host window.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

*optionsStr* is used to further qualify the list of guides. It is a string containing keyword-value pairs separated by commas. Use "" to list all guides. Available options are:

|              |                                                                                                                                                                                                |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TYPE:type    | type = BuiltIn: List only built-in guides.<br>type = User: List only user-defined guides, those created by the DefineGuide operation or by manually dragging a new guide from an existing one. |
| HORIZONTAL:h | h = 0: List only non-horizontal (that is, vertical) guides.<br>h = 1: List only horizontal guides.                                                                                             |

### Example

```
String list = GuideNameList("Graph0", "TYPE:BuiltIn,HORIZONTAL:1")
```

### See Also

The **DefineGuide** operation and the **GuideInfo** function.

## Hanning

**Hanning** waveName [, waveName]...

**Note:** The **WindowFunction** operation has replaced the Hanning operation.

The Hanning operation multiplies the named waves by a Hanning window (which is a raised cosine function).

You can use Hanning in preparation for performing an FFT on a wave if the wave is not an integral number of cycles long.

## Hash

---

The Hanning operation is not multidimensional aware. See Chapter II-6, **Multidimensional Waves**, particularly **Analysis on Multidimensional Waves** on page II-95 for details.

### See Also

The **WindowFunction** operation implements the Hanning window as well as other forms such as Hamming, Parzen, and Bartlet (triangle).

**ImageWindow**, **DPSS**

## Hash

**Hash**(*inputStr*, *method*)

The Hash function returns a cryptographic hash of the data in *inputStr*.

### Parameters

*inputStr* is string of length up to 2<sup>31</sup> bytes. *inputStr* can contain binary or text data.

*method* is a number indicating the hash algorithm to use:

|   |                 |
|---|-----------------|
| 1 | SHA-256 (SHA-2) |
| 2 | MD4             |
| 3 | MD5             |
| 4 | SHA-1           |
| 5 | SHA-224 (SHA-2) |
| 6 | SHA-384 (SHA-2) |
| 7 | SHA-512 (SHA-2) |

---

Prior to Igor Pro 7.00, only method 1 was supported.

### See Also

**WaveHash**, **StringCRC**, **WaveCRC**

## HCluster

**HCluster** [ *flags* ] *sourceWave*

The HCluster operation computes the information needed to create a cluster dendrogram using an agglomerative hierarchical clustering algorithm. "HCluster" stands for "hierarchical clustering". The HCluster operation was added in Igor Pro 9.00.

For background information, see **Hierarchical Clustering** on page III-162.

The input *sourceWave* represents either vectors in some data space or a square vector dissimilarity matrix (also called a "distance" matrix). You indicate which type of input you are providing using the */ITYP* flag.

HCluster creates an output vector dissimilarity matrix *wave* or an output dendrogram *wave* or both, depending on the */OTYP* flag. The output *wave* names default to *M\_HCluster\_Dissimilarity* and *M\_HCluster\_Dendrogram* but you can override the default using */DEST*.

### Flags

|                 |                                                                                      |
|-----------------|--------------------------------------------------------------------------------------|
| <i>/ITYP=it</i> | <i>it</i> is a keyword specifying the kind of data in <i>sourceWave</i> :            |
|                 | <i>it=Vectors</i> : <i>sourceWave</i> rows represent data vectors (default).         |
|                 | <i>it=DMatrix</i> : <i>sourceWave</i> contains a square vector dissimilarity matrix. |

- /OTYP=ot* *ot* is a keyword specifying what type of output to be produced:
- ot=DMatrix*: The output is a vector dissimilarity matrix. You can use */OTYP=DMatrix* only if */ITYP=Vectors* or if you omit */ITYP*.
- ot=Dendrogram*: The output is a multi-column wave describing the nodes in a dendrogram illustrating the way original data is joined into clusters. This is the default if you omit */OTYP*.
- ot=Both*: The output is both the vector dissimilarity matrix and a dendrogram.
- See the */DEST* flag for further discussion of the output wave or waves.
- /LINK=linkMethod*
- linkMethod* is a keyword specifying the method used to determine the dissimilarity between nodes in the dendrogram that represent more than one data vector. This is also referred to as the "linkage" method. Our definitions of node dissimilarities follows Python `scipy.cluster.hierarchy.linkage`.
- The available keywords for *linkMethod* are listed and described under **HCluster Linkage Calculation Methods** on page III-166.
- If you omit */LINK*, HCluster defaults to the average method.
- /DISS=dm* *dm* is a keyword specifying the vector dissimilarity metric for calculating the dissimilarity between two data vectors. Our definitions of vector dissimilarity follows Python `scipy.spatial.distance.pdist`.
- The available */DISS* keywords are listed and described under **HCluster Vector Dissimilarity Calculation Methods** on page III-163.
- If you omit */DISS*, HCluster defaults to the Euclidean metric.
- /P=pow* *pow* is the power for the Minkowski vector dissimilarity metric. The value of *pow* must be positive. The default is 2.0, equivalent to the Euclidean vector dissimilarity metric. Values that are too large can lead to floating-point overflow. Values less than 1.0 may give surprising results, as this can cause an inversion of the usual distance ordering. If the vector dissimilarity metric is not Minkowski this flag is ignored.
- /VARW=varWave* Specifies the normalizing values  $V_j$  for use with the SEuclidean vector dissimilarity metric. Usually, the wave elements are variances of the vector elements over all the vectors. Thus, if you have a multi-column wave in which rows represent individual vectors, *varWave* should be filled with variances of the wave's columns. If your vectors have length of  $M$ , then *varWave* should be a 1D wave with  $M$  elements. This wave can be conveniently created using the MatrixOP operation, like this:
- $$\text{MatrixOp}/O \text{ varWave} = \text{VarCols}(\text{rowVectorMatrix})^t$$
- If the vector dissimilarity matrix is not SEuclidean, the */VARW* flag is ignored.
- /DEST=outWaveName* Specifies the output waves when you have specified */OTYP=DMatrix* or */OTYP=Dendrogram*.
- If you specified */OTYP=DMatrix*, *outWaveName* is the name of the output vector dissimilarity matrix wave to be created or overwritten, optionally preceded by a data folder path. If you omit */DEST*, HCluster creates an output vector dissimilarity matrix named `M_HCluster_Dissimilarity` in the current data folder.
- If you specified */OTYP=Dendrogram*, *outWaveName* is the name of the output dendrogram wave to be created or overwritten, optionally preceded by a data folder path. If you omit */DEST*, HCluster creates an output dendrogram named `M_HCluster_Dendrogram` in the current data folder.

*/DEST={dMatrixName, dendrogramName}*

Specifies the output waves when you have specified */OTYP=Both*.

*dMatrixName* and *dendrogramName* are names of waves to be created or overwritten, optionally preceded by data folder paths.

If you specify */OTYP=Both* and omit */DEST*, HCluster creates an output vector dissimilarity matrix named *M\_HCluster\_Dissimilarity* and an output dendrogram wave named *M\_HCluster\_Dendrogram*, both in the current data folder.

*/O*

If present, allows the destination waves specified by the */DEST* flag to overwrite a pre-existing wave.

### Parameter

If you specify */ITYP=Vectors* or omit */ITYP*, *sourceWave* is an N row x M column matrix containing N data vectors of length M in the rows. HCluster creates a vector dissimilarity matrix from this input using the distance calculation method specified by */LINK*.

If you specify */ITYP=DMatrix*, *sourceWave* is a square matrix of dissimilarities between data vectors. If you choose this format, you are responsible for computing the dissimilarities between vectors. If none of the vector dissimilarity metrics provided by the */DISS* flag are suitable, or if you require more processing after computing dissimilarities, you can use this format.

### Dendrogram Output Wave

The HCluster operation optionally produces a dendrogram output wave that can be used to create a dendrogram plot. See **Dendrogram Wave Format** on page III-167 for a description of the dendrogram output wave format.

### Reference

The HCluster operation is based on code developed by Daniel Müllner. This reference gives details of the algorithm and the various distance and vector dissimilarity measures and node agglomeration methods:

Daniel Müllner, *fastcluster: Fast Hierarchical, Agglomerative Clustering Routines for R and Python*, Journal of Statistical Software, 53 (2013), no. 9, 1–18, <http://www.jstatsoft.org/v53/i09/>.

### See Also

**Hierarchical Clustering** on page III-162

## hcsr

**hcsr**(*cursorName* [, *graphNameStr*])

The **hcsr** function returns the horizontal coordinate of the named cursor (A through J) in the coordinate system of the top (or named) graph's X axis.

### Parameters

*cursorName* identifies the cursor, which can be cursor A through J.

*graphNameStr* specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Details

The X axis used is the one that controls the trace on which the cursor is placed.

### Examples

```
Variable xAxisValueAtCursorA = hcsr(A) // not hcsr("A")
String str="A"
Variable xA= hcsr($str,"Graph0") // $str is a name, too
```

### See Also

The **pcsr**, **qcsr**, **vcscr**, **xcscr**, and **zcscr** functions.

**Programming With Cursors** on page II-309.

## HDF5AttributeInfo

**HDF5AttributeInfo**(*locationID*, *objectNameStr*, *objectType*, *attributeNameStr*, *options*, *di*)

The HDF5AttributeInfo function stores information about the attribute such as its rank, dimension sizes and type in the HDF5DataInfo structure pointed to by *di*.

Documentation for the HDF5AttributeInfo function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5AttributeInfo"
```

## HDF5CloseFile

**HDF5CloseFile** [/A /Z] *fileID*

The HDF5CloseFile operation closes an HDF5 file previously opened by HDF5OpenFile or HDF5CreateFile.

Documentation for the HDF5CloseFile operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5CloseFile"
```

## HDF5CloseGroup

**HDF5CloseGroup** [/Z] *groupID*

The HDF5CloseGroup operation closes an HDF5 group that you opened via HDFCreateGroup or HDF5OpenGroup.

Documentation for the HDF5CloseGroup operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5CloseGroup"
```

## HDF5Control

**HDF5Control** [ *keyword=value* [, *keyword=value*] ]

The HDF5Control HDF5Control provides control of aspects of Igor's use of the HDF5 file format.

Documentation for the HDF5CreateFile operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5Control"
```

## HDF5CreateFile

**HDF5CreateFile** [/I /O /P=*pathName* /Z] *fileID* as *fileNameStr*

The HDF5CreateFile operation creates a new HDF5 file or overwrites an existing HDF5 file.

Documentation for the HDF5CreateFile operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5CreateFile"
```

## HDF5CreateGroup

**HDF5CreateGroup** [/Z] *locationID*, *nameStr*, *groupID*

The HDF5CreateGroup operation creates an HDF5 group in the HDF5 file. It returns a group ID via *groupID*.

Documentation for the HDF5CreateGroup operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5CreateGroup"
```

## HDF5CreateLink

---

### HDF5CreateLink

```
HDF5CreateLink [/EXT={pathName, filePath} /HARD=makeHardLink /Q /Z]
 targetLocationID, targetName, linkLocationID, linkName
```

The HDF5CreateLink operation creates a new hard, soft or external link in an HDF5 file.

Documentation for the HDF5CreateLink operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5CreateLink"
```

### HDF5DataInfo

The HDF5DataInfo structure is used with the HDF5DataInfo and HDF5AttributeInfo functions.

Documentation for the HDF5DataInfo structure is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5DataInfo"
```

### HDF5DatasetInfo

```
HDF5DatasetInfo(locationID, datasetNameStr, options, di)
```

The HDF5DatasetInfo function stores information about the dataset such as its rank, dimension sizes and type in the HDF5DataInfo structure referenced by *di*.

Documentation for the HDF5DatasetInfo function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5DatasetInfo"
```

### HDF5DatatypeInfo

The HDF5DatatypeInfo structure is used with the HDF5TypeInfo function.

Documentation for the HDF5DatatypeInfo structure is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5DatatypeInfo"
```

### HDF5DimensionScale

```
HDF5DimensionScale [flags] [keyword=value [, keyword=value]]
```

The HDF5DimensionScale operation supports the creation and querying of HDF5 dimension scales.

Documentation for the HDF5DimensionScale operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5DimensionScale"
```

### HDF5Dump

```
HDF5Dump [flags] fileNameStr
```

The HDF5Dump operation dumps information about the specified HDF5 file.

Documentation for the HDF5Dump operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5Dump"
```

### HDF5DumpErrors

```
HDF5DumpErrors [/CLR=clear /Q]
```

The HDF5DumpErrors operation dumps information about HDF5 library errors encountered by Igor.

Documentation for the HDF5DumpErrors operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5DumpErrors"
```

---

## HDF5FlushFile

**HDF5FlushFile** [/A /Z] *fileID*

The HDF5FlushFile operation flushes an HDF5 file previously opened by HDF5OpenFile or HDF5CreateFile.

Documentation for the HDF5FlushFile operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5FlushFile"
```

## HDF5LibraryInfo

**HDF5LibraryInfo** (*options*)

The HDF5LibraryInfo function returns information about the HDF5 library used by the currently-running version of Igor.

Documentation for the HDF5LibraryInfo function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5LibraryInfo"
```

## HDF5LinkInfo

**HDF5LinkInfo** (*locationID*, *pathStr*, *options*, *li*)

The HDF5LinkInfo function stores information about an HDF5 link in the HDF5LinkInfoStruct structure pointed to by *li*.

Documentation for the HDF5LinkInfo function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5LinkInfo"
```

## HDF5LinkInfoStruct

The HDF5LinkInfoStruct structure is used with the HDF5LinkInfo function.

Documentation for the HDF5LinkInfoStruct structure is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5LinkInfoStruct"
```

## HDF5ListAttributes

**HDF5ListAttributes** [/TYPE=*type* /Z] *locationID*, *nameStr*

The HDF5ListAttributes operation returns a semicolon-separated list of attributes associated with the object specified by *locationID* and *nameStr*.

Documentation for the HDF5ListAttributes operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5ListAttributes"
```

## HDF5ListGroup

**HDF5ListGroup** [*flags*] *locationID*, *nameStr*

The HDF5ListGroup operation returns a semicolon-separated list of the names of objects in the HDF5 file or group specified by *locationID* and *nameStr*.

Documentation for the HDF5ListGroup operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5ListGroup"
```

## HDF5LoadData

---

### HDF5LoadData

**HDF5LoadData** [*flags*] *locationID*, *nameStr*

The HDF5LoadData operation loads a dataset or attribute from an HDF5 file.

Documentation for the HDF5LoadData operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5LoadData"
```

### HDF5LoadGroup

**HDF5LoadGroup** [*flags*] *dataFolderSpec*, *locationID*, *nameStr*

The HDF5LoadGroup operation loads an HDF5 group and its datasets into an Igor Pro data folder.

Documentation for the HDF5LoadGroup operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5LoadGroup"
```

### HDF5LoadImage

**HDF5LoadImage** [*flags*] *locationID*, *nameStr*

The HDF5LoadImage operation loads an image dataset and in some cases a palette dataset from an HDF5 file using the format specified in the HDF5 Image and Palette Specification version 1.2.

Documentation for the HDF5LoadImage operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5LoadImage"
```

### HDF5OpenFile

**HDF5OpenFile** [/I /P=*pathName* /R /Z] *fileID* as *fileNameStr*

The HDF5OpenFile operation opens an existing HDF5 file for reading or for reading and writing.

Documentation for the HDF5OpenFile operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5OpenFile"
```

### HDF5OpenGroup

**HDF5OpenGroup** [/Z] *locationID*, *nameStr*, *groupID*

The HDF5OpenGroup operation opens an existing HDF5 group in the HDF5 file.

Documentation for the HDF5OpenGroup operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5OpenGroup"
```

### HDF5SaveData

**HDF5SaveData** [*flags*] *wave*, *locationID* [, *nameStr*]

The HDF5SaveData operation saves a single wave in an HDF5 file as a dataset or as an attribute if /A is present.

Documentation for the HDF5SaveData operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5SaveData"
```

### HDF5SaveDataHookStruct

The HDF5SaveDataHookStruct structure is used with the HDF5SaveDataHook function.

Documentation for the HDF5DatatypeInfo structure is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5SaveDataHookStruct"
```

## HDF5SaveGroup

**HDF5SaveGroup** [*flags*] *dataFolderSpec*, *locationID*, *nameStr*

The HDF5SaveGroup operation saves the contents of an Igor data folder in an HDF5 file.

Documentation for the HDF5SaveGroup operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5SaveGroup"
```

## HDF5SaveImage

**HDF5SaveImage** [*flags*] *keyword* [=*value*]

The HDF5SaveImage operation saves an image dataset and in some cases a palette dataset in an HDF5 file using the format specified in the HDF5 Image and Palette Specification version 1.2.

Documentation for the HDF5SaveImage operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5SaveImage"
```

## HDF5TypeInfo

**HDF5TypeInfo**(*locationID*, *datasetOrGroupNameStr*, *attributeNameStr*, *memberName*, *options*, *dti*)

The HDF5TypeInfo function stores information about the datatype of a dataset or attribute in the HDF5DataTypeInfo structure referenced by *dti*.

Documentation for the HDF5TypeInfo function is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5TypeInfo"
```

## HDF5UnlinkObject

**HDF5UnlinkObject** [/Z] *locationID*, *nameStr*

The HDF5UnlinkObject operation unlinks the specified object (a group, dataset, datatype or link) from the HDF5 file.

Documentation for the HDF5UnlinkObject operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "HDF5UnlinkObject"
```

## hermite

**hermite**(*n*, *x*)

The hermite function returns the Hermite polynomial of order *n*:

$$H_n(x) = (-1)^n \exp(x^2) \frac{d^n}{dx^n} \exp(-x^2).$$

The first few polynomials are:

$$1$$

$$2x$$

$$4x^2 - 2$$

$$8x^3 - 12x$$

**See Also**

The **hermiteGauss** function.

### hermiteGauss

**hermiteGauss** (*n*, *x*)

The hermiteGauss function returns the normalized Hermite polynomial of order *n*:

$$H_n(x) = \frac{1}{\sqrt{\sqrt{\pi} 2^n n!}} (-1)^n \exp(x^2) \frac{d^n}{dx^n} \exp(-x^2).$$

Here the normalization was chosen such that

$$\int_{-\infty}^{\infty} e^{-x^2} H_n(x) H_m(x) dx = \delta_{nm},$$

where  $\delta_{nm}$  is the Kronecker symbol.

You can verify the Hermite-Gauss normalization using the following functions:

```
Function TestNormalization(order)
 Variable order

 Variable/G theOrder = order
 // The integrand vanishes in double-precision outside [-30,30]
 Print/D Integrate1D(hermiteIntegrand,-30,30,2)
End

Function HermiteIntegrand(inX)
 Variable inX

 NVAR n = root:theOrder
 return HermiteGauss(n,inX)^2*exp(-inX*inX)
End
```

#### See Also

The **hermite** function.

### hide

**#pragma hide = value**

The hide pragma allows you to make a procedure file invisible.

#### See Also

The **The hide Pragma** on page IV-53 and **#pragma**.

### HideIgorMenus

**HideIgorMenus** [*MenuNameStr* [, *MenuNameStr* ]...

The HideIgorMenus operation hides the named built-in menus or, if none are explicitly named, hides all built-in menus in the menu bar.

The effect of HideIgorMenus is lost when a new experiment is opened. The state of HideIgorMenus is saved with the experiment.

User-defined menus are not hidden by HideIgorMenus unless attached to built-in menus and the menu definition uses the hideable keyword.

#### Parameters

*MenuNameStr*      The name of an Igor menu, like "File", "Data", or "Graph".

#### Details

The optional menu names are in English and not abbreviated. This ensures that code developed for a localized version of Igor will run on all versions.

The built-in menus that can be shown or hidden (the Help menu can be hidden only on Windows) are those that appear in the menu bar:

---

|        |          |       |           |        |         |       |
|--------|----------|-------|-----------|--------|---------|-------|
| File   | Edit     | Data  | Analysis  | Macros | Windows | Graph |
| Layout | Notebook | Panel | Procedure | Table  | Misc    | Help  |

Hiding a built-in menu to which a user-defined menu is attached results in a built-in menu with only the user-defined items. For example, if this menu definition attaches items to the built-in Graph menu:

```
Menu "Graph"
 "Do My Graph Thing", ThingFunction()
End
```

Calling `HideIgorMenus "Graph"` will still leave a Graph menu showing (when a Graph is the top-most target window) with only the user-defined menu(s) in it: in this example the one "Do My Graph Thing" item.

Hiding the Macros menu hides menus created from Macro definitions like:

```
Macro MyMacro()
 Print "Hello, world."
End
```

but does not hide normal user-defined "Macros" definitions like:

```
Menu "Macros"
 "Macro 1", MyMacro(1)
End
```

You can set user-defined menus to hide and show along with built-in menus by adding the optional `hideable` keyword to the menu definition:

```
Menu "Graph", hideable
 "Do My Graph Thing", ThingFunction()
End
```

Then `HideIgorMenus "Graph"` will hide those items, too. If all user-defined Graph menu definitions use the `hideable` keyword, then no Graph menu will appear in the menu bar.

Some WaveMetrics procedures use the `hideable` keyword so that only customer-defined menus remain when `HideIgorMenus` is executed.

#### See Also

**ShowIgorMenus**, **DoIgorMenu**, **SetIgorMenuMode**, Chapter IV-5, **User-Defined Menus**

## HideInfo

**HideInfo** [/W=*winName*]

The `HideInfo` operation removes the info panel from a graph if it was previously shown by the **ShowInfo** operation.

#### Flags

*/W=winName*      Hides the info panel in the named window.

#### See Also

The **ShowInfo** operation.

**Programming With Cursors** on page II-309.

## HideProcedures

**HideProcedures**

The `HideProcedures` operation hides all procedure windows without closing or killing them.

#### See Also

The **DisplayProcedure** and **DoWindow** operations.

## HideTools

**HideTools** [/A/W=*winName*]

The `HideTools` operation hides the tool palette in the top graph or control panel if it was previously shown by the **ShowTools** operation.

## HilbertTransform

---

### Flags

- `/A` Sizes the window automatically to make extra room for the tool palette. This preserves the proportion and size of the actual graph area.
- `/W=winName` Hides the tool palette in the named window. This must be the first flag specified when used in a Proc or Macro or on the command line.
- winName* must be either the name of a top-level window or a path leading to an exterior panel window (see **Exterior Control Panels** on page III-443).

### See Also

The **ShowTools** operation.

## HilbertTransform

**HilbertTransform** [`/Z`] [`/O`] [`/DEST=destWave`] *srcWave*

The HilbertTransform operation computes the Hilbert transformation of *srcWave*, which is a real or complex (single or double precision) wave of 1-3 dimensions. The result of the HilbertTransform is stored in *destWave*, or in the wave `W_Hilbert` (1D) or `M_Hilbert` in the current data folder.

### Flags

- `/DEST=destWave` Creates a real wave reference for the destination wave in a user function. See **Automatic Creation of WAVE References** on page IV-71 for details.
- `/O` Overwrites *srcWave* with the transform.
- `/PAD={dim1 [, dim2, dim3, dim4]}`
- Converts *srcWave* into a padded wave of dimensions *dim1, dim2, ...*. The padded wave contains the original data at the start of the dimension and adds zero entries to each dimension up to the specified dimension size. The *dim1... dim4* values must be greater than or equal to the corresponding dimension size of *srcWave*. If you need to pad just the lowest dimension(s) you can omit the remaining dimensions; for example, `/PAD=dim1` will set *dim2* and above to match the dimensions in *srcWave*.
- This flag was added in Igor Pro 7.00.
- `/Z` No error reporting.

### Details

The Hilbert transform of a function  $f(x)$  is defined by:

$$F(t) = \frac{1}{\pi t} \int_{-\infty}^{\infty} \frac{f(x) dx}{x - t}.$$

Theoretically, the integral is evaluated as a Cauchy principal value. Computationally one can write the Hilbert transform as the convolution:

$$F(t) = \frac{-1}{\pi t} * f(t),$$

which by the convolution theorem of Fourier transforms, may be evaluated as the product of the transform of  $f(x)$  with  $-i * \text{sgn}(x)$  where:

$$\text{sgn}(x) = \begin{cases} -1 & x < 0 \\ 0 & x = 0 \\ 1 & x > 0 \end{cases}.$$

Note that the Hilbert transform of a constant is zero. If you compute the Hilbert transform in more than one dimension and one of the dimensions does not vary (is a constant), the transform will be zero (or at least numerically close to zero).

There are various definitions for the extension of the Hilbert transform to more than one dimension. In two dimensions this operation computes the transform by multiplying the 2D Fourier transform of the input by the factor  $(-i)\text{sgn}(x)(-i)\text{sgn}(y)$  and then computing the inverse Fourier Transform. A similar procedure is used when the input is 3D.

### Examples

Extract the instantaneous amplitude and frequency of a narrow-band signal.

```
Make/O/N=1000 w0,amp,phase
SetScale/I x 0,50,"", w0,amp,phase
w0 = exp(-x/10)*cos(2*pi*x)
HilbertTransform /DEST=w0h w0 // w0+i*w0h is the "analytic signal", i=cplx(0,1)
amp = sqrt(w0^2 + w0h^2) // extract the envelope
phase = atan2(-w0h,w0) // extract the phase [SIGN CONVENTION?]
Unwrap 2*pi, phase // eliminate the 2*pi phase jumps
Differentiate phase /D=freq // would have less noise if fit to a line
// over interior points
freq /= 2*pi // phase = 2*pi*freq*time
Display w0,amp // original waveform and its envelope; note boundary effects
Display freq // instantaneous frequency estimate, with boundary effects
```

## Histogram

**Histogram** [*flags*] *srcWaveName*, *destWaveName*

The Histogram operation generates a histogram of the data in *srcWaveName* and puts the result in *destWaveName* or in *W\_Histogram* or in the wave specified by */DEST*.

### Parameters

*srcWaveName* specifies the wave containing the data to be histogrammed.

For historical reasons the meaning and use of *destWaveName* depend on the binning mode as specified by */B*. See **Histogram Destination Wave** on page V-349 below for details.

### Flags

*/A* Accumulates the histogram result with the existing values in the destination wave instead of replacing the existing values with the result. Assumes */B=2* unless the */B* flag is present.

**Note:** The result will be incorrect if you also use */P*.

## Histogram

---

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/B=mode</code>                        | <p>Controls binning:</p> <p><i>mode=1</i>: Semi-automatic mode that sets the bin range based on the range of the Y values in <i>srcWaveName</i>. The number of bins is determined by the number of points in the destination wave.</p> <p><i>mode=2</i>: Uses the bin range and number of bins determined by the X scaling and number of points in the destination wave.</p> <p><i>mode=3</i>: Uses Sturges' method to determine optimal number of bins and redimensions the destination wave as necessary. By this method</p> $\text{numBins}=1+\log_2(N)$ <p>where N is the number of data points in <i>srcWaveName</i>. The bins will be distributed so that they include the minimum and maximum values.</p> <p><i>mode=4</i>: Uses a method due to Scott, which determines the optimal bin width as</p> $\text{binWidth}=3.49*\sigma*N^{-1/3}$ <p>where N is the number of data points in <i>srcWaveName</i> and <math>\sigma</math> is the standard deviation of the distribution. The bins will be distributed so that they include the minimum and maximum values.</p> <p><i>method=5</i>: Uses the Freedman-Diaconis method where</p> $\text{binWidth}=2*IQR*N^{-1/3}$ <p>where IQR is the interquartile distance (see <b>StatsQuantiles</b>) and the bins are evenly distributed between the minimum and maximum values.</p> |
| <code>/B={binStart,binWidth,numBins}</code> | <p>Sets the histogram bins from these parameters rather than from <i>destWaveName</i>. Changes the X scaling and length of the destination wave.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>/C</code>                             | <p>Sets the X scaling so that X values are in the centers of the bins, which is required when you do a curve fit to the histogram output. Ordinarily, wave scaling of the output wave is set with X values at the left bin edges.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>/CUM</code>                           | <p>Requests a cumulative histogram in which each bin is the sum of bins to the left. The last bin will contain the total number of input data points, or, with /P, 1.0.</p> <p>/CUM cannot be used with a weighted histogram (/W flag).</p> <p>When used with /A, the destination wave must be the result of a histogram created with /CUM.</p> <p>Note that if you use a binning mode (/B flag) that sets a bin range that does not include the entire range of the input data, then the output will not count all of input points and the last bin will not contain the total number of input points. Input points whose values fall below the left edge of the first bin or above the right edge of the last bin will not be counted.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <code>/DP</code>                            | <p>Causes Histogram to create the destination wave as double-precision floating point instead of single-precision floating point. The /DP flag was added in Igor Pro 8.00.</p> <p>Single-precision precisely represents integers up to 16,677,721 only. Double-precision precisely represents integers up to about 9 trillion.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

- `/N` Creates a wave named `W_SqrtN` containing the square root of the number of counts in each bin. This is an appropriate wave to use as a weighting wave when doing a curve fit to the histogram results. `/N` cannot be used with a weighted histogram (`/W` flag).
- `/NLIN=binsWave` Computes a non-linear histogram using the bins specified in the wave *binsWave*. This option is not compatible with the flags `/A`, `/B`, `/C`, `/CUM`, `/N`, `/P`, `/W`.  
The bins must be contiguous and non-overlapping so that *binsWave* contains monotonically increasing values with no NaNs and INFs. For example, if you want the 3 bins `[1,10],[10,100],[100,1000]`, execute:  
Make/O/N=4 *bins*={1,10,100,1000}  
The upper end of each bin is open.  
The `/NLIN` flag was added in Igor Pro 7.00.
- `/P` Normalizes the histogram as a probability distribution function, and shifts wave scaling so that data correspond to the bin centers.  
When using the results with **Integrate**, you must use `/METH=0` or `/METH=2` to select rectangular integration methods.
- `/R=(startX,endX)` Specifies the range of *X* values of *srcWaveName* over which the histogram is to be computed.
- `/R=[startP,endP]` Specifies the range of points of *srcWaveName* over which the histogram is to be computed.
- `/RMD=[firstRow,lastRow][firstColumn,lastColumn][firstLayer,lastlayer][firstChunk,lastChunk]`  
Designates a contiguous range of data in the source wave to which the operation is to be applied. This flag was added in Igor Pro 7.00.  
You can include all higher dimensions by leaving off the corresponding brackets. For example:  
`/RMD= [firstRow, lastRow]`  
includes all available columns, layers and chunks.  
You can use empty brackets to include all of a given dimension. For example:  
`/RMD= [] [firstColumn, lastColumn]`  
means "all rows from column A to column B".  
You can use a `*` to specify the end of any dimension. For example:  
`/RMD= [firstRow, *]`  
means "from *firstRow* through the last row".
- `/W=weightWave` Creates a "weighted" histogram. In this case, instead of adding a single count to the appropriate bin, the corresponding value from *weightWave* is added to the bin. *weightWave* may be any number type, and it may be complex. If it is complex, then the destination wave will be complex.  
`/W` cannot be used with a cumulative histogram (`/CUM` flag).

### Histogram Destination Wave

For historical reasons there are multiple ways to specify the destination wave and the meaning and use of *destWaveName* depend on the binning mode as specified by `/B`. This section explains the details and then provides guidance and when to use which mode.

In binning modes 1 and 2 (`/B=1` and `/B=2`, described above), the destination wave plays a role in determining the binning and *destWaveName* must be the name of an existing wave. If you omit `/DEST` then the output is written to *destWaveName*. If you provide `/DEST` then the output is written to the wave specified by `/DEST`.

In binning modes 3, 4 and 5 (`/B=3`, `/B=4` and `/B=5`, described above), the destination wave plays no role in determining the binning. If you omit *destWaveName* and `/DEST`, Histogram stores its output in a wave named `W_Histogram` in the current data folder. If you omit `/DEST` and provide *destWaveName*, then

## Histogram

*destWaveName* must name an existing wave to which the output is written. If you provide /DEST, you can omit *destWaveName*. If you provide both /DEST and *destWaveName* then *destWaveName* must name an existing wave but the operation ignores it.

Here is the recommended usage:

If you want to use specific binning that you have determined, use /B={*binStart,binWidth,numBins*}, use /DEST to specify the destination wave, and omit *destWaveName*.

If you want Igor to determine the binning, use /B=3, /B=4 or /B=5, use /DEST to specify the destination wave, and omit *destWaveName*.

For backward compatibility with Igor Pro 6, use /B=1, /B=2, /B=3, /B=4 or /B={*binStart,binWidth,numBins*}, create a destination wave, use it as *destWaveName* and omit /DEST.

### Details

If you use /B={*binStart, binWidth, numBins*}, then the initial number of data points in the wave is immaterial since the Histogram operation changes the number of points.

Only one /B and only one /R flag is allowed.

If both /A and /B flags are missing, the bin range and number of bins is calculated as if /B=1 had been specified.

When accumulating multiple histograms in one output wave, typically you will want to use /B={*binStart,binWidth,numBins*} for the first histogram, and /A for successive histograms.

The Histogram operation works on single precision floating point destination waves. If necessary, Histogram redimensions the destination wave to be single precision floating point. However, Histogram/A requires that the destination wave already be single precision floating point.

For a weighted histogram, the destination wave will be double-precision.

If you specify the range as /R=(*start*), then the end of the range is taken as the end of *srcWaveName*.

In an ordinary histogram, input data is examined one data point at a time. The operation determines which bin a data value falls into and a single count is added to that bin. A weighted histogram works similarly, except that it adds to the bin a value from another wave in which each row corresponds to the same row in the input wave.

Normal Histogram

Weighted Histogram

The Histogram operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details. In fact, the Histogram operation can be usefully applied to multidimensional waves, such as those that represent images. The /R flag will not work as expected, however.

### Examples

```
// Create histogram of two sets of data.
Make/N=1000 data1=gnoise(1), data2=gnoise(1)
Make/N=1 histResult

// Sets bins, does histogram.
Histogram/B={-5,1,10} data1, histResult
Display histResult; ModifyGraph mode=5

// Accumulates into existing bins.
Histogram/A data2, histResult
```

## hyperG0F1

**hyperG0F1**(*b*, *z*)

The hyperG0F1 function returns the confluent hypergeometric limit function

$${}_0F_1(b; z) = \sum_{i=0}^{\infty} \frac{z^i}{i!(b)_i},$$

where  $(b)_i$  is the Pochhammer symbol

$$(b)_i = b(b+1)\dots(b+i-1).$$

The series evaluation may be computationally intensive. You can abort the computation by pressing the **User Abort Key Combinations**.

## hyperGNoise

**hyperGNoise(m, n, k)**

The hyperGNoise function returns a pseudo-random value from the hypergeometric distribution whose probability distribution function is

$$f(x,m,n,k) = \frac{\binom{n}{x} \binom{m-n}{k-x}}{\binom{m}{k}}$$

where  $m$  is the total number of items,  $n$  is the number of marked items, and  $k$  is the number of items in a sample.

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable "random" numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

## i

### i

The *i* function returns the loop index of the inner most iterate loop in a macro. Not to be used in a function. Iterate loops are archaic and should not be used.

## ICA

### ICA [*flags*] *srcWave*

The ICA operation performs independent component analysis using the FastICA algorithm. Input data is in the form of a 2D wave where each column represents the equivalent of a single data acquisition channel. The results of the operation are stored in the waves M\_ICAComponents, M\_ICAUnMix and M\_matrixW in the current data folder.

The ICA operation was added in Igor Pro 7.00.

### Flags

|                 |                                                                                                                                                                                                                                                                                                                           |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/A=alpha</i> | <i>alpha</i> is a constant used as a factor in the argument of the logCosh function. It is not used with the exp function.<br><br><i>alpha</i> is in the range [1,2] and its default value is 1.<br><br>You will rarely need to change this value to affect the rate of convergence or the quality of the results.        |
| <i>/CF=num</i>  | Specifies the contrast function, also called the non-quadratic function, used by ICA.<br><br><i>num</i> =0: logCosh (default)<br><i>num</i> =1: exp                                                                                                                                                                       |
| <i>/COLS</i>    | Preconditions the input by subtracting the mean and then normalizing the input on a column-by-column basis. The algorithm appears to converge and produce better results when this flag is used.<br><br>As of Igor Pro 9.00, the input is preconditioned by default so <i>/COLS</i> is no longer required or recommended. |
| <i>/DFLT</i>    | Use the deflation/vector method where iterations solve for a single vector of the "unmixing" matrix at a time. By default the operation uses the matrix method which solves for the complete unmixing matrix at one time.                                                                                                 |

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/PCA</code>                  | Save the output of the "PCA" stage which is also the form of the data before the fastICA iterations. The SVD U matrix is saved in the wave <code>M_PCA</code> and the eigenvalues are saved in the wave <code>W_PCAEV</code> . Both are created in the current data folder.                                                                                                                                                                                                                                                     |

### Details

`srcWave` is a 2D wave of `nRows` by `nCols`. It must be a single or double precision real-valued wave containing no NaNs or INFs. Each column of `srcWave` corresponds to a single data acquisition channel that is assumed to consist of a linear superposition of independent components. This can be expressed as a matrix product

$$\mathbf{X} = \mathbf{A} (\mathbf{S}^t)$$

where  $\mathbf{S}$  is an `nRows` by `nCols` matrix of independent components,  $^t$  denotes the transpose,  $\mathbf{A}$  is an `nCols` by `nCols` mixing matrix and  $\mathbf{X}$  is the "mixed" input. The ICA operation attempts to find the independent components of  $\mathbf{S}$  from the transformation

$$\mathbf{S} = \mathbf{W} \mathbf{X}$$

so that the mutual information between the resulting columns of  $\mathbf{S}$  is minimized. Since mutual information is not affected by a multiplication of components by scalar constants, the resulting independent components can be specified up to a scalar factor.

The operation uses the FastICA algorithm to compute the independent components.

The algorithm has two available methods for computation. The default is to attempt to evaluate the full  $\mathbf{W}$  matrix at once. The second method (`/DFLT` flag) also known as "deflation" computes one row of  $\mathbf{W}$  at a time. The deflation method might have advantages in cases where there are fewer independent components than there are columns in the input.

### Example

```
// Create the source
Make/O/N=(1000,3) ddd
ddd[] [0]=sin(2*pi*x/13)
ddd[] [1]=sin(2*pi*x/17)
ddd[] [2]=sin(2*pi*x/23)

// Create mixing matrix
Make/O/N=(3,3) AA
AA[0] [0]= {0.291,0.6557,-0.5439}
AA[0] [1]= {0.5572,0.3,-0.2}
AA[0] [2]= {-0.1,-0.7,0.4}

// Do the mixing
MatrixOp/O xx=ddd x AA

// Try the ICA
ICA/DFLT/COLS xx
Display M_ICAComponents [] [0]
Display M_ICAComponents [] [1]
Display M_ICAComponents [] [2]
```

PCA

**if-elseif-endif**

```
if (<expression1>)
 <TRUE part 1>
elseif (<expression2>)
 <TRUE part 2>
[...]
[else
 <FALSE part>]
endif
```

In an if-elseif-endif conditional statement, when an expression first evaluates as TRUE (nonzero), then only code corresponding to the TRUE part of that expression is executed, and then the conditional statement is exited. If all expressions evaluate as FALSE (zero) then *FALSE part* is executed when present. After executing code in any TRUE part or the FALSE part, execution will next continue with any code following the if-elseif-endif statement.

**See Also**

If-Elseif-Endif on page IV-40 for more usage details.

**if-endif**

```
if (<expression>)
 <TRUE part>
[else
 <FALSE part>]
endif
```

An if-endif conditional statement evaluates *expression*. If *expression* is TRUE (nonzero) then the code in *TRUE part* is executed, or if FALSE (zero) then the optional *FALSE part* is executed.

**See Also**

If-Else-Endif on page IV-39 for more usage details.

**IFFT**

**IFFT** [*flags*] *srcWave*

The IFFT operation calculates the Inverse Discrete Fourier Transform of *srcWave* using a multidimensional fast prime factor decomposition algorithm. This operation is the inverse of the **FFT** operation.

**Output Wave Name**

For compatibility with earlier versions of Igor, if you use IFFT without /ROWS or /COLS, the operation overwrites *srcWave*.

If you use the /ROWS flag, IFFT uses the default output wave name M\_RowFFT and if you use the /COLS flag, IFFT uses the default output wave name M\_ColFFT.

We recommend that you use the /DEST flag to make the output wave explicit and to prevent overwriting *srcWave*.

**Parameters**

*srcWave* is a complex wave. The IFFT of *srcWave* is either a real or complex wave, according to the length and flags.

**Flags**

/C Forces the result of the IFFT to be complex. Normally, the IFFT produces a real result unless certain special conditions are detected as described in **Details**.

| <code>/R</code>             | Forces real output when, due to a power of 2 number of points, IFFT would otherwise automatically produce a complex result.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>/ROWS</code>          | Calculates the IFFT of only the first dimension of 2D <i>srcWave</i> . It computes the 1D FFT one row at a time. You must specify a destination wave using the <code>/DEST</code> flag (no other flags are allowed). See the <code>/COLS</code> flag and corresponding flags of the <b>FFT</b> operation.                                                                                                                                                                                                                                                |
| <code>/Z</code>             | Will not rotate <i>srcWave</i> when computing the IDFT of a complex wave whose length is an integral power of 2.<br><br>This length indicates that the Inverse DFT result will also be a complex wave. When the result is complex, and the x scaling of <i>srcWave</i> is such that the first point is <i>not</i> $x=0$ , it normally rotates <i>srcWave</i> by $-N/2$ points before performing the IFFT. This inverts the process of performing an FFT on a complex wave. However when <code>/Z</code> is specified, it does not perform this rotation. |

### Details

The data type of *srcWave* must be complex and must not be an integer type. You should be aware that an IFFT on a number of points that is prime can be slow.

By default, IFFT assumes you are performing an inverse transform on data that was originally real and therefore it produces a real result. However, for historical and compatibility reasons, IFFT detects the special conditions of a one-dimensional wave containing an integral power of 2 data points and automatically creates a complex result.

When the result is complex, the number of points (N) in the resulting wave will be of the same length. Otherwise the resulting wave will be real and of length  $(N-1)*2$ .

In either the complex or real case the X units of the output wave are changed to "s". The X scaling also is changed appropriately, cancelling out the adjustments made by the **FFT** operation. When the data is multidimensional, the same considerations apply to the additional dimensions. The scaling description and IDFT equation below pretend that the IFFT is not performed in-place. After computing the IFFT values, the X scaling of *waveOut* is changed as if Igor had executed these commands:

```
Variable points // time-domain points, NtimeDomain
if(waveIn was complex wave)
 points= numpnts(waveIn)
else // waveIn was real wave
 points= (numpnts(waveIn) - 1) * 2
endif
Variable deltaT= 1 / (points*deltaX(waveIn)) // 1/(NtimeDomaindx)
SetScale/P waveOut 0,deltaT,"s"
```

The IDFT equation is:

$$waveOut[n] = \frac{1}{N} \sum_{k=0}^{N-1} waveIn[k] \exp\left(\frac{2\pi i k n}{N}\right), \quad \text{where } i = \sqrt{-1}.$$

| IGORVERS       | The version number of the Igor application. Also see IGORFILEVERSION returned by IgorInfo(3).                                                                                                                                                                                                                                                                                                                                                                                         |
| NSCREENS       | Number of screens currently attached to the computer and used for the desktop.                                                                                                                                                                                                                                                                                                                                                                                                        |
| SCREEN1        | A description of the characteristics of screen 1.<br>The format of the SCREEN1 description is:<br>SCREEN1:DEPTH= <i>bitsPerPixel</i> ,RECT= <i>left,top,right,bottom</i> ;<br><i>left, top, right, and bottom</i> are all in pixels.<br>If there are multiple screens, there will be additional SCREEN keywords, such as SCREEN2 and SCREEN3.                                                                                                                                         |

**Selector = 1**

IgorInfo(1) returns the name of the current Igor experiment.

Use IgorInfo(12) to get the file name including the extension.

## IgorInfo

---

### *Selector = 2*

IgorInfo(2) returns the name of the current platform: "Macintosh" or "Windows".

### *Selector = 3*

IgorInfo(3) returns a collection of more detailed information about the operating system, localization information, and the actual file version of the Igor executable. The keywords are OS, OSVERSION, LOCALE, and IGORFILEVERSION.

| <b>Keyword</b>  | <b>Information Following Keyword For IgorInfo(3)</b>                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IGORFILEVERSION | The actual version number of the Igor application file.<br><br>On Macintosh, the version number is a floating point number with a possible suffix. Igor Pro 7.00, for example, returns "7.00". Igor Pro 8.01 Beta 1 returns "8.01B01".<br><br>On Windows, the version format is a period-separated list of four numbers. Igor Pro 7.02 returns "7.0.2.X" where X is a subminor revision number. A revision to Igor Pro 7.02 would be indicated in the last digit, such as "7.0.2.12". |
| LOCALE          | Country for which this version of Igor Pro is localized. "US" for most versions, "Japan" for the Japanese versions.                                                                                                                                                                                                                                                                                                                                                                   |
| OS              | On Macintosh, the OS value is "Macintosh OS X".<br><br>On Windows, this might be "Windows 10 Home". The actual build number and format of the text will vary with the operating system.                                                                                                                                                                                                                                                                                               |
| OSVERSION       | Operating system number.<br><br>On Macintosh, this is something like "10.13.1".<br><br>On Windows, this is something like "6.3.16299".                                                                                                                                                                                                                                                                                                                                                |

---

### *Selector = 4*

IgorInfo(4) returns the name of the current processor architecture. Currently this is always "Intel".

### *Selector = 5*

IgorInfo(5) returns, as a string, the serial number of the program if it is registered or "\_none\_" if it isn't registered. Use **str2num** to store the result in a numeric variable. str2num returns NaN if the program isn't registered.

### *Selector = 6*

IgorInfo(6) returns, as a string, the version of the Qt library under which Igor is running, for example "5.9.4". This selector value was added in Igor Pro 7.00.

### *Selector = 7*

IgorInfo(7) returns, as a string, the name of the current user. This selector value was added in Igor Pro 7.00.

### *Selector = 8*

IgorInfo(8) returns, as a string, the group of the current user on Macintosh. On Windows, an empty string is always returned. This selector value was added in Igor Pro 8.00.

### *Selector = 9*

IgorInfo(9) returns "admin" if Igor's process is being run as an administrator (*Windows*) or if the user that started Igor's process is an administrator (*Macintosh*). Otherwise it returns "". This selector value was added in Igor Pro 8.00.

### *Selector = 10*

IgorInfo(10) returns a semicolon-separated list containing the names of activated XOPs. This selector value was added in Igor Pro 8.00.

### *Selector = 11*

IgorInfo(11) returns a string specifying the type of the current experiment. This will be one of the following: See **Saving Experiments** on page II-16 for a discussion of the various experiment file formats.

|               |                                              |
|---------------|----------------------------------------------|
| "Packed"      | Current experiment file is a .pxp file       |
| "HDF5 packed" | Current experiment file is a .h5xp file      |
| "Unpacked"    | Current experiment file is a .uxp file       |
| ""            | Current experiment was never saved to a file |

**Selector = 12**

IgorInfo(12) returns a string specifying the name of the current experiment file including the extension. If the experiment was never saved to a file, it returns "".

This selector value was added in Igor Pro 9.00.

Use IgorInfo(1) to get the file name without the extension.

**Selector = 13**

In Igor Pro 9.00 and later, IgorInfo(13) returns a collection of information about the autosave settings. See **Autosave** on page II-36 for background information.

This selector value was added in Igor Pro 9.00.

**Selector = 14**

IgorInfo(14) returns a collection of information about the HDF5 default compression settings. See **HDF5 Default Compression** on page II-202 for background information.

This selector value was added in Igor Pro 9.00.

The keywords are as follows:

| Keyword  | Information Following Keyword For IgorInfo(3)                                                                                                                                                                                                                                                                                                                                       |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENABLED  | 0: Autosave is disabled<br>1: Autosave is enabled                                                                                                                                                                                                                                                                                                                                   |
| MODE     | 1: Direct (saves to original files)<br>2: Indirect (saves to .autosave files)                                                                                                                                                                                                                                                                                                       |
| INTERVAL | The interval in minutes between autosaves if autosave is enabled.                                                                                                                                                                                                                                                                                                                   |
| OPTIONS  | A bitwise value with each bit indicating if a given feature is off (bit is 0) or on (bit is 1):<br>Bit 0: Autosave entire experiment<br>Bit 1: Autosave standalone procedure files<br>Bit 2: Autosave standalone plain text notebooks<br>Bit 3: Autosave standalone formatted text notebooks<br><br>See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings. |

See **Autosave** on page II-36 for details.

**Selector = 15**

IgorInfo(15) returns a string specifying the default experiment file format.

This selector value was added in Igor Pro 9.00.

The returned value will be one of the following:

|               |                                         |
|---------------|-----------------------------------------|
| "Packed"      | Default experiment file format is .pxp  |
| "HDF5 packed" | Default experiment file format is .h5xp |
| "Unpacked"    | Default experiment file format is .uxp  |

See **Saving Experiments** on page II-16 for a discussion of the various experiment file formats.

## IgorVersion

---

### *Selector = 16*

IgorInfo(16) returns the total number of waves of all kinds (global, free, local) that currently exist. This selector value was added in Igor Pro 9.00.

IgorInfo(16) can help advanced Igor programmers detect wave leaks in their procedures. For details, see **Detecting Wave Leaks** on page IV-206.

### Examples

```
Print NumberByKey("NSCREENS", IgorInfo(0)) // Number of active displays
Function RunningWindows() // Returns 0 if Macintosh, 1 if Windows
 String platform = UpperStr(IgorInfo(2))
 Variable pos = strsearch(platform, "WINDOWS", 0)
 return pos >= 0
End
```

## IgorVersion

### **#pragma IgorVersion = versNum**

When a procedure file contains the directive, `#pragma IgorVersion=versNum`, an error will be generated if *versNum* is greater than the current Igor Pro version number. It prevents procedures that use new features added in later versions from running under older versions of Igor in which these features are missing. However, this version check is limited because it does not work with versions of Igor older than 4.0.

### See Also

The **The IgorVersion Pragma** on page IV-53 and **#pragma**.

## IgorVersion

The IgorVersion function returns version number of the Igor application as a floating point number. Igor Pro 8.00 returns 8.00, as does Igor Pro 8.00A.

### Details

You can use IgorVersion in conditionally compile code expressions, which can be used to omit calls to new Igor features or to provide backwards compatibility code.

```
#if (IgorVersion() >= 8.00)
 [Code that compiles only on Igor Pro 8.00 or later]
#else
 [Code that compiles only on earlier versions of Igor]
#endif
```

If at all possible, it is better to require your users to use a later version of Igor rather than writing conditional code. Attempting this kind of backward-compatibility multiplies your testing requirements and the chances for bugs.

### See Also

**IgorInfo**, **Conditional Compilation** on page IV-108, **The IgorVersion Pragma** on page IV-53

## ilim

### **ilim**

The ilim function returns the ending loop count for the inner most iterate loop. Not to be used in a function. Iterate loops are archaic and should not be used.

## imag

### **imag(z)**

The imag function returns the imaginary component of the complex number *z* as a real (not complex) number.

### See Also

The **cmplx**, **conj**, **p2rect**, **r2polar**, and **real** functions.

## ImageAnalyzeParticles

**ImageAnalyzeParticles** [*flags*] *keyword imageMatrix*

The ImageAnalyzeParticles operation performs one of two particle analysis operations on a 2D or 3D source wave *imageMatrix*. The source image wave must be binary, i.e., an unsigned char format where the particles are designated by 0 and the background by 255 (the operation will produce erroneous results if your data uses the opposite designation). Note that all nonzero values in the source image will be considered part of the background. Grayscale images must be thresholded before invoking this operation (you may need to use the /I flag with the **ImageThreshold** operation).

**Note:** ImageAnalyzeParticles does not take into account wave scaling. All image metrics are in pixels and all pixels are assumed to be square.

### Parameters

*keyword* is one of the following names:

- mark** Creates a masking image for a single particle, which is specified by an internal (seed) pixel using the /L flag. The masking image is stored in the wave M\_ParticleMarker, which is an unsigned char wave. All points in M\_ParticleMarker are set to 64 (image operations on binary waves use the value 64 to designate the equivalent of NaN) except points in the particle which are set to the 0. This wave is designed to be used as an overlay on the original image (using the explicit=1 mode of ModifyImage). This keyword is superseded by the **ImageSeedFill** operation.
- stats** Measures the particles in the image. See **ImageAnalyzeParticles Stats** on page V-363 for details.

### Flags

- /A=*minArea*** Specifies a minimum area as a threshold that must be exceeded for a particle to be counted (e.g., use *minArea*=0 to find single pixel particles). The minimum area is measured in pixels; its default value is *minArea*=5.  
When the source wave is 3D, *minArea* specifies the minimum number of voxels that constitute a particle.  
*/A* has no effect when used with the *mark* method.
- /B** Erases a 1 pixel wide frame inset from the boundary. This insures that no particles will have boundary pixels (see /EBPC below) and all boundary waves will describe close contours.
- /CIRC={*minCircularity,maxCircularity*}**  
Use this flag to filter the output so that only particles in the range of the specified circularity are counted.
- /D=*dataWave*** Specify a wave from which the minimum, maximum, and total particle intensity are sampled when used with the stats keyword. *dataWave* must be of the same dimensions as the input binary image *imageMatrix*. It can be of any real numeric type. Results are returned in the waves W\_IntMax, W\_IntMin, and W\_IntAvg.
- /E** Calculates an ellipse that best fits each particle. The equivalent ellipse is calculated by first finding the moments of the particle (i.e., average x-value, average y-value, average  $x^2$ , average  $y^2$ , and average  $x*y$ ), and then requiring that the area of the ellipse be equal to that of the particle. The resulting ellipses are saved in the wave M\_Moments. When *imageMatrix* is a 2D wave, the results returned in M\_Moments are the columns: the X-center of the ellipse, the Y-center of the ellipse, the major axis, the minor axis, and the angle (radians) that the major axis makes with the X-direction. When *imageMatrix* is a 3D wave, the results in M\_Moments include the sum of the X, Y, and Z components as well as all second order permutations of their products. They are arranged in the order: sumX, sumY, sumZ, sumXX, sumYY, sumZZ, sumXY, sumXZ, and sumYZ.

## ImageAnalyzeParticles

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/EBPC</code>         | Use this flag to exclude from counting any particle that has one or more pixels on any boundary of the image.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>/F</code>            | Fills 2D particles having internal holes and adjusts their area measure for the removal of holes. Internal boundaries around the holes are also eliminated. When the boundary of the particle consists of thin elements that cannot be traversed as a single closed path which passes each boundary pixel only once, the particle will not be filled. Note that filling particles may increase execution time considerably and on some images it may require large amount of memory. It is likely that a more efficient approach would be to preprocess the binary image and remove holes using morphology operations. This flag is not supported when <i>imageMatrix</i> is a 3D wave.        |
| <code>/FILL</code>         | Use <code>/FILL</code> to fill holes inside particles. The reported values of area and perimeter are computed as if there are no holes. The filling algorithm could fail if, for example, there is a closed contour of zeros around the particles.<br>If you specify both <code>/F</code> and <code>/FILL</code> the operation used <code>/FILL</code> only.<br>Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                        |
| <code>/L=(row,col)</code>  | Specifies a 2D particle location in connection with the mark method. ( <i>row, col</i> ) is a seed value corresponding to any pixel inside the particle. If the seed belongs to the particle boundary, the particle will not be filled. This flag is not supported when <i>imageMatrix</i> is a 3D wave.                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>/M=markerVal</code>  | Use this flag with the stats mode for 2D images. See <b>stats</b> keyword for a full description of the following waves:<br><i>markerVal</i> =0: No marker waves.<br><i>markerVal</i> =1: M_ParticlePerimeter.<br><i>markerVal</i> =2: M_ParticleArea.<br><i>markerVal</i> =3: M_Particle.<br>This flag does not apply to 3D waves.                                                                                                                                                                                                                                                                                                                                                            |
| <code>/MAXA=maxArea</code> | Specifies an upper limit of the area of an acceptable particle when used with the stats keyword. The area is measured in pixels and the default value of <i>maxArea</i> is the number of pixels in the image. In 3D the maximum value applies to the number of voxels.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>/NSW</code>          | Creates the marker wave (see <code>/M</code> flag) but not the particle statistics waves when used with the stats keyword. This should reduce execution time in images containing many particles.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>/P=plane</code>      | Specifies the plane when operating on a single layer of a 3D wave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>/PADB</code>         | Use this flag with the stats keyword to pad the image with a 1 pixel wide background. This has the effect that particles touching the image boundary are now interior particles with closed perimeter (that extend one pixel beyond the original image frame). In addition, entries in the wave <i>W_ObjPerimeter</i> will be longer for all boundary particles which will also affect other derived parameters such as circularity.<br><code>/PADB</code> is different from <code>/B</code> in that it takes into account all pixels belonging to the particle that lie on the boundary of the image. The two flags are mutually exclusive.<br><code>/PADB</code> was added in Igor Pro 7.00. |
| <code>/PDLG</code>         | Displays a progress dialog.<br><code>/PDLG</code> is useful when you are processing very large 3D images. The progress dialog provides feedback and allows the user to abort the operation.<br><code>/PDLG</code> was added in Igor Pro 9.00.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>/Q</code>            | Quiet flag, does not report the number of particles to the history area.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /R= <i>roiWave</i> | Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u) that has the same number of rows and columns as <i>imageMatrix</i> . The ROI itself is defined by the entries or pixels in the <i>roiWave</i> with value of 0. Pixels outside the ROI may have any nonzero value. The ROI does not have to be contiguous. When <i>imageMatrix</i> is a 3D wave, <i>roiWave</i> can be either a 2D wave (matching the number of rows and columns in <i>imageMatrix</i> ) or it can be a 3D wave that must have the same number of rows, columns and layers as <i>imageMatrix</i> . When using a 2D <i>roiWave</i> with a 3D <i>imageMatrix</i> the ROI is understood to be defined by <i>roiWave</i> for each layer in the 3D wave.<br><br>See <b>ImageGenerateROIMask</b> for more information on creating 2D ROI waves. |
| /U                 | Saves the wave M_ParticleMarker as an 8-bit unsigned instead of the default 16-bit when used with the mark keyword.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| /W                 | Creates boundary waves W_BoundaryX, W_BoundaryY, and W_BoundaryIndex for a 2D <i>imageMatrix</i> wave. W_BoundaryX and W_BoundaryY contain the pixels along the particle boundaries. The boundary of each particle ends with a NaN entry in both waves. Each entry in W_BoundaryIndex is the index to the start of a new particle in W_BoundaryX and W_BoundaryY, so that you can quickly locate the boundary of each particle.<br><br>When there are holes in particles, the entries in W_BoundaryX and W_BoundaryY start with the external boundary followed by all the internal boundaries for that particle. There are no index entries for internal boundaries.<br><br>This flag is not supported when <i>imageMatrix</i> is a 3D wave.                                                                                                             |

### Details

Particle analysis is accomplished by first converting the data from its original format into a binary representation where the particle is designated by zero and the background by any nonzero value. The algorithm searches for the first pixel or voxel that belongs to a particle and then grows the particle from that seed while keeping count of the area, perimeter and count of pixels or voxels in the particle. If you use additional flags, the algorithm must compute additional quantities for each pixel or voxel belonging to the particle.

If your goal is to mask only the particle, a more efficient approach is to use the **ImageSeedFill** operation, which similarly follows the particle but does not spend processing time on computing unrelated particle properties. ImageSeedFill also has the additional advantage of not requiring that the input wave be binary, which will save time on performing the initial threshold and, in fact, may produce much better results with the adaptive/fuzzy features that are not available in ImageAnalyzeParticles.

### ImageAnalyzeParticles Stats

The ImageAnalyzeParticles stats keyword measures the particles in the image. Results of the measurements are reported for all particles whose area exceeds the *minArea* specified by the /A flag. The results of the measurements are:

|                     |                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_NumParticles      | Number of particles that exceed the <i>minArea</i> limit.                                                                                                                                                                                                                                                                                                                                      |
| W_ImageObjArea      | Area (in pixels) for each particle.                                                                                                                                                                                                                                                                                                                                                            |
| W_ImageObjPerimeter | Perimeter (in pixels) of each particle. The perimeter calculation involves estimates for 45-degree pixel edges resulting in noninteger values.                                                                                                                                                                                                                                                 |
| W_circularity       | Ratio of the square of the perimeter to ( $4*\pi*$ objectArea). This value approaches 1 for a perfect circle.                                                                                                                                                                                                                                                                                  |
| W_rectangularity    | Ratio of the area of the particle to the area of the inscribing (nonrotated) rectangle. This ratio is $\pi/4$ for a perfectly circular object and unity for a nonrotated rectangle.                                                                                                                                                                                                            |
| W_SpotX and W_SpotY | Contain a single x, y point from each object. There is one entry per particle and the entries follow the same order as all other waves created by this operation. Each (x,y) point from these waves can be used to define the position of a tag or annotation for a particle. Points can also be used as seed pixels for the associated <i>mark</i> method or for the ImageSeedFill operation. |

## ImageBlend

---

`W_xmin, W_xmax, W_ymin, W_ymax`

Contain a single point for each particle defining an inscribing rectangular box with axes along the X and Y directions.

One of the following waves can be created depending on the `/M` specification. The waves are designed to be used as an overlay on the original image (using the `explicit=1` mode of **ModifyImage**). **Note:** the additional time required to create these waves is negligible compared with the time it takes to generate the stats data.

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>M_ParticlePerimeter</code> | Masking image of particle boundaries. It is an unsigned char wave that contains 0 values for the object boundaries and 64 for all other points.                                                                                                                                                                                                                                                                                                                                   |
| <code>M_ParticleArea</code>      | Masking image of the area occupied by the particles. It is an unsigned char wave containing 0 values for the object boundaries and 64 for all other points. It is also different from the input image in that particles smaller than the minimum size, specified by <code>/A</code> , are absent.                                                                                                                                                                                 |
| <code>M_Particle</code>          | Image of both the area and the boundary of the particles. It is an unsigned char wave that contains the value 16 for object area, the value 18 for the object boundaries and the value 64 for all other points.                                                                                                                                                                                                                                                                   |
| <code>M_rawMoments</code>        | Contains five columns. The first column is the raw sum of the x values for each particle, and the second column contains the sum of the y values. To obtain the average or "center" of a particle divide these values by the corresponding area. The third column contains the sum of $x^2$ , the fourth column the sum of $y^2$ , and the fifth column the sum of $x*y$ . The entries of this wave are used in calculating a fit to an ellipse (using the <code>/E</code> flag). |

When *imageMatrix* is a 3D wave, the different results are packed into a single 2D wave `M_3DParticleInfo`, which consists of one row and 11 columns for each particle. Columns are arranged in the following order: `minRow, maxRow, minCol, maxCol, minLayer, maxLayer, xSeed, ySeed, zSeed, volume, and area`. Use `Edit M_3DParticleInfo.lid` to display the results in a table with dimension labels describing the different columns.

### Examples

Convert a grayscale image (blobs) into a proper binary input:

```
ImageThreshold/M=4/Q/I blobs
```

Get the statistics on the thresholded image of blobs and create an image mask output wave for the perimeter of the particles:

```
ImageAnalyzeParticles/M=1 stats M_ImageThresh
```

Display an image of the blobs with a red overlay of the perimeter image:

```
NewImage/F blobs; AppendImage M_ParticlePerimeter
ModifyImage M_ParticlePerimeter explicit=1, eval={0,65000,0,0}
```

## ImageBlend

```
ImageBlend [/A=alpha /W=alphaWave] srcWaveA, srcWaveB [, destWave]
```

The **ImageBlend** operation takes two RGB images (3D waves) in *srcWaveA* and *srcWaveB* and computes the alpha blending so that

$$destWave = srcWaveA * (1 - alpha) + srcWaveB * alpha$$

for each color component. If *destWave* is not specified or does not already exist, the result is saved in the current data folder in the wave `M_alphaBlend`.

The source and destination waves must be of the same data types and the same dimensions. The *alphaWave*, if used, must be a single precision (SP) float wave and it must have the same number of rows and columns as the source waves.

**Flags**

|                     |                                                                     |
|---------------------|---------------------------------------------------------------------|
| <i>/A=alpha</i>     | Specifies a single alpha value for the whole image                  |
| <i>/W=alphaWave</i> | Single precision wave that specifies an alpha value for each pixel. |

**See Also****ImageComposite****ImageBoundaryToMask**

**ImageBoundaryToMask** width=*w*, height=*h*, xwave=*xwavename*, ywave=*ywavename* [, scalingWave=*scalingWaveName*, [seedX=*xVal*, seedY=*yVal*]]

The ImageBoundaryToMask operation scan-converts a pair of XY waves into an ROI mask wave.

**Parameters**

|                                      |                                                                                                                                                                                                                                 |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| height = <i>h</i>                    | Specifies the mask height in pixels.                                                                                                                                                                                            |
| scalingWave = <i>scalingWaveName</i> | 2D or 3D wave that provides scaling for the mask. If specified, the scaling of the first two dimensions of scalingWave are copied to M_ROIMask, and both the X and Y waves are assumed to describe pixels in the scaled domain. |
| seedX = <i>xVal</i>                  | Specifies seed pixel location. The operation fills the region defined by the seed and the boundary with the value 1. Background pixels are set to zero. Requires seedY.                                                         |
| seedY = <i>yVal</i>                  | Specifies seed pixel location. The operation fills the region defined by the seed and the boundary with the value 1. Background pixels are set to zero. Requires seedX.                                                         |
| width = <i>w</i>                     | Specifies the mask width in pixels.                                                                                                                                                                                             |
| xwave = <i>xwavename</i>             | Name of X wave for mask region.                                                                                                                                                                                                 |
| ywave = <i>ywavename</i>             | Name of Y wave for mask region.                                                                                                                                                                                                 |

**Details**

ImageBoundaryToMask generates an unsigned char 2D wave named M\_ROIMask, of dimensions specified by width and height. The wave consists of a background pixels that are set to 0 and pixels representing the mask that are set to 1.

The x and y waves can be of any type. However, if the waves describe disjoint regions there must be at least one NaN entry in each wave corresponding to the discontinuity, which requires that you use either single or double precision waves. The values stored in the waves must correspond to zero-based integer pixel values.

If the x and y waves include a vertex that lies outside the mask rectangle, the offending vertex is moved to the boundary before the associated line segment is scan converted.

If you want to obtain a true ROI mask in which closed regions are filled, you can specify the seedX and seedY keywords. The ROI mask is set with zero outside the boundary of the domain and 1 everywhere inside the domain.

**Examples**

```
Make/O/N=(100,200) src=gnoise(5) // create a test image
SetScale/P x 500,1,"", src;DelayUpdate // give it some funny scaling
SetScale/P y 600,1,"", src
Display; AppendImage src
Make/O/N=201 xxx,yyy // create boundary waves
xxx=550+25*sin(p*pi/100) // representing a close ellipse
yyy=700+35*cos(p*pi/100)
AppendToGraph yyy vs xxx
```

Now create a mask from the ellipse and scale it so that it will be appropriate for src:

```
ImageBoundaryToMask ywave=yyy,xwave=xxx,width=100,height=200,scalingwave=src
```

## ImageComposite

---

To generate an ROI masked filled with 1 in a region defined by a seed value and the boundary curves:

```
ImageBoundaryToMask
 ywave=yyy, xwave=xxx, width=100, height=200, scalingwave=src, seedx=550, seedy=700
```

### See Also

The **ImageAnalyzeParticles** and **ImageSeedFill** operations. For another example see **Converting Boundary to a Mask** on page III-378.

## ImageComposite

**ImageComposite** [/Z /FREE /DEST=*destWave*] *srcImageA*, *srcImageB*

The ImageComposite operation creates a new image by combining *srcImageA* and *srcImageB* subject to one of 12 Porter-Duff compositing modes.

The ImageComposite operation was added in Igor Pro 8.00.

### Flags

|                       |                                                                                                                                                                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/AALP=aWave</i>    | Specifies a 2D single-precision wave as the alpha associated with <i>srcImageA</i> . Alpha values are in the range 0 (transparent) to 1 (opaque).                                                                                |
| <i>/ACON=a1</i>       | Specifies a single alpha value for the whole <i>srcImageA</i> . <i>a1</i> is in the range 0 (transparent) to 1 (opaque).                                                                                                         |
| <i>/BALP=aWave</i>    | Specifies a 2D single-precision wave as the alpha associated with <i>srcImageB</i> . Alpha values are in the range 0 (transparent) to 1 (opaque).                                                                                |
| <i>/BCON=a1</i>       | Specifies a single alpha value for the whole <i>srcImageB</i> . <i>a1</i> is in the range 0 (transparent) to 1 (opaque).                                                                                                         |
| <i>/DEST=destWave</i> | Specifies the wave to hold the composite image. If you omit <i>/DEST</i> the operation stores the image in the wave <i>M_ImageComposite</i> in the current data folder.                                                          |
| <i>/FREE</i>          | Creates output wave as free waves.<br><br><i>/FREE</i> is permitted in user-defined functions only, not from the command line or in macros.<br><br>If you use <i>/FREE</i> then <i>destWave</i> must be simple name, not a path. |
| <i>/NMOD=mode</i>     | Selects one of the 12 Porter-Duff compositing modes. <i>mode</i> is a value from 1 to 12. The default is <i>mode=4</i> corresponding to "A over B". See <b>Compositing Modes</b> on page V-366.                                  |
| <i>/OUT=layers</i>    | Specifies the number of layers of the output image. Valid values are 3 (RGB) or 4 (RGBA). By default the operation creates an RGB image.                                                                                         |
| <i>/PMA=pmState</i>   | Set <i>pmState</i> to 1 if the RGB components in <i>srcImageA</i> are pre-multiplied. Use <i>pmState=0</i> otherwise. By default <i>srcImageA</i> is assumed to be pre-multiplied. See <b>Pre-multiplication</b> on page V-366.  |
| <i>/PMB=pmState</i>   | Set <i>pmState</i> to 1 if the RGB components in <i>srcImageB</i> are pre-multiplied. Use <i>pmStates=0</i> otherwise. By default <i>srcImageB</i> is assumed to be pre-multiplied. See <b>Pre-multiplication</b> on page V-366. |
| <i>/Z</i>             | No error reporting. The operation sets <i>V_Flag</i> to 0 if it succeeds or to an error code otherwise. You can use <b>GetErrorMessage</b> to obtain a description of the error.                                                 |

### Pre-multiplication

An RGB value can be raw or pre-multiplied. "Pre-multiplied" means that the red, green, and blue values have been multiplied by normalized alpha values in the range 0 (transparent) to 1 (opaque). ImageComposite operation is faster when working with pre-multiplied values. ImageComposite assumes that your RGB values are pre-multiplied unless you specify otherwise using */PMA=0* and */PMB=0*.

### Compositing Modes

Here are the 12 compositing modes supported by ImageComposite:

### Details

ImageComposite computes an output RGB or RGBA image that result from compositing *srcImageA* and *srcImageB* using one of the Porter-Duff compositing modes shown in the table above. The waves *srcImageA* and *srcImageB* must have the same number of pixels and the same number type.

Supported number types are: unsigned char, unsigned short, unsigned int, single precision floating point and double precision floating point. When using integer waves expected alpha values are in the range  $[0, 2^N - 1]$  where  $N$  is the number of bits of the number type. Floating point waves should include alpha in the range  $[0, 1]$ .

There are three options to specify the alpha associated with each image:

1. The alpha can be expressed as the 4th layer in the wave.
2. The alpha can be specified by a single-precision wave that has the same number of pixels as the image using the /AALP and /BALP flags.
3. The alpha can be specified by a single number in the range  $[0, 1]$  using the /ACON and /BCON flags.

Options 2 and 3 cannot override an alpha channel that is present in a source wave. To use these options you must delete the alpha channel in the source wave, if any.

### Example

```
Function SetupImageCompositeDemo() // Setup - Create two sample images
 Make/O/N=(128,128,4)/B/U imageA=0, imageB=0
 imageA[0,64][][0]=255
 imageA[0,64][][3]=128
 NewImage/S=0/N=imageAW imageA
 imageB[][0,64][1]=255
 imageB[][0,64][3]=128
 NewImage/S=0/N=imageBW imageB
 AutoPositionWindow/M=0/R=imageAW imageBW
End

Function CompositeAOverB() // Composite A over B
 Wave imageA, imageB
 ImageComposite/PMA=0/PMB=0/DEST=M_Comp1/NMOD=4 imageA,imageB
 NewImage/S=0/N=comp1 M_Comp1
 AutoPositionWindow/M=0/R=imageBW
End

Function CompositeAInB() // Composite A in B
 Wave imageA, imageB
 ImageComposite/PMA=0/PMB=0/DEST=M_Comp2/NMOD=6 imageA,imageB
 NewImage/S=0/N=comp2 M_Comp2
```

## ImageEdgeDetection

---

```
 AutoPositionWindow/M=0/R=comp1
End
Function RemoveAlphaChannel() // Remove the alpha channel from imageA
 Wave imageA
 Duplicate/R=[] [0,2] imageA, imageA_rgb
 NewImage/S=0 imageA_rgb
End
```

## ImageEdgeDetection

**ImageEdgeDetection** [*flags*] **Method** *imageMatrix*

The ImageEdgeDetection operation performs one of several standard image edge detection operations on the source wave *imageMatrix*.

Unless the /O flag is specified, the resulting image is saved in the wave M\_ImageEdges.

The edge detection methods produce binary images on output; the background is set to 0 and the edges to 255. This is due, in most cases to a thresholding performed in the final stage.

Except for the case of marr and shen detectors, you can use the /M flag to specify a method for automatic thresholding; see the **ImageThreshold** /M flag.

### Parameters

*Method* selects type of edge detection. *Method* is one of the following names:

|         |                                                                                                                                                                                                                                                                                                              |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| canny   | Canny edge detector uses smoothing before edge detection and thresholding. You can optionally specify the threshold using the /T flag and the smoothing factor using /S.                                                                                                                                     |
| frei    | Calculates the Frei-Chen edge operator (see Pratt p. 503) using only the row and column filters.                                                                                                                                                                                                             |
| kirsch  | Kirsch edge detector (see Pratt p. 509). Performs convolution with 8 masks calculating gradients.                                                                                                                                                                                                            |
| marr    | Marr-Hildreth edge detector. Performs two convolutions with Laplacian of Gaussian and then detects zero crossings. Use the /S flag to define the width of the convolution kernel.                                                                                                                            |
| prewitt | Calculates the Prewitt compass gradient filters. Returns the result for the largest filter response.                                                                                                                                                                                                         |
| roberts | Calculates the square root of the magnitude squared of the convolution with the Robert's row and column edge detectors.                                                                                                                                                                                      |
| shen    | Shen-Castan optimized edge detector. Supposed to be effective in the presence of noise. The flags that modify this operation are: /F for the threshold ratio (0.9 by default), /S for smoothness factor (0.9 by default), /W for window width (default is 10), /H for thinning factor which by default is 1. |
| sobel   | Sobel edge detector using convolutions with row and column edge gradient masks (see Pratt p. 501).                                                                                                                                                                                                           |

### Flags

|                     |                                                                                                                                                                                                                                                                                               |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /F= <i>fraction</i> | Determines the threshold value for the shen algorithm by starting from the histogram of the image and choosing a threshold such that <i>fraction</i> specifies the portion of the image pixels whose values are below the threshold. Valid values are in the interval ( $0 < fraction < 1$ ). |
| /H= <i>thinning</i> | Thins edges when used with shen edge detector. By default the thinning value is 1. Higher values produce thinner edges.                                                                                                                                                                       |
| /I                  | Inverts the output, i.e., sets the edges to 255 and the background to 0.                                                                                                                                                                                                                      |

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/M=threshMethod</i> | See the <b>ImageThreshold</b> automatic methods for obtaining a threshold value. Methods 1, 2, 4 and 5 are supported in this operation. If you use <i>threshMethod</i> = -1, threshold is not applied.<br><br>If you want to apply your own thresholding algorithm, use <i>/M=6</i> to bypass the thresholding completely. The wave <i>M_RawCanny</i> contains the result regardless of any other flags you may have used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>/N</i>              | Sets the background level to 64 (i.e., NaN)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>/O</i>              | Overwrites the source image with the output image.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>/P=layer</i>        | Applies the operation to the specified layer of a 3D wave.<br><i>/P</i> is incompatible with <i>/O</i> .<br><i>/P</i> was added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>/R=roiSpec</i>      | Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte ( <i>/b/u</i> ). The ROI wave must have the same number of rows and columns as the image wave. The ROI itself is defined by entries/pixels whose values are 0. Pixels outside the ROI can be any nonzero value. The ROI does not have to be contiguous and can be any arbitrary shape. See <b>ImageGenerateROIMask</b> for more information on creating ROI waves.<br><br>In general, the <i>roiSpec</i> has the form { <i>roiWaveName</i> , <i>roiFlag</i> }, where <i>roiFlag</i> can take the following values:<br><i>roiFlag</i> =0: Set pixels outside the ROI to 0.<br><i>roiFlag</i> =1: Set pixels outside the ROI as in original image.<br><i>roiFlag</i> =2: Set pixels outside the ROI to NaN (=64).<br><br>By default <i>roiFlag</i> is set to 1 and it is then possible to use the <i>/R</i> flag using the abbreviated form <i>/R=roiWave</i> . |
| <i>/S=smoothVal</i>    | Specifies the standard deviation or the width of the smoothing filter. By default the operation uses 1. Larger values require longer computation time. In the shen operation the default value is 0.9 and the valid range is ( $0 < \textit{smoothVal} < 1$ ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>/T=thresh</i>       | Sets a manual threshold for any method above that uses a single threshold. This is faster than using <i>/M</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>/W=width</i>        | Specifies window width when used in the shen operation. By default width is set to 10 and it is clipped to 49.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### ImageFileInfo

**ImageFileInfo** [/P=*pathName*] *fileNameStr*

ImageFileInfo is no longer supported and always returns an error.

It is obsolete because it used QuickTime to obtain graphics file information and Apple is phasing out QuickTime.

### ImageFilter

**ImageFilter** [*flags*] **Method** *dataMatrix*

The ImageFilter operation is identical to **MatrixFilter**, accepting the same parameters and flags, with the exception of the additional features described below.

#### Parameters

*Method* selects the filter type. *Method* is one of the following names:

|              |                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| avg3d        | <i>n</i> × <i>n</i> × <i>n</i> average filter for 3D waves.                                                                                                                                                                                                                                                                                                       |
| gauss3d      | <i>n</i> × <i>n</i> × <i>n</i> gaussian filter for 3D waves.                                                                                                                                                                                                                                                                                                      |
| hybridmedian | Implements ranking pixel values between two groups of pixels in a 5×5 neighborhood. The first group includes horizontal and vertical lines through the center, the second group includes diagonal lines through the center, and both groups include the center pixel itself. The resulting median value is the ranked median of both groups and the center pixel. |
| max3d        | <i>n</i> × <i>n</i> × <i>n</i> maximum rank filter for 3D waves.                                                                                                                                                                                                                                                                                                  |
| median3d     | <i>n</i> × <i>n</i> × <i>n</i> median filter for 3D waves where <i>n</i> must be of the form 3 <sup><i>r</i></sup> (integer <i>r</i> ), e.g., 3×3×3, 9×9×9 etc. The filter does not change the value of the voxel it is centered on if any of the filter voxels lies outside the domain of the data.                                                              |
| min3d        | <i>n</i> × <i>n</i> × <i>n</i> minimum rank filter for 3D waves.                                                                                                                                                                                                                                                                                                  |
| point3d      | <i>n</i> × <i>n</i> × <i>n</i> point finding filter using normalized $(n^3 - 1) * center - outer$ for 3D waves.                                                                                                                                                                                                                                                   |

#### Flags

|              |                                                                                                                                                                            |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /N= <i>n</i> | Specifies the filter size. By default <i>n</i> =3. In most situations it will be useful to set <i>n</i> to an odd number in order to preserve the symmetry in the filters. |
| /O           | Overwrites the source image with the output image. Used only with the hybridmedian filter, which does not automatically overwrite the source wave.                         |

#### Details

You can operate on 3D waves using the 3D filters listed above. These filters are extensions of the 2D filters available under MatrixFilter. The avg3d, gauss3d, and point3d filters are implemented by a 3D convolution that uses an averaging compensation at the edges.

This operation does not support complex waves.

## ImageFocus

**ImageFocus** [*flags*] *stackWave*

The ImageFocus operation creates in focus image(s) from a stack of images that contain in and out of focus regions. It computes the variance in a small neighborhood around each pixel and then takes the pixel value from the plane in which the highest variance is found.

### Flags

|                     |                                                                                                                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/ED=edepth</i>   | Sets the effective depth in planes. For example, an effective depth of one means that it computes the best focus for each plane using a stack of three planes, which includes the current plane and any one adjacent plane above and below it. Does not affect the default method ( <i>/METH=0</i> ). |
| <i>/METH=method</i> | Specifies the calculation method.<br><i>method=0</i> : Computes a single plane output for the stack (default).<br><i>method=1</i> : Computes the best image for each plane using <i>/ED</i> .                                                                                                         |
| <i>/Q</i>           | Quiet mode; no output to history area.                                                                                                                                                                                                                                                                |
| <i>/Z</i>           | No error reporting.                                                                                                                                                                                                                                                                                   |

## ImageFromXYZ

**ImageFromXYZ** [*flags*] *xyzWave*, *dataMatrix*, *countMatrix*

**ImageFromXYZ** [*flags*] {*xWave*, *yWave*, *zWave*}, *dataMatrix*, *countMatrix*

ImageFromXYZ converts XYZ data to matrix form. You might use it, for example, to convert a "sparse matrix" to an actual matrix for easier display and processing.

You provide the input data in the XYZ triplet *xyzWave* or in 1D waves *xwave*, *ywave*, and *zwave*.

*dataMatrix* and *countMatrix* receive output data but you must create them prior to calling ImageFromXYZ.

For each XY location in the input data, ImageFromXYZ adds the corresponding Z value to an element of *dataMatrix*. The element is determined based on the input XY location and the X and Y scaling of *dataMatrix*.

For each XY location in the input data, ImageFromXYZ increments the corresponding element of *countMatrix*. This permits you to obtain an average Z value if multiple input values fall into a given element of *dataMatrix*.

### Parameters

*xyzWave* is a triplet wave containing the input XYZ data.

*xWave*, *yWave* and *zWave* are 1D input waves containing XYZ data.

You specify either *xyzWave* by itself or *xWave*, *yWave* and *zWave* in braces.

*dataMatrix* is a 2D wave to which the Z values are added. It must be either single-precision or double-precision floating point. The X and Y scaling of *dataMatrix* determines how input values are mapped to output matrix elements.

*countMatrix* is a 2D wave the elements of which store the number of Z values added to each corresponding element of *dataMatrix*. ImageFromXYZ sets it to 32-bit integer if it is not already so.

### Flags

|            |                                                                                                                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/AS</i> | If <i>/AS</i> (autoscale) is specified, ImageFromXYZ clears both <i>dataMatrix</i> and <i>countMatrix</i> and sets the X and Y scaling of <i>dataMatrix</i> based on the range of X and Y input values. |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Details

For each point in the XYZ input data, ImageFromXYZ adds the Z value to the appropriate element of *dataMatrix* and increments the corresponding element of *countMatrix*. Normally you will clear *dataMatrix* and *countMatrix* before calling it.

## ImageGenerateROIMask

---

You can combine multiple XYZ datasets in one matrix by calling ImageFromXYZ multiple times with different input data and the same *dataMatrix* and *countMatrix*. In this case you would clear *dataMatrix* and *countMatrix* before the first call to ImageFromXYZ only.

What you do with the output is up to you but one technique is to divide *dataMatrix* by *countMatrix* to get the average and then use **MatrixFilter** NanZapMedian to eliminate any NaN values that result from zero divided by zero.

### Example

```
Make /N=1000 /O wx=enoise(2), wy= enoise(2), wz= exp(-(wx^2+wy^2))
Make /O /N=(100,100) dataMat=0
SetScale x,-2,2,dataMat
SetScale y,-2,2,dataMat
Duplicate /O dataMat,countMat
ImageFromXYZ /AS {wx,wy,wz}, dataMat, countMat

// Execute these one at a time
NewImage dataMat
dataMat /= countMat // Replace cumulative z value with average
MatrixFilter NanZapMedian, dataMat // Apply median filter, zapping NaNs
```

## ImageGenerateROIMask

**ImageGenerateROIMask** [/W=*winName*/E=*e*/I=*i*] *imageInstance*

The ImageGenerateROIMask operation creates a Region Of Interest (ROI) mask for use with other ImageXXX commands. It assumes the top (or /W specified) graph contains an image and that the user has drawn shapes using Igor's drawing tools in a specific manner.

ImageGenerateROIMask creates an unsigned byte mask matrix with the same x and y dimensions and scaling as the specified image. The mask is initially filled with zeros. Then the drawing layer, progFront, in the graph is scanned for suitable fillable draw objects. The area inside each shape is filled with ones unless the fill mode for the shape is set to erase in which case the area is filled with zeros.

### Flags

|                    |                                                                                                                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /E= <i>e</i>       | Changes value used for the exterior from the default zero values to <i>e</i> .                                                                                                                                                                                                                                                       |
| /I= <i>i</i>       | Changes value used for the interior from the default one values to <i>i</i> .                                                                                                                                                                                                                                                        |
| /W= <i>winName</i> | Looks for the named graph window or subwindow containing appropriate image masks drawn by the user. If /W is omitted, ImageGenerateROIMask uses the top graph window or subwindow.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |

### Details

To generate an ROI wave for use with most image processing operations you need to set the values of interior pixels to zero and exterior pixels to one using /E=1/I=0.

Suitable objects are those that can be filled (rectangles, ovals, etc.) and which are plotted in axis coordinate mode specified using the same axes by which the specified image instance is displayed. Objects plotted in plot relative mode are also used. However, this is not recommended because it will give correct results only if the image exactly fills the plot rectangle. If you use axis coordinate mode then you can zoom in or out as desired and the resulting mask will still be correct.

Note that the shapes can have their fill mode set to none. This still results in a fill of ones. This is to allow the drawn ROI to be visible on the graph without obscuring the image. However cutouts (fills with erase mode) will obscure the image.

Note also that nonfill drawing objects are ignored. You can use this fact to create callouts and other annotations.

In a future version of Igor, we may create a new drawing layer in graphs dedicated to ROIs.

The mask generated is named M\_ROIMask and is generated in the current data folder.

Variable `V_flag` is set to 1 if the top graph contained draw objects in the correct layer and 0 if not. If 0 then the `M_ROIMask` wave was not generated.

### Examples

```
Make/O/N=(200,400) jack=x*y; NewImage jack; ShowTools
SetDrawLayer ProgFront
SetDrawEnv linefgc=(65535,65535,0), fillpat=0, xcoord=top, ycoord=left, save
DrawRect 63.5,79.5,140.5,191.5
DrawRRect 61.5,206.5,141.5,280.5
SetDrawEnv fillpat= -1
DrawOval 80.5,169.5,126.5,226.5
ImageGenerateROIMask jack
NewImage M_ROIMask
AutoPositionWindow/E
```

For another example see **Generating ROI Masks** on page III-378.

## ImageGLCM

**ImageGLCM** [*flags*] *srcWave*

The ImageGLCM operation calculates the gray-level co-occurrence matrix for an 8-bit grayscale image and optionally evaluates Haralick's texture parameters.

The ImageGLCM operation was added in Igor Pro 7.00.

### Flags

*/D=distance* Sets the offset in pixels for which the co-occurrence matrix is calculated. The default value is 1.

*/DEST=destGLCM* Specifies the wave to hold the co-occurrence matrix. If you omit */DEST* the operation stores the matrix in the wave `M_GLCM` in the current data folder.

*/DETP=destParamWave*

Specifies the wave to hold the computed texture parameters. If you omit */DETP* the operation stores the texture parameters in the wave `W_TextureParams` in the current data folder.

If the destination wave already exists it is overwritten. Note that you must specify the */HTFP* flag to compute the texture parameters.

*/E=structureBits* *structureBits* is a bitwise setting that lets you control the combination of co-occurrences that you want to compute.

Consider a wave displayed in a table and a pixel at position `x`

|   |          |   |
|---|----------|---|
| 0 | 3        | 5 |
| 1 | <i>x</i> | 6 |
| 2 | 4        | 7 |

The *structureBits* corresponding to co-occurrence between `x` and any direction is simply  $2^{\text{direction}}$ . By default the operation computes all combinations. This is equivalent to *structureBits*=255.

Note that the *structureBits* only define directions. The combination of the distance (*/D*) and the *structureBits* define the full co-occurrence calculation.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

|          |                                                                                                                                                                                                                                                                                                        |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /FREE    | Creates output waves as free waves.<br>/FREE is permitted in user-defined functions only, not from the command line or in macros.<br>If you use /FREE then <i>destGLCM</i> and <i>destParamWave</i> must be simple names, not paths.<br>See <b>Free Waves</b> on page IV-90 for details on free waves. |
| /HTFP    | Computes Haralick's texture parameters. See the discussion in the Details section below for more information about the texture parameters.                                                                                                                                                             |
| /P=plane | If the image consists of more than one plane you can use this flag to determine which plane in <i>srcWave</i> is analysed. By default it is plane zero.                                                                                                                                                |
| /Z       | No error reporting.                                                                                                                                                                                                                                                                                    |

## Details

ImageGLCM computes the co-occurrence matrix for the image in *srcWave* and optionally evaluates Haralick's texture parameters. The operation supports 8-bit grayscale images and generates a 256x256 single-precision floating point co-occurrence matrix.

The elements of the matrix  $P[i][j]$  are defined as the normalized number of pixels that have a spatial relationship defined by the distance ( $D$ ) and the structure ( $E$ ) such that the first pixel has gray-level  $i$  and the second pixel has gray-level  $j$ . The matrix is normalized so that the sum of all its elements is 1.

If you specify the /HTFP flag the operation computes the 13 Haralick texture parameters and stores them sequentially in the destination wave (see /DETP). The wave is saved with dimension labels defining each element. The expressions for the texture parameters are:

$$f_1 = \sum_i \sum_j (p[i][j])^2,$$

$$f_2 = \sum_{n=0}^{254} n^2 \left\{ \sum_{\substack{i=0 \\ |i-j|=n}}^{255} \sum_{j=0}^{255} p[i][j] \right\},$$

$$f_3 = \sum_i \sum_j \frac{(i - \mu_x)(j - \mu_y)p[i][j]}{\sigma_x \sigma_y},$$

$$f_4 = \sum_i \sum_j (i - \mu)^2 p[i][j],$$

$$f_5 = \sum_i \sum_j \frac{1}{1 + (i - j)^2} p[i][j],$$

$$f_6 = \sum_i ip_{x+y}(i),$$

$$f_7 = \sum_i (i - f_6)^2 p_{x+y}(i),$$

$$f_8 = -\sum_i p_{x+y}(i) \log(p_{x+y}(i)),$$

$$f_9 = -\sum_i \sum_j p[i][j] \log(p[i][j]),$$

$$f_{10} = \text{Variance}(p_{x-y}),$$

$$f_{11} = \sum_i p_{x-y}(i) \log(p_{x-y}(i)),$$

$$f_{12} = \frac{f_9 - HXY1}{\max(HX, HY)},$$

$$f_{13} = \sqrt{1 - \exp(-2(HXY2 - f_9))}.$$

Here

$$p_x(i) = \sum_j p[i][j], \quad p_y(j) = \sum_i p[i][j],$$

$$\mu_x = \sum_i i p_x(i), \quad \mu_y = \sum_i i p_y(i), \quad \mu = (\mu_x + \mu_y) / 2.$$

$$\sigma_x = \sqrt{\sum_i (1 - \mu_x)^2 p_x(i)}, \quad \sigma_y = \sqrt{\sum_i (1 - \mu_y)^2 p_y(i)},$$

$$p_{x+y}(k) = \sum_i \sum_{\substack{j \\ i+j=k}} p[i][j],$$

$$p_{x-y}(k) = \sum_i \sum_{\substack{j \\ |i-j|=k}} p[i][j],$$

$$HXY1 = -\sum_i \sum_j p[i][j] \log(p_x(i)p_y(j)),$$

$$HXY2 = -\sum_i \sum_j p_x(i)p_y(j) \log(p_x(i)p_y(j)),$$

$$HX = -\sum_i p_x(i) \log(p_x(i)), \quad HY = -\sum_i p_y(i) \log(p_y(i)).$$

There are at least two versions of *f7* used in the literature and in software. We know of at least three versions of *f14* so ImageGLCM does not compute it.

## ImageHistModification

**ImageHistModification** [*flags*] *imageMatrix*

The ImageHistModification operation performs a modification of the image histogram and saves the results in the wave *M\_ImageHistEq*. If */W* is not specified, the operation is a simple histogram equalization of *imageMatrix*. If */W* is specified, the operation attempts to produce an image with a histogram close to *waveName*. If */A* is specified, the operation performs an adaptive histogram equalization. *imageMatrix* is a wave of any noncomplex numeric type. Adaptive histogram equalization applies only to 2D waves and the other parts apply to both 2D and 3D waves.

### Flags

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/A</i>          | Performs an adaptive histogram equalization by subdividing the image into a minimum of 4 rectangular domains and using interpolation to account for the boundaries between adjacent domains. When the <i>/C</i> flag is specified with contrast factor greater than 1, this operation amounts to contrast-limited adaptive histogram equalization. By default the operation divides the image into 8 horizontal and 8 vertical regions. See <i>/H</i> and <i>/V</i> . |
| <i>/B=bins</i>     | Specifies the number of <i>bins</i> used with the <i>/A</i> flag. If not specified, this value defaults to 256.                                                                                                                                                                                                                                                                                                                                                       |
| <i>/C=cFactor</i>  | Specifies a contrast factor (or clipping value) above which pixels are equally distributed over the whole range. <i>cFactor</i> must be greater than 1, in the limit as <i>cFactor</i> approaches 1 the operation is a regular adaptive histogram equalization. <b>Note:</b> this flag is used only with the <i>/A</i> flag.                                                                                                                                          |
| <i>/H=hRegions</i> | Specifies the number of horizontal subdivisions to be used with the <i>/A</i> feature. Note, the number of image pixels in the horizontal direction must be an integer multiple of <i>hRegions</i> .                                                                                                                                                                                                                                                                  |
| <i>/I</i>          | Extends the standard histogram equalization by using $2^{16}$ bins instead of $2^8$ when calculating histogram equalization. This feature does not apply to the adaptive histogram equalization ( <i>/A</i> flag).                                                                                                                                                                                                                                                    |
| <i>/O</i>          | Overwrites the source image. If this flag is not specified, the resulting image is saved in the wave <i>M_ImageHistEq</i> .                                                                                                                                                                                                                                                                                                                                           |

*/R=roiSpec* Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (*/b/u*). The ROI wave must have the same number of rows and columns as *imageMatrix*. The ROI itself is defined by the entries whose values are 0. Regions outside the ROI can take any nonzero value. The ROI does not have to be contiguous and can take any arbitrary shape.

In general, the *roiSpec* has the form *{roiWaveName, roiFlag}*, where *roiFlag* can take the following values:

*roiFlag=0*: Set pixels outside the ROI to 0.

*roiFlag=1*: Set pixels outside the ROI as in original image (default).

*roiFlag=2*: Set pixels outside the ROI to NaN (=64).

By default *roiFlag* is set to 1 and it is then possible to use the */R* flag with the abbreviated form */R=roiWave*. When *imageMatrix* is a 3D wave, *roiWave* can be either a 2D wave (matching the number of rows and columns in *imageMatrix*) or it can be a 3D wave which must have the same number of rows, columns, and layers as *imageMatrix*. When using a 2D *roiWave* with a 3D *imageMatrix*, the ROI is understood to be defined by *roiWave* for each layer in the 3D wave.

See **ImageGenerateROIMask** for more information on creating ROI waves.

*/N=vRegions* Specifies the number of vertical subdivisions to be used with the */A* flag. The number of image pixels in the horizontal direction must be an integer multiple of *vRegions*. If the image dimensions are not divisible by the number of regions that you want, you can pad the image using ImageTransform **padImage**.

*/W=waveName* Specifies a 256-point wave that provides the desired histogram. The operation will attempt to produce an image having approximately the desired histogram values. This flag does not apply to the adaptive histogram equalization (*/A* flag)

## ImageHistogram

**ImageHistogram** [*flags*] *imageMatrix*

The ImageHistogram operation calculates the histogram of *imageMatrix*. The results are saved in the wave *W\_ImageHist*. If *imageMatrix* is an RGB image stored as a 3D wave, the resulting histograms for each color plane are saved in *W\_ImageHistR*, *W\_ImageHistG*, *W\_ImageHistB*.

*imageMatrix* must be a real-valued numeric wave.

#### Flags

*/I* Calculates a histogram with 65536 bins evenly distributed between the minimum and maximum data values. The operation first finds the extrema and then calculates the bins and the resulting histogram. Data can be a 2D wave of any type including float or double.

*/P=plane* Restricts the calculation of the histogram to a specific plane when *imageMatrix* is a non RGB 3D wave.

## ImageInfo

---

- /R=roiWave* Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (*/b/u*) that has the same number of rows and columns as *imageMatrix*. The ROI itself is defined by the entries of pixels in the *roiWave* with value of 0. Pixels outside the ROI may have any nonzero value. The ROI does not have to be contiguous. When *imageMatrix* is a 3D wave, *roiWave* can be either a 2D wave (matching the number of rows and columns in *imageMatrix*) or it can be a 3D wave that must have the same number of rows, columns and layers as *imageMatrix*. When using a 2D *roiWave* with a 3D *imageMatrix* the ROI is understood to be defined by *roiWave* for each layer in the 3D wave.
- See **ImageGenerateROIMask** for more information on creating 2D ROI waves.
- /S* Computes the histogram for a whole 3D wave possibly subject to 2D or 3D ROI masking. The */S* and */P* flags are mutually exclusive.

### Details

The ImageHistogram operation works on images, but it handles both 2D and 3D waves of any data type. Unless you use one of the special features of this operation (e.g., ROI or */P* or */I*) you could alternatively use the **Histogram** operation, which computes the histogram for the full wave and includes additional options for controlling the number of bins.

If the data type of *imageMatrix* is single byte, the histogram will have 256 bins from 0 to 255. Otherwise, the 256 bins will be distributed between the minimum and maximum values encountered in the data. Use the */I* flag to increase the number of bins to 65536, which may be useful for unsigned short (*/W/U*) data.

## ImageInfo

**ImageInfo**(*graphNameStr*, *imageWaveNameStr*, *instanceNumber*)

The ImageInfo function returns a string containing a semicolon-separated list of information about the specified image in the named graph window or subwindow.

### Parameters

*graphNameStr* can be "" to refer to the top graph.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

*imageWaveNameStr* contains either the name of a wave displayed as an image in the named graph, or an image instance name (wave name with "#n" appended to distinguish the nth image of the wave in the graph). You might get an image instance name from the **ImageNameList** function.

If *imageWaveNameStr* contains a wave name, *instanceNumber* identifies which instance you want information about. *instanceNumber* is usually 0 because there is normally only one instance of a wave displayed as an image in a graph. Set *instanceNumber* to 1 for information about the second image of the wave, etc. If *imageWaveNameStr* is "", then information is returned on the *instanceNumber*th image in the graph.

If *imageWaveNameStr* contains an instance name, and *instanceNumber* is zero, the instance is taken from *imageWaveNameStr*. If *instanceNumber* is greater than zero, the wave name is extracted from *imageWaveNameStr*, and information is returned concerning the *instanceNumber*th instance of the wave.

## Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon for ease of use with **StringByKey**. The keywords are as follows:

| Keyword    | Information Following Keyword                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AXISFLAGS  | Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| COLORMODE  | A number indicating how the image colors are derived: <ol style="list-style-type: none"> <li>1: Color table (see <b>Image Color Tables</b> on page II-380).</li> <li>2: Scaled color index wave (see <b>Indexed Color Details</b> on page II-388).</li> <li>3: Point-scaled color index (See <b>Example: Point-Scaled Color Index Wave</b> on page II-389).</li> <li>4: Direct color (see <b>Direct Color Details</b> on page II-389).</li> <li>5: Explicit Mode (see <b>ModifyImage</b> explicit keyword).</li> <li>6: Color table wave (see <b>Color Table Waves</b> on page II-387).</li> </ol> |
| RECREATION | Semicolon-separated list of <i>keyword=modifyParameters</i> commands for the <b>ModifyImage</b> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| XAXIS      | X axis name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| XWAVE      | X wave name if any, else blank.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| XWAVEDF    | The full path to the data folder containing the X wave or blank if there is no X wave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| YAXIS      | Y axis name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| YWAVE      | Y wave name if any, else blank.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| YWAVEDF    | The full path to the data folder containing the Y wave or blank if there is no Y wave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ZWAVE      | Name of wave containing Z data used to calculate the image plot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ZWAVEDF    | The full path to the data folder containing the Z data wave.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the ";", prepend "**ModifyImage**", replace the "x" with the name of a image plot ("data#1" for instance) and then **Execute** the resultant string as a command.

### Example 1

This example gets the image information for the second image plot of the wave "jack" (which has an instance number of 1) and applies its **ModifyImage** settings to the first image plot.

```
#include <Graph Utility Procs>, version=>6.1 // For WMGetRECREATIONFromInfo
// Make two image plots of the same data on different left and right axes
Make/O/N=(20,20) jack=sin(x/5)+cos(y/4)
Display;AppendImage jack // bottom and left axes
AppendImage/R jack // bottom and right axes
// Put image plot jack#0 above jack#1
ModifyGraph axisEnab(left)={0.5,1},axisEnab(right)={0,0.5}
// Set jack#1 to use the Rainbow color table instead of the default Grays
ModifyImage jack#1 ctab={*,*,Rainbow,0}
```

## ImageInterpolate

---

Now we peek at some of the image information for the second image plot of the wave "jack" (which has an instance number of 1) displayed in the top graph:

```
Print ImageInfo("", "jack", 1) [69, 148] // Just the interesting stuff
;ZWAVE:jack;ZWAVERDF:root:;COLORMODE:1;RECREATION:ctab= {*,*,Rainbow,0};plane= 0;
// Apply the color table, etc from jack#1 to jack:
String info= WMGetRECREATIONFromInfo(ImageInfo("", "jack", 1))
info= RemoveEnding(info) // Remove trailing semicolon

// Use comma instead of semicolon separators
String text = ReplaceString(";", info, ",")
Execute "ModifyImage jack " + text
```

### Example 2

This example gets the full path to the wave containing the Z data from which the first image plot in the top graph was calculated.

```
String info= ImageInfo("", "", 0) // 0 is index of first image plot
String pathToZ= StringByKey("ZWAVERDF", info)+StringByKey("ZWAVE", info)
Print pathToZ
 root:jack
```

## ImageInterpolate

**ImageInterpolate** [*flags*] *Method srcWave*

The ImageInterpolate operation interpolates the source *srcWave* and stores the results in the wave M\_InterpolatedImage in the current data folder unless you specify a different destination wave using the /DEST flag.

**Parameters**

*Method* selects type of interpolation. *Method* is one of the following names:

- Affine2D** Performs an affine transformation on *srcWave* using parameters specified by the /APRM flag. The transformation applies to a general combination of rotation, scaling, and translation represented by a 3x3 matrix

$$M = \begin{bmatrix} r_{11} & r_{12} & t_x \\ r_{21} & r_{22} & t_y \\ 0 & 0 & w \end{bmatrix}.$$

The upper 2x2 matrix is a composite of rotation and scaling,  $t_x$  and  $t_y$  are composite translations and  $w$  is usually 1. It computes the dimensions of the output wave and then uses the inverse transformation and bilinear interpolation to compute the value of each output pixel. When an output pixel does not map back into the source domain it is set to the user-specified background value. It supports 2D and 3D input waves. If *srcWave* is a 3D wave it applies on a layer by layer basis.

The output is stored in the wave M\_Affine in the current data folder.

- Bilinear** Performs a bilinear interpolation subject to the specified flag. You can use either the /F or /S flag, but not both.

- Kriging** Uses Kriging to generate an interpolated matrix from a sparse data set. Kriging calculates interpolated values for a rectangular domain specified by the /S flag. The Kriging parameters are specified via the /K flag.

Kriging is computed globally for a single user-selected variogram model. If there are significant spatial variances within the domain occupied by the data, you should consider subdividing the domain along natural boundaries and use a single variogram model in each subdivision.

If there are N data points, the algorithm first computes the NxN matrix containing the distances between the data and then inverts an associated matrix of similar size to compute the result for the selected variogram model. Because inversion of an NxN matrix can be computationally expensive, you should consider restricting the calculation to regions that are similar to the range implied by the variogram. Such an approach can also be justified in the sense that the local interpolation should not be affected by a remote datum.

**Note:** Kriging does not support data containing NaNs or INFs. Wave scaling has no effect.

- Pixelate** Creates a lower resolution (pixelated) version of *srcWave* by averaging the pixels inside domain specified by /PXSZ flag. The results are saved in the wave M\_PixelatedImage in the current data folder.

The computed wave has the same numeric type as *srcWave* so the averaging may be inaccurate in the case of integer waves.

When *srcWave* is a 3D wave you have the option of averaging only over data in each layer using /PXSZ={nx,ny} or averaging over data in a rectangular cube using /PXSZ={nx,ny,nz}.

When not averaging over layers, the number of rows and columns of the new image are obtained by integer division of the original number by the respective size of the averaging rectangle and adding one more pixel for any remainder.

When averaging over layers the resulting rows and columns are obtained by truncated integer division ignoring remainders (if any).

See also **Multidimensional Decimation** on page II-98.

**Resample** Computes a new image based on the selected interpolation function and transformation parameters. Set the interpolation function with the /FUNC flag. Use the /TRNS flag to specify transformation parameters for grayscale images, or /TRNR, /TRNG, and /TRNB for the red, green, and blue components, respectively, of RGB images. M\_InterpolatedImage contains the output image in the current data folder.

There are currently two transformation functions: the first magnifies an image and the second applies a radial polynomial sampling. The radial polynomial affects pixels based on their position relative to the image center. A linear polynomial reproduces the same image. Any nonlinear terms contribute to distortion (or correction thereof).

**Spline** Computes a 2D spline interpolation for 2D matrix data. The degree of the spline is specified by the /D flag.

**Voronoi** Generates an interpolated matrix from a sparse data set (*srcWave* must be a triplet wave) using Voronoi polygons. It calculates interpolated values for a rectangular domain as specified by the /S or /RESL flags.

It first computes the Delaunay triangulation of X, Y locations in the Z=0 plane (assuming that X, Y positions occupy a convex domain in the plane). It then uses the Voronoi dual to interpolate the Z values for X and Y pairs from the grid defined by the /S flag. The computed grid may exceed the bounds of the convex domain defined by the triangulation. Interpolated values for points outside the convex domain are set to NaN or the value specified by the /E flag.

Use the /I flag to iterate to finer triangulation by subdividing the original triangles into smaller domains. Each iteration increases computation time by approximately a factor of two, but improves the smoothness of the interpolation.

If you have multiple sets of data in which X,Y locations are unchanged, you can use the /STW flag to store one triangulation and then use the /PTW flag to apply the precomputed triangulation to a new interpolation. To use this option you should use the Voronoi keyword first with a triplet wave for *srcWave* and set  $x_n = x_0$  and  $y_n = y_0$ . The operation creates the wave W\_TriangulationData that you use in the next triangulation with a 1D wave as *srcWave*.

Voronoi interpolation is similar to what can be accomplished with the **ContourZ** function except that it does not require an existing contour plot, it computes the whole output matrix in one call, and it has the option of controlling the subdivision iterations.

See **Voronoi Interpolation Example** below.

**XYWaves** Performs bilinear interpolation on a matrix scaled using two X and Y 1D waves (specified by /W). The interpolation range is defined by /S. The data domain is defined between the centers of the first and last pixels (X in this example):

```
xmin=(xWave[0]+xWave[1])/2
xmax=(xWave[last]+xWave[last-1])/2
```

Values outside the domain of the data are set to NaN. The interpolation is contained in the M\_InterpolatedImage wave, which is single precision floating point or double precision if *srcWave* is double precision.

**Warp** Performs image warping interpolation using a two step algorithm with three optional interpolation methods. The operation warps the image based on the relative positions of source and destination grids. The warped image has the same size as the source image. The source and destination grids are each specified by a pair of 2D X and Y waves where the rows and columns correspond to the relative location of the source grid. The smallest supported dimensions of grid waves are 2x2. All grid waves must be double-precision floating point and must have the same number of points corresponding to pixel positions within the image. Grid waves must not contain NaNs or INFs. Wave scaling is ignored.

### Flags

/APRM={r11,r12,tx,r21,r22,ty,w,background}

Sets elements of the affine transformation matrix and the background value.

---

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /ATOL                  | <p>Allows ImageInterpolate to use a tolerance value if the result of the interpolation at any point is NaN. The algorithm returns the first non-NaN value it finds by adding or subtracting 1/10000th of the size of the X or Y interpolation step. At worst this algorithm is 5 times slower than the default algorithm if the interpolation is performed in a region which is completely outside the convex source domain.</p> <p>/ATOL was added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                               |
| /CMSH                  | <p>Use this flag in Voronoi interpolation to create a triangle mesh surface representing the input data. After triangulating the X, Y locations (in a plane <math>z=\text{const}</math>), the mesh is generated from a sequence of XYZ vertices of all the resulting triangles. The output is stored in the wave <code>M_ScatterMesh</code> in the current data folder. It is in the form of a triplet wave where every consecutive 3 rows represent a disjoint triangle.</p> <p>If the input contains a NaN or INF in any column, the corresponding row is excluded from the triangulation.</p> <p>If you want to generate this mesh without generating the interpolated matrix you can omit the /S flag.</p> <p>/CMSH was added in Igor Pro 7.00.</p> |
| /CSAF= <i>factor</i>   | <p>In rare situations that usually involve spatial degeneracy, the Voronoi interpolation algorithm may need additional memory. You can use the /CSAF flag with an integer factor greater than 1 to increase the memory allocation.</p> <p>/CSAF was added in Igor Pro 9.00.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| /D= <i>splineDeg</i>   | <p>Specifies the spline degree with the Spline method. The default spline degree is 2. Supported values are 2, 3, 4, and 5.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| /DEST= <i>destWave</i> | <p>Specifies the wave to contain the output of the operation. If the specified wave already exists, it is overwritten.</p> <p>Creates a wave reference for the destination wave in a user function. See <b>Automatic Creation of WAVE References</b> on page IV-71 for details.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| /E= <i>outerValue</i>  | <p>Assigns <i>outerValue</i> to all points outside the convex domain of the Delaunay triangulation. By default <i>outerValue</i> = NaN.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| /F={ <i>fx,fy</i> }    | <p>Calculates a bilinear interpolation of all the source data. Here <i>fx</i> is the sampling factor for the X-direction and <i>fy</i> is the sampling factor in the Y-direction. The output number of points in a dimension is <math>\text{factor} * (\text{number of data intervals}) + 1</math>. The number of data intervals is one less than the number of points in that dimension.</p> <p>For example, if <i>srcWave</i> is a 2x2 matrix (you have a single data interval in each direction) and you use /F={2,2}, then the output wave is a 3x3 matrix (i.e., 2x2 intervals) which is a factor of 2 of the input. Sampling factors can be noninteger values.</p>                                                                                |
| /FDS                   | <p>Performs spline interpolation to a “local” cubic spline that depends only on the 2D neighboring data. The interpolation goes exactly through the original data and provides continuity of the function and its first derivative. The second derivative is set to vanish on the boundary. The implemented algorithm was provided by Francis Dalaudier. /FDS was added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                                                                                                           |
| /FEQS                  | <p>When performing Voronoi interpolation, forces the algorithm to use equal scaling for both axes. Normally the scaling for each axis is determined from its range. When the ranges of the two axes are different by an order of magnitude or more, it is helpful to force the larger range to be used for scaling both axes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                       |

*/FUNC=funcName* Specifies the interpolation function. *funcName* can be:

- nn* Nearest neighbor interpolation uses the value of the nearest neighbor without interpolation. This is the fastest function.
- bilinear* Bilinear interpolation uses the immediately surrounding pixels and computes a linear interpolation in each dimension. This is the second fastest function.
- cubic* Cubic polynomial (photoshop-like) uses a 4x4 neighborhood value to compute the sampled pixel value.
- spline* Spline smoothed sampled value uses a 4x4 neighborhood around the pixel.
- sinc* Slowest function using a 16x16 neighborhood.

*/I=iterations* Specifies the number of times the original triangulation is subdivided with the Voronoi interpolation method. By default the Voronoi interpolation computes the original triangulation without subdivision.

*/K={model, nugget, sill, range}*

Specifies the variogram parameters for kriging using standard notation, models are expressed in terms of the nugget value  $C_0$ , sill value  $C_0+C_1$ , and range  $a$ .

*model* Selects the variogram model. Values and models are:

1: Spherical.  $\gamma(h) = C_0 + C_1 \cdot (3h/2a - 0.5 \cdot h^3/a^3)$

2: Exponential.  $\gamma(h) = C_0 + C_1 \cdot (1 - \exp[-3 \cdot h/a])$

3: Gaussian.  $\gamma(h) = C_0 + C_1 \cdot (1 - \exp[-3 \cdot (h/a)^2])$

*nugget* Specifies the lowest value in the variogram.

*sill* Specifies the maximum (plateau) value in the variogram range the characteristic length of the different variogram models.

Wave scaling has no effect on kriging calculations.

*/PFTL=tol* In Voronoi interpolation, controls the rectangular neighborhood about each datum position XY where the algorithm returns the original Z-value. The tolerance value  $0 \leq tol < 1$  is tested separately in X and Y (i.e., it is not a geometric distance) when both X and Y are normalized to the range [0,1]. By default  $tol=1e-15$ .

Added in Igor Pro 7.00.

*/PTW=tWave* Uses a previous triangulation wave with Voronoi interpolation. *tWave* will be the wave saved by the */STW* flag. You can't use a triangulation wave that was computed and saved on a different computer platform.

See **PTW Flag Example** on page V-386.

- /PXSZ={nx,ny}* Specifies the size in pixels of the averaging rectangle used by the Pixelate operation. *nx* is the number of rows and *ny* is the number of columns that are averaged to yield a single output pixel. If *srcWave* is a 3D wave the resulting wave has the same number of layers as *srcWave* with pixelation computed on a layer-by-layer basis.
- /PXSZ={nx,ny,nz}* Specifies the size in pixels of the averaging rectangle used by the Pixelate operation. *nx* is the number of rows and *ny* is the number of columns and *nz* is the number of layers that are averaged to yield a single output pixel.  
This form of the */PXSZ* flag was added in Igor Pro 7.00.
- /RESL={nx, ny}* Specifies resampling the full input image to an output image having *nx* rows by *ny* columns.
- /S={x0,dx,xn,y0,dy,yn}*  
Calculates a bilinear interpolation of a subset of the source data. Here *x0* is the starting point in the X-direction, *dx* is the sampling increment, *xn* is the end point in the X-direction and the corresponding values for the Y-direction. If you set *x0* equal to *xn* the operation will compute the triangulation but not the interpolation.
- /SPRT* Skips the XY perturbation step. The perturbation step is designed to break degeneracies that originate when the XY data are sampled on a rectangular grid. If your data are not sampled on a rectangular grid you can skip the perturbation and get better accuracy in reproducing the Z-values at the sampled locations. See also **ModifyContour** with the keyword *Perturbation*.  
Added in Igor Pro 7.00.
- /STW* Saves the triangulation information in the wave *W\_TriangulationData* in the current data folder. *W\_TriangulationData* can only be used on the computer platform where it was created.
- /SV* Saves the Voronoi interpolation in the 2D wave *M\_VoronoiEdges*, which contains sequential edges of the Voronoi polygons. Edges are separated from each other by a row of NaNs. The outer most polygons share one or more edges with a large triangle containing the convex domain.
- /TRNS={transformFunc,p1,p2,p3,p4}*  
Determines the mapping between a pixel in the destination image and the source pixel. *transformFunc* can be:
- scaleShift* Sets image scaling which could be anamorphic if the X and Y scaling are different.
- radialPoly* Corrects both color as well as barrel and pincushion distortion. In *radialPoly* the mapping from a destination pixel to a source pixel is a polynomial in the pixel's radius relative to the center of the image.  
A source pixel, *sr*, satisfies the equation:
- $$sr = ar + br^2 + cr^3 + dr^4,$$
- where *r* is the radius of a destination pixel having an origin at the center of the destination image.
- The corresponding parameters are:
- | <i>transformFunc</i> | <i>p1</i> | <i>p2</i> | <i>p3</i> | <i>p4</i> |
|----------------------|-----------|-----------|-----------|-----------|
| <i>scaleShift</i>    | xOffset   | xScale    | yOffset   | yScale    |
| <i>radialPoly</i>    |           |           |           |           |
- /U=uniformScale* Calculates a bilinear interpolation of all the source data as with the */F* flag but with two exceptions: A single uniform scale factor applies in both dimensions, and the scale factor applies to the number of points — not the intervals of the data.

*/W={xWave, yWave}* Provides the scaling waves for XYWaves interpolation. Both waves must be monotonic and must have one more point than the corresponding dimension in *srcWave*. The waves contain values corresponding to the edges of data points in *srcWave*, so that the X value at the first data point is equal to  $(xWave[0] + xWave[1]) / 2$ .

### Flags for Warp

*/dgrx=wave* Sets the wave containing the destination grid X data.  
*/dgry=wave* Sets the wave containing the destination grid Y data.  
*/sgrx=wave* Sets the wave containing the source grid X data.  
*/sgry=wave* Sets the wave containing the source grid Y data.  
*/WM=im* Sets the interpolation method for warping an image.  
*im=1:* Fast selection of original data values.  
*im=2:* Linear interpolation.  
*im=3:* Smoothing interpolation (slow)

### Details

When computing Bilinear or Spline interpolation *srcWave* can be a 2D or a 3D wave. When *srcWave* is a 3D wave the interpolation is computed on a layer by layer basis and the result is stored in a corresponding 3D wave. When the interpolation method is Kriging or Voronoi, *srcWave* is a 2D triplet wave (3-column wave) where each row specifies the X, Y, Z values of a datum. *srcWave* can be of any real data type. Results are stored in the wave *M\_InterpolatedImage*. If *srcWave* is double precision so is *M\_InterpolatedImage*; otherwise *M\_InterpolatedImage* is a single precision wave.

### Voronoi Interpolation Example

```
Function DemoVoronoiInterpolation()
 Make/O/N=(100,3) sampleTriplet
 sampleTriplet[] [0]=enoise(5)
 sampleTriplet[] [1]=enoise(5)
 sampleTriplet[] [2]=sqrt(sampleTriplet[p][0]^2+sampleTriplet[p][1]^2)

 // Interpolate the data to a rectangular grid of 50x50 pixels
 ImageInterpolate/RESL={50,50}/DEST=firstImage voronoi sampleTriplet

 // Triangulate the XY locations and save the triangulation wave
 ImageInterpolate/STW voronoi sampleTriplet

 // Use the previous triangulation on the Z column of the sample
 MatrixOp/O zData=col(sampleTriplet,2)
 Wave W_TriangulationData
 ImageInterpolate/PTW=W_TriangulationData/RESL={50,50}/DEST=secondImage voronoi zData
End
```

### PTW Flag Example

```
Function DemoPTW()
 // Create some random data
 Make/O/N=(100,3) eee = enoise(5)

 // Compute triangulation wave
 ImageInterpolate/RESL={1,1}/STW voronoi eee
 Wave W_TriangulationData

 // Copy the Z-column to a 1D wave
 MatrixOp/O e3 = col(eee,2)

 // Use the previous triangulation with 1D wave
 ImageInterpolate/PTW=W_TriangulationData /RESL={100,100} voronoi e3
 Wave M_InterpolatedImage
 Duplicate/O M_InterpolatedImage, oneD

 // Direct computation for comparison
 ImageInterpolate/RESL={100,100} voronoi eee
```

```
// Display
NewImage M_InterpolatedImage
NewImage oneD
End
```

## ImageLineProfile

**ImageLineProfile** [*flags*] *xWave*=*xwave*, *yWave*=*ywave*, *srcWave*=*srcWave* [, *width*=*value*, *widthWave*=*wWave*]

The ImageLineProfile operation provides sampling of a source image along an arbitrary path specified by the two waves: *xWave* and *yWave*. The arbitrary path is made of line segments between every two consecutive vertices of *xWave* and *yWave*. In each segment the profile is calculated at a number of points (profile points) equivalent to the sampling density of the original image (unless the /V flag is used). Both *xWave* and *yWave* should have the same scaling as *srcWave*. If *srcWave* does not have the same scaling in both dimensions you should remove the scaling to compute an accurate profile.

At each profile point, the profile value is calculated by averaging samples along the normal to the profile line segment. The number of samples in the average is determined by the keyword *width*. The operation actually averages the interpolated values at N equidistant points on the normal to profile line segment, with  $N=2(\text{width}+0.5)$ . Samples outside the domain of the source image do not contribute to the profile value.

The profile values are stored in the wave *W\_ImageLineProfile*. The actual locations of the profile points are stored in the waves *W\_LineProfileX* and *W\_LineProfileY*. The scaled distance measured along the path is stored in the wave *W\_LineProfileDisplacement*.

When the averaging width is greater than zero, the operation can also calculate at each profile point the standard deviation of the values sampled for that point (see /S flag). The results are then stored in the wave *W\_LineProfileStdv*. When using this operation on 3D RGB images, the profile values are stored in the 3 column waves *M\_ImageLineProfile* and *M\_LineProfileStdv* respectively.

### Parameters

|                                 |                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>srcWave</i> = <i>srcWave</i> | Specifies the image for which the line profile is evaluated. The image may be a 2D wave of any type or a 3D wave or RGB data.                                                                                                                                                                                                                |
| <i>xWave</i> = <i>xwave</i>     | Specifies the wave containing the x coordinate of the line segments along the path.                                                                                                                                                                                                                                                          |
| <i>yWave</i> = <i>ywave</i>     | Specifies the wave containing the y coordinate of the line segments along the path.                                                                                                                                                                                                                                                          |
| <i>width</i> = <i>value</i>     | Specifies the width (diameter) in pixels (need not be an integer value) in a direction perpendicular to the path over which the data is interpolated and averaged for each path point. If you do not specify width or use width=0, only the interpolated value at the path point is used.                                                    |
| <i>widthWave</i> = <i>wWave</i> | Specifies the width of the profile (see definition above) on a segment by segment basis. <i>wWave</i> should be a 1D wave that has the same number of entries as <i>xWave</i> and <i>yWave</i> . If you provide a <i>widthWave</i> any value assigned with the width keyword is ignored. All values in the wave must be positive and finite. |

## ImageLoad

---

### Flags

*/IRAD=nRadIntervals*

*/IRAD* was added in Igor Pro 9.00.

Use */IRAD* to estimate the integrated intensity for an annular domain defined by the */RAD* flag and the width parameter. For example, to integrate the intensity in the annular domain centered around  $X_c=50$ ,  $Y_c=50$  for the radial range [24,25]:

```
Make/O/N=(100,100) ddd=sqrt((x-50)^2+(y-50)^2)
ImageLineProfile/RAD={50,50,24.5,.5,.001}/IRAD=100 srcWave=ddd
Print V_integral
```

*/P=plane*

Specifies which plane (layer) of a 3D wave is to be profiled. By default *plane* =-1 and the profiles are of either the single layer of a 2D wave or all three layers of a 3D RGB wave. Use *plane* =-2 if you want to profile all layers of a 3D wave.

*/RAD={Xc, Yc, RADc, radWidth [, deltaAngle]}*

*/RAD* was added in Igor Pro 9.00.

Use */RAD* to compute a circular profile that is centered at  $(X_c, Y_c)$  with a radius  $RAD_c$ .  $X_c$ ,  $Y_c$ , and  $RAD_c$  are expressed in terms of the scaled coordinates.

*radWidth* is in units of image pixels.

*deltaAngle* is the angle increment between samples in radians. If you omit it, the operation first computes the maximum radius (if *width*>0) and then computes the increment angle such that there are 5 (linearly interpolated) samples per path pixel. If your image data is relatively smooth you could reduce this sampling by specifying a large *deltaAngle*.

Here is an example using */RAD*:

```
Make/O/N=(100,100) ddd=x*y // Default scaling
ImageLineProfile/RAD={50,50,24.5,0} srcWave=ddd
Display W_ImageLineProfile
```

*/S*

Calculates standard deviations for each profile point.

*/SC*

Saves *W\_LineProfileX* and *W\_LineProfileY* using the X and Y scaling of *srcWave*.

*/V*

Calculate profile points only at the vertices of *xWave* and *yWave*.

### Examples

```
Make/N=(50, 50) sampleData
sampleData = sin((x-25) / 10) * cos((y-25) / 10)
NewImage sampleData
Make/n=2 xTrace={0,50} ,yTrace={20,20}
ImageLineProfile srcWave=sampleData, xWave=xTrace, yWave=yTrace
AppendtoGraph/T yTrace vs xTrace
Display W_ImageLineProfile
```

### See Also

For additional examples see **ImageLineProfile Operation** on page III-372.

## ImageLoad

**ImageLoad** [*flags*] [*fileNameStr*]

The **ImageLoad** operation loads an image file into an Igor wave. It can load PNG, JPEG, BMP, TIFF, and Sun Raster Files.

### Parameters

The file to be loaded is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

If you want to force a dialog to select the file, omit the *fileNameStr* parameter or pass "" for it.

### Flags

- /AINF** Loads all of the image files in a disk folder into the current data folder. For example, if you have created an Igor symbolic path named ImagePath that points to a folder containing image files, you can execute:
- ```
ImageLoad/P=ImagePath/T=TIFF/AINF
```
- When using /AINF, you must omit *fileNameStr* and you must include /T to specify the type of image file to be loaded.
- This flag requires Igor Pro 7.03 or later.
- /BIGT=mode** When mode is 1, ImageLoad uses the LibTIFF library to load TIFF files. This is the default if you omit /BIGT. The LibTIFF library supports the traditional TIFF file format and the Big TIFF file format, which supports file sizes greater than 4 GB and files containing compressed data.
- When mode is 0, ImageLoad uses Igor's internal TIFF code to load image data. This internal code does not support Big TIFF and is limited to file sizes less than 2 GB.
- If you omit /BIGT, ImageLoad first attempts to load the file using LibTIFF. If an error occurs, it automatically attempts to load the file using Igor's internal TIFF code.
- The /SCNL, /STRP and /TILE flags require using LibTIFF. If you use any of these flags, /BIGT=1 is automatically in effect.
- The /RAT and /RTIO flags require using Igor's internal TIFF code. If you use these flags, /BIGT=0 is automatically in effect.
- See *Loading TIFF Files* below for more information about supported data types.
- /C=count** Specifies the number of images to load from a TIFF stack containing multiple images. The images are stored in individual waves if /LR3D is omitted or in a single 3D wave if /LR3D is present.
- By default, it loads only a single image (i.e., /C=1). Use /C=-1 to load all images. Images must be either 8 bits, 16 bits, or 32 bits/pixel for this option.
- To load a subset of the images in a TIFF stack, use /S to specify the starting image.
- If you specify a *count* that exceeds the number of images in the file, ImageLoad loads all images beginning with the first image or the image specified by /S.
- /G** Displays the loaded image in a new image plot window.
- /LR3D** Specifies that the images in a TIFF stack are to be loaded into a 3D wave rather than into multiple 2D waves. This option works with grayscale images only, not with full color (e.g., RGB).
- To load a subset of the images into the 3D wave, also use /S and /C.
- /LTMD** Reads data stored in TIFF tags belonging to the main Image File Directory. /LTMD works only when you use /BIGT=1 and is ignored otherwise. It was added in Igor Pro 8.00.
- /LTMD creates a data folder named "Tag*n*" for each loaded image. The name of the data folder has the numeric suffix *n* starting from zero.
- The "Tag*n*" data folder contains a text wave named T_Tags where each row contains the metadata associated with a single tag. The order of the rows in the wave T_Tags is indeterminate.
- If you need to parse the metadata, you can search for the tag descriptor which always appears at the start of the line and is followed by a colon and one space (": ").

ImageLoad

- /N=baseName* Stores the waves using *baseName* as the wave name. Only when *baseName* conflicts with an existing wave name will a numeric suffix be appended to the new wave names.
- If you omit */N*, ImageLoad uses the name of the file as the base name.
- /O* Overwrites an existing wave with the same name.
- If you omit */O* and there is an existing wave with the same name, a numeric suffix is appended to the image name to create a unique name.
- /P=pathName* Specifies the folder to look in for the file. *pathName* is the name of an existing symbolic path.
- /Q* Quiet mode. Suppresses printing a description of the loaded data to the history area.
- /RAT* Read All Tags reads all of the tags in a TIFF file into one or more waves.
- If you use */RAT*, */BIGT=0* is automatically in effect. To load tags with */BIGT=1*, use */LTMD* instead of */RAT*.
- /RAT* creates a data folder named "Tag*n*" with a numeric suffix, *n*, starting from zero for each loaded image. When reading multiple images from a stack TIFF file, */RAT* creates a corresponding number of data folders.
- Each data folder contains a text wave named T_Tags consisting of 5 columns. The first row contains the offset of the current Image File Directory (IFD) from the start of the file. The remaining rows describe the individual TIFF Tags as they appear in the IFD.
- The first column contains the tag number, the second contains the tag description, the third contains the tag type, the fourth contains the tag length, and the fifth contains either the value of the tag or a statement identifying the name of the wave in which the data was stored. For example, a simple tag that contains a single value has the form:
- | Num | Desc | Type | Length | Value |
|-----|------------|------|--------|-------|
| 256 | IMAGEWIDTH | 4 | 1 | 2560 |
- A tag that contains more data, such as an array of values has the form:
- | Num | Desc | Type | Length | Value |
|-----|--------------|------|--------|-----------|
| 273 | STRIPOFFSETS | 4 | -120 | tifTag273 |
- Here the Length field is negative ($-1*\text{realLength}$) and the Value field contains the name of the wave *tifTag273* which contains the array of strip offsets.
- When the Value field consists of ASCII characters it is stored in the T_Tags wave itself. All other types are stored in a wave in the same Tag data folder.
- Private tags are usually designated by negative tag numbers. If their data type is anything other than ASCII, they are saved in separate waves.
- /RONI* Stores the number of images in a TIFF stack file in the variable *V_numImages*. No images are loaded from the file. This file is not compatible with */BIGT=0*. */RONI* was added in Igor Pro 9.00.
- /RTIO* Reads tag information only from a TIFF file. */RTIO* is similar to */RAT* but it loads tag information only without loading any images.
- If you use */RTIO*, */BIGT=0* is automatically in effect. To load tags with */BIGT=1*, use */LTMD* instead of */RAT*.
- If you are loading a stack of images you can use the */C* and */S* flags to obtain tags from a specific range of images.

<i>/S=start</i>	Specifies the first image to load from a TIFF stack containing multiple images. <i>start</i> is zero-based and defaults to 0. Use <i>/C</i> to specify the number of images to load.																
<i>/SCNL=num</i>	Reads the specified scanline from a TIFF file using LibTiff. Added in Igor Pro 7.00.																
<i>/STRP=num</i>	Reads the specified strip from a TIFF file using LibTiff. Added in Igor Pro 7.00.																
<i>/T=type</i>	Identifies what kind of image file to load. <i>type</i> is one of the following image file formats:																
	<table> <thead> <tr> <th><i>type</i></th> <th>Loads this Image Format</th> </tr> </thead> <tbody> <tr> <td>any</td> <td>Any graphic file type</td> </tr> <tr> <td>bmp</td> <td>Windows bitmap file</td> </tr> <tr> <td>jpeg</td> <td>JPEG file</td> </tr> <tr> <td>png</td> <td>PNG file</td> </tr> <tr> <td>rpng</td> <td>Raw PNG file (see Details)</td> </tr> <tr> <td>sunraster</td> <td>Sun Raster file</td> </tr> <tr> <td>tiff</td> <td>TIFF file (see also Loading TIFF Files).</td> </tr> </tbody> </table>	<i>type</i>	Loads this Image Format	any	Any graphic file type	bmp	Windows bitmap file	jpeg	JPEG file	png	PNG file	rpng	Raw PNG file (see Details)	sunraster	Sun Raster file	tiff	TIFF file (see also Loading TIFF Files).
<i>type</i>	Loads this Image Format																
any	Any graphic file type																
bmp	Windows bitmap file																
jpeg	JPEG file																
png	PNG file																
rpng	Raw PNG file (see Details)																
sunraster	Sun Raster file																
tiff	TIFF file (see also Loading TIFF Files).																
	<p>If you omit <i>/T</i> or specify <i>/T=any</i>, Igor makes a guess based on the file name extension. ImageLoad reports an error if it is unable to determine the image file type.</p> <p><i>/T=any</i> allows the user to choose any file, regardless of its file name extension, if ImageLoad displays an Open File dialog.</p> <p>When loading TIFF, we recommend that you use <i>/T=tiff</i>. See Loading TIFF Files below for details.</p>																
<i>/TILE=num</i>	Reads the specified tile from a TIFF file using LibTiff. Added in Igor Pro 7.00.																
<i>/Z</i>	No error reporting.																

Details

The name of the wave created by ImageLoad is based on the file name or on *baseName* if you provide the */N=baseName* flag. In either case, if and only if there is a name conflict, ImageLoad appends a number to create a unique wave name.

If you use */P=pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-22 for details.

Output Variables

ImageLoad sets the following variables:

<i>V_flag</i>	Set to 1 if the image was successfully loaded or to 0 otherwise.
<i>S_fileName</i>	Set to the name of the file that was loaded.
<i>V_numImages</i>	Set to the number of images loaded. Applies to TIFF files only. Also set by <i>/RONI</i> flag.
<i>S_path</i>	Set to the file system path to the folder containing the file.
<i>S_waveNames</i>	Set to a semicolon-separated list of the names of loaded waves.

S_path uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon.

ImageLoad

Loading PNG Files

If you use `/T=rpng` (“raw PNG”) or if you omit `/T` and the file as a `.png` extension, ImageLoad interprets the PNG file as raw data.

We recommend that you use `/T=rpng` and use `/T=png` only if `/T=rpng` does not produce the desired results.

`/T=rpng` creates an 8-bit or 16-bit unsigned integer wave with 1 to 4 layers.

PNG images with physical units produce waves with X and Y units of meters.

If a PNG image has a color table, ImageLoad creates two waves: a main image wave with one layer and a color table wave of the same name but with an “_pal” suffix. If the name is too long it creates a wave named `PNG_pal` instead.

Loading TIFF Files

ImageLoad/`BIGT=0` supports 1-bit, 8-bit, 16-bit, 24-bit, and 32-bit TIFF files as well as floating point TIFFs.

1-bit/pixel images are loaded into a unsigned byte waves

8-bit/pixel images are loaded into a unsigned byte waves

16-bit/pixel images are loaded into unsigned 16-bit waves

24-bit/pixel images and 32-bit/pixel images loaded into 3D RGB and RGBA waves respectively

ImageLoad/`BIGT=1` supports the following data formats:

8-bit/sample signed or unsigned

12-bits/sample (packed into 16-bit unsigned)

16-bit/sample signed or unsigned

32-bit/sample IEEE single precision floating point, signed integer or unsigned integer

64-bit/sample IEEE double precision floating point, signed integer or unsigned integer

Loading a TIFF File With a Color Table

If your TIFF file includes a color table, ImageLoad/`T=tiff/BIGT=0` loads the data into a 2D wave and loads the color table into a separate color table wave which can be used when creating an image plot.

If you want to load the TIFF file into a 3D RGB wave, use `/T=tiff` to load it into a 2D wave plus a color table and then use **ImageTransform** `cmap2RGB` to create the 3D RGB wave.

Loading TIFF Stacks

A TIFF stack is a TIFF file that contains multiple images. When loading a stack, you can:

- Load all images
- Load a range of images specified by `/S` (starting image) and `/C` (image count)

You can also load the images into:

- Separate 2D waves by omitting the `/LR3D` flag
- A single 3D wave by using the `/LR3D` flag

When you use `/LR3D`, ImageLoad stores each image from the TIFF file in a layer of the 3D output wave. This option works with grayscale images only, not with full color (e.g., RGB).

EXIF Metadata

Some applications embed metadata (information about the image) in EXIF format. In both JPEG and TIFF files, the metadata is stored using TIFF tags. To read the metadata, use the `/RAT` flag, even if you are loading a JPEG file.

Examples

```
// Load all images from a TIFF stack into separate 2D waves
ImageLoad /C=-1 /T=TIFF
```

```
// Load a single image from a TIFF stack into a 2D wave
ImageLoad/S=10/C=1/T=TIFF // Load image 10 (zero based)
```

```
// Load all images from a TIFF stack into a single 3D wave
ImageLoad/LR3D/S=0/C=-1/T=TIFF
```

```
// Read all tags without loading any images
ImageLoad/C=-1/T=TIFF/RTIO
```

```
// Get the number of images in a TIFF stack
NewDataFolder/O/S tmp
ImageLoad/C=-1/T=TIFF/RTIO
Print V_numImages
KillDataFolder :
```

Loading Image Files on page II-148.

The **ImageSave** operation for saving waves as image files.

ImageMorphology

ImageMorphology [*flags*] **Method** *imageMatrix*

The ImageMorphology operation performs one of several standard image morphology operations on the source *imageMatrix*. Unless the /O flag is specified, the resulting image is saved in the wave M_ImageMorph. The operation applies only to waves of type unsigned byte. All ImageMorphology methods except for watershed use a structure element. The structure element may be one of the built-in elements (see /E flag) or a user specified element.

Erosion, Dilation, Opening, and Closing are the only methods supported for a 3D *imageMatrix*.

Parameters

Method is one of the following names:

BinaryErosion	Erodes the source binary image using a built-in or user specified structure element (see /E and /S flags).
BinaryDilation	Dilates the source binary image using a built-in or user specified structure element (see /E and /S flags).
Closing	Performs the closing operation (dilation followed by erosion). The same structure element is used in both erosion and dilation. Note that this operation is an idempotent, which means that there is no point of executing it more than once.
Dilation	Performs a dilation of the source grayscale image using either a built-in structure element or a user specified structure element. The operation supports only 8-bit gray images.
Erosion	Erodes the source grayscale image using either a built-in structure element or a user specified structure element. The operation supports only 8-bit gray images.
Opening	Performs an opening operation (erosion followed by dilation). The same structure element is used in both erosion and dilation. Note that this operation is an idempotent which means that there is no point of executing it more than once.
TopHat	Calculates the difference between the eroded image and dilated image using the same structure element.
Watershed	Calculates the watershed regions for grayscale or binary image. Use the /N flag to mark all nonwatershed lines as NaNs. The /L flag switches from using 4 neighboring pixels (default) to 8 neighboring pixels.

Flags

/E=id

Uses a particular built in structure element. The following are the built-in structure element. The following are the built-in structure elements; make sure to use the appropriate id for the dimensionality of *imageMatrix*:

<i>id</i>	Element	Origin	Shape
1	2x2	(0,0)	square (default)
2	1x3	(1,1)	row (in 3x3 square)
3	3x1	(1,1)	column (in 3x3 square)
4	3x3	(1,1)	cross (in 3x3 square)
5	5x5	(2,2)	circle (in 5x5 square)
6	3x3	(1,1)	full 3x3 square
200	2x2x2	(1,1,1)	symmetric cube
202	2x2x2	(1,1,1)	2 voxel column in Y direction
203	2x2x2	(1,1,1)	2 voxel column in X direction
204	2x2x2	(1,1,1)	2 voxel column in Z direction
205	2x2x2	(1,1,1)	XY plane
206	2x2x2	(1,1,1)	YZ plane
207	2x2x2	(1,1,1)	XZ plane
300	3x3x3	(1,1,1)	symmetric cube
301	3x3x3	(1,1,1)	symmetric ball
302	3x3x3	(1,1,1)	3 voxel column in Y direction
303	3x3x3	(1,1,1)	3 voxel column in X direction
304	3x3x3	(1,1,1)	3 voxel column in Z direction
305	3x3x3	(1,1,1)	XY plane
306	3x3x3	(1,1,1)	YZ plane
307	3x3x3	(1,1,1)	XY plane
500	5x5x5	(2,2,2)	symmetric cube
501	5x5x5	(2,2,2)	symmetric ball
700	7x7x7	(3,3,3)	symmetric cube
701	7x7x7	(3,3,3)	symmetric ball

Note that this flag has no effect on watershed calculations.

/I= iterations

Repeats the operation the specified number of *iterations*.

/L

Uses 8-connected neighbors instead of 4.

/N

Sets the background level to 64 (= NaN).

/O

Overwrites the source wave with the output.

- /R=roiSpec* Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u). The ROI wave must have the same number of rows and columns as the image wave. The ROI itself is defined by the entries/pixels whose values are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous and can take any arbitrary shape. See **ImageGenerateROIMask** for more information on creating ROI waves.
- In general, the *roiSpec* has the form {*roiWaveName*, *roiFlag*}, where *roiFlag* can take the following values:
- roiFlag*=0: Set pixels outside the ROI to 0.
 - roiFlag*=1: Set pixels outside the ROI as in original image.
 - roiFlag*=2: Set pixels outside the ROI to NaN (=64).
- By default *roiFlag* is set to 1 and it is then possible to use the */R* flag using the abbreviated form */R=roiWave*.
- /S= seWave* Specifies your own structure element.
- seWave* must be of type unsigned byte with pixels that belong to the structure element set to 1 and background pixels set to 0.
- There are no limitations on the size of the structure element and you can use the */X* and */Y* flags to specify the origin of your structure element.
- /W= whiteVal* Sets the white value in the binary image if it is different than 255. The black level is assumed to be zero.
- /X= xOrigin* Specifies the X-origin of a user-defined structure element starting at 0. If you do not use this flag Igor sets the origin to the center of the specified structure element.
- /Y= yOrigin* Specifies the Y-origin of a user defined structure element starting at 0. If you do not use this flag Igor sets the origin to the center of the specified structure element.
- /Z= zOrigin* Specifies the Z-origin of the element for 3D structure elements. If you do not use this flag Igor sets the origin to the center of the specified structure element.

Examples

If you would like to apply a morphological operation to a wave whose data type is not an unsigned byte and you wish to retain the wave's dynamic range, you can use the following approach:

```
Function ScaledErosion(inWave)
    Wave inWave

    WaveStats/Q inWave
    Variable nor=255/(V_max-V_min)
    MatrixOp/O tmp=nor*(inWave-V_min)
    Redimension/B/U tmp
    ImageMorphology/E=5 Erosion tmp
    Wave M_ImageMorph
    MatrixOp/O inWave=(M_ImageMorph/nor)+V_min
    KillWaves/Z tmp,M_ImageMorph
End
```

The **ImageGenerateROIMask** operation for creating ROIs. For details and usage examples see **Morphological Operations** on page III-368 and **Particle Analysis** on page III-375.

ImageNameList

ImageNameList(*graphNameStr*, *separatorStr*)

The **ImageNameList** function returns a string containing a list of image names in the graph window or subwindow identified by *graphNameStr*.

ImageNameToWaveRef

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

separatorStr should contain a single ASCII character such as "," or ";" to separate the names.

An image name is defined as the name of the 2D wave that defines the image with an optional #ddd suffix that distinguishes between two or more images that have the same wave name. Since the image name has to be parsed, it is quoted if necessary.

Examples

The following command lines create a very unlikely image display. If you did this, you would want to put each image on different axes, and arrange the axes such that they don't overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack,'jack # 2';  
Display;AppendImage jack  
AppendImage/T/R jack  
AppendImage 'jack # 2'  
AppendImage/T/R 'jack # 2'  
Print ImageNameList("",";")
```

```
prints jack;jack#1;jack # 2';jack # 2'#1;
```

See Also

Another command related to images and waves: **ImageNameToWaveRef**.

For commands referencing other waves in a graph: **TraceNameList**, **WaveRefIndexed**, **XWaveRefFromTrace**, **TraceNameToWaveRef**, **CsrWaveRef**, **CsrXWaveRef**, **ContourNameList**, and **ContourNameToWaveRef**.

ImageNameToWaveRef

ImageNameToWaveRef (*graphNameStr*, *imageNameStr*)

The **ImageNameToWaveRef** function returns a wave reference to the 2D wave corresponding to the given image name in the graph window or subwindow named by *graphNameStr*.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The image is identified by the string in *imageNameStr*, which could be a string determined using **ImageNameList**. Note that the same image name can refer to different waves in different graphs.

The **ImageNameList** function.

For a discussion of wave references, see **Wave Reference Functions** on page IV-197.

ImageRegistration

ImageRegistration [*flags*] [*testMask=testMaskWave*] [*refMask=refMaskWave*]
testWave=imageWave1, *refWave=imageWave2*

The **ImageRegistration** operation adjusts the test image wave, *testWave*, to match the reference image wave, *refWave*, possibly subject to auxiliary mask waves. The registration may involve offset, rotation, scaling or skewing.

Image data may be in two or three dimensions.

ImageRegistration is designed to find accurate registration for relatively small variation on the order of a few degrees of rotation and a few pixels offset between the reference and test images.

All the input waves are expected to be single precision float (SP) so you may have to redimension your images before using **ImageRegistration**.

ImageRegistration does not tolerate NaNs or INFs; use the masks if you need to exclude pixels from the registration process.

Parameters

<code>refMask=<i>refMaskWave</i></code>	Specifies an optional ROI wave used to mask <code>refWave</code> . Omit <code>refMask</code> to use all of the <code>refWave</code> . The wave must have the same dimensions as <code>refWave</code> . <code>refMask</code> is a single precision floating point wave with nonzero entries marking the "ON" state. Note that the operation modifies this wave and that you should not use the same wave for both the reference and the test masks.
<code>refWave=<i>imageWave2</i></code>	Specifies the name of the reference image wave used to adjust <code>testWave</code> .
<code>testMask=<i>testMaskWave</i></code>	Specifies an optional ROI wave used to mask <code>testWave</code> . Omit <code>testMask</code> to use all of the <code>testWave</code> . The wave must have the same dimensions as <code>refWave</code> . <code>testMask</code> is a single precision floating point wave with nonzero entries marking the "ON" state. Note that the operation modifies this wave and that you should not use the same wave for both the reference and the test masks.
<code>testWave=<i>imageWave1</i></code>	Specifies the name of the image wave that will be adjusted to match <code>refWave</code> .

`testMaskWave` and `refMaskWave` are optional ROI waves. The waves must have the same dimensions as `testWave` and `refWave` respectively. They must be single precision floating point waves with nonzero entries marking the "ON" state. If you need to include the whole region described by `testWave` or the whole region described by `refWave` you can omit the respective mask wave

Flags

<code>/ASTP=<i>val</i></code>	Sets the adaptation step for the Levenberg-Marquardt algorithm. Default value is 4.
<code>/BVAL=<i>val</i></code>	Enables clipping and sets the background values to which masked out voxels of the test data will be set.
<code>/CONV=<i>val</i></code>	Sets the convergence method. <code>val=0:</code> Gravity, use if the difference between the images is only in translation. This option is frequently useful as a first step when the test and reference data are too far apart for accurate registration. The result of this registration is then passed to a subsequent ImageRegistration with <code>/CONV=1</code> . <code>val=1:</code> Marquardt.
<code>/CSNR=<i>val</i></code>	Determines if the operation calculates the signal to noise ratio (SNR) <code>val=0:</code> The SNR is not calculated. <code>val=1:</code> The SNR is calculated (default). Skipping the SNR calculation saves time and may be particularly useful when performing the registration on a stack of images.
<code>/FLVL=<i>val</i></code>	Specifies the finest level on which the optimization is to be performed. If this is the same as <code>/PRDL</code> , then only the coarsest registration calculation is done. If <code>/FLVL=1</code> (default), then the full multiresolution pyramid is processed. You can use this flag to terminate the computation at a specified coarseness level greater than 1.
<code>/GRYM</code>	Optimizes the gray level scaling factor. It is sometimes dangerous to let the program adjust for gray levels because in some situations it might result in a null image.
<code>/GRYR</code>	Renders output using the gray scaling parameter. This is more meaningful if the operation computes the optimal gray scaling (see <code>/GRYM</code>).

ImageRegistration

<code>/GWDT={sx,sy,sz}</code>	Sets the three fields to the half-width of a Gaussian window that is used to smooth the data when computing the default masks. Defaults are {1,1,1}. See <code>/REFM</code> and <code>/TSTM</code> for more details.
<code>/INTR=val</code>	Sets the interpolation method. <code>val=0:</code> Nearest neighbor. Used when registering the center of gravity of the test and reference images. <code>val=1:</code> Trilinear. <code>val=2:</code> Tricubic (default).
<code>/ISOS</code>	Optimizes the isometric scaling. This option is inappropriate if voxels are not cubic.
<code>/ISR</code>	Computes the multiresolution pyramid with isotropic size reduction. If the flag is not specified, the size reduction is in the XY plane only.
<code>/MING=val</code>	Sets the minimum gain at which the computations will stop. Default value is zero, but you can use a slightly larger value to stop the iterations earlier.
<code>/MSKC=val</code>	Sets mask combination value. During computation the masks for the test data and the mask for the reference data are also transformed. This flag determines how the two masks are to be combined. The registration criteria are computed for the combination of the two masks. <code>val=0:</code> or. <code>val=1:</code> nor. <code>val=2:</code> and (default). <code>val=3:</code> nand. <code>val=4:</code> xor. <code>val=5:</code> nxor.
<code>/PRDL=depth</code>	Specifies the depth of the multiresolution pyramid. The finest level is <code>depth=1</code> . Each level of the pyramid decreases the resolution by a factor of 2. By default, the pyramid <code>depth=4</code> , which corresponds to a resolution reduction by a factor of $2^{(depth-1)}=8$. The algorithm starts by computing the first registration on large scale features in the image (deepest level of the pyramid). It then makes small corrections to the registration at each consecutive pyramid level. For best results, the coarsest representation the data should be between 30 and 60 pixels on a side. For example, for an image that is H by V pixels, you should choose the depth such that $H/2^{(depth-1)} \approx 30$.
<code>/PSTK</code>	When performing registration of a stack of images, use this flag to apply the registration parameters of the previous layer as the initial guess for the registration of each layer after the first in the 3D stack.
<code>/Q</code>	Quiet mode; no messages printed in the history area.
<code>/REFM=val</code>	Sets the reference mask. <code>val=0:</code> To leave blank and then every pixel is taken into account. <code>val=1:</code> Value will be set if a valid reference mask is provided. <code>val=2:</code> The test mask is computed (default). When computing the reference mask it is assumed that brighter features are more important. This is done by using a low pass filter on the data (using the parameters in <code>/GWDT</code>) which is then converted into a binary mask. Note that you do not need to specify <code>/REFM=1</code> if you are providing a reference mask wave. See also <code>/TSTM</code> .
<code>/ROT={rotX,rotY,rotZ}</code>	

	Determines if optimization will take into account rotation about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding rotation parameter. Defaults are {0,0,1}, which are the appropriate values for rotating images.
<code>/SKEW={skewX,skewY,skewZ}</code>	Determines if optimization will take into account skewness about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding skewness parameter. Defaults are {0,0,0}. Note that skewing and rotation or isometric scaling are mutually exclusive operations.
<code>/STCK</code>	Use <code>/STCK</code> to perform the registration between a 2D reference image and each of the layers in a 3D image. The number of rows and columns of the <code>refWave</code> must match exactly the number of rows and columns in <code>testWave</code> . The transformation parameters are saved in the wave <code>M_RegParams</code> where each column contains the parameters for the corresponding layer in <code>testWave</code> .
<code>/STRT=<i>val</i></code>	Sets the first value of the adaptation parameter in the Levenberg-Marquardt algorithm. The default value of this parameter is 1.
<code>/TRNS={transX,transY,transZ}</code>	Determines if optimization will take into account translation about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding translation parameter. Defaults are {1,1,0}, which are appropriate for finding the X and Y translations of an image.
<code>/TSTM=<i>val</i></code>	Sets the test mask. <i>val</i> =0: To leave blank and then every pixel is taken into account. <i>val</i> =1: This value will be set if a valid reference mask is provided. <i>val</i> =2: The reference mask is computed. This is the default value. The test image mask is computed in the same way as the reference image mask (see <code>/REFM</code>) using the same set of smoothing parameters. Note that you do not need to specify <code>/TSTM=1</code> if you are providing a test mask wave.
<code>/USER=<i>pWave</i></code>	Provides a user transformation that will be applied to the input <code>testWave</code> in order to create the transformed image. <i>pWave</i> must be a double precision wave which contains the same number of rows as <code>W_RegParams</code> . Note: If you use a previously created <code>W_RegParams</code> make sure to change its name as it is overwritten by the operation. If <i>pWave</i> has only one column and <code>testWave</code> contains multiple layers, then the same transformation applies to all layers. If <i>pWave</i> contains more than one column, then each layer of <code>testWave</code> is processed with corresponding column. If there are more layers than columns the first column is used in place of the missing columns.
<code>/ZMAN</code>	Modifies the test and reference data by subtracting their mean values prior to optimization.

Details

ImageRegistration will register images that have sufficiently similar features. It will not work if key features are too different. For example, ImageRegistration can handle two images that are rotated relative to each other by a few degrees, but cannot register images if the relative rotation is as large as 45 degrees. The algorithm is capable of subpixel resolution but it does not handle large variations between the test image and the reference image. If the centers of the two images are too far from each other, you should first try ImageRegistration using `/CON=0` to remove the translation offset before proceeding with a finer registration of details.

The algorithm is based on an iterative processing that proceeds from coarse to fine detail. Optimization uses a modified Levenberg-Marquardt algorithm and produces an affine transformation for the relative rotation

ImageRegistration

and translation as well as for isometric scaling and contrast adjustment. The algorithm is most effective with square images where the center of rotation is not far from the center of the image.

When using gravity for convergence, skew parameters can't be evaluated (only translation is supported). Skew and isoscaling are mutually exclusive options. Mask waves are defined to have zero entries for pixels outside the region of interest and nonzero entries otherwise. If a mask is not provided, every pixel is used.

ImageRegistration creates the waves M_RegOut and M_RegMaskOut, which are both single precision waves. In addition, the operation creates the wave W_RegParams which stores 20 double precision registration parameters. M_RegOut contains the transformed (registered) test image and M_RegMaskOut contains the transformed mask (which is not affected by mask combination). ImageRegistration ignores wave scaling; images are compared and registered based on pixel values only.

The results printed in the history include:

dx, dy, dz	translation offsets measured in pixels.
aij	Elements in the skewing transformation matrix.
phi	Rotation angle in degrees about the X-axis. Zero for 2D waves.
tht	Rotation angle in degrees about the Y-axis. Zero for 2D waves.
psi	Rotation angle in degrees about the Z-axis.
det	Absolute value of determinant of the skewing matrix (aij).
err	Mean square error defined as

$$\frac{1}{N} \sum (x_i - y_i)^2,$$

where x_i is the original pixel value, y_i the computed value, and N is the number of pixels.

snr	Signal to noise ratio in dB. It is given by:
-----	--

$$10 \log \left(\frac{\sum x_i^2}{\sum (x_i - y_i)^2} \right).$$

These parameters are stored in the wave W_RegParams (or M_RegParams in the case of registering a stack). Angles are in radians. Dimension labels are used to describe the contents of each row of the output wave. Each column of the wave consists of the following rows (also indicated by dimension labels):

Point	Contents	Point	Contents	Point	Contents	Point	Content
0	dx	6	a21	12	gamma	17	origin_x
1	dy	7	a22	13	phi	18	origin_y
2	dz	8	a23	14	theta	19	origin_z
3	a11	9	a31	15	psi	21	MSE
4	a12	10	a32	16	lambda	21	SNR
5	a13	11	a33				

You can view the output waves with dimension labels by executing:

```
Edit W_RegParams.ld
```

ImageRemoveBackground

ImageRemoveBackground /R=*roiWave* [*flags*] *srcWave*

The ImageRemoveBackground operation removes a general background level, described by a polynomial of a specified order, from the image in *srcWave*. The result of the operation are stored in the wave M_RemovedBackground.

Flags

/F	Computes only the background surface fit. Will only store the resulting fit in M_RemovedBackground. This will not subtract the fit from the image.
/O	Overwrites the original wave.
/P= <i>polynomial order</i>	Specifies the order of the polynomial fit to the background surface. If omitted, the order is assumed to be 1.
/R= <i>roiWave</i>	Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/B/U), which has the same number of rows and columns as the image wave. Set the pixels that define the background region to 1. The remaining pixels can be any value other than 1. We recommend using 64 which Igor image processing operations often interpret as "blank" in unsigned byte image waves. The ROI does not have to be contiguous. See ImageGenerateROIMask for more information on creating ROI waves.
/W	Specifies that polynomial coefficients are to be saved in the wave W_BackgroundCoeff.

Details

The identification of the background is done via the ROI wave. Set the pixels that define the background region to 1. The remaining pixels can be any value other than 1. We recommend using 64 which Igor image processing operations often interpret as "blank" in unsigned byte image waves.

The operation first performs a polynomial fit to the points designated by the ROI wave using the specified polynomial order. A polynomial of order N corresponds to the function:

$$F_N(x, y) = \sum_{m=0}^N \sum_{n=0}^m c_{nm} x^{m-n} y^n.$$

Using the polynomial fit, a surface corresponding to the polynomial is subtracted from the source wave and the result is saved in M_RemovedBackground, unless the /O flag is used, in which case the original wave is overwritten.

Use the /W flag if you want polynomial coefficients to be saved in the W_BackgroundCoeff wave. Coefficients are stored in the same order as the terms in the sums above.

If you do not specify the polynomial order using the /P flag, the default order is 1, which means that the operation subtracts a plane (fitted to the ROI data) from the source image.

Note, if the image is stored as a wave of unsigned byte, short, or long, you might consider converting it into single precision (using `Redimension/S`) before removing the background. To see why this is important, consider an image containing a region of pixels equal to zero and subtracting a background plane corresponding to a nonconstant value. After subtraction, at least some of the pixels in the zero region should become negative, but because they are stored as unsigned quantities, they appear incorrectly as large values.

Examples

See **Background Removal** on page III-379.

ImageRestore

See Also

The `ImageGenerateROIMask` operation for creating ROIs.

ImageRestore

`ImageRestore [flags] srcWave=wSrc, psfWave=wPSF [, relaxationGamma=h, startingImage=wRecon]`

The `ImageRestore` operation performs the Richardson-Lucy iterative image restoration.

Flags

- `/DEST=destWave` Specifies the desired output wave.
If `/DEST` is omitted, the output from the operation is stored in the wave `M_Reconstructed` in the current data folder.
- `/ITER=iterations` Specifies the number of iterations. The default number of iterations is 100.
- `/Z` Do not report errors.

Parameters

- `psfWave=wPSF` Specifies a known point spread function. `wPSF` must be a 2D (square NxN) wave of the same numeric type as `wSRC`. N must be an odd number greater than 1.
- `relaxationGamma=h` Specifies positive power gamma of in the relaxation mapping (see Details).
- `startingImage=wRecon` Use this keyword to specify a starting image that could be for example the output from a previous call to this operation. `wRecon` must have the same dimensions as `wSRC` and the same numeric type.
You must make sure that `wRecon` is not the user-specified or the default destination wave of the operation.
- `srcWave=wSrc` Specifies the degraded image which must be a 2D single-precision or double-precision real wave.

Details

`ImageRestore` performs the Richardson-Lucy iteration solution to the deconvolution of an image. The input consists of the degraded image and point spread function as well as the desired number of iterations.

The operation allows you to apply additional iterations by setting the starting image to the restored output wave from a previous call to `ImageRestore` using the `startingImage` keyword. If `startingImage` is omitted, the starting image is created by `ImageRestore` with each pixel set to the value 1.

In the case of stellar images it may be useful to apply a relaxation step that involves scaling the correction evaluated at each iteration by

$$factor(v) = \sin\left(\frac{\pi}{2} \frac{v - v_{\min}}{v_{\max} - v_{\min}}\right)^\gamma,$$

where v is pixel value, v_{\max} and v_{\min} are the maximum and minimum level pixels in the image and γ is the user-specified `relaxationGamma`.

ImageRotate

ImageRotate [*flags*] *imageMatrix*

The ImageRotate operation rotates the image clockwise by *angle* (degrees) or counter-clockwise if /W is used.

The resulting image is saved in the wave M_RotatedImage unless the /O flag is specified. The size of the resulting image depends on the angle of rotation.

The portions of the image corresponding to points outside the domain of the original image are set to the default value 64 or the value specified by the /E flag.

You can apply ImageRotate to 2D and 3D waves of any data type.

Flags

- /A=angle* Specifies the rotation angle measured in degrees in a clockwise direction. For rotations by exactly 90 degrees use /C or /W instead.
- /C* Specifies clockwise rotation.
Clockwise is the default direction so the rotation will be clockwise whether you use /C or not, so long as you do not use /W.
- /E= val* Specifies the value for pixels that are outside the domain of the original image. By default pixels are set to 64. If you specify */E= (NaN)* and your data is of type char, short, or long, the operation sets the external values to 64.
- /F* Rotates image by 180 degrees.
- /H* Flip the image horizontally.
- /O* Overwrites the original image with the rotated image.
- /Q* Quiet mode. Without this flag the operation writes warnings in the history area.
- /RGBA=[R, G, B [, A])*
Specifies the RGB or RGBA values of pixels that lie outside the domain occupied by the original image. This flag was added in Igor Pro 7.00.
- /S* Uses source image wave scaling to preserve scaling and relative locations of objects in the image for rotation angles that are multiples of 90 degrees.
- /V* Flip the image vertically.
- /W* Specifies counter-clockwise rotation.
- /Z* Ignore errors.

See Also

The **MatrixTranspose** operation.

ImageSave

ImageSave [*flags*] *waveName* [[*as*] *fileNameStr*]

The ImageSave operation saves the named wave as an image file.

Previously this operation used QuickTime to implement the saving of some file formats. As of Igor Pro 7.00, it no longer uses QuickTime. Consequently, some file formats are no longer supported and some flags have changed.

Parameters

The file to be written is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

ImageSave

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

If you want to force a dialog to select the file, omit the *fileNameStr* parameter or specify "" for *fileNameStr* or use the /I flag. The "as" keyword before *fileNameStr* is optional.

In Igor Pro 7.00 or later, if you specify "Clipboard" for *fileNameStr* and the file type is JPEG or PNG, Igor writes the image to the clipboard.

In Igor Pro 7.00 or later, if the file type is PNG or JPEG you can write the image to the picture gallery using the magic path name `_PictGallery_`. For example

```
ImageSave/T=PNG/P=_PictGallery_ waveName
```

Flags

/ALPH=mode Sets the value used for the ExtraSamples tag (338) in the TIFF file format. This flag was added in Igor Pro 7.00.

The tag tells a TIFF file reader how to use the alpha values. Supported modes are 1 for premultiplied and 2 for unassociated alpha. Premultiplied means that the RGB components have already been multiplied by alpha. Unassociated means that the RGB components are raw.

By default, alpha is assumed to be premultiplied (*mode=1*).

/BIGT Saves TIFF files in BigTIFF format, a newer TIFF standard that allows you to save large images (over 2GB) and provides support for several compression formats. Many applications that load TIFF files do not support BigTIFF.

The /BIGT flag was added in Igor Pro 9.00.

/C=comp Specifies the compression to use when saving BigTIFF:

<i>comp</i>	BigTIFF Compression
1	No compression (default)
2	CITTRLE
3	CCITTFAX3
4	CCITTFAX4
5	LZW
7	JPG
8	ADOBE_DEFLATE
32773	PACKBITS
32946	DEFLATE
32947	DCS
34712	JP2000s

The /C flag was added in Igor Pro 9.00.

/D=depth This flag is deprecated and should not be used in new code.

Specifies color depth in bits-per-pixel. Integer values of 1, 8, 16, 24, 32, and 40 are supported. A *depth* of 40 specifies 8-bit grayscale; a *depth* of 8 saves the file as 8-bits/pixel with a color lookup table. If /D is omitted, it acts like /D=8.

Saving with a color table may cause some loss of fidelity.

See also the discussion of saving TIFF files below.

<i>/DS=depth</i>	Saves TIFF data in <i>depth</i> bits/sample. Values for <i>depth</i> of 8, 16, 32 and 64 are supported. The default is 8. The total number of bits/pixel is: (bits/sample) * (samples/pixel). When using 32 or 64 bits/sample, <i>srcWave</i> is saved without normalization.										
<i>/F</i>	This flag is deprecated and should not be used in new code. Saves the wave as single precision float. The data is not normalized. Applies only to TIFF files.										
<i>/I</i>	Interactive mode. Forces ImageSave to display a Save File dialog, even if the file and folder location are fully specified.										
<i>/IGOR</i>	In Igor6 this flag told Igor to use internal code rather than QuickTime to write TIFF files. Igor no longer uses QuickTime and always uses internal code. This flag is still accepted but has no effect.										
<i>/O</i>	Overwrites the specified file if it exists. If <i>/O</i> is omitted and the file exists, ImageSave displays a Save File dialog.										
<i>/P=pathName</i>	Specifies the folder in which to save the image file. <i>pathName</i> is the name of an existing symbolic path.										
<i>/Q=quality</i>	Specifies the quality of the compressed image. <i>quality</i> is a number between 0 and 1, with 1 being the highest quality. This is only applicable when saving in formats with lossy compression like JPEG.										
<i>/S</i>	Saves as stack. Applies only to 3D or 4D source waves saved as TIFF files.										
<i>/T=fileTypeStr</i>	Specifies the type of file to be saved. <table border="1"> <thead> <tr> <th><i>fileTypeStr</i></th> <th>Saved Image Format</th> </tr> </thead> <tbody> <tr> <td>"jpeg"</td> <td>JPEG file</td> </tr> <tr> <td>"png"</td> <td>PNG file</td> </tr> <tr> <td>"rpng"</td> <td>raw PNG file (see Saving as Raw PNG)</td> </tr> <tr> <td>"tiff"</td> <td>TIFF file</td> </tr> </tbody> </table> <p>If <i>/T</i> is omitted, the default type is "tiff".</p>	<i>fileTypeStr</i>	Saved Image Format	"jpeg"	JPEG file	"png"	PNG file	"rpng"	raw PNG file (see Saving as Raw PNG)	"tiff"	TIFF file
<i>fileTypeStr</i>	Saved Image Format										
"jpeg"	JPEG file										
"png"	PNG file										
"rpng"	raw PNG file (see Saving as Raw PNG)										
"tiff"	TIFF file										
<i>/U</i>	Prevents normalization. This works when saving TIFF only. See Saving as TIFF below.										
<i>/WT=tagWave</i>	Saves TIFF files with file tags as specified by <i>tagWave</i> , which is a text wave consisting of a row and 5 columns for each tag (see description of the <i>/RAT</i> flag under ImageLoad). It ignores any information in the second column but will write the tags sequentially (only in the first Image File Directory (IFD) if there is more than one image). If the fourth column contains a negative number, there must be a wave, whose name is given in the fifth column of <i>tagWave</i> , in the same data folder as <i>tagWave</i> . You must make sure that: (1) tag numbers are legal and do not conflict with any existing tags; (2) the data type and data size are consistent with the amount of data saved in external waves.										
<i>/Z</i>	No error reporting.										

Details

Image files are characterized by the number of color components per pixel and the bit-depth of each component. Igor displays images that consist of 1 component (gray-scale/false color), 3 components (RGB) or 4 components (RGBA) per pixel. You can display waves of all real numeric types as images, but wave data are assumed to be either in the range of [0,255] for 8-bits/components or [0,65535] for all other numeric types. For more information see **Creating an Image Plot** on page II-374.

When you save a numeric wave as image file your options depend on the number of components (layers) of your wave and its number type.

Saving as PNG

You can save an Igor wave as a PNG file with 24 bits per pixel or 32 bits per pixel. The following table describes how the wave's data type corresponds to the PNG pixel format.

Source Wave	PNG Pixel Format
1-layer any type	RGB 24 bits per pixel gray normalized [0,255]
3-layer unsigned byte	RGB 24 bits per pixel no scaling
3-layer unsigned short	RGB 24 bits per pixel data divided by 256
3-layer all other types	RGB 24 bits per pixel data normalized [0,255]
4-layer unsigned byte	RGBA 32 bits per pixel no scaling
4-layer unsigned short	RGBA 32 bits per pixel data divided by 256
4-layer all other types	RGBA 32 bits per pixel data normalized [0,255]

Gray means that the three components of each pixel have the identical value. Data normalization consists of finding the global (over all layers) minimum and maximum values of *srcWave* followed by scaling to the full range, e.g.,

```
minValue = WaveMin(srcWave)
maxValue = WaveMax(srcWave)
outValue[i][j][k] = 255*(srcWave[i][j][k]-minValue)/(maxValue-minValue)
```

Saving as Raw PNG

The rpng image format requires a wave in 8- or 16-bit unsigned integer format with 1 to 4 layers. Use one layer for grayscale, 3 layers for rgb color, and the extra layer for an alpha channel. If X or Y scaling is not unity, they both must be valid and must be either inches per pixel or meters per pixel. If the units are not inches they are taken to be meters.

Saving as TIFF

ImageSave supports saving uncompressed TIFF images of 8, 16, 32 and 64 bits per color component with 1, 3 or 4 components per pixel.

Depending on the data type of your wave and the depth of the image file being created, ImageSave may save a "normalized" version of your data. The normalized version is scaled to fit in the range of the image file data type. For example, if you save a 16-bit Igor wave containing pixel values from -1000 to +1000 in an 8-bit grayscale TIFF file, ImageSave will map the wave values -1000 and +1000 to the file values 0 and 255 respectively. When saving an image file of 16-bits/component, Igor normalizes to 65535 as the full-scale value.

There is no normalization when you save in floating point (32 or 64 bits/component). Normalization is also not done when saving 8-bit wave data to an 8-bit image file. You can disable normalization with the /U flag.

Saving in floating point can lead to large image files (e.g., 64-bit/component RGBA has 256 bits/pixel) which are not supported by many applications.

Saving 3D or 4D Waves as a Stack of TIFF Images

If your Igor data is a 3D wave other than an RGB wave or a 4D wave, you can save it as a stack of grayscale images without a color map.

Use /S to indicate that you want to save a stack of images rather than a single image from the first layer of the wave.

Use /D=8 to save as 8 bits. Normalization is done except if the wave data is 8 bits.

Use /D=16 to save as 16 bits with normalization.

Use /F to save as single-precision floating point without normalization. Many programs can not read this format.

Use /U to prevent normalization.

Stacked images are normalized on a layer by layer basis. If you want to have uniform scaling and normalization you should convert your wave to the file data type before executing ImageSave.

See Also

The **ImageLoad** operation for loading image files into waves.

ImageSeedFill

ImageSeedFill [*flags*] [*keyword*], *seedX=xLoc*, *seedY=yLoc*, *target=setValue*,
srcWave=srcImage

The ImageSeedFill operation takes a seed pixel and fills a contiguous region with the target value, storing the result in the wave M_SeedFill. The filled region is defined by all contiguous pixels that include the seed pixel and whose pixel values lie between the specified minimum and maximum values (inclusive). ImageSeedFill works on 2D and 3D waves.

Parameters

keyword is one of the following names:

adaptive=factor Invokes the adaptive algorithm where a pixel or voxel is accepted if its value is between the specified minimum and maximum or its value satisfies:

$$|val - avg| < factor * stdv.$$

Here *val* is the value of the pixel or voxel in question, *avg* is the average value of the pixels or voxels in the neighborhood and *stdv* is the standard deviation of these values. By choosing a small *factor* you can constrain the acceptable values to be very close to the neighborhood average. A large *factor* allows for more deviation assuming that the *stdv* is greater than zero.

This requirement means that a connected pixel has to be between the specified minimum and maximum value **and** satisfy the adaptive relationship. In most situations it is best to set wide limits on the minimum and maximum values and allow the adaptive parameter to control the local connectivity.

fillNumber=num Specifies the number, in the range 1 to 26, of voxels in each 3x3x3 cube that belong to the set. If *fillNumber* is exceeded, the operation fills the remaining members of the cube. If you do not specify this keyword, the operation does not fill the cube. Used only in the fuzzy algorithm.

fuzzyCenter=fcVal Specifies the center value for the fuzzy probability with the fuzzy algorithm (see **Details**). The default value is 0.25. Its standard range is 0 to 0.5, although interesting results might be obtained outside this range.

fuzzyProb=fpVal Specifies a probability threshold that must be met by a voxel to be accepted to the seeded set. The value must be in the range 0 to 1. The default value is 0.75.

fuzzyScale=fsVal Determines if a voxel is to be considered in a second stage using fuzzy probability. *fsVal* must be nonzero in order to invoke the fuzzy algorithm. The scale is used in comparing the value of the voxel to the value of the seed voxel. The scale should normally be in the range 0.5 to 2.0.

fuzzyWidth=fwVal Defines the width of the fuzzy probability distribution with the fuzzy algorithm (see **Details**). In most situations you should not need to specify this parameter. The default value is 1.

min=minval Specifies the minimum value that is accepted in the seeded set. Not needed when using fuzzy algorithm.

max=maxval Specifies the maximum value that is accepted to the seeded set. Not needed when using the fuzzy algorithm.

ImageSeedFill

<code>seedP=row</code>	Specifies the integer row location of the seed pixel or voxel. This avoids roundoff issues when <code>srcWave</code> has wave scaling. You must provide either <code>seedP</code> or <code>seedX</code> with all algorithms. It is sometimes convenient to use this with cursors e.g., <code>seedP=pcsr(a)</code> .
<code>seedQ=col</code>	Specifies the integer column location of the seed pixel or voxel. This avoids roundoff difficulties when <code>srcWave</code> has wave scaling. You must provide either <code>seedQ</code> or <code>seedY</code> with all algorithms.
<code>seedR=layer</code>	Specifies the integer layer position of the seed voxel. When <code>srcWave</code> is a 3D wave you must use either <code>seedR</code> or <code>seedZ</code> .
<code>seedX=xLoc</code>	Specifies the pixel or voxel index. If <code>srcWave</code> has wave scaling, <code>seedX</code> must be expressed in terms of the scaled coordinate. This keyword or <code>seedP</code> is required with all algorithms.
<code>seedY=yLoc</code>	Specifies the pixel or voxel index. If <code>srcWave</code> has wave scaling, <code>seedY</code> must be expressed in terms of the scaled coordinate. This keyword or <code>seedQ</code> is required with all algorithms.
<code>seedZ=zLoc</code>	Specifies the voxel index. If <code>srcWave</code> has wave scaling, <code>seedZ</code> must be expressed in terms of the scaled coordinate. You must use this keyword or <code>seedR</code> whenever <code>srcWave</code> is 3D.
<code>srcWave=srcImage</code>	Specifies the source image wave.
<code>target=val</code>	Sets the value assigned to pixels or voxels that belonging to the seeded set.

Flags

<code>/B=bValue</code>	Specifies the value assigned to pixels or voxels that do not belong to the filled area. If you omit <code>/B</code> , these pixels or voxels are assigned the corresponding values of the wave specified by the <code>srcWave</code> keyword.
<code>/C</code>	Uses 8-connectivity where a pixel can be connected to any one of its neighbors and with which it shares as little as a single boundary point. The default setting is 4-connectivity where pixels can be connected if they are neighbors along a row or a column. This has no effect in 3D, where 26-connectivity is the only option.
<code>/K=killCount</code>	Terminates the fill operation after <i>killCount</i> elements have been accepted.
<code>/O</code>	Overwrites the source wave with the output (2D only).
<code>/R=roiWave</code>	Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (<code>/b/u</code>), that has the same number of rows and columns and layers as the image wave. The ROI itself is defined by the entries/pixels whose value are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous. See <code>ImageGenerateROIMask</code> for more information on creating ROI waves.

Details

In two dimensions, the operation takes a seed pixel, optional minimum and maximum pixel values and optional adaptive coefficient. It then fills a contiguous region (in a copy of the source image) with the target value. There are two algorithms for 2D seed fill. In direct seed fill (only `min`, `max`, `seedX` and `seedY` are specified) the filled region is defined by all contiguous pixels that include the seed pixel and whose pixel values lie between the specified minimum and maximum values (inclusive). In adaptive fill, there is an additional condition for the pixel or voxel to be selected, which requires that the pixel value must be within the standard deviation of the average in the 3x3 (2D) or 3x3x3 (3D) nearest neighbors. If you do not specify the minimum and maximum values then the operation selects only values identical to that of the seed pixel.

In 3D, there are three available algorithms. The direct seed fill algorithm uses the limits specified by the user to fill the seeded domain. In adaptive seed fill the algorithm requires the limits as well as the adaptive parameter. It fills the domain by accepting only voxels that lie within the adaptive factor times the standard deviation of the immediate voxel neighborhood. To invoke the third algorithm you must set `fuzzyScale` to a nonzero value. The fuzzy seed fill uses two steps to determine if a voxel should be in the filled domain. In the first step the value of the voxel is compared to the seed value using the fuzzy scale. If accepted, it

passes to the second stage where a fuzzy probability is calculated based on the number of voxels in the 3x3x3 cell which passed the first step together with the user-specified probability center (fuzzyCenter) and width (fuzzyWidth). If the result is greater than fuzzyProb, the voxel is set to belong to the filled domain.

If the /O flag is not specified, the result is stored in the wave M_SeedFill.

If you specify a background value with the /B flag, the resulting image consists of the background value and the target value in the area corresponding to the seed fill. Although the wave is now bi-level, it retains the same number type as the source image.

ImageSeedFill returns a “bad seed pixel specification” if the seed pixel location derived from the various keywords above satisfies one or more of the following conditions:

- The computed integer pixel/voxel is outside the image.
- The value stored in the computed integer pixel/voxel location does not satisfy the min/max or fuzzy conditions. This is the most common condition when srcWave has wave scaling. To avoid this difficulty you should use the keywords seedP, seedQ, and seedR.

Examples

Using Cursor A position and value to supply parameter inputs for a 2D seedFill (**Warning:** command wrapped over two lines):

```
ImageSeedFill
  seedP=pcsr(a), seedQ=qcsr(a), min=zcsr(a), max=zcsr(a), target=0, srcwave=image0
```

Using the fuzzy algorithm for a 3D wave (**Warning:** command wrapped over two lines):

```
ImageSeedFill seedX=232, seedY=175, seedZ=42, target=1, fillnumber=10, fuzzycenter=.25,
  fuzzywidth=1, threshold=1, fuzzyprob=0.4, srcWave=ddd
```

For an additional example see **Seed Fill** on page III-377. To display the result of the operation for 3D waves it is useful to convert the 3D wave M_SeedFill into an array of quads. See ImageTransform **vol2surf**.

ImageSnake

ImageSnake [*flags*] *srcWave*

The ImageSnake operation creates or modifies an active contour/snake in the grayscale image srcWave. The operation iterates to find the “lowest total energy” snake. The energy is defined by a range of optional flags, each corresponding to an individual term in the total energy expression. Iterations terminate by reaching the maximum number of iterations, when the snake does not move between iterations or when the user aborts the operation.

Flags

/ALPH= <i>alpha</i>	Sets the coefficient of the energy term arising from the “tightness” of the snake.
/BETA= <i>beta</i>	Sets the coefficient of the energy term corresponding to curvature of the snake. A high value for beta makes the snake more rounded.
/DELTA= <i>delta</i>	Sets the coefficient of the repulsion energy. A high value of <i>delta</i> keeps nonconsecutive snake points far from each other.
/EPS= <i>num</i>	Sets the maximum number of vertices which are allowed to move in one iteration. If the number of vertices which move during an iteration is smaller than <i>num</i> then iterations terminate.
/EXEF= <i>eta</i>	Sets the coefficient of the optional external energy component. By default this value is set to zero and there is no external energy contribution to the snakes energy. Note, this component is referred to as “external” because it is completely up to the user to specify both its coefficient and the value associated with each pixel. It should not be confused with what is called external snake energy in the literature, which usually applies to energy proportional to the gradient image (see /GAMM and /GRDI).

<code>/EXEN=<i>wave</i></code>	<p>Specify a wave that contains energy values that will be added to the snakes energy calculation. The wave must have the same dimensions as <i>srcWave</i> and must be single precision float. Each pixel value corresponds to user defined energy which will be multiplied by the <code>/EXEF</code> coefficient and added to the sum which the snake minimizes. Note that when <code>/EXEF</code> is set to zero this component is ignored. An external energy wave may be useful, for example, if you want to attract the snake to the picture boundaries. In that case you can set:</p> <pre>Duplicate/O srcWave,extWave Redimension/S extWave Variable rows=DimSize(srcWave,0)-1 Variable cols=DimSize(srcWave,1)-1 extWave=(p==0 q==0 p==rows q==cols) ? 0:1</pre>
<code>/GAMM=<i>gamma</i></code>	<p>Sets the coefficient of the energy term corresponding to the gradient. A high value of gamma makes the snake follow lines of high image gradient.</p>
<code>/GRDI=<i>gWave</i></code>	<p>Specify the gradient image. This wave must have the same dimensions as <i>srcWave</i> and it must be single precision float. The wave corresponds to the quantity $\text{abs}(\text{grad}(\text{gauss}^{**}\text{srcWave}))$, where <code>grad</code> is the gradient operator and <code>**</code> denotes convolution of the source wave with a Gaussian kernel. It is best to run the operation the first time without specifying this wave. When the operation executes, it creates the wave <code>M_GradImage</code> which can then be used in subsequent executions of this operation. If you want to modify the wave to express some other form of energy that you want the operation to minimize, you should use the <code>/EXEN</code> and <code>/EXEF</code> flags.</p>
<code>/ITER=<i>iterations</i></code>	<p>Sets the maximum number of iterations. Convergence can be achieved if the value specified by <code>/EPS</code> is met. You can also terminate the process earlier by pressing the User Abort Key Combinations.</p>
<code>/N=<i>snakePts</i></code>	<p>Specify the number of vertices in the snake or the number of snake points. Note that if you are providing snake waves in <code>/SX</code> and <code>/SY</code>, you do not need to specify this flag. If you do not specify this flag the default value is 40.</p>
<code>/SIG=<i>sigma</i></code>	<p>Sets the size of the Gaussian kernel that is used to convolve the input image when creating the gradient image. Note that you do not need to use this flag if you provide a gradient image. <i>sigma</i> is 3 by default. You can use larger odd integers for larger Gaussian kernels which would correspond to a stronger blur.</p>
<code>/STRT={<i>centerX, centerY, radius</i>}</code>	<p>Sets the starting snake to be a circle with the given center and radius. If you use this flag you should also provide the number of snake points using the <code>/N</code> flag.</p>
<code>/STEP=<i>pixels</i></code>	<p>Sets the maximum radius of search. By default the radius of the search is 6 pixels and the search follows a clockwise pattern from radius of 1 pixel to maximum radius specified by this flag. Note: the search radius should be smaller than the dimension of a typical feature in the image. If the radius is larger the snake may encompass more than one object. Larger radius is also less efficient because many of the pixels in that range would result in a snake that crosses itself and hence get rejected in the process.</p>
<code>/SX=<i>xSnake</i></code>	<p>Provide an X-wave for the starting snake. You must also provide an appropriate Y-wave using <code>/SY</code>.</p>
<code>/SY=<i>ySnake</i></code>	<p>Provide a Y-Wave for the starting snake. Must work in combination with <code>/SX</code>.</p>

/UPDM=mode Sets the update mode using any combination of the following:

Value	Update
0	Once when the operation terminates.
1	Once at the end of every iteration.
2	Once after every snake vertex moves.
4	Once for every search position.

/Q Quiet mode; don't print information in the history.

/Z Don't report any errors.

Details

A snake is a two-dimensional, usually closed, path drawn over an image. The snake is described by a pair of XY waves consisting of N vertices (sometimes called "snake elements" or "snaksels"). In this implementation it is assumed that the snake is closed so that the last point in the snake is connected to the first. Snakes are used in image segmentation, when you want to automatically select a contiguous portion of the plane based on some criteria. Unlike the classic contours, snakes do not have to follow a constant level. Their structure (or path) is found by associating the concept of energy with every snake configuration and attempting to find the configuration for which the associated energy is a minimum. The search for a minimum energy configuration is usually time consuming and it strongly depends on the format of the energy function and the initial conditions (as defined by the starting snake). The operation computes the energy as a sum of the following 5 terms:

1. The coefficient alpha times a sum of absolute deviations from the average snake segment length. This term tends to distribute the vertices of the snake at even intervals.
2. The coefficient beta times a sum of energies associated with the curvature of the snake at each vertex.
3. The coefficient gamma times a sum of energies computed from the negative magnitude of the gradient of a Gaussian kernel convolved with the image. This term is usually referred to in the literature as the external energy and usually drives the snake to follow the direction of high image gradients.
4. The coefficient delta times a repulsion energy. Repulsion is computed as an inverse square law by adding contributions from all vertices except the two that are immediately connected to each vertex. This energy term is designed to make sure that the snake does not fold itself into "valleys".
5. The coefficient eta times the sum of values corresponding to the positions of all snake vertices in the wave you provide in */EXEN*.

The energy calculation skips all terms for which the coefficient is zero. In addition there is a built-in scan which adds a very high penalty for configurations in which the snake crosses itself.

ImageSkeleton3D

ImageSkeleton3D [*/DEST=destWave /METH=method /Z*] *srcWave*

The ImageSkeleton3D operation computes the skeleton of a 3D binary object in *srcWave* by "thinning". Thinning is a layer-by-layer erosion until only the "skeleton" of an object remains. (See reference below.) It is used in neuroscience to trace neurons.

The ImageSkeleton3D operation was added in Igor Pro 7.00.

Parameters

srcWave is a 3D unsigned-byte wave where object voxels are set to 1 and the background is set to 0.

ImageStats

Flags

- `/DEST=destWave` Specifies the wave to contain the output of the operation. If the specified wave already exists, it is overwritten.
When used in a user-defined function, ImageSkeleton3D creates wave reference for *destWave* if it is a simple name. See **Automatic Creation of WAVE References** on page IV-71 for details.
If you omit `/DEST` the output wave is `M_Skeleton` in the current data folder.
- `/METH=m` Sets the method used to compute the skeleton.
m=1: Uses elements of an algorithm by Kalman Palagyi (default).
This is currently the only supported method.
- `/Z` Do not report any errors.

Details

The output is stored in the wave `M_Skeleton` in the current data folder or in the wave specified by `/DEST`. Skeleton voxels are set to the value 1 and background voxels are set to 0.

Example

```
// Create a cube with orthogonal square holes
Make/B/U/N=(30,30,30) ddd=0
ddd[2,27][2,27][2,27]=1
ddd[2,27][10,20][10,20]=0
ddd[10,20][2,27][10,20]=0
ddd[10,20][10,20][2,27]=0
ImageSkeleton3D ddd
```

ImageStats

ImageStats [flags] *imageWave*

The ImageStats operation calculates wave statistics for specified regions of interest in a real matrix wave. The operation applies to image pixels whose corresponding pixels in the ROI wave are set to zero. It does not print any results in the history area.

Flags

- `/BEAM` Computes the average, minimum, and maximum pixel values in each layer of a 3D wave and 2D ROI. Output is to waves `W_ISBeamAvg`, `W_ISBeamMax`, and `W_ISBeamMin` in the current data folder. Use `/RECT` to improve efficiency for simple ROI domains. `V_` variable results correspond to the last evaluated layer of the 3D wave. Do not use `/G`, `/GS`, or `/P` with this flag. Set `/M=1` for maximum efficiency.
- `/BRXY={xWave, yWave}`

Use this option with a 3D imageWave. It provides a more efficient method for computing average, minimum and maximum values when the set of points of interest is much smaller than the dimensions of an image.

Here *xWave* and *yWave* are 1D waves with the same number of points containing XY integer pixel locations specifying arbitrary pixels for which the statistics are calculated on a plane by plane basis as follows:

$$W_ISBeamAvg[k] = \frac{1}{n} \sum_{i=1}^n Image[xWave[i]][yWave[i]].$$

Pixel locations are zero-based; non-integer entries may produce unpredictable results.

The calculated statistics for each plane are stored in the current data folder in the waves *W_ISBeamAvg*, *W_ISBeamMax* and *W_ISBeamMin*.

Note: This flag is not compatible with any other flag except */BEAM*.

/C=chunk When imageWave is a 4D wave, */C* specifies the chunk for which statistics are calculated. By default *chunk = 0*.

Added in Igor Pro 7.00.

/G={startP, endP, startQ, endQ}

Specifies the corners of a rectangular ROI. When this flag is used an ROI wave is not required. This flag requires that $startP \leq endP$ and $startQ \leq endQ$. When the parameters extend beyond the image area, the command will not execute and *V_flag* will be set to -1. You should therefore verify that *V_flag=0* before using the results of this operation.

/GS={sMinRow,sMaxRow,sMinCol,sMaxCol}

Specifies a rectangular region of interest in terms of the scaled image coordinates. Each one of the 4 values will be translated to an integer pixel using truncation.

This flag, */G*, and an ROI specification are mutually exclusive.

/M=val

Calculates the average and locates the minimum and the maximum in the ROI when */M=1*. This will save you the computation time associated with the higher order statistical moments.

/P=planeNumber

Restricts the calculation to a particular layer of a 3D wave. By default, *planeNumber=-1* and only the first layer of the wave is processed.

/R=roiWave

Specifies a region of interest (ROI) in the image. The ROI is defined by a wave of type unsigned byte (*/b/u*), which has the same number of rows and columns as the image wave. The ROI itself is defined by the entries/pixels whose value are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous. See **ImageGenerateROIMask** for more information on creating ROI waves.

/RECT={minRow, maxRow, minCol, maxCol}

Limits the range of the ROI to a rectangular pixel range with */BEAM*.

Details

The image statistics are returned via the following variables:

<i>V_adev</i>	Average deviation of pixel values.
<i>V_avg</i>	Average of pixel values.
<i>V_kurt</i>	Kurtosis of pixel values.
<i>V_min</i>	Minimum pixel value.

ImageThreshold

V_minColLoc	Specifies the location of the column in which the minimum pixel value was found or the first eligible column if no single column was found.
V_minRowLoc	Specifies the location of the row in which the minimum pixel value was found or the first eligible row if no single minimum was found.
V_max	Maximum pixel value.
V_maxColLoc	Specifies the location of the column in which the maximum pixel value was found or the first eligible column if no single column was found.
V_maxRowLoc	Specifies the location of the row in which the maximum pixel value was found or the first eligible row if no single maximum was found.
V_npnts	Number of points in the ROI.
V_rms	Root mean squared of pixel values.
V_sdev	Standard deviation of pixel values.
V_skew	Skewness of pixel values.

Most of these statistical results are similarly defined as for the WaveStats operation. WaveStats will be more convenient to use when calculating statistics for an entire wave.

If *imageWave* is 4D it is often useful to use the reversible conversion

```
Redimension/N=(rows,cols, layers*chunks) ImageWave
```

which allows you to obtain the statistics for each layer and all chunks of the wave. To convert back to 4D, execute:

```
Redimension/N=(rows,cols, layers, chunks) ImageWave
```

See Also

The **ImageGenerateROIMask** and **WaveStats** operations. **ImageStats Operation** on page III-371.

ImageThreshold

ImageThreshold [*flags*] *imageMatrix*

The ImageThreshold operation converts a grayscale *imageMatrix* into a binary image. The operation supports all data types. However, the source wave must be a 2D matrix. If *imageMatrix* contains NaNs, the pixels corresponding to NaN values are mapped into the value 64. The values for the On and Off pixels are 255 and 0 respectively. The resulting image is stored in the wave M_ImageThresh.

Flags

/C	Calculates the correlation coefficient between the original image and the image generated by the threshold operation. The correlation value is printed to the history area (unless the /Q flag is specified), it is also stored in the variable V_correlation.
/I	Inverts values written to the image, i.e., sets to zero all pixels above threshold.

<i>/M= method</i>	Specifies the thresholding method. The calculated value will be printed to the history area (unless <i>/Q</i> is specified) and stored in the variable <i>V_threshold</i> .
<i>method=0:</i>	Default. In this case you must use the <i>/T</i> flag to specify a manually-selected threshold.
<i>method=1:</i>	Automatically calculate a threshold value using an iterative method.
<i>method=2:</i>	Image histogram is a simple bimodal distribution.
<i>method=3:</i>	Adaptive thresholding. Evaluates threshold based on the last 8 pixels in each row, using alternating rows.
	The output wave <i>M_ImageThresh</i> has the same numeric type as the input wave. In particular, when the input is signed byte, the on and off pixel values are 127 and 0 respectively.
	Note that this method is not supported when used as part of the operation ImageEdgeDetection .
<i>method=4:</i>	Fuzzy thresholding using entropy as the measure for "fuzziness".
<i>method=5:</i>	Fuzzy thresholding using a method that minimizes a "fuzziness" measure involving the mean gray level in the object and background.
<i>method=6:</i>	Determines an ideal threshold by histogramming the data and representing the image as a set of clusters that is iteratively reduced until there are two clusters left. The threshold value is then set to the highest level of the lower cluster. This method is based on a paper by A.Z. Arifin and A. Asano (see reference below) but modified for handling images with relatively flat histograms.
	If the image histogram results in less than two clusters, it is impossible to determine a threshold using this method and the threshold value is set to NaN.
	Added in Igor Pro 7.00.
<i>method=7:</i>	Determines the ideal threshold value by maximizing the total variance between the "object" and the "background". See http://en.wikipedia.org/wiki/Otsu%27s_method .
<i>/N</i>	Sets the background level to 64 (i.e., NaN).
<i>/O</i>	Overwrites the original image with the calculated threshold image. If you do not specify the <i>/O</i> flag, the threshold image is written into the wave <i>M_ImageThresh</i> .
<i>/P=layer</i>	When <i>imageMatrix</i> is a 3D wave <i>/P</i> selects a specific layer for which to compute the threshold. <i>layer</i> is the zero-based layer index. If <i>layer</i> is -1, which is the default value, the threshold is computed for all layers of <i>imageMatrix</i> . The <i>/P</i> flag is not compatible with <i>/O</i> . The <i>/P</i> flag was added in Igor Pro 7.00.
<i>/Q</i>	Suppresses printing calculated correlation coefficients (<i>/C</i>) and calculated thresholds (<i>/M</i>) to the history area.
<i>/R=roiSpec</i>	Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (<i>/b/u</i>). The ROI wave must have the same number of rows and columns as the image wave. The ROI itself is defined by the entries/pixels whose values are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous and can take any arbitrary shape. See ImageGenerateROIMask for more information on creating ROI waves.

In general, the *roiSpec* has the form {*roiWaveName*, *roiFlag*}, where *roiFlag* can take the following values:

roiFlag=0: Set pixels outside the ROI to 0.

roiFlag=1: Set pixels outside the ROI as in original image.

roiFlag=2: Set pixels outside the ROI to NaN (=64).

By default *roiFlag* is set to 1 and it is then possible to use the /R flag using the abbreviated form /R=*roiWave*.

/T=*thresh*

Sets the threshold value.

/W= *Twave*

Sets the threshold intervals. Each interval is specified by a pair of values in the wave *Twave*. The first element in each pair is the low value and the second element is the high value. Pixel values that lie outside all the specified intervals are set to 0.

For usage examples see **Threshold Examples** on page III-356. The **ImageGenerateROIMask** and **ImageEdgeDetection** operations.

ImageTransform

ImageTransform [*flags*] *Method imageMatrix*

The ImageTransform operation performs one of a number of transformations on *imageMatrix*. The result of using most keywords is a new wave stored in the current data folder. Most flags in this operation are exclusive to the keywords in which they are mentioned.

Parameters

Method selects type of transform. It is one of the following names:

averageImage Computes an average image for a stack of images contained in 3D *imageMatrix*. The average image is stored in the wave M_AveImage and the standard deviation for each pixel is stored in the wave M_StdvImage in the current data folder. You can use this keyword together with the optional /R flag where a region of interest is defined by zero value points in a ROI wave. The operation sets to NaN the entries in M_AveImage and M_StdvImage that correspond to pixels outside the ROI. *imageMatrix* must have at least three layers.

averageRGBImage Computes an average image from a sequence of RGB images represented by a 4D wave. The average is computed separately for the R, G and B channels and the resulting RGB image is stored in the wave M_AverageRGBImage in the current data folder. The operation supports all real data types.

Added in Igor Pro 7.00.

backProjection	<p>Reconstructs the source image from a projection slice and stores the result in the wave M_BackProjection. The projection slice should either be a wave produced by the projectionSlice keyword of this operation or a wave that would be similarly scaled. The input must be a single or double precision real 2D wave. Row scaling must range symmetrically about zero. For example, if the reconstructed image is expected to have 256 rows then the row scaling of the input should be from -128 to 127. Similarly, the column scaling of the input should range between zero and π. An equivalent implementation as a user function is provided in the demo experiment. You can use this implementation as a starting point if you want to develop filtered back projection.</p> <p>See the projectionSlice keyword and the RadonTransformDemo experiment. For algorithm details see the chapter “Reconstruction of cross-sections and the projection-slice theorem of computerized tomography” in Born and Wolf, 1999.</p>
ccsubdivision	<p>Performs a Catmull-Clark recursive generation of B-spline surfaces. There are two valid inputs: triangular meshes or quad meshes.</p> <p>Quad meshes are assumed to be in the form of a 3D wave where the first plane contains the X-values, the second the Y-values and the third the Z-values.</p> <p>Triangle meshes are much more complicated to convert into face-edge-vertex arrays so they are less desirable. They are stored in a three column (triplet) wave where the first column corresponds to the X coordinate, the second to the Y coordinate and the third to the Z coordinate. Each triangle is described by three rows in the wave and common vertices have to be repeated so that each sequential three rows in the triplet wave correspond to a single triangle. You can also associate a scalar value with each vertex and it will be suitably interpolated as new vertices are computed and old ones are shifted. In this case the input source wave contains one more column in the case of a triplet wave or one more plane in the case of a quad wave. The scalar value is added everywhere as an additional dimension to the spatial part of any point calculation.</p> <p>You can specify the number of iterations using the /I flag. By default the operation executes a single iteration. The output is saved in a quad wave M_CCBSplines that consists of 4 columns. Each row corresponds to a Quad where the 3 planes contain the X, Y, and Z components. If you are using an optional scalar in the input, the scalar result is stored in the wave M_CCBScalar.</p> <p>In some situations you may encounter spatial degeneracies when two or more parts of the surface meet at common vertices. This leads to one or more error messages in the history area of the command window. You can try to break a degeneracy yourself by adding a small perturbation to the input coordinates or you can use the /PRTF flag which adds a random perturbation on the order of 1e-10 times the extent of the data in each dimension. The perturbation does not affect the scalar.</p>
cmap2rgb	<p>Converts an image and its associated colormap wave (specified using the /C flag) into an RGB image stored in a 3D wave M_RGBOut.</p>
CMYK2RGB	<p>Converts a CMYK image, stored as 4 layer unsigned byte wave, into a 3 layer, standard RGB image wave. The output wave is M_CMYK2RGB that is stored in the current data folder.</p>
compress	<p>Compresses the data in the <i>imageWave</i> using a nonlossy algorithm and stores it in the wave W_Compressed in the current data folder. The compressed wave includes all data associated with <i>imageWave</i> including its units and wavenote. Use the decompress keyword to recover the original wave. The operation supports all numeric data types.</p> <p>NOTE: The compression format for waves greater than 2GB in size was changed in version 6.30B02. If you compressed a wave greater than 2 GB in IGOR64 6.30B01, you will need to decompress it using the same version. You can not decompress it in 6.30B02 or later.</p>
convert2gray	<p>Converts an arbitrary 2D wave into an 8-bit normalized 2D wave. The default output wave name is M_Image2Gray.</p>

ImageTransform

decompress	<p>Decompresses a compressed wave. It saves a copy of the decompressed wave under the name <i>W_DeCompressed</i> in the current data folder.</p> <p>NOTE: The compression format for waves greater than 2GB in size was changed in version 6.30B02. If you compressed a wave greater than 2 GB in IGOR64 6.30B01, you will need to decompress it using the same version. You can not decompress it in 6.30B02 or later.</p>
distance	<p>Computes the distance transform, also called "distance map", for the input image. Added in Igor Pro 7.00.</p> <p>The distance transform/map is an image where every pixel belonging to the "object" is replaced by the shortest distance of that pixel from the background/boundary.</p> <p><i>imageMatrix</i> must be a 2D wave of type unsigned byte (Make/B/U) where pixels corresponding to the object are set to zero and pixels corresponding to the background are set to 255. Such an image can be obtained, for example, using ImageThreshold with the /I flag.</p> <p>The resulting distance map is stored in the wave <i>M_DistanceMap</i> in the current data folder. The operation supports three metrics (Manhattan, Euclidean, Euclidean + scaling) set via the /METR flag.</p>
extractSurface	<p>Extracts values corresponding to a plane that intersects a 3D volume wave (<i>imageMatrix</i>). You must specify the extraction parameters using the /X flag. The volume is defined by the wave scaling of the 3D wave. The result, obtained by trilinear interpolation, is stored in the wave <i>M_ExtractedSurface</i> and is of the type NT_FP64. Points in the plane that lie outside the volume are set to NaN.</p>
fft	<p>Performs a Fast Hartley Transform subject to the /T flag. The source wave must be a 2D real matrix with a power of 2 number of rows and columns. Default output is saved in the double-precision wave <i>M_Hartley</i> in the current data folder. If you use the /O flag the result overwrites <i>imageMatrix</i> without changing the numeric type. If <i>imageMatrix</i> is single-precision float the conversion is straightforward. All other numeric types are scaled. Single- and double-byte types are scaled to the full dynamic range. 32 bit integers are scaled to the range of the equivalent 16 bit types (i.e., unsigned int is scaled to unsigned short range etc.). It does not support wave scaling or NaN entries.</p>
fillImage	<p>Fills a 2D target image wave with data from a 1D image wave (specified using /D). Both waves must be the same data type, and the number of data points in the target wave must match the number of points in the data wave. There are four fill modes that are specified via the /M flag. The operation supports all noncomplex numeric data types.</p>
findLakes	<p>Originally intended to identify lakes in geographical data, this operation creates a mask for a 2D wave for all the contiguous points whose values are close to each other. You can determine the minimum number of pixels within a contiguous region using the /LARA=<i>minPixels</i> flag (default is 100). You can determine how close values must be in order to belong to a contiguous region using the /LTOL=<i>tolerance</i> flag (default is zero). You can also limit the search region using the /LRCT flag. Use the flag /LTAR=<i>target</i> to set the value of the masked regions. By default, the algorithm uses 4-connectivity when looking at adjacent pixels. You can set it to 8-connectivity using the /LCVT flag. The result of the operation is saved in the wave <i>M_LakeFill</i>. It has the same data type as the source wave and contains all the source values outside the masked pixels.</p>
flipCols	<p>Rearrange pixels by exchanging columns symmetrically about a center column or the center of the image (if the number of columns is even). The exchange is performed in place and can be reverted by repeating the operation. When working with 3D waves, use the /P flag to specify the plane that you want to operate on.</p>

flipRows	Rearrange pixels in the image by exchanging rows symmetrically about the middle row or the middle of the image (if the image has an even number of rows). The exchange is performed in place and can be reverted by repeating the operation. When working with 3D waves, use the /P flag to specify the plane that you want to operate on.
flipPlanes	Rearrange data in a 3D wave by exchanging planes symmetrically about the middle plane. The operation is performed in place and can be reverted by repeating the operation.
fuzzyClassify	<p>Segments grayscale and color images using fuzzy logic. Iteration stops when it reaches convergence defined by /TOL or the maximum number of iterations specified by /I. It is a good practice to specify the tolerance and the number of iterations. If the number of classes is small, the operation prints the class values in the history. Use /Q to eliminate printing and increase performance. Use /CLAS to specify the number of classes and optionally use /CLAM to modify the fuzzy probability values. Use /SEG to generate the segmentation image. The classes are stored in the wave W_FuzzyClasses in the current data folder and it will be overwritten if it already exists.</p> <p>When <i>imageMatrix</i> is a grayscale image, each class is a single wave entry. When <i>imageMatrix</i> is a RGB image, classes are stored consecutively in the wave W_FuzzyClasses. If you request more classes than are present in <i>imageMatrix</i>, you will likely find a degeneracy where the space of a data class is spanned by more than one class. It is a good idea to compute the Euclidean distance between every possible pair of classes and eliminate degeneracies when the distance falls below some threshold.</p> <p>Any real data type is allowed but values in the range [0,255] are optimal. You can segment 3D waves of more than 3 layers in which a class will be a vector of dimensionality equal to the number of layers in <i>imageMatrix</i>.</p> <p>For examples see Examples/Imaging/fuzzyClassifyDemo.pxp.</p>
getBeam	<p>Extracts a beam from a 3D wave.</p> <p>A “beam” is a 1D array in the Z-direction. If a row is a 1D array in the first dimension and a column is a 1D array in the second dimension then a beam is a 1D array in the third dimension.</p> <p>The number of points in a beam is equal to the number of layers in <i>imageWave</i>. Specify the beam with the /BEAM={row,column} flag. It stores the result in the wave W_Beam in the current data folder. W_Beam has the same numeric type as <i>imageWave</i>. Use setBeam to set beam values. (See also, MatrixOp beam.)</p>
getChunk	Extracts the chunk specified by chunk index /CHIX from <i>imageMatrix</i> and stores it in the wave M_Chunk in the current data folder. For example, if <i>imageMatrix</i> has the dimensions (10,20,3,10), the resulting M_Chunk has the dimensions (10,20,3). See also setChunk and insertChunk .
getCol	Extracts a 1D wave, named W_ExtractedCol, from any type of 2D or 3D wave. You specify the column using the /G flag. For a 3D source wave, it will use the first plane unless you specify a plane using the /P flag. <i>imageMatrix</i> can be real or complex. (See also putCol keyword, MatrixOp col.)
getPlane	Creates a new wave, named M_ImagePlane, that contains data in the plane specified by the /P flag. The new wave is of the same data type as the source wave. You can specify the type of plane using the /PTYP flag. (See also setPlane keyword, MatrixOp .)
getRow	Extracts a 1D wave, named W_ExtractedRow, from any type of 2D or 3D wave. You specify the row using the /G flag. For a 3D source wave, it will use the first plane unless you specify a plane using the /P flag. <i>imageMatrix</i> can be real or complex. (See also setRow keyword, MatrixOp row.)

Hough	<p>Performs the Hough transform of the input wave. The result is saved to a 2D wave <i>M_Hough</i> in which the columns correspond to angle and the rows correspond to the radial domain.</p> <p>By default the output consists of 180 columns. Use the <i>/F</i> flag to modify the angular resolution.</p> <p>If the input image has <i>N</i> rows and <i>M</i> columns then the number of rows in the <i>M_Hough</i> is set to $1+\sqrt{N^2+M^2}$. The output radius should be read relative to the center row.</p> <p>It is assumed that the input wave has square pixels of unit size and that is binary (<i>/B/U</i>) where the background value is 0.</p> <p>See also Hough Transform on page III-364.</p>												
hsl2rgb	<p>Transforms a 3-plane HSL wave into a 3-plane RGB wave. If the source wave for this operation is of any type other than byte or unsigned byte, the HSL values are expected to be between 0 and 65535. For all source wave types the resulting RGB wave is of type unsigned short. The result of the operation is the wave <i>M_HSL2RGB</i> (of type unsigned word), where the RGB values are in the range 0 to 65535.</p>												
hslSegment	<p>Creates a binary image of the same dimensions as the source image, in which all pixels that belong to all three of the specified Hue, Saturation, and Lightness ranges are set to 255 and the others to zero. You can specify the HSL ranges using the <i>/H</i>, <i>/S</i>, and <i>/L</i> flags. Each flag takes as an argument either a pair of values or a wave containing pairs of values. You must specify the <i>/H</i> flag but you can omit the <i>/S</i> and <i>/L</i> flags in which case the default values (corresponding to full range 0 to 1) are used. <i>imageMatrix</i> is assumed to be an RGB image.</p>												
imageToTexture	<p>Transforms a 2D or 3D image wave into a 1D wave of contiguous pixel components. The transformation is useful for creating an OpenGL texture (for Gizmo) or for saving a color image in a format requiring either RGB or RGBA sequences.</p> <p>The <i>/O</i> flag does not apply to <i>imageToTexture</i>.</p> <p>Use the <i>/TEXT</i> flag to specify the type of transformation. <i>imageMatrix</i> must be an unsigned byte wave. A 1D unsigned byte wave named <i>W_Texture</i> is created in the current data folder.</p> <p><i>W_Texture</i>'s wave note is set to a semicolon-separated list of keyword -value pairs that can be parsed using StringByKey and NumberByKey:</p> <table border="0" style="margin-left: 20px;"> <thead> <tr> <th style="text-align: left; padding-right: 20px;">Keyword</th> <th>Information Following Keyword</th> </tr> </thead> <tbody> <tr> <td style="padding-right: 20px;">WIDTHPIXELS</td> <td>DimSize(<i>imageMatrix</i>,0) or truncated to nearest power of 2 if <i>/TEXT</i> value is odd</td> </tr> <tr> <td style="padding-right: 20px;">HEIGHTPIXELS</td> <td>DimSize(<i>imageMatrix</i>,1) or truncated to nearest power of 2</td> </tr> <tr> <td style="padding-right: 20px;">LAYERS</td> <td>DimSize(<i>imageMatrix</i>,2)</td> </tr> <tr> <td style="padding-right: 20px;">TEXTUREMODE</td> <td>val parameter from <i>/TEXT</i> flag</td> </tr> <tr> <td style="padding-right: 20px;">SOURCEWAVE</td> <td>GetWavesDataFolder(<i>imageMatrix</i>, 2)</td> </tr> </tbody> </table>	Keyword	Information Following Keyword	WIDTHPIXELS	DimSize (<i>imageMatrix</i> ,0) or truncated to nearest power of 2 if <i>/TEXT</i> value is odd	HEIGHTPIXELS	DimSize (<i>imageMatrix</i> ,1) or truncated to nearest power of 2	LAYERS	DimSize (<i>imageMatrix</i> ,2)	TEXTUREMODE	val parameter from <i>/TEXT</i> flag	SOURCEWAVE	GetWavesDataFolder (<i>imageMatrix</i> , 2)
Keyword	Information Following Keyword												
WIDTHPIXELS	DimSize (<i>imageMatrix</i> ,0) or truncated to nearest power of 2 if <i>/TEXT</i> value is odd												
HEIGHTPIXELS	DimSize (<i>imageMatrix</i> ,1) or truncated to nearest power of 2												
LAYERS	DimSize (<i>imageMatrix</i> ,2)												
TEXTUREMODE	val parameter from <i>/TEXT</i> flag												
SOURCEWAVE	GetWavesDataFolder (<i>imageMatrix</i> , 2)												
indexWave	<p>Creates a 1D wave <i>W_IndexedValues</i> in the current data folder containing values from <i>imageMatrix</i> that are pointed to by the index wave (see <i>/IWAV</i>). Each row in the index wave corresponds to a single value of <i>imageMatrix</i>. If any row does not point to a valid index (within the dimensions of <i>imageMatrix</i>), the corresponding value is set to zero and the operation returns an error. Indices are zero based integers; the operation does not support interpolation and ignores wave scaling.</p>												

insertChunk	Inserts a chunk (a 3D wave specified by the /D flag) into <i>imageMatrix</i> at chunk index specified by the /CHIX flag. The dimensions of the inserted chunk must match the first three dimensions of <i>imageMatrix</i> . The wave must also have the same numeric type. The 4th dimension of <i>imageMatrix</i> is incremented by 1 to accommodate the new data. See also getChunk and setChunk .
insertImage	Inserts the image specified by the flag /INSI into <i>imageMatrix</i> starting at the position specified by the flags /INSX and /INSY. If the <i>imageMatrix</i> is a 3D wave then it inserts the image in the layer specified by the /P flag. The inserted image and <i>imageMatrix</i> must be the same data type. The inserted data is clipped to the boundaries of <i>imageMatrix</i> .
insertXplane	Inserts a 2D wave as a new plane perpendicular to the X-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be cols x layers of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 20x30. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder.
insertYplane	Inserts a 2D wave as a new plane perpendicular to the Y-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be rows x layers of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 10x30. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder.
insertZplane	Inserts a 2D wave as a new plane perpendicular to the Z-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be rows x cols of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 10x20. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder. This keyword is included for completeness. You can accomplish the same task using InsertPoints.
invert	Converts pixel values using the formula $newValue = 255 - oldValue$. Works on waves of any dimension, but only on waves of type unsigned byte. The result is stored in the wave M_Inverted unless specifying the /O flag.
matchPlanes	<p>Finds pixels that match test conditions in all layers of a 3D wave. It creates a 2D unsigned byte output wave, M_matchPlanes, that is set to the values 0 and 255. A value of 255 indicates that the corresponding pixel has satisfied test conditions in all layers of the wave for which conditions were provided. Otherwise the pixel value is 0.</p> <p>Test conditions are entered as a 2D wave using the /D flag. The condition wave must be double precision and it must contain the same number of columns as the number of layers in the 3D source wave. A condition for layer j of the source wave is specified by two rows in column j of the condition wave. The first row entry, say A, and the second row entry, say B, imply a condition on pixels in layer j such that $A \leq x < B$. You can have more than one condition for a given layer by adding pairs of rows to the condition wave. For example, if you add in consecutive rows the values C and D, this implies the test:</p>

$$(A \leq x \leq B) \parallel (C \leq x \leq D).$$

If you do not have any conditions for some layer, set its corresponding condition column to NaN. Similarly, if you have two conditions for the first layer and one condition for the second layer, pad the bottom of column 1 in the condition wave with NaNs. See Examples for use of this keyword to perform hue/saturation segmentation.

ImageTransform

offsetImage	<p>Shifts an image in the XY plane by dx, dy pixels (specified by the /IOFF flag). Pixels outside the shifted image will be set to the specified background value. The operation works on 2D waves or on 3D waves with the optional /P flag. When shifting a 3D wave with no specified plane, it creates a 3D wave with all planes offset by the same amount. The wave M_OffsetImage contains the result in the current data folder.</p> <p>The /O flag is not supported with offsetImage.</p>
padImage	<p>Resizes the source image. When enlarged, values from the last row and column fill in the new area. The /N flag specifies the new image size in terms of the rows and columns change. The /W flag specifies whether data should be wrapped when padding the image. Unless you use the /O flag, the result is stored in the wave M_PaddedImage in the current data folder.</p>
projectionSlice	<p>Computes a projection slice for a parallel fan of rays going through the image at various angles. For every ray in the fan the operation computes a line integral through the image (equivalent to the sum of the line profile along the ray). The operation computes the line integrals for multiple fans defined by the number and position of the rays as well as the angle that they make with the positive X-direction. Use the /PSL flag to specify the projection parameters. The projection slice itself is stored in a 2D wave M_ProjectionSlice where the rows correspond to the rays and the columns correspond to the selected range of angles. The operation does not support wave scaling. If the source wave is 3D the projection slice currently supports slices that are perpendicular to the z-axis and specified by their plane number.</p> <p>See the backProjection keyword and the RadonTransformDemo experiment. For algorithm details see the chapter “Reconstruction of cross-sections and the projection-slice theorem of computerized tomography” in Born and Wolf, 1999.</p>
putCol	<p>Sets a column of <i>imageMatrix</i> to the values in the wave specified by the /D flag. Use the /G flag to specify column number and the /P flag to specify the plane. Note that if there is a mismatch in the number of entries between the specified waves, the operation uses the smaller number. See also getCol keyword.</p>
putRow	<p>Sets a row of <i>imageMatrix</i> to the values in the wave specified by the /D flag. Use the /G flag to specify column number and the /P flag to specify the plane. Note that if there is a mismatch in the number of entries between the specified waves, the operation uses the smaller number. See also getRow keyword.</p>
removeXplane	<p>Removes one or more planes perpendicular to the X-axis from a 3D wave. The /P flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the /NP flag. If you do not use the /O flag, it saves the result in the wave M_ReducedWave in the current data folder.</p>
removeYplane	<p>Removes one or more planes perpendicular to the Y-axis from a 3D wave. The /P flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the /NP flag. If you do not use the /O flag, it saves the result in the wave M_ReducedWave in the current data folder.</p>
removeZplane	<p>Removes one or more planes perpendicular to the Z-axis from a 3D wave. The /P flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the /NP flag. If you do not use the /O flag, it saves the result in the wave M_ReducedWave in the current data folder.</p>

- rgb2cmap** Computes a default color map of 256 colors to represent the input RGB image. The colors are computed by clustering the input pixels in RGB space. The resulting color map is stored in the wave `M_ColorIndex` in the current data folder. The operation also saves the wave `M_IndexImage` which contains an index into the colormap that can be used to display the image using the commands:
- ```
NewImage M_IndexImage
ModifyImage M_IndexImage cindex= M_ColorIndex
```
- To change the default number of colors use the `/NCLR` flag. When the number of colors are greater than 256, `M_IndexImage` will be a 16-bit unsigned integer or a 32 bit integer wave depending on the number. `rgb2cmap` supports input images in the form of 3D waves of type unsigned byte or single precision float. The floating point option may be used to input images in colorspace that use signed numeric data.
- rgb2gray** When the input *imageMatrix* is a 3D RGB wave, `rgb2gray` produces a 2D wave of type unsigned byte containing the grayscale representation of the input. By default, the operation stores the output in the wave `M_RGB2Gray` in the current data folder. The RGB values are converted into the luminance *Y* of the YIQ standard using:
- $$Y = 0.299R + 0.587G + 0.114B$$
- When the input *imageMatrix* is a 4D wave containing multiple (3 layer) RGB chunks, the conversion produces a 3D wave where each layer corresponds to the grayscale conversion of the corresponding chunk in the input wave. In this case the numeric type of the output is the same as that of the input but the conversion formula is the same. The `/O` flag is not supported when transforming a 4D RGB wave.
- rgb2hsl** Converts an RGB image stored in a 3D wave into another 3D wave in which the three planes correspond to Hue, Saturation and Lightness in the HSL color model. Values of all components are normalized to the range 0 to 255 unless the `/U` flag is used or if the source wave is not 8-bit, in which case the range is 0 to 65535. The default output wave name is `M_RGB2HSL`.
- rgb2i123** Performs a colorspace conversion of an RGB image into the following quantities:
- $$I_1 = |R - G|D$$
- $$I_2 = |R - B|D \quad \text{where } D = \frac{255}{|R - G| + |R - B| + |G - B|}$$
- $$I_3 = |G - B|D,$$
- I*<sub>1</sub>, *I*<sub>2</sub>, and *I*<sub>3</sub> are stored in the wave `M_I123` (using the same data type as the original RGB wave) in the current data folder. *I*<sub>1</sub> is stored in the first layer, *I*<sub>2</sub> in the second and *I*<sub>3</sub> in the third. This color transformation is said to have useful applications in machine vision.
- For more information see: Gevers and Smeulders (1999).
- rgb2xyz** Converts a 3D RGB image wave into a 3D wave containing the XYZ color space equivalent. The conversion is based on the D65 white point and uses the following transformation:
- $$\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 0.412453 & 0.357580 & 0.180423 \\ 0.212671 & 0.715160 & 0.072169 \\ 0.019334 & 0.119193 & 0.950227 \end{bmatrix} \begin{bmatrix} R \\ G \\ B \end{bmatrix}$$
- The XYZ values are stored in a wave named "`M_RGB2XYZ`" unless the `/O` flag is used, in which case the source image is overwritten and converted into single precision wave (`NT_FP32`).

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| roiTo1D     | <p>Copies all pixels in an ROI and saves them sequentially in a 1D wave. The ROI is specified by /R. The ROI wave must have the same dimensions as <i>imageMatrix</i>. If <i>imageMatrix</i> is a 3D wave, the ROI must have as many layers as <i>imageMatrix</i>. The wave <i>W_roi_to_1d</i> contains the output in the current data folder, has the same numeric type as <i>imageMatrix</i>, and contains the selected pixels in a column-major order.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| rotateCols  | <p>Rotates rows in place. This operation is analogous to the <b>Rotate</b> operation except that it works on images and rotates an integer number of rows. The number of rows is specified by the /G flag.</p> <p>When <i>imageMatrix</i> contains multiple layers you can use the /P flag to specify the layer of the wave that will undergo rotation. By default, if you do not specify the /P flag and if <i>imageMatrix</i> consists of three layers (RGB), then all three layers are rotated. Otherwise the operation rotates only the first layer of the wave.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| rotateRows  | <p>Rotates columns in place. This operation is analogous to the <b>Rotate</b> operation except that it works on images and rotates an integer number of columns. The number of columns is specified by the /G flag.</p> <p>When <i>imageMatrix</i> contains multiple layers you can use the /P flag to specify the layer of the wave that will undergo rotation. By default, if you do not specify the /P flag and if <i>imageMatrix</i> consists of three layers (RGB), then all three layers are rotated. Otherwise the operation rotates only the first layer of the wave.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| scalePlanes | <p>Scales each plane of the 3D wave, <i>imageMatrix</i>, by a constant taken from the corresponding entry in the 1D wave specified by the /D flag. The result is stored in the wave <i>M_ScaledPlanes</i> unless the /O flag is specified, in which case scaling is done in place.</p> <p>When using /O, first redimension the wave to a different data type to make sure there are no artifacts due to type clipping.</p> <p>If <i>imageMatrix</i> is double precision, <i>M_ScaledPlanes</i> is double precision. Otherwise <i>M_ScaledPlanes</i> is single precision.</p> <p>This operation also supports the optional flag.</p> <p>Note that when you display <i>M_ScaledPlanes</i>, which has three planes that originated from scaling byte data, you will have to multiply the wave by 255 to see the image because the RGB format for single and double precision data requires values in the range 0 to 65535.</p>                                                                                                                                                                                                                                                                                       |
| selectColor | <p>Creates a mask for the image in which pixel values depend on the proximity of the color of the image to a given central color. The central color, the tolerance and a grayscale indicator must be specified using the /E flag.</p> <p>For example, /E={ 174 , 187 , 75 , 10 , 1 } specifies an RGB of (174,187,75), a tolerance level of 10 and a requested grayscale output.</p> <p>RGB values must be provided in a range appropriate for the source image. If the source wave type is not byte or unsigned byte, then the range of the RGB components should be 0 to 65535.</p> <p>The color proximity is calculated in the nonuniform RGB space and the tolerance applies to the maximum component difference from the corresponding component of the central color.</p> <p>The tolerance, just like the central color, should be appropriate to the type of the source wave.</p> <p>The generated mask is stored in the wave <i>M_SelectColor</i> in the current data folder. If a wave by that name exists prior to the execution of this operation, it is overwritten. You can also use the /R flag with this operation to limit the color selection to pixels in the ROI wave whose value is zero.</p> |

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| setBeam    | <p>Sets the data of a particular beam in <i>imageMatrix</i>.</p> <p>A “beam” is a 1D array in the Z-direction. If a row is a 1D array in the first dimension and a column is a 1D array in the second dimension then a beam is a 1D array in the third dimension.</p> <p>Specify the beam with the <code>/BEAM={row,column}</code> flag and the 1D beam data wave with the <code>/D</code> flag. The beam data wave must have the same number of elements as the number of layers and same numeric type as <i>imageMatrix</i>. Use <b>getBeam</b> to extract the beam.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| setChunk   | <p>Overwrites the data in the wave <i>imageMatrix</i> at chunk index specified by <code>/CHIX</code> with the data contained in a 3D wave specified by the <code>/D</code> flag. The assigned data must be contained in a wave that matches the first three dimensions of <i>imageMatrix</i> and must have the same number type. See also <b>getChunk</b> and <b>insertChunk</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| setPlane   | <p>Sets a plane (given by the <code>/P</code> flag) in the designated image with the data in a wave specified by the <code>/D</code> flag. It is designed as a complement of the <b>getPlane</b> keyword to provide an easier (faster) way to create multiplane images. Note that the operation supports setting a plane when the source data is smaller than the destination plane in which case the source data is placed in memory contiguously starting from the corner pixel of the destination plane. If the source data is larger than the destination plane it is clipped to the appropriate rows and columns. If you are setting all planes in the destination wave using algorithmically named source waves you could use the <b>stackImages</b> keyword instead. See also <b>getPlane</b> keyword.</p>                                                                                                                                                                                                             |
| shading    | <p>Calculates relative reflectance of a surface for a light source position defined by the <code>/A</code> flag.</p> <p>The operation estimates the slope of the surface and then computes a relative reflectance defined as the dot product of the direction of the light and the normal to the surface at the point of interest. Reflectivity is scaled using the expression:</p> $outPixel = shadingA * (sunDirection \cdot surfaceNormal) + shadingB$ <p>By default <i>shadingA</i>=1, <i>shadingB</i>=0.</p> <p>The result is stored in the wave <code>M_ShadedImage</code>, which has the same data type as the source wave.</p> <p>If the source wave is any integer type, and the value of <i>shadingA</i>=1 the operation sets that value to 255.</p> <p>The smallest supported wave size is 4x4 elements.</p> <p>Values along the boundary (1 pixel wide) are arbitrary because there are no derivatives calculable for those pixels, so these pixels are filled with duplicates of the inner rows and columns.</p> |
| shrinkBox  | <p>Shrinks 3D <i>imageMatrix</i> to include only the minimum three dimension rectangular range that contains all the voxels whose values are different from an outer value. The outer value is specified with the <code>/F</code> flag. This feature is useful in situations where <b>ImageSeedFill</b> has set the voxels around an object of interest to some outer value and it is desired to extract the smallest box that contains interesting data. The output is stored in the wave <code>M_shrunkBox</code>.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| shrinkRect | <p>Shrinks <i>imageMatrix</i> to include only the minimum rectangle that contains all the pixels whose value is different from an outer value. The outer value is specified with the <code>/F</code> flag. This is useful in situations where <b>ImageSeedFill</b> has set the pixels around the object of interest to some outer value and it is desired to extract the smallest rectangle that contains interesting data. The output is stored in the wave <code>M_Shrunk</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| stackImages  | <p>Creates a 3D or 4D stack from individual image waves in the current data folder. The waves should be of the form <i>baseNameN</i>, where <i>N</i> is a numeric suffix specifying the sequence order. <i>imageMatrix</i> should be the name of the first wave that you want to add to the stack. You can use the /NP flag to specify the number of waves that you want to add to the stack.</p> <p>The result is a 3D or 4D wave named M_Stack, which overwrites any existing wave of that name in the current data folder.</p> <p>With /K, it kills all waves copied into the stack.</p> |
| sumAllCols   | Creates a wave W_sumCols in which every entry is the sum of the pixels on the corresponding image column. For a 3D wave, unless you specify a plane using the /P flag it will use the first plane by default.                                                                                                                                                                                                                                                                                                                                                                               |
| sumAllRows   | Creates a wave W_sumRows in which every entry is the sum of the pixels on the corresponding image row. For a 3D wave, unless you specify a plane using the /P flag it will use the first plane by default.                                                                                                                                                                                                                                                                                                                                                                                  |
| sumCol       | Stores in the variable V_value the sum of the elements in the column specified by /G flag and optionally the /P flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| sumPlane     | Stores in the variable V_value the sum of the elements in the plane specified by the /P flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| sumPlanes    | Creates a 2D wave M_SumPlanes which contains the same number of rows and columns as the 3D source wave. Each entry in M_SumPlanes is the sum of the corresponding pixels in all the planes of the source wave. M_SumPlanes is a double precision wave if the source wave is double precision. Otherwise it is a single precision wave.                                                                                                                                                                                                                                                      |
| sumRow       | Stores in the variable V_value the sum of the elements of a row specified by /G flag and optionally the /P flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| swap         | Swaps image data following a 2D FFT. The transform swaps diagonal quadrants of the image in one or more planes. This keyword does not support any flags. The swapping is done in place and it overwrites the source wave.                                                                                                                                                                                                                                                                                                                                                                   |
| swap3D       | Swaps data following a 3D FFT. The transform swaps diagonal quadrants of the data. This keyword does not support any flags. The swapping is done in place and the source wave is overwritten.                                                                                                                                                                                                                                                                                                                                                                                               |
| transpose4D  | <p>Converts a 4D wave into a new 4D wave where the data are reordered by dimensions specified by the /TM4D flag. The results are stored in the wave M_4DTranspose in the current data folder. There is no option to overwrite the input wave so /O has no effect with transpose4D.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                       |
| transposeVol | <p>Transposes a 3D wave. The transposed wave is stored in M_VolumeTranspose. The /O flag does not apply. The operation supports the following 5 transpose modes which are specified using the /G flag:</p>                                                                                                                                                                                                                                                                                                                                                                                  |

| <i>mode</i> | <b>Equivalent Command</b>                         |
|-------------|---------------------------------------------------|
| 1           | M_VolumeTranspose= <i>imageMatrix</i> [p] [r] [q] |
| 2           | M_VolumeTranspose= <i>imageMatrix</i> [r] [p] [q] |
| 3           | M_VolumeTranspose= <i>imageMatrix</i> [r] [q] [p] |
| 4           | M_VolumeTranspose= <i>imageMatrix</i> [q] [r] [p] |
| 5           | M_VolumeTranspose= <i>imageMatrix</i> [q] [p] [r] |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vol2surf    | Creates a quad-wave output (appropriate for display in Gizmo) that wraps around 3D “particles”. A particle is defined as a region of nonzero value voxels in a 3D wave. The algorithm effectively computes a box at the resolution of the input wave which completely encloses the data. The output wave <code>M_Boxy</code> is a 2D single precision wave of 12 columns where each row corresponds to one disjoint quad and the columns provide the sequential X, Y, and Z coordinates of the quad vertices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| voronoi     | <p>Computes the voronoi tessellation of a convex domain defined by the X, Y positions of the input wave. <i>imageMatrix</i> must be a triplet wave where the first column contains the X-values, the second column contains the Y-values and the third column is an arbitrary (zero is recommended) constant. The result of the operation is stored in the two column wave <code>M_VoronoiEdges</code> which contains sequential edges of the Voronoi polygons. Edges are separated from each other by a row of NaNs. The outer most polygons share one or more edges with a large triangle which contains the convex domain.</p> <p>The operation creates two output waves:</p> <p><code>M_Circles</code> is a three column wave containing the center and radius of each natural neighborhood. The radius is correct only if equal scaling is applied.</p> <p><code>M_DelaunayTriangles</code> consists of 3 columns for the vertices of the triangles. Each triangle consists of 4 vertices. The 4th vertex is equal to the first. An extra row of NaNs used as a separator.</p> <p>For an example, see Voronoi Tessellation Example below.</p> |
| xProjection | Computes the projection in the X-direction and stores the result in the wave <code>M_xProjection</code> . See <b>zProjection</b> for more information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| xyz2rgb     | <p>Converts a 3D single precision XYZ color-space data into RGB based on the D65 white point. The transformation used is:</p> $\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \begin{bmatrix} 3.240479 & -1.537150 & -0.498535 \\ -0.969256 & 1.875992 & 0.041556 \\ 0.055648 & -0.204043 & 1.057311 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix}.$ <p>If you do not specify the <code>/O</code> flag, the results are saved in a single precision 3D wave (NT_FP32) “<code>M_XYZ2RGB</code>”.</p> <p>Note that not all XYZ values map into positive RGB triplets (consider colors that reside outside the RGB triangle in the XYZ diagram). This operation gives you the following choices: by default, the output wave is a single precision wave that will include possible negative RGB values. If you specify the <code>/U</code> flag, for unsigned short output wave, the operation will set to zero all negative components and scale the remaining ones in the range 0 to 65535.</p>                                                                                                                                              |
| yProjection | Computes the projection in the Y-direction and stores the result in the wave <code>M_yProjection</code> . See <b>zProjection</b> for more information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| zDot        | Computes the dot product of a beam in <i>srcWave</i> with a 1D <i>zVector</i> wave (specified with the <code>/D</code> flag). This will convert stacked images of spectral scans into RGB or XYZ depending on the scaling in <i>zVector</i> . The <i>srcWave</i> and <i>zVector</i> must be the same data type (float or double). The wave <code>M_StackDot</code> contains the result in the current data folder.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| zProjection | Computes the projection in the Z-direction and stores the result in the wave <code>M_zProjection</code> . The source wave must be a 3D wave of arbitrary data type. The value of the projection depends on the method specified via the <code>/METH</code> flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### Flags

`/A={azimuth, elevation [, shadingA, shadingB]}`

|                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                 | Specifies parameters for shade. Position of the light source is given by <i>azimuth</i> (measured in degrees counter-clockwise) and <i>elevation</i> (measured in degrees above the horizon).                                                                                                                                                                                                                                              |
|                                                 | The parameters <i>shadingA</i> and <i>shadingB</i> are optional. By default their values are 1 and 0, respectively.                                                                                                                                                                                                                                                                                                                        |
| <i>/Beam={row,column}</i>                       | Designates a beam in a 3D wave; both <i>row</i> and <i>column</i> are zero based.                                                                                                                                                                                                                                                                                                                                                          |
| <i>/BPJ={width,height}</i>                      | Specifies the <b>backProjection</b> parameters: <i>width</i> and <i>height</i> are the width and height of the reconstructed image and should be equal to the size of the original wave.                                                                                                                                                                                                                                                   |
| <i>/C=CMapWave</i>                              | Specifies the colormap wave for <b>cmap2rgb</b> keyword. The <i>CMapWave</i> is expected to be a 2D wave consisting of three columns corresponding to the RGB entries.                                                                                                                                                                                                                                                                     |
| <i>/CHIX=chunkIndex</i>                         | Identifies the chunk index for getting, inserting or setting a chunk of data in a 4D wave. <i>chunkIndex</i> ranges from 0 to the number of chunks in <i>imageMatrix</i> .                                                                                                                                                                                                                                                                 |
| <i>/CLAM=fuzzy</i>                              | Sets the value used to compute the fuzzy probability in <b>fuzzyClassify</b> . It must satisfy <i>fuzzy</i> > 1 (default is 2).                                                                                                                                                                                                                                                                                                            |
| <i>/CLAS=num</i>                                | Sets the number of requested classes in <b>fuzzyClassify</b> . If you don't know the number of expected classes and <i>num</i> is too high, <b>fuzzyClassify</b> will likely produce some degenerate classes.                                                                                                                                                                                                                              |
| <i>/D=waveName</i>                              | Specifies a data wave. Check the appropriate keyword documentation for more information about this wave.                                                                                                                                                                                                                                                                                                                                   |
| <i>/F=value</i>                                 | Increases the sampling in the angle domain when used with the Hough keyword. By default <i>value</i> =1 and the operation results in single degree increments in the interval 0 to 180, and if <i>value</i> =1.5 there will be 180*1.5 rows in the transform.<br><br>Specifies the outer pixel value surrounding the region of interest when used with <b>shrinkRect</b> keyword.                                                          |
| <i>/FEQS</i>                                    | When performing Voronoi tessellation, forces the algorithm to use equal scaling for both axes. Normally the scaling for each axis is determined from its range. When the ranges of the two axes are different by an order of magnitude or more, it is helpful to force the larger range to be used for scaling both axes.                                                                                                                  |
| <i>/G=colNumber</i>                             | Specifies either the row or column number used in connection with <b>getRow</b> or <b>getCol</b> keywords. This flag also specifies the transpose <i>mode</i> with the <b>transposeVol</b> keyword.                                                                                                                                                                                                                                        |
| <i>/H={minHue, maxHue}</i><br><i>/H=hueWave</i> | Specifies the range of hue values for selecting pixels. The hue values are specified in degrees in the range 0 to 360. Hue intervals that contain the zero point should be specified with the higher value first, e.g., <i>/H={330, 10}</i> .<br><br>Use <i>hueWave</i> when you have more than one pair of hue values that bracket the pixels that you want to select.<br><br>See <b>HSL Segmentation</b> on page III-374 for an example. |
| <i>/I=iterations</i>                            | Sets the number of iterations in <i>ccsubdivision</i> and in <b>fuzzyClassify</b> .                                                                                                                                                                                                                                                                                                                                                        |
| <i>/INSI=imageWave</i>                          | Specifies the wave, <i>imageWave</i> , to be used with the <b>insertImage</b> keyword. <i>imageWave</i> is a 2D wave of the same numeric data type as <i>imageMatrix</i> .                                                                                                                                                                                                                                                                 |
| <i>/INSW=wave</i>                               | Specifies the 2D wave to be inserted into a 3D wave using the keywords: <b>insertXplane</b> , <b>insertYplane</b> , or <b>insertZplane</b> .                                                                                                                                                                                                                                                                                               |
| <i>/INSX=xPos</i>                               | Specifies the pixel position at which the first row is inserted. Ignores wave scaling.                                                                                                                                                                                                                                                                                                                                                     |
| <i>/INSY=yPos</i>                               | Specifies the pixel position at which the first column is inserted. Ignores wave scaling.                                                                                                                                                                                                                                                                                                                                                  |

|                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/IOFF={dx,dy,bgValue}</i>                              | Specifies the amount of positive or negative integer offset with <i>dx</i> and <i>dy</i> and the new background value, <i>bgValue</i> , with the <code>offsetImage</code> keyword.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>/IWAV=wave</i>                                         | Specifies the wave which provides the indices when used with the keyword <b>indexWave</b> . The wave should have as many columns as the dimensions of <i>imageMatrix</i> (2, 3, or 4). For example, to specify indices for pixels in an image, the wave should have two columns. The first column corresponds to the row designation and the second to the column designation of the pixel. The wave can be of any number type (other than complex) and entries are assumed to be integer indices; there is no support for interpolation or for wave scaling.                                              |
| <i>/L={minLight, maxLight}</i><br><i>/L=lightnessWave</i> | Specifies the range of lightness for selecting pixels. The lightness values are in the range 0-1. If you do not use the <i>/L</i> flag than the default full range is used.<br><br>Use <i>lightnessWave</i> when you have more than one pair of lightness values corresponding to the pixels that you want to select. For each pair, values should be arranged so that the smaller one is first and the larger is second. There is no restriction on the order of pairs in the wave except that they match the other waves used by the operation.                                                          |
| <i>/LARA=minPixels</i>                                    | Specifies the minimum number of pixels required for an area to be masked by the <b>findLakes</b> keyword. If you do not specify this flag, the default value used is 100.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>/LCVT</i>                                              | Use 8-connectivity instead of 4-connectivity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>/LRCT={minX,minY,maxX,maxY}</i>                        | Sets the rectangular region of interest for the <b>findLakes</b> keyword. The operation will not affect the original data outside the specified rectangle. The X and Y values are the scaled values (i.e., using wave scaling).                                                                                                                                                                                                                                                                                                                                                                            |
| <i>/LTAR=target</i>                                       | Set the target value for the masked region in the <b>findLakes</b> keyword.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>/LTOL=tol</i>                                          | Specifies the tolerance for the <b>findLakes</b> keyword. By default the tolerance is zero. The tolerance must be a positive number. The operation uses the tolerance by requiring neighboring pixels to have a value between that of the current pixel <i>V</i> and <i>V+tol</i> .                                                                                                                                                                                                                                                                                                                        |
| <i>/M=n</i>                                               | Specifies the method by which a 2D target image is filled with data from a 1D wave using the <b>fillImage</b> keyword.<br><br><i>n</i> =0: Straight column fill, which you can also accomplish by a redimension operation.<br><br><i>n</i> =1: Straight row fill.<br><br><i>n</i> =2: Serpentine column fill. The points from the data wave are sequentially loaded onto the first column and continue from the last to the first point of the second column, and then sequentially through the third column, etc.<br><br><i>n</i> =3: Serpentine row fill.                                                |
| <i>/METH=method</i>                                       | Determines the values of the projected pixels for <b>xProjection</b> , <b>yProjection</b> , and <b>zProjection</b> keywords.<br><br><i>method</i> =1: Pixel (i,j) in <i>M_zProjection</i> is assigned the maximum value that (i,j,*) takes among all layers of <i>imageMatrix</i> (default).<br><br><i>method</i> =2: Pixel (i,j) in <i>M_zProjection</i> is assigned the average value that (i,j,*) takes among all layers of <i>imageMatrix</i> .<br><br><i>method</i> =3: Pixel (i,j) in <i>M_zProjection</i> is assigned the minimum value that (i,j,*) takes among all layers of <i>imageMatrix</i> . |

## ImageTransform

---

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/METR=method</i>                     | Sets the metric used by the distance transform. Added in Igor Pro 7.00.<br><i>method=0</i> : Manhattan distance. Default.<br><i>method=1</i> : Euclidean distance where the distance is measured between centers of pixels (assumed square).<br><i>method=2</i> : Euclidean distance that also takes into account actual pixel size using the input's wave scaling.<br><br><i>method=0</i> executes faster than the other methods. <i>method=2</i> can be 2x slower especially if different scaling is applied along the two axes.                                             |
| <i>/N={rowsToAdd, colsToAdd}</i>        | Creates an image that is larger or smaller by <i>rowsToAdd, colsToAdd</i> . The additional pixels are set by duplicating the values in the last row and the last column of the source image.                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>/NCLR=M</i>                          | Specifies the maximum number of colors to find with the <b>rgb2cmap</b> keyword. <i>M</i> must be a positive number; the default value is 256 colors.<br><br>The result of the operation is saved in the wave <b>M_paddedImage</b> .                                                                                                                                                                                                                                                                                                                                           |
| <i>/NP=numPlanes</i>                    | Specifies the number of planes to remove from a 3D wave when using the <b>removeXplane</b> , <b>removeYplane</b> , or <b>removeZplane</b> keywords. Specifies the number of waves to be added to the stack with the <b>stackImages</b> keyword.                                                                                                                                                                                                                                                                                                                                |
| <i>/O</i>                               | Overwrites the input wave with the result except in the cases of <b>Hough</b> transform and <b>cmap2rgb</b> . Does not apply to the <b>transposeVol</b> parameter.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>/P=planeNum</i>                      | Specifies the plane on which you want to operate with the <b>rgb2gray</b> or <b>getPlane</b> keywords. Also used for <b>getRow</b> or <b>getCol</b> if the source wave is 3D.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>/PSL={xStart,dx,Nx,aStart,da,Na}</i> | Specifies projection slice parameters. <i>xStart</i> is the first offset of the parallel rays measured from the center of the image. <i>dx</i> is the directed offset to the next ray in the fan and <i>Nx</i> is the number of rays in the fan. <i>aStart</i> is the first angle for which the projection is calculated. The angle is measured between the positive X-direction and the direction of the ray. <i>da</i> is the offset to the next angle at which the fan of rays is rotated and <i>Na</i> is the total number of angles for which the projection is computed. |
| <i>/PTRF</i>                            | Use <i>/PTRF</i> with the <b>ccsubdivision</b> keyword to apply small perturbation to the input coordinates in order to break spatial degeneracies that may occur when multiple facets meet at some point in space. See <b>ccsubdivision</b> above for details. <i>/PTRF</i> was added in Igor Pro 9.00.                                                                                                                                                                                                                                                                       |
| <i>/PTYP=num</i>                        | Specifies the plane to use with the <b>getPlane</b> keyword.<br><i>num=0</i> : XY plane.<br><i>num=1</i> : XZ plane.<br><i>num=2</i> : YZ plane.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>/Q</i>                               | Quiet flag. When used with the <b>Hough</b> transform, it suppresses report to the history of the angle corresponding to the maximum.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>/R=roiWave</i>                       | Specifies a region of interest (ROI) defined by <i>roiWave</i> . For use with the keywords: <b>averageImage</b> , <b>scalePlanes</b> and <b>selectColor</b> .                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>/S={minSat, maxSat}</i>              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <i>/S=saturationWave</i>                     | <p>Specifies the range of saturation values for selecting pixels. The saturation values are in the range 0 to 1. If you do not use the <i>/S</i> flag, the default value is the full saturation range.</p> <p>Use <i>saturationWave</i> when you have more than one pair of saturation values. If you use a saturation wave you must also use a lightness wave (see <i>/L</i>). <i>saturationWave</i> should consist of pairs of values where the first point is the lower saturation value and the second point is the higher saturation value. There is no restriction on the order of pairs within the wave.</p>                                                                                                                                                                                                                                                                                                                             |            |         |   |                                                                                            |   |                                                                    |   |                                                                            |   |                                                      |    |                                                                                               |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|---------|---|--------------------------------------------------------------------------------------------|---|--------------------------------------------------------------------|---|----------------------------------------------------------------------------|---|------------------------------------------------------|----|-----------------------------------------------------------------------------------------------|
| <i>/SEG</i>                                  | <p>Computes the segmentation image for <b>fuzzyClassify</b>. The image is stored in the 2D wave <i>M_FuzzySegments</i>. The value of each pixel is <math>255 \cdot \text{classIndex} / \text{number of classes}</math>. Here <i>classIndex</i> is the index of the class to which the pixel belongs with the highest probability.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |            |         |   |                                                                                            |   |                                                                    |   |                                                                            |   |                                                      |    |                                                                                               |

| 2                                            | Creates a 1D texture (all other textures are for 2D applications).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |            |         |   |                                                                                            |   |                                                                    |   |                                                                            |   |                                                      |    |                                                                                               |
| 4                                            | Creates a single channel texture suitable for alpha or luminance channels.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |            |         |   |                                                                                            |   |                                                                    |   |                                                                            |   |                                                      |    |                                                                                               |
| 8                                            | Creates a RGB texture from a 3 (or more) layer data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |            |         |   |                                                                                            |   |                                                                    |   |                                                                            |   |                                                      |    |                                                                                               |
| 16                                           | Creates a RGBA texture. If <i>imageMatrix</i> does not have a 4th layer, alpha is set to 255.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |         |   |                                                                                            |   |                                                                    |   |                                                                            |   |                                                      |    |                                                                                               |
| <i>/TOL=tolerance</i>                        | <p>Sets the tolerance for iteration convergence with <b>fuzzyClassify</b>. Convergence is satisfied when the sum of the squared differences of all classes drops below <i>tolerance</i>, which must not be negative.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |            |         |   |                                                                                            |   |                                                                    |   |                                                                            |   |                                                      |    |                                                                                               |
| <i>/TM4D=mode</i>                            | <p>Used with <i>transpose4D</i> to specify the format of the output wave. Here <i>mode</i> is a 4 digit integer that describes the mapping of the transformation. The digit 1 is used to represent the first dimension, 2 for the second, 4 for the third and 8 for the 4th dimension such that the original wave corresponds to <i>mode=1248</i>. All other modes are obtained by permuting one or more of the four digits and <i>mode</i> must consist of 4 distinct digits.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                                                                                                                                                                               |            |         |   |                                                                                            |   |                                                                    |   |                                                                            |   |                                                      |    |                                                                                               |

## ImageUnwrapPhase

---

### Examples

If you want to insert a 2D ( $M \times N$ ) wave, plane0, into plane number 0 of an ( $M \times N \times 3$ ) wave, rgbWave:

```
ImageTransform /P=0/D=plane0 setPlane rgbWave
```

If your source wave is 100 rows by 100 columns and you want to create a montage of this image use:

```
ImageTransform /W/N={200,200} padImage srcWaveName
```

### Hue and Saturation Segmentation Example

```
Function hueSatSegment (hslW,lowH,highH,lowS,highS)
 Wave hslW
 Variable lowH,highH,lowS,highS

 Make/D/O/N=(2,3) conditionW
 conditionW={{lowH,highH},{lowS,highS},{NaN,NaN}}
 ImageTransform/D=conditionW matchPlanes hslW
 KillWaves/Z conditionW
End
```

### Voronoi Tesselation Example

```
Make/O/N=(33,3) ddd=gnoise(4)
ImageTransform voronoi ddd
Display ddd[] [1] vs ddd[] [0]
ModifyGraph mode=3,marker=19,msize=1,rgb=(0,0,65535)
AppendToGraph M_VoronoiEdges[] [1] vs M_VoronoiEdges[] [0]
SetAxis left -15,15
SetAxis bottom -5,10
```

## ImageUnwrapPhase

**ImageUnwrapPhase** [*flags*] [*qualityWave=qWave*,] *srcwave=waveName*

The ImageUnwrapPhase operation unwraps the 2D phase in srcWave and stores the result in the wave M\_UnwrappedPhase in the current data folder. srcWave must be a real valued wave of single or double precision. Phase is measured in cycles (units of  $2\pi$ ).

### Parameters

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| qualityWave= <i>qWave</i> | Specifies a wave, <i>qWave</i> , containing numbers that rate the quality of the phase stored in the pixels. <i>qWave</i> is 2D wave of the same dimensions as srcWave that can be any real data type and values can have an arbitrary scale. If used with /M=1 the quality values determine the order of phase unwrapping subject to branch cuts, with higher quality unwrapped first. If used with /M=2 the unwrapping is guided by the quality values only. This wave must not contain any NaNs or INFs. |
| srcwave= <i>waveName</i>  | Specifies a real-valued SP or DP wave that may contain NaNs or INFs but is otherwise assumed to contain the phase modulo 1.                                                                                                                                                                                                                                                                                                                                                                                 |

### Flags

|    |                                                                                                                                                                                                                                                                                                                                     |
|----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /E | Eliminate dipoles. Only applies to Goldstein's method (/M=1). Dipoles are a pair of a positive and negative residues that are side by side. They are eliminated from the unwrapping process by replacing them with a branch cut. The variable V_numResidues contains the number of residues remaining after removal of the dipoles. |

| <i>/R=roiWave</i>        | <p>Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (<i>/B/U</i>) that has the same number of rows and columns as <i>waveName</i>. The ROI itself is defined by entries or pixels in the <i>roiWave</i> with value of 1. Pixels outside the ROI should be set to zero. The ROI does not have to be contiguous but it is best if you choose a convex ROI in order to make sure that any branch cuts computed by the algorithm lie completely inside the ROI domain.</p>                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>/REST = threshold</i> | <p>Sets the threshold value for evaluating a residue. The residue is evaluated by the equivalent of a closed path integral. If the path integral value exceeds the threshold value, the top-left corner of the quad is taken to be a positive residue. If the path integral is less than <i>-threshold</i>, it is a negative residue.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Details

Phase unwrapping in two dimensions is difficult because the result of the operation needs to be such that any path integral over a closed contour will vanish. In many practical situations, certain points in the plane have the property that a path integral around them is not zero. These nonzero points are residues. We use the definition that when a counterclockwise path integral leads to a positive value the residue is called a positive residue.

ImageUnwrapPhase uses the modified Itoh’s method by default. Phase is unwrapped with an offset equal to the first element that is allowed by the ROI starting at (0,0) and scanning by rows. If there are no residues or if you unwrap the phase using Itoh’s algorithm, then the phase is unwrapped only subject to the optional ROI using a seed-fill type algorithm that unwraps by growing a region outward from the seed pixel. Each time that the region growing is terminated by boundaries (external or due to the ROI), the algorithm returns to the row scanning to find a new starting point.

If there are residues and you choose Goldstein’s method, the residues are first mapped into a lookup table (LUT) and branch-cuts are determined between residues and boundaries. It is also possible to remove some residues (dipoles) using the */E* flag. Phase is then unwrapped in regions bounded by branch cuts using a seed-fill type algorithm that does not cross branch cuts. With a quality wave, the algorithm follows the same seed-fill approach except that it gives priority to pixels with high quality level. The phase on the branch cuts themselves is subsequently calculated.

## ImageWindow

---

The output wave `M_UnwrappedPhase` has the same wave scaling and dimension units as `srcWave`. The unwrapped phase is units of cycles; you will have to multiply it by  $2\pi$  if you need the results in radians.

The operation creates two variables:

|                            |                                                                                                                                                                     |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>V_numResidues</code> | Number of residues encountered(if using <code>/M=1</code> ).                                                                                                        |
| <code>V_numRegions</code>  | Number of independent phase regions. In Goldstein's method the regions are bounded by branch cuts, but in Itoh's method they depend on the content of the ROI wave. |

### Examples

```
// Unwrap the phase of a complex wave wCmplx
MatrixOP/O phaseWave=atan2(imag(wCmplx),real(wCmplx))/(2*pi)
ImageUnwrapPhase/M=1 srcWave=phaseWave

// Find the locations of positive residues in the phase
ImageUnwrapPhase/M=1/L srcWave=phaseWave
MatrixOP/O ee=greater(bitAnd(M_PhaseLUT,2),0)

// Find the branch cuts
MatrixOP/O bc=greater(bitAnd(M_PhaseLUT,8),0)
```

## ImageWindow

**ImageWindow** [`/I/O/P=param`] *method* `srcWave`

The **ImageWindow** operation multiplies the named waves by the specified windowing method.

**ImageWindow** is useful in preparing an image for FFT analysis by reducing FFT artifacts produced at the image boundaries.

### Parameters

|                |                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------|
| <i>srcWave</i> | Two-dimensional wave of any numerical type. See <b>WindowFunction</b> for windowing one-dimensional data. |
| <i>method</i>  | Selects the type of windowing filter. See <b>ImageWindow Methods</b> on page V-435.                       |

### Flags

|                       |                                                                                                                                                                                          |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/I</code>       | Creates only the output wave containing the windowing filter values that are used to multiply each pixel in <i>srcWave</i> . It does not filter the source image.                        |
| <code>/O</code>       | Overwrites the source image with the output image. If <code>/O</code> is not used then the operation creates the <code>M_WindowedImage</code> wave containing the filtered source image. |
| <code>/P=param</code> | Specifies the design parameter for the Kaiser window.                                                                                                                                    |

### Details

The 1-dimensional window for each column is multiplied by the value of the corresponding row's window value. In other words, each point is multiplied by the both the row-oriented and column-oriented window value.

This means that all four edges of the image are decreased while the center remains at or near its original value. For example, applying the Bartlett window to an image whose values are all equal results in a trapezoidal pyramid of values:

The default output wave is created with the same data type as the source image. Therefore, if the source image is of type unsigned byte (/b/u) the result of using /I will be identically zero (except possibly for the middle-most pixel). If you keep in mind that you need to convert the source image to a wave type of single or double precision in order to perform the FFT, it is best if you convert your source image (e.g., `Redimension/S srcImage`) before using the ImageWindow operation.

The windowed output is in the `M_WindowedImage` wave unless the source is overwritten using the /O flag. The necessary normalization value (equals to the average squared window factor) is stored in `V_value`.

### ImageWindow Methods

This section describes the supported keywords for the `method` parameter. In all equations,  $L$  is the array width and  $n$  is the pixel number.

Hanning:

$$w(n) = \frac{1}{2} \left[ 1 - \cos\left(\frac{2\pi n}{L-1}\right) \right] \quad 0 \leq n \leq L-1$$

Hamming:

$$w(n) = 0.54 - 0.46 \cos\left(\frac{2\pi n}{L-1}\right) \quad 0 \leq n \leq L-1$$

Bartlett:

Synonym for Bartlett.

Bartlett:

$$w(n) = \begin{cases} \frac{2n}{L-1} & 0 \leq n \leq \frac{L-1}{2} \\ 2 - \frac{2n}{L-1} & \frac{L-1}{2} \leq n \leq L-1 \end{cases}$$

Blackman:

$$w(n) = 0.42 - 0.5 \cos\left(\frac{2\pi n}{L-1}\right) + 0.08 \cos\left(\frac{4\pi n}{L-1}\right) \\ 0 \leq n \leq L-1$$

Kaiser:

$$\frac{I_0\left(\omega_a \sqrt{\left(\frac{L-1}{2}\right)^2 - \left(n - \frac{L-1}{2}\right)^2}\right)}{I_0\left(\omega_a \left(\frac{L-1}{2}\right)\right)} \quad 0 \leq n \leq L-1$$

where  $I_0\{\dots\}$  is the zeroth-order Bessel function of the first kind and  $\omega_a$  is the design parameter specified by  $/P=param$ .

$$w(n) = \frac{I_0\left(\pi\alpha \sqrt{1 - \left(\frac{n}{L/2}\right)^2}\right)}{I_0(\pi\alpha)} \quad 0 \leq |n| \leq \frac{L}{2}$$

KaiserBessel20:  $\alpha = 2.0$

KaiserBessel25:  $\alpha = 2.5$

KaiserBessel30:  $\alpha = 3.0$

$$I_0(x) = \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{(k!)^2}$$

### Examples

To see which one of the windowing filters looks like:

```
Make/N=(80,80) wShape // Make a matrix
ImageWindow/I/O Blackman wShape // Replace with windowing filter
Display;AppendImage wShape // Display windowing filter
Make/N=2 xTrace={0,79},yTrace={39,39} // Prepare for 1D section
AppendToGraph yTrace vs xTrace
ImageLineProfile srcWave=wShape, xWave=xTrace, yWave=yTrace
Display W_ImageLineProfile // Display 1D section of filter
```

## IndependentModule

```
#pragma IndependentModule = imName
```

The IndependentModule pragma designates groups of one or more procedure files that are compiled and linked separately. Once compiled and linked, the code remains in place and is usable even though other procedures may fail to compile. This allows functioning control panels and menus to continue to work regardless of user programming errors.

### See Also

**Independent Modules** on page IV-236, **The IndependentModule Pragma** on page IV-54 and **#pragma**.

## IndependentModuleList

### **IndependentModuleList** (*listSepStr*)

The IndependentModuleList function returns a string containing a list of independent module names separated by *listSepStr*.

Use **StringFromList** to access individual names.

### **Parameters**

*listSepStr* contains the character, usually ";", to be used to separate the names in the returned list.

### **Details**

In Igor6, only the first byte of *listSepStr* was used. In Igor7 and later, all bytes are used.

ProcGlobal is not in the returned list, and the order of returned names is not defined.

### **See Also**

**Independent Modules** on page IV-236.

**GetIndependentModuleName**, **StringFromList**, **FunctionList**.

## IndexedDir

### **IndexedDir** (*pathName*, *index*, *flags*)

The IndexedDir function returns a string containing the name of or the full path to the *indexth* folder in the folder referenced by *pathName*.

### **Parameters**

*pathName* is the name of an Igor symbolic path pointing to the parent directory.

*index* is the index number of the directory (within the parent directory) of interest starting from 0. If *index* is -1, IndexedDir will return the name of *all* of the folders in the parent, separated by semicolons.

*flags* is a bitwise parameter:

Bit 0:               Set if you want a full path. Cleared if you want just the directory name.

All other bits are reserved and should be cleared.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

### **Details**

You create the symbolic path identifying the parent directory using the **NewPath** operation or the New Path dialog (Misc menu).

Prior to Igor Pro 3.1, IndexedDir was an external function and took a string as the first parameter rather than a name. The *pathName* parameter can now be either a name or a string containing a name. Any of the following will work:

```
String str = "IGOR"
Print IndexedDir(IGOR, 0, 0) // First parameter is a name.
Print IndexedDir($str, 0, 0) // First parameter is a name.
Print IndexedDir("IGOR", 0, 0) // First parameter is a string.
Print IndexedDir(str, 0, 0) // First parameter is a string.
```

The acceptance of a string is for backward compatibility only. New code should be written using a name.

The returned path uses the native conventions of the OS under which Igor is running.

### **Examples**

#### **Example: Recursively Listing Directories and Files**

Here is an example for heavy-duty Igor Pro programmers. It is an Igor Pro user-defined function that prints the paths of all of the files and folders in a given folder with or without recursion. You can rework this to do something with each file instead of just printing its path.

To try the function, copy and paste it into the Procedure window. Then execute the example shown in the comments.

```
// PrintFoldersAndFiles(pathName, extension, recurse, level)
```

## IndexedDir

---

```
// Shows how to recursively find all files in a folder and subfolders.
// pathName is the name of an Igor symbolic path that you created
// using NewPath or the Misc->New Path menu item.
// extension is a file name extension like ".txt" or "???" for all files.
// recurse is 1 to recurse or 0 to list just the top-level folder.
// level is the recursion level - pass 0 when calling PrintFoldersAndFiles.
// Example: PrintFoldersAndFiles("Igor", ".ihf", 1, 0)
Function PrintFoldersAndFiles(pathName, extension, recurse, level)
String pathName // Name of symbolic path in which to look for folders and files.
String extension // File name extension (e.g., ".txt") or "???" for all files.
Variable recurse // True to recurse (do it for subfolders too).
Variable level // Recursion level. Pass 0 for the top level.

Variable folderIndex, fileIndex
String prefix

// Build a prefix (a number of tabs to indicate the folder level by indentation)
prefix = ""
folderIndex = 0
do
 if (folderIndex >= level)
 break
 endif
 prefix += "\t" // Indent one more tab
 folderIndex += 1
while(1)

// Print folder
String path
PathInfo $pathName // Sets S_path
path = S_path
Printf "%s%s\r", prefix, path

// Print files
fileIndex = 0
do
 String fileName
 fileName = IndexedFile($pathName, fileIndex, extension)
 if (strlen(fileName) == 0)
 break
 endif
 Printf "%s\t%s%s\r", prefix, path, fileName
 fileIndex += 1
while(1)

if (recurse) // Do we want to go into subfolder?
 folderIndex = 0
 do
 path = IndexedDir($pathName, folderIndex, 1)
 if (strlen(path) == 0)
 break // No more folders
 endif

 String subFolderPathName = "tempPrintFoldersPath_" + num2istr(level+1)

 // Now we get the path to the new parent folder
 String subFolderPath
 subFolderPath = path

 NewPath/Q/O $subFolderPathName, subFolderPath
 PrintFoldersAndFiles(subFolderPathName, extension, recurse, level+1)
 KillPath/Z $subFolderPathName

 folderIndex += 1
 while(1)
endif
End
```

### Example: Fast Scan of Directories

Calling IndexedDir for each directory is an  $O(N^2)$  problem because to get the  $n$ th directory the OS routines underlying IndexedDir need to iterate through directories  $0..n-1$ . This becomes an issue only if you are dealing with hundreds or thousands of directories.

This function illustrates a technique for converting this to an O(N) problem by getting a complete list of paths from IndexedDir in one call and storing them in a text wave. This approach could also be used with IndexedFile.

```
Function ScanDirectories(pathName, printDirNames)
 String pathName // Name of Igor symbolic path
 Variable printDirNames // True if you want to print the directory names

 Variable t0 = StopMSTimer(-2)

 String dirList = IndexedDir($pathName, -1, 0)
 Variable numDirs = ItemsInList(dirList)

 // Store directory list in a free text wave.
 // The free wave is automatically killed when the function returns.
 Make/N=(numDirs)/T/FREE dirs = StringFromList(p, dirList)

 String dirName
 Variable i
 for(i=0; i<numDirs; i+=1)
 dirName = dirs[i]
 Print i, dirName
 endfor

 Variable t1 = StopMSTimer(-2)
 Variable elapsed = (t1 - t0) / 1E6
 Printf "Took %g seconds\r", elapsed
End
```

## IndexedFile

**IndexedFile**(*pathName*, *index*, *fileTypeOrExtStr* [, *creatorStr*])

If *index* is greater than or equal to zero, IndexedFile returns a string containing the name of the *index*th file in the folder specified by *pathName* which matches the file type or extension specified by *fileTypeOrExtStr*.

If *index* is -1, IndexedFile returns a semicolon-separated list of all matching files.

IndexedFile returns an empty string (" ") if there is no such file.

### Parameters

*pathName* is the *name* of an Igor symbolic path. It is *not* a string.

*index* normally starts from zero. However, if *index* is -1, IndexedFile returns a string containing a semicolon-separated list of the names of all files in the folder associated with the specified symbolic path which match *fileTypeOrExtStr*.

*fileTypeOrExtStr* is either:

- A string starting with ".", such as ".txt", ".bwav", or ".c". Only files with a matching file name extension are indexed. Set *fileTypeOrExtStr* to "." to index file names that end with "." such as "myFileNameEndsWithThisDot."
- A string containing exactly four ASCII characters, such as "TEXT" or "IGBW". Only files of the specified Macintosh file type are indexed. However, if *fileTypeOrExtStr* is "????", files of any type are indexed.
- On Windows, Igor considers files with ".txt" extensions to be of type TEXT. It does similar mappings for other extensions. See **File Types and Extensions** on page III-457 for details.

*creatorStr* is an optional string argument containing four ASCII characters such as "IGR0". Only files with the specified Macintosh creator code are indexed. Set *creatorStr* to "?????" to index all files (or omit the argument altogether). This argument is ignored on Windows systems.

### Order of Files Returned By IndexedFile

The order in which files are returned by IndexedFile is determined by the operating system. If the order matters to you, you should explicitly sort the file names.

For example, assume you have files named "File1.txt", "File2.txt" and "File10.txt". An alphabetic order gives you: "File1.txt;File10.txt;File2.txt;". Often what you really want is a combination of alphabetic and numeric sorting returning "File1.txt;File2.txt;File10.txt;". Here is a function that does that:

```
Function DemoIndexedFile()
 String pathName = "Igor" // Refers to "Igor Pro Folder"
```

## IndexSort

---

```
// Get a semicolon-separated list of all files in the folder
String list = IndexedFile($pathName, -1, ".txt")

// Sort using combined alpha and numeric sort
list = SortList(list, ";", 16)

// Process the list
Variable numItems = ItemsInList(list)
Variable i
for(i=0; i<numItems; i+=1)
 String fileName = StringFromList(i, list)
 Print i, fileName
endfor
End
```

### Treatment of Macintosh Dot-Underscore Files

IndexedFile ignores "dot-underscore" files unless *fileTypeOrExtStr* is "????".

A dot-underscore file is a file created by Macintosh when it writes to a non-HFS volume, for example, when it writes to a Windows volume via SMB file sharing. The dot-underscore file stores Macintosh HFS-specific data such as the file's type and creator codes, and the file's resource fork, if it has one.

For example, if a file named "wave0.ibw" is copied via SMB to a Windows volume, Mac OS X creates two files on the Windows volume: "wave0.ibw" and "\_wave0.ibw". Mac OS X makes these two files appear as one to Macintosh applications. However, Windows does not do this. As a consequence, when a Windows program sees "\_wave0.ibw", it expects it to be a valid .ibw file, but it is not. This causes problems.

By ignoring dot-underscore files, IndexedFile prevents this type of problem. However, if *fileTypeOrExtStr* is "????", IndexedFile will return dot-underscore files on Windows.

### Examples

```
NewPath/O myPath "MyDisk:MyFolder:"
Print IndexedFile(myPath, -1, "TEXT") // all text-type files
Print IndexedFile(myPath, 0, "TEXT") // only the first text file
Print IndexedFile(myPath, -1, ".dat") // *.dat
Print IndexedFile(myPath, -1, "TEXT", "IGR0") // all Igor text files
Print IndexedFile(myPath, -1, "????") // all files, all creators
```

See **IndexedDir** for another example using IndexedFile and for a method for speeding up scanning of very large numbers of files.

### See Also

The **TextFile** and **IndexedDir** functions.

## IndexSort

**IndexSort** [ /DIML ] *indexWaveName*, *sortedWaveName* [, *sortedWaveName*]...

The IndexSort operation sorts the values in each *sortedWaveName* wave according to the Y values of *indexWaveName*.

### Flags

/DIML            Moves the dimension labels with the values (keeps any row dimension label with the row's value).

### Details

*indexWaveName* can not be complex. *indexWaveName* is presumed to have been the destination of a previous **MakeIndex** operation.

This has the effect of putting the *sortedWaveName* waves in the same order as the wave from which the index values in *indexWaveName* was made.

All of the *sortedWaveName* waves must be of equal length.

### See Also

**Sorting** on page III-132, **MakeIndex** and **IndexSort** on page III-134, **Sort**, **MakeIndex**

## IndexToScale

**IndexToScale**(*wave*, *index*, *dim*)

The IndexToScale function returns the scaled coordinate value corresponding to wave element index in the specified dimension.

The IndexToScale function was added in Igor Pro 7.00.

### Details

The function returns the expression:

$\text{DimOffset}(\textit{wave}, \textit{dim}) + \textit{index} * \text{DimDelta}(\textit{wave}, \textit{dim})$

*index* is an integer.

*dim* is 0 for rows, 1 for columns, 2 for layers or 3 for chunks.

The function returns NaN if *dim* is not a valid dimension or if *index* is greater than the number of elements in the specified dimension.

### Examples

```
Make/N=(10,20,30,40) w4D
SetScale/P y 2,3,"", w4D
SetScale/P z 4,5,"", w4D
SetScale/P t 6,7,"", w4D
Print IndexToScale(w4D,1,0)
Print IndexToScale(w4D,1,1)
Print IndexToScale(w4D,1,2)
Print IndexToScale(w4D,1,3)
Print IndexToScale(w4D,1,4)
Print IndexToScale(w4D,-1,0)
Print IndexToScale(w4D,11,0)
```

### See Also

**ScaleToIndex**, **pnt2x**, **DimDelta**, **DimOffset**

**Waveform Model of Data** on page II-62 for an explanation of wave scaling.

## Inf

**Inf**

The Inf function returns the “infinity” value.

## InsertPoints

**InsertPoints** [ /M=*dim* /V=*value* ] *beforePoint*, *numPoints*, *waveName* [, *waveName*]...

The InsertPoints operation inserts *numPoints* points in front of point *beforePoint* in each *waveName*. The new points have the value zero.

### Flags

- /M=*dim* Specifies the dimension into which elements are to be inserted. Values are 0 for rows, 1 for columns, 2 for layers, 3 for chunks. If /M is omitted, InsertPoints inserts in the rows dimension.
- /V=*value* When used with numeric waves, *value* specifies the value for new elements. If you omit /V, new elements are set to zero. The /V flag was added in Igor Pro 8.00.

### Details

Trying to insert points into any but the rows of a zero-point wave results in a zero-point wave. You must first make the number of rows nonzero before anything else has an effect.

### See Also

**Lists of Values** on page II-78.

### InstantFrequency

**InstantFrequency** [**flags**] *srcWave* [ (*startX*, *endX*) ]

The InstantFrequency operation computes the instantaneous frequency, and optionally the instantaneous amplitude, of *srcWave*. InstantFrequency was added in Igor Pro 9.00.

InstantFrequency creates an output wave whose name and location depends on the /DEST and /OUT flags as described under *InstantFrequency Output Wave* below.

#### Parameters

*srcWave* specifies the wave to be analyzed.

[*startX*,*endX*] is an optional subrange to analyze in point numbers.

(*startX*,*endX*) is an optional subrange to analyze in X values.

If you omit the subrange, *startX* defaults to the first point in *srcWave* and *endX* defaults to the last point in *srcWave*.

#### Flags for all Methods

- /DEST=destWave** Specifies the output wave created by the operation.  
*destWave* can be a simple wave name, a data folder path plus wave name, or a wave reference to an existing wave.  
It is an error to specify the same wave as both *srcWave* and *destWave*.  
If you omit /DEST, the output wave name depends on /OUT.  
When used in a function, the InstantFrequency operation by default creates a real wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-71 for details.  
See *InstantFrequency Output Wave* below for further discussion.
- /FREE** Creates a free destination wave (see **Free Waves** on page IV-90).  
/FREE is allowed only in functions and only if you include /DEST=destWave where *destWave* is a simple name or an valid wave reference.
- /METH=method** Specifies the method by which the calculation is performed.  
*method=0:* Osculating Circle (default)  
*method=1:* Gabor  
*method=2:* Spectrogram using center of mass  
*method=3:* Spectrogram using maximum amplitude
- /OUT=mode** Specifies the type of output to be created.  
*mode=1:* Frequency only (default)  
*mode=2:* Amplitude only  
*mode=3:* Frequency and amplitude  
*mode=4:* Signed amplitude only  
*mode=5:* Debugging output
- If you omit /DEST, the output wave is created in the current data folder with a name determined by mode as follows:  
*mode=1:* W\_InstantFrequency  
*mode=2:* W\_InstantAmplitude  
*mode=3:* M\_InstantFrequency  
*mode=4:* W\_InstantAmplitude  
*mode=5:* M\_InstantFrequency

**Flags for Spectrogram Method (/METH=2) Only**

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/HOPS=<i>hopSize</i></code>    | Specifies the offset in points between centers of consecutive source segments. By default <i>hopSize</i> is 1 and the transform is computed for segments that are offset by a single points from each other.                                                                                                                                                                                                                                                |
| <code>/PAD=<i>newSize</i></code>     | Converts each segment of <i>srcWave</i> into a padded array of length <i>newSize</i> . The padded array contains the original data at the center of the array with zeros elements on both sides.                                                                                                                                                                                                                                                            |
| <code>/SEGS=<i>segSize</i></code>    | Sets the length of the segment sampled from <i>srcWave</i> in points. The segment is optionally padded to a larger dimension (see /PAD) and multiplied by a window function prior to FFT. <i>segSize</i> must be 32 or greater.<br><br>Defining <i>n</i> as <code>numpts(<i>srcWave</i>)</code> , the default segment size, used if you omit /SEGS, is:<br><br>$n/200$ if $n \geq 25600$<br><br>128 if $130 \leq n \leq 25599$<br><br>$n-2$ if $n \leq 129$ |
| <code>/WINF=<i>windowKind</i></code> | Premultiplies a data segment with the selected window function. The default window is Hanning. See <i>Window Functions</i> in the documentation for FFT for details.                                                                                                                                                                                                                                                                                        |

**InstantFrequency Output Wave**

If you use the /FREE flag then the output wave is created as a free wave using the name or wave reference specified by /DEST=*destWave*.

If you include the /DEST flag and omit /FREE then the output wave location and name is specified by the *destWave* parameter. *destWave* can be a simple wave name, a data folder path plus wave name, or a wave reference to an existing wave.

If you omit the /DEST and /FREE flags then the output wave is created in the current data folder with the default name W\_InstantFrequency (/OUT=1), W\_InstantAmplitude (/OUT=2 or 4), or M\_InstantFrequency (/OUT=3 or 5), depending on the /OUT flag.

**Gabor Method (/METH=1)**

The Gabor method uses the Hilbert Transform to synthesize an "analytic" signal that is a copy of the source wave, shifted by 90 degrees, but with the constant ("DC") component removed.

A complex "phasor" wave is generated whose real part is the source wave, and the imaginary part is this analytic signal.

The phase at each time point is computed as `atan2(imag(phasor[p]),real(phasor[p]))`. This phase calculation is affected by any constant component of the source wave. The derivative of this phase with respect to time is the instantaneous frequency.

The instantaneous amplitude is the magnitude of the `phasor[p]`.

See the **HilbertTransform** operation example for an equivalent implementation.

The /OUT=5 debugging output for the Gabor method is:

```
destWave [] [0] // Instant frequency
destWave [] [1] // Instant amplitude
destWave [] [2] // Unwrapped phase wave
destWave [] [3] // Trajectory Y wave (Hilbert transform of input wave)
```

**Osculating Circle Method (/METH=0)**

The primary drawback of the Gabor method is that any sizeable constant level distorts the phase such that it isn't always increasing, which results in negative frequencies being computed. The Osculating Circle Method does not have this problem.

The Osculating Circle method constructs the same analytic phasor as the Gabor method, but computes the phase and derivative differently in a way that eliminates the constant level distortion: at each point the phasor's previous, current, and next complex values (the "trajectory") are fit to a circle in the complex plane.

## Int

---

That circle's origin is used to measure both the phase and amplitude at that point, instead of the origin at (0+i0) that the Gabor method uses.

The /OUT=5 debugging output for the Osculating Circle method is:

```
destWave [] [0] // Instant frequency
destWave [] [1] // Signed instant amplitude
destWave [] [2] // Unwrapped phase wave
destWave [] [3] // Trajectory Y wave (Hilbert transform of input wave)
destWave [] [4] // Trajectory dY wave
destWave [] [5] // Trajectory ddY wave
destWave [] [6] // Trajectory dX wave
destWave [] [7] // Trajectory ddYX wave
destWave [] [8] // Origin Y wave
destWave [] [9] // Origin X wave
```

### Spectrogram (/METH=2 or 3)

The Spectrogram method for determining instant frequency and amplitude is based on measuring the Short-Time Fourier Transform, the 2D time-frequency representation for a 1D array. The scaled magnitude of the transform is known as the "spectrogram" for time series or "sonogram" in the case of sound input. Methods 2 and 3 are comprised of the following steps:

1. Compute the Short-Time Fourier Transform according to the various spectrogram parameters. This results in a 2D wave, where the columns of each row comprise the scaled magnitude spectrum at one point in time.
2. For each spectrum determine where the dominant frequency lies, and its magnitude.

For /METH=2, the dominant frequency is found using the centerMass function.

For /METH=3, the dominant frequency is found by locating the maximum value.

The /OUT=5 debugging output for the Spectrogram method is the 2D spectrogram that would have been used as the output of step 1.

## Int

**int localName**

In a user-defined function or structure, declares a local 32-bit integer in IGOR32, a local 64-bit integer in IGOR64.

Int is available in Igor Pro 7 and later. See **Integer Expressions** on page IV-37 for details.

### See Also

**Int64, UInt64**

## Int64

**int64 localName**

Declares a local 64-bit integer in a user-defined function or structure.

Int64 is available in Igor Pro 7 and later. See **Integer Expressions** on page IV-37 for details.

**Int, UInt64**

## Integrate

```
Integrate [type flags] [flags] yWaveA [/X = xWaveA] [/D = destWaveA]
[, yWaveB [/X = xWaveB] [/D = destWaveB] [, ...]]
```

The Integrate operation calculates the 1D numeric integral of a wave. X values may be supplied by the X-scaling of the source wave or by an optional X wave. Rectangular integration is used by default.

Integrate is multi-dimension-aware in the sense that it computes a 1D integration along the dimension specified by the /DIM flag or along the rows dimension if you omit /DIM.

Complex waves have their real and imaginary components integrated individually.

### Flags

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /DIM= <i>d</i>  | Specifies the wave dimension along which to integrate when <i>yWave</i> is multidimensional.<br><i>d</i> =-1: Treats entire wave as 1D (default).<br><i>d</i> =0: Integrates along rows.<br><i>d</i> =1: Integrates along columns.<br><i>d</i> =2: Integrates along layers.<br><i>d</i> =3: Integrates along rows.<br><br>For example, for a 2D wave, /DIM=0 integrates each row and /DIM=1 integrates each column.                                                                                   |
| /METH= <i>m</i> | Sets the integration method.<br><i>m</i> =0: Rectangular integration (default). Results at a point are stored at the same point (rather than at the next point as for /METH=2). This method keeps the dimension size the same.<br><i>m</i> =1: Trapezoidal integration.<br><i>m</i> =2: Rectangular integration. Results at a point are stored at the next point (rather than at the same point as for /METH=0). This method increases the dimension size by one to provide a place for the last bin. |
| /P              | Forces point scaling.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| /T              | Trapezoidal integration. Same as /METH=1.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### Type Flags (*used only in functions*)

Integrate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-73 and **WAVE Reference Type Flags** on page IV-73 for a complete list of type flags and further details.

For example, when the input (and output) waves are complex, the output wave will be complex. To get the Igor compiler to create a complex output wave reference, use the /C type flag with /D=destwave:

```
Make/O/C cInput=cmplx(sin(p/8), cos(p/8))
Make/O/C/N=0 cOutput
Integrate/C cInput /D=cOutput
```

## Integrate

---

### Wave Parameters

**Note:** All wave parameters must follow *yWave* in the command. All wave parameter flags and type flags must appear immediately after the operation name (*Integrate*).

*/D=destWave* Specifies the name of the wave to hold the integrated data. It creates *destWave* if it does not already exist or overwrites it if it exists.

*/X=xWave* Specifies the name of corresponding X wave. For rectangular integration, the number of points in the X wave must be one greater than the number of elements in the Y wave dimension being integrated.

### Details

The computation equation for rectangular integration using */METH=0* is:

$$waveOut[p] = \sum_{i=0}^p waveIn[i] \cdot \Delta x.$$

The computation equation for rectangular integration using */METH=2* is:

$$waveOut[0] = 0$$

$$waveOut[p+1] = \sum_{i=0}^p (x_{i+1} - x_i) waveIn[i].$$

The inverse of this rectangular integration is the backwards difference.

Trapezoidal integration (*/METH=1*) is a more accurate method of computing the integral than rectangular integration. The computation equation is:

$$waveOut[0] = 0$$

$$waveOut[p] = waveOut[p-1] + \frac{\Delta x}{2} (waveIn[p-1] + waveIn[p]).$$

If the optional */D = destWave* flag is omitted, then the wave is integrated in place overwriting the source wave.

When using an X wave, the X wave must be a 1D wave with data type matching the Y wave (excluding the complex type flag). Rectangular integration (*/METH=0* or *2*) requires an X wave having one more point than the number of elements in the dimension of the Y wave being integrated. X waves with number points plus one are allowed for rectangular integration with methods needing only the number of points. X waves are not used with integer source waves.

Although it is mathematically suspect, rectangular integration using */METH=0* would be correct if the X scaling of the output wave is offset by  $\Delta X$ .

*Differentiate/METH=1/EP=1* is the inverse of *Integrate/METH=2*, but *Integrate/METH=2* is the inverse of *Differentiate/METH=1/EP=1* only if the original first data point is added to the output wave.

*Integrate* applied to an XY pair of waves does not check the ordering of the X values and doesn't care about it. However, it is usually the case that your X values should be monotonic. If your X values are not monotonic, you should be aware that the X values will be taken from your X wave in the order they are found, which will result in random X intervals for the X differences. It is usually best to sort the X and Y waves first (see **Sort**).

## Integrate1D

**Integrate1D**(UserFunctionName, min\_x, max\_x [, options [, count [, pWave]]])

The Integrate1D function performs numerical integration of a user function between the specified limits (*min\_x* and *max\_x*).

### Parameters

*UserFunctionName* must have this format:

```
Function UserFunctionName (inX)
 Variable inX
 ... do something
 return result
End
```

However, if you supply the optional *pWave* parameter then it must have this format:

```
Function UserFunctionName (pWave, inX)
 Wave pWave
 Variable inX
 ... do something
 return result
End
```

*options* is one of the following:

- 0: Trapezoidal integration (default).
- 1: Romberg integration.
- 2: Gaussian Quadrature integration.

By default, *options* is 0 and the function performs trapezoidal integration. In this case Igor evaluates the integral iteratively. In each iteration the number of points where Igor evaluates the function increases by a factor of 2. The iterations terminate at convergence to tolerance or when the number of evaluations is  $2^{23}$ .

The *count* parameter specifies the number of subintervals in which the integral is evaluated. If you specify 0 or a negative number for count, the function performs an adaptive Gaussian Quadrature integration in which Igor bisects the interval and performs a recursive refining of the integration only in parts of the interval where the integral does not converge to tolerance.

*pWave* is an optional parameter that, if present, is passed to your function as the first parameter. It is intended for your private use, to pass one or more values to your function, and is not modified by Igor. The *pWave* parameter was added in Igor Pro 7.00.

### Details

You can integrate complex-valued functions using a function with the format:

```
Function/C complexUserFunction (inX)
 Variable inX
 Variable/C result
 //... do something
 return result
End
```

The syntax used to invoke the function is:

```
Variable/C cIntegralResult=Integrate1D (complexUserFunction, min_x, max_x...)
```

You can also use Integrate1D to perform a higher dimensional integrals. For example, consider the function:

$$F(x,y) = 2x + 3y + xy.$$

In this case, the integral

$$h = \int dy \int f(x,y) dx$$

can be performed by establishing two user functions:

```
Function Do2dIntegration (xmin, xmax, ymin, ymax)
 Variable xmin, xmax, ymin, ymax

 Variable/G globalXmin=xmin
 Variable/G globalXmax=xmax
 Variable/G globalY
```

## Integrate2D

---

```
 return Integrate1d(userFunction2,ymin,ymax,1) // Romberg integration
End
Function UserFunction1(inX)
 Variable inX
 NVAR globalY=globalY
 return (3*inX+2*globalY+inX*globalY)
End
Function UserFunction2(inY)
 Variable inY
 NVAR globalY=globalY
 globalY=inY
 NVAR globalXmin=globalXmin
 NVAR globalXmax=globalXmax
 // Romberg integration
 return Integrate1D(userFunction1,globalXmin,globalXmax,1)
End
```

This method can be extended to higher dimensions.

If the integration fails to converge or if the integrand diverges, Integrate1D returns NaN. When a function fails to converge it is a good idea to try another integration method or to use a user-defined number of intervals (as specified by the count parameter). Note that the trapezoidal method is prone to convergence problems when the absolute value of the integral is very small.

## Integrate2D

**Integrate2D** [*flags*] [*keyword = value* [, *keyword = value* ...]]

The Integrate2D operation calculates a two-dimensional numeric integral of a real-valued user-defined function or a wave. The result of the operation is stored in the variable V\_value and the variable V\_Flag is set to zero if there are no errors.

This operation was added in Igor Pro 7.00.

**Keywords**

|                                           |                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>epsilon=<i>ep</i></code>            | Specifies the convergence parameter. By default $ep=1e-5$ . Smaller values lead to more accurate integration result but the tradeoff is longer computation time.                                                                                                                                                                                       |
| <code>integrand=<i>uF</i></code>          | Specifies the user function to be integrated. See <b>The Integrand Function</b> below for details.                                                                                                                                                                                                                                                     |
| <code>innerLowerLimit=<i>y1</i></code>    | Specifies the lower limit of the inner integral if this limit is fixed, i.e., if it is not a function of $x$ . See the <code>innerLowerFunc</code> keyword if you need to specify a function for this limit.                                                                                                                                           |
| <code>innerUpperLimit=<i>y2</i></code>    | Specifies the upper limit of the inner integral if this limit is fixed, i.e., if it is not a function of $x$ . See the <code>innerUpperFunc</code> keyword if you need to specify a function for this limit.                                                                                                                                           |
| <code>innerLowerFunc=<i>y1Func</i></code> | Specifies a user-defined function for the lower limit of the inner integral. See <b>The Limit Functions</b> below.                                                                                                                                                                                                                                     |
| <code>innerUpperFunc=<i>y2Func</i></code> | Specifies a user-defined function for the upper limit of the inner integral. See <b>The Limit Functions</b> below.                                                                                                                                                                                                                                     |
| <code>outerLowerLimit=<i>x1</i></code>    | Specifies the lower limit of the outer integral.                                                                                                                                                                                                                                                                                                       |
| <code>outerUpperLimit=<i>x2</i></code>    | Specifies the upper limit of the outer integral.                                                                                                                                                                                                                                                                                                       |
| <code>paramWave=<i>pWave</i></code>       | Specifies a wave to be passed to the integrand and limit user-defined functions as the <code>pWave</code> parameter. The wave may contain any number of values that you might need to evaluate the integrand or the integration limits.<br><br>If you omit <code>paramWave</code> then the <code>pWave</code> parameter to the functions will be NULL. |
| <code>srcWave=<i>mWave</i></code>         | If you need to perform 2D integration of some data, you can specify the data directly instead of providing a user-defined function that returns interpolated data. <code>mWave</code> must be a 2D wave. Higher dimensional waves are accepted but only the first layer of the wave is used in the integration.                                        |

**The Integrand Function**

Integrate2D computes the general two-dimensional integral of a user-defined integrand function which you specify using the `integrand` keyword. The integrand function has this form:

```
Function integrandFunc(pWave, inX, inY)
 Wave/Z pWave
 Variable inX, inY

 ... do something
 return result
End
```

The function can have any name - `integrandFunc` is just an example. The function must take the parameters shown and must return a real numeric result. Returning a NaN terminates the integration.

`pWave` is a parameter wave that you specify using the `paramWave` keyword. The operation passes this wave on every call to the integrand function. If you omit `paramWave` when invoking Integrate2D then `pWave` will be NULL.

**The Limit Functions**

The limit functions provide lower and/or upper limits of integration for the inner integral if they are functions of  $x$  rather than fixed values. You specify a limit function using the `innerLowerFunc` and `innerUpperFunc` keywords. The form of the limit function is:

```
Function limitFunction(pWave, inX)
 Wave/Z pWave
 Variable inX

 ... do something
```

## Integrate2D

---

```
 return result
End
```

### Details

The operation computes the general two-dimensional integral of the form

$$I = \int_{x1}^{x2} dx \int_{y1(x)}^{y2(x)} f(x,y)dy.$$

Here  $y1$  and  $y2$  are in general functions of  $x$  but could also be simple constants, and  $f(x,y)$  is real valued function. The integral is evaluated by considering the "outer" integral

$$I = \int_{x1}^{x2} G(x)dx,$$

where  $G(x)$  is the "inner" integral

$$G(x) = \int_{y1(x)}^{y2(x)} f(x,y)dy.$$

The operation allows you to specify different algorithms for integrating the inner and outer integrals. The simplest integration algorithm is the Trapezoidal method. You can typically improve on the accuracy of the calculation using Romberg integration and the performance of Gaussian quadrature depends significantly on the nature of the integrand.

### Example 1: Integrating a 2D function over fixed limits

Suppose we wanted to check the normalization of the built-in two-dimensional Gauss function. The user-defined function would be:

```
Function myIntegrand1(pWave,inX,inY)
 Wave/Z pWave
 Variable inX,inY
 return Gauss(inX,50,10,inY,50,10)
End
```

To perform the integration, execute:

```
Integrate2D outerLowerLimit=0, outerUpperLimit=100, innerLowerLimit=0,
 innerUpperLimit=100, integrand=myIntegrand1
Print/D V_Value
```

### Example 2: Integrating a 2D function using function limits

In this example we compute the volume of a sphere of radius 1. To do so we use symmetry and integrate the volume in one octant only. The limits of integration are  $[0,1]$  in the  $x$  direction and  $[0,\sqrt{1-x^2}]$  in the  $y$  direction. In this case we need to define two user-defined functions: one for the integrand and one for the upper limit of the inner integral:

```
Function myIntegrand2(pWave,inX,inY)
 Wave/Z pWave
 Variable inx,iny
 Variable r2=inX^2+inY^2
 if(r2>=1)
 return 0
 else
 return sqrt(1-r2)
 endif
End
```

```
Function y2Func(pWave,inX)
 Wave pWave
 Variable inX
 return sqrt(1-inX^2)
End
```

To perform the integration, execute:

```
Integrate2D outerLowerLimit=0, outerUpperLimit=1, innerLowerLimit=0,
 innerUpperFunc=y2Func, integrand=myIntegrand2
Print/D 4*pi/3 -8*V_Value // Calculation error
```

Note that the integrand function tests that  $r2$  does not exceed 1. This is because the `sqrt` function would return a NaN if  $r2 > 1$  which can happen due to floating point rounding errors. Returning a NaN terminates the integration.

### Example 3: Integrating a 2D wave using fixed limits

In this example we compute the volume between the surface defined by the wave `my2DWave` and the plane  $z=0$  with integration limits  $[0,1]$  in the  $x$ -direction and  $[0,2]$  in the  $y$ -direction. For simplicity we set the wave's value to be a constant ( $\pi$ ).

```
Make/O/N=(5,9) my2DWave=pi
SetScale/P x 0,0.3,"", my2DWave
SetScale/P y 0,0.4,"", my2DWave
Integrate2D outerLowerLimit=0, outerUpperLimit=1, innerLowerLimit=0, innerUpperLimit=2,
 srcWave=my2DWave
Print/D 2*pi-V_Value // Calculation error
```

## IntegrateODE

**IntegrateODE** [*flags*] *derivFunc*, *cwaveName*, *ywaveSpec*

The `IntegrateODE` operation calculates a numerical solution to a set of coupled ordinary differential equations by integrating derivatives. The derivatives are user-specified via a user-defined function, *derivFunc*. The equations must be a set of first-order equations; a single second-order equation must be recast as two first-order equations, a third-order equation to three first order equations, etc. For more details on how to write the function, see [Solving Differential Equations](#) on page III-322.

`IntegrateODE` offers two ways to specify the values of the independent variable (commonly called  $X$  or  $t$ ) at which output  $Y$  values are recorded. You can specify the  $X$  values or you can request a “free-run” mode.

The algorithms used by `IntegrateODE` calculate results at intervals that vary according to the characteristics of the ODE system and the required accuracy. You can set specific  $X$  values where you need output (see the `/X` flag below) and arrangements will be made to get values at those specific  $X$  values. In between those values, `IntegrateODE` will calculate whatever spacing is needed, but intermediate values will not be output to you.

If you specify free-run mode, `IntegrateODE` will simply output all steps taken regardless of the spacing of the  $X$  values that results.

### Parameters

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>cwaveName</i> | Name of wave containing constant coefficients to be passed to <i>derivFunc</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>derivFunc</i> | Name of user function that calculates derivatives. For details on the form of the function, see <a href="#">Solving Differential Equations</a> on page III-322.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>ywaveSpec</i> | Specifies a wave or waves to receive calculated results. The waves also contain initial conditions. The <i>ywaveSpec</i> can have either of two forms:<br><br><i>ywaveName</i> : <i>ywaveName</i> is a single, multicolumn wave having one column for each equation in your equation set (if you have just one equation, the wave will be a simple 1D wave).<br><br><i>{ywave0, ywave1, ...}</i> : The <i>ywaveSpec</i> is a list of 1D waves, one wave for each equation. The ordering is important — it must correspond to the elements of the $y$ wave and $dydx$ wave passed to <i>derivFunc</i> .<br><br>Unless you use the <code>/R</code> flag to alter the start point, the solution to the equations is calculated at each point in the waves, starting with row 1. You must store the initial conditions in row 0. |

### Flags

`/CVOP={solver, jacobian, extendedErrors [, maxStep]}`

Selects options that affect how the Adams-Moulton and BDF integration schemes operate. This flag applies only when using  $/M = 2$  or  $/M = 3$ . These methods are based on the CVODE package, hence the flag letters "CV".

The *solver* parameter selects a solver method for each step. The values of *solver* can be:

*solver*=0: Select the default for the integration method. That is functional for  $/M=2$  or Newton for  $/M=3$ .

*solver*=1: Functional solver.

*solver*=2: Newton solver.

The *jacobian* parameter selects the method used to approximate the jacobian matrix (matrix of  $df/dy_i$  where  $f$  is the derivative function).

*jacobian*=0: Full jacobian matrix.

*jacobian*=1: Diagonal approximation.

In both cases, the derivatives are approximated by finite differences.

In our experience, *jacobian* = 1 causes the integration to proceed by much smaller steps. It might decrease overall integration time by reducing the computation required to approximate the jacobian matrix.

If the *extendedErrors* parameter is nonzero, extra error information will be printed to the history area in case of an error during integration using  $/M=2$  or  $/M=3$ . This extra information is mostly of the sort that will be meaningful only to WaveMetrics software engineers, but may occasionally help you to solve problems. It is printed out as a bug message (BUG: . . .) regardless of whether it is our bug or yours.

If *maxStep* is present and greater than zero, this option sets the maximum internal step size that the CVODE package is allowed to take. This is particularly useful with  $/M=3$ , as the BDF method is capable of taking extremely large steps if the derivatives don't change much. Use of this option may be necessary to make sure that the CVODE package doesn't step right over a brief excursion in, say, a forcing function. If you have something in your derivative function that may be step-like and brief, set *maxStep* to something smaller than the duration of the excursion.

If you want to set *maxStep* only, set the other three options to zero.

*/E=eps*

Adjusts the step size used in the calculations by comparing an estimate of the truncation error against a fraction of a scaled number. The fraction is *eps*. For instance, to achieve error less than one part in a thousand, set *eps* to 0.001. The number itself is set by a combination of the */F* flag and possibly the wave specified with the */S* flag. See **Solving Differential Equations** on page III-322 for details.

If you do not use the */E* flag, *eps* is set to  $10^{-6}$ .

For details, see **Error Monitoring** on page III-332.

- /F=errMethod* Adjusts the step size used in the calculations by comparing an estimate of the truncation error against a scaled number. *errMethod* is a bitwise parameter that specifies what to include in that number:
- bit 0: Add a constant from the error scaling wave set by the */S* flag.
  - bit 1: Add the current value of the results.
  - bit 2: Add the current value of the derivatives.
  - bit 3: Multiply by the current step size (*/M=0* or */M=1* only).
- Each bit that you set of bits 0, 1, or 2 adds a term to the number; setting bit 3 multiplies the sum by the current step size to achieve a global error limit. Note that bit 3 has no effect if you use the Adams or BDF integrators (*/M=2* or */M=3*). See **Setting Bit Parameters** on page IV-12 for further details about bit settings.
- If you don't include the */F* flag, a constant is used. Unless you use the */S* flag, that constant is set to 1.0.
- For details, see **Error Monitoring** on page III-332.
- /M=m* Specifies the method to use in calculating the solution.
- m=0*: Fifth-order Runge-Kutta-Fehlberg (default).
  - m=1*: Bulirsch-Stoer method using Richardson extrapolation.
  - m=2*: Adams-Moulton method.
  - m=3*: BDF (Backwards Differentiation Formula, or Gear method). This method is the preferred method for stiff problems.
- If you don't specify a method, the default is the Runge-Kutta method (*m=0*). Bulirsch-Stoer (*m=1*) should be faster than Runge-Kutta for problems with smooth solutions, but we find that this is often not the case. Simple experiments indicate that Adams-Moulton (*m=2*) may be fastest for nonstiff problems. BDF (*m=3*) is definitely the preferred one for stiff problems. Runge-Kutta is a robust method that may work on problems that fail with other methods.
- /Q [= quiet]* *quiet* = 1 or simply */Q* sets quiet mode. In quiet mode, no messages are printed in the history, and errors do not cause macro abort. The variable *V\_flag* returns an error code. See **Details** for the meanings of the *V\_flag* error codes.
- /R=(startX,endX)* Specifies an X range of the waves in *ywaveSpec*.
- /R=[startP,endP]* Specifies a point range in *ywaveSpec*.
- If you specify the range as */R=[startP]* then the end of the range is taken as the end of the wave. If */R* is omitted, the entire wave is evaluated. If you specify only the end point (*/R = [,endP]*) the start point is taken as point 0.
- You must store initial conditions in *startP*. The first point is *startP+1*.
- /S=errScaleWaveName*
- If you set bit 0 of *errMethod* using the */F* flag, or if you don't include the */F* flag, a constant is required for scaling the estimated error for each differential equation. By default, the constants are simply set to 1.0.
- You provide custom values of the constants via the */S* flag and a wave. Make a wave having one element for each derivative, set a reasonable scale factor for the corresponding equation, and set *errScaleWaveName* to the name of that wave.
- If you don't use the */S* flag, the constants are all set to 1.0.
- /STOP = {stopWave, mode}*

Requests that IntegrateODE stop when certain conditions are met on either the solution values (Y values) or the derivatives.

*stopWave* contains information that IntegrateODE uses to determine when to stop.

*mode* controls the logical operations applied to the elements of *stopWave*:

*mode=0*: OR mode. If *stopWave* contains more than one condition, any one condition will stop the integration when it is satisfied.

*mode=1*: AND mode. If *stopWave* contains more than one condition, all conditions must be satisfied to cause the integration to stop.

See Details, below, for more information.

*/U=u* Update the display every *u* points. By default, it will update the display every 10 points. To disable updates, set *u* to a very large number.

*/X=xvaluespec* Specifies the values of the independent variable (commonly called *x* or *t*) at which values are to be calculated (see parameter *ywaveSpec*).

You can provide a wave or *x0* and *deltaX*:

*/X = xWaveName*

Use this form to provide a list of values for the independent variable. They can have arbitrary spacing and may increase or decrease, but should be monotonic.

If you use the */XRUN* flag to specify free-run mode, */X = xWaveName* is required. In this case, the X wave becomes an output wave and any contents are overwritten. See the description of */XRUN* for details.

*/X = {x0, deltaX}*

If you use this form, *x0* is the initial value of the independent variable. This is the value at which the initial conditions apply. It will calculate the first result at *x0+deltaX*, and subsequent results with spacing of *deltaX*.

*deltaX* can be negative.

If you do not use the *xValues* keyword, it reads independent variable values from the X scaling of the results wave (see *ywaveSpec* parameter).

*/XRUN={dx0, Xmax}*

If *dx0* is nonzero, the output is generated in a free-running mode. That is, the output values are generated at whatever values if the independent variable (*x* or *t*) the integration method requires to achieve the requested accuracy. Thus, you will get solution points at variably-spaced X values.

The parameter *dx0* sets the step size for the first integration step. If this is smaller than necessary, the step size will increase rapidly. If it is too large for the requested accuracy, the integration method will decrease the step size as necessary.

If *dx0* is set to zero, free-run mode is not used; this is the same as if the *XRUN* flag is not used.

When using free-run mode, you must provide an X wave using */X = xWaveName*. Set the first value of the wave (this is usually point zero, but may not be if you use the */R* flag) to the initial value of X.

As the integration proceeds, the X value reached for each output point is written into the X wave. The integration stops when the latest step taken goes beyond *Xmax* or when the output waves are filled.

### Details

The various waves you may use with the IntegrateODE operation must meet certain criteria. The wave to receive the results (*ywaveSpec*), and which contains the initial conditions, must have exactly one column for each equation in your system of equations, or you must supply a list of waves containing one wave for each equation. Because IntegrateODE can't determine how many equations there are from your function, it uses the number of columns or the number of waves in the list to determine the number of equations.

If you supply a list of waves for *ywaveSpec*, all the waves must have the same number of rows. If you supply a wave containing values of the independent variable or to receive X values in free-run mode (using */X=waveName*) the wave must have the same number of rows as the *ywaveSpec* waves.

The wave you provide for error scaling via the */S* flag must have one point for each equation. That is, one point for each *ywaveSpec* wave, or one point for each column of a multicolumn *ywaveSpec*.

By default, the display will update after each tenth point is calculated. If you display one of your *ywaveSpec* waves in a graph, you can watch the progress of the integration.

The display update may slow down the calculation considerably. Use the */U* flag to change the interval between updates. To disable the updates entirely, set the update interval to a number larger than the length of the waves in *ywaveSpec*.

In free-run mode, it is impossible to predict how many output values you will get. IntegrateODE will stop when either your waves are filled, or when the X value exceeds *Xmax* set in the */XRUN* flag. The best strategy is to make the waves quite large; unused rows in the waves will not be touched. To avoid having “funny” traces on a graph, you can prefill your waves with NaN. Make sure that you don’t set the initial condition row and initial X value row to Nan!

### Stopping IntegrateODE

In some circumstances it is useful to be able to stop the integration early, before the full number of output values has been computed. You can do this two ways: using the */STOP* flag to put conditions on the solution, or by returning 1 from your derivative function.

When using */STOP={stopWave, mode}*, *stopWave* must have one column for each equation in your system or, equivalently, a number of columns equal to the order of your system. Each column represents a condition on either the solution value or the derivatives for a given equation in your system.

Row 0 of *stopWave* contains a flag telling what sort of condition to apply to the solution values. If the flag is zero, that value is ignored. If the flag is 1, the integration is stopped if the solution value exceeds the value you put in row 1. If the flag is -1, integration is stopped when the solution value is less than the value in row 1.

Rows 2 and 3 work just like rows 0 and 1, but the conditions are applied to the derivatives rather than to the solution values.

If *stopWave* has two rows, only the solution values are checked. If *stopWave* has four rows, you can specify conditions on both solution values and derivatives.

You can set more than one flag value non-zero. If you do that, then *mode* determines how the multiple conditions are applied. If *mode* is 0, then any one condition can stop integration when it is satisfied. If *mode* is 1, all conditions with a non-zero flag value must be satisfied at the same time. If row 0 and row 2 have nothing but zeroes, then *stopWave* is ignored.

For further discussion, see **Stopping IntegrateODE on a Condition** on page III-335.

### Output Variables

The IntegrateODE operation sets a variety of variables to give you information about the integration. These variables are updated at the same time as the display so you can monitor an integration in progress. They are:

|                    |                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------|
| V_ODEStepCompleted | Point number of the last result calculated.                                                                               |
| V_ODEStepSize      | Size of the last step in the calculation.                                                                                 |
| V_ODETotalSteps    | Total number of steps required to arrive at the current result. In free-run mode, this is the same as V_ODEStepCompleted. |
| V_ODEMinStep       | Minimum step size used during the entire calculation.                                                                     |
| V_ODEFunctionCalls | The total number of calls made to your derivative function.                                                               |
| V_Flag             | Indicates why IntegrateODE stopped.                                                                                       |

The values for V\_Flag are:

- 0: Finished normally.
- 1: User aborted the integration.

## interp

---

- 2: Integration stopped because the step size became too small.  
That is,  $dX$  was so small that  $X + dX = X$ .
- 3: IntegrateODE ran out of memory.
- 4: In  $/M=2$  or  $/M=3$ , the integrator received illegal inputs. Please report this to WaveMetrics (see **Technical Support** on page II-4 for contact details).
- 5: In  $/M=2$  or  $/M=3$ , the integrator stopped with a failure in the step solver. The method chosen may not be suitable to the problem.
- 6: Indicates a bug in IntegrateODE. Please report this to WaveMetrics (see **Technical Support** on page II-4 for contact details).
- 7: An error scaling factor was zero (see  $/S$  and  $/F$  flags).
- 8: IntegrateODE stopped because the conditions specified by the  $/STOP$  flag were met.
- 9: IntegrateODE stopped because the derivative function returned a value requesting the stop.

The Runge-Kutta ( $/M=0$ ) and Bulirsch-Stoer ( $/M=1$ ) methods are based on routines in Press, William H., *et al.*, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992, and are used by permission.

The Adams-Moulton ( $/M=2$ ) and BDF methods ( $/M=3$ ) are based on the CVODE package developed at Lawrence Livermore National Laboratory:

Cohen, Scott D., and Alan C. Hindmarsh, *CVODE User Guide*, LLNL Report UCRL-MA-118618, September 1994.

The CVODE package was derived in part from the VODE package. The parts used in Igor are described in this paper:

Brown, P.N., G. D. Byrne, and A. C. Hindmarsh, VODE, a Variable-Coefficient ODE Solver, *SIAM J. Sci. Stat. Comput.*, 10, 1038-1051, 1989.

## interp

**interp**(*x1*, *xwaveName*, *ywaveName*)

The **interp** function returns a linearly interpolated value at the location  $x = x1$  of a curve whose X components come from the Y values of *xwaveName* and whose y components come from the Y values of *ywaveName*.

### Details

**interp** returns nonsense if the waves are complex or if *xwaveName* is not monotonic or if either wave contains NaNs.

The **interp** function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details.

## Examples

The **Interp2D**, **Interp3D** and **ContourZ** functions.

## Interp2D

**Interp2D**(*srcWaveName*, *xV*, *y*)

The **Interp2D** function returns a double precision number as the bilinear interpolation value at the specified coordinates of the source wave. It returns NaN if the point is outside the source wave domain or if the source wave is complex.

## Parameters

*srcWaveName* is the name of a 2D wave which wave must be real.

*x* is the X location of the interpolated point.

*y* is the Y location of the interpolated point.

## See Also

The **ImageInterpolate** operation. **Interpolation** on page III-114.

## Interp3D

**Interp3D**(*srcWave*, *x*, *y*, *z* [, *triangulationWave*])

The **Interp3D** function returns an interpolated value for location  $P=(x, y, z)$  in a 3D scalar distribution *srcWave*.

If *srcWave* is a 3D wave containing a scalar distribution sampled on a regular lattice, the function returns a linearly interpolated value for any  $P=(x, y, z)$  location within the domain of *srcWave*. If *P* is outside the domain, the function returns NaN.

To interpolate a 3D scalar distribution that is not sampled on a regular lattice, *srcWave* is a four column 2D wave where the columns correspond to *x*, *y*, *z*, *f(z, y, z)*, respectively. You must also use a “triangulation” wave for *srcWave* (use **Triangulate3D/out=1** to obtain the triangulation wave). If *P* falls within the convex domain defined by the tetrahedra in *triangulationWave*, the function returns the barycentric linear interpolation for *P* using the tetrahedron where *P* is found. If *P* is outside the convex domain the function returns NaN.

## Examples

```
Make/O/N=(10,20,30) ddd=gnoise(10)
Print interp3D(ddd,1,0,0)
Print interp3D(ddd,1,1,1)
```

```
Make/O/N=(10,4) ddd=gnoise(10)
Triangulate3D/OUT=1 ddd
Print interp3D(ddd,1,0,0,M_3DVertexList)
Print interp3D(ddd,1,1,1,M_3DVertexList)
```

### Interp3DPath

**Interp3DPath** *3dWave tripletPathWave*

The Interp3DPath operation computes the trilinear interpolated values of *3dWave* for each position specified by a row of in *tripletPathWave*, which is a 3 column wave in which the first column represents the X coordinate, the second represents the Y coordinate and the third represents the Z coordinate. Interp3DPath stores the resulting interpolated values in the wave *W\_Interpolated*. Interp3DPath is equivalent to calling the Interp3D() function for each row in *tripletPathWave* but it is computationally more efficient.

If the position specified by the *tripletPathWave* is outside the definition of the *3dWave* or if it contains a NaN, the operation stores a NaN in the corresponding output entry.

Both *3dWave* and *tripletPathWave* can be of any numeric type. *W\_Interpolated* is always of type NT\_FP64.

### Interpolate2

**Interpolate2** [*flags*] [*xWave*,] *yWave*

The Interpolate2 operation performs linear, cubic spline and smoothing cubic spline interpolation on 1D waveform or XY data. It produces output in the form of a waveform or an XY pair.

The cubic spline interpolation is based on a routine from "Numerical Recipes in C".

The smoothing spline is based on "Smoothing by Spline Functions", Christian H. Reinsch, *Numerische Mathematic* 10, 177-183 (1967).

For background information, see **The Interpolate2 Operation** on page III-115.

#### Parameters

*xWave* specifies the wave which supplies the X coordinates for the input curve. If you omit it, X coordinates are taken from the X values of *yWave*.

*yWave* specifies the wave which supplies the Y coordinates for the input curve.

#### Flags

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Interpolate3D

**Interpolate3D** [*/Z* ] */RNGX={x0, dx, nx}/RNGY={y0, dy, ny}/RNGZ={z0, dz, nz}*  
*/DEST=dataFolderAndName, triangulationWave=tWave, srcWave=sWave*

The Interpolate3D operation uses a precomputed triangulation of *sWave* (see **Triangulate3D**) to calculate regularly spaced interpolated values from an irregularly spaced source. The interpolated values are calculated for a lattice defined by the range flags */RNGX*, */RNGY*, and */RNGZ*. *sWave* is a 4 column wave where the first three columns contain the spatial coordinates and the fourth column contains the associated scalar value. Interpolate3D is essentially equivalent to calling the **Interp3D** function for each interpolated point in the range but it is much more efficient.

### Parameters

*triangulationWave=tWave*

Specifies a 2D index wave, *tWave*, in which each row corresponds to one tetrahedron and each column (tetrahedron vertex) is represented by an index of a row in *sWave*. Use **Triangulate3D** with */OUT=1* to obtain *tWave*.

*srcWave=sWave*

Specifies a real-valued 4 column 2D source wave, *sWave*, in which columns correspond to *x*, *y*, *z*, *f(x, y, z)*. Requires that the domain occupied by the set of  $\{x, y, z\}$  be convex.

### Flags

*/DEST=dataFolderAndName*

Saves the result in the specified destination wave. The destination wave will be created or overwritten if it already exists. *dataFolderAndName* can include a full or partial path with the wave name.

*/RNGX={x0,dx,nx}*

Specifies the range along the X-axis. The interpolated values start at *x0*. There are *nx* equally spaced interpolated values where the last value is at  $x0+(nx-1)dx$ . If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a YZ plane would have *nx=1*.

- `/RNGY={y0,dy,ny}` Specifies the range along the Y-axis. The interpolated values start at  $y_0$ . There are  $ny$  equally spaced interpolated values where the last value is at  $y_0+(ny-1)dy$ . If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a XZ plane would have  $ny=1$ .
- `/RNGZ={z0,dz,nz}` Specifies the range along the Z-axis. The interpolated values start at  $z_0$ . There are  $nz$  equally spaced interpolated values where the last value is at  $z_0+(nz-1)dz$ . If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a XY plane would have  $nz=1$ .
- `/Z` No error reporting.

### Details

The triangulation wave defines a set of tetrahedra that spans the convex source domain. If the requested range consists of points outside the domain, the interpolated values will be set to NaN. The interpolation process for points inside the convex domain consists of first finding the tetrahedron in which the point resides and then linearly interpolating the scalar value using the barycentric coordinate of the interpolated point.

In some cases the interpolation may result in NaN values for points that are clearly inside the convex domain. This may happen when the preceding `Triangulate3D` results in tetrahedra that are too thin. You can try using `Triangulate3D` with the flag `/OUT=4` to get more specific information about the triangulation. Alternatively you can introduce a slight random perturbation to the input source wave before the triangulation.

### Example

```
Function Interpolate3DDemo()
 Make/O/N=(50,4) ddd=gnoise(20) // First 3 columns store XYZ coordinates
 ddd[] [3]=ddd[p] [2] // Fourth column stores a scalar which is set to z
 Triangulate3D ddd // Perform the triangulation
 Wave M_3dVertexList
 Interpolate3D /RNGX={-30,1,80}/RNGY={-40,1,80}/RNGZ={-40,1,80}
 /DEST=W_Interp triangulationWave=M_3dVertexList,srcWave=ddd
End
```

## inverseErf

### inverseErf(x)

The `inverseErf` function returns the inverse of the error function.

### Details

The function is calculated using rational approximations in several regions followed by one iteration of Halley's algorithm.

### See Also

The `erf`, `erfc`, `dawson`, and `inverseErfc` functions.

## inverseErfc

### inverseErfc(x)

The `inverseErfc` function returns the inverse of the complementary error function.

### Details

The function is calculated using rational approximations in several regions followed by one iteration of Halley's algorithm.

### See Also

The `erf`, `erfc`, `erfcw`, `dawson`, and `inverseErf` functions.

### ItemsInList

**ItemsInList**(*listStr* [, *listSepStr*])

The **ItemsInList** function returns the number of items in *listStr*. *listStr* should contain items separated by *listSepStr* which typically is ";".

Use **ItemsInList** to count the number of items in a string containing a list of items separated by a string (usually a single ASCII character), such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

If *listStr* is "" then 0 is returned.

*listSepStr* is optional. If missing, *listSepStr* defaults to ";".

#### Details

*listStr* is searched for item strings bound by *listSepStr* on the left and right.

An item can be empty. The lists "abc;def;;ghi" and ";abc;def;;ghi;" have four items (the third item is "").

*listStr* is treated as if it ends with a *listSepStr* even if it doesn't. The search is case-sensitive.

In Igor6, only the first byte of *listSepStr* was used. In Igor7 and later, all bytes are used.

#### Examples

```
Print ItemsInList ("wave0;wave1;wave1#1;") // prints 3
Print ItemsInList ("key1=val1,key2=val2", ",") // prints 2
Print ItemsInList ("1 \t 2 \t", "\t") // prints 2
Print ItemsInList (";") // prints 1
Print ItemsInList (";;") // prints 2
Print ItemsInList (";a;") // prints 2
Print ItemsInList (";;;") // prints 3
```

#### See Also

The **AddListItem**, **StringFromList**, **FindListItem**, **RemoveListItem**, **RemoveFromList**, **WaveList**, **TraceNameList**, **StringList**, **VariableList**, and **FunctionList** functions.

## j

### j

The **j** function returns the loop index of the 2nd innermost iterate loop in a macro. Not to be used in a function. Iterate loops are archaic and should not be used.

## JCAMPLoadWave

**JCAMPLoadWave** [*flags*] [*fileNameStr*]

The **JCAMPLoadWave** operation loads data from the named JCAMP-DX file into waves.

#### Parameters

If *fileNameStr* is omitted or is "", or if the /I flag is used, **JCAMPLoadWave** presents an Open File dialog from which you can choose the file to load.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

## Flags

|                          |                                                                                                                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/A</code>          | Automatically assigns arbitrary wave names using "wave" as the base name. Skips names already in use.                                                                                      |
| <code>/A=baseName</code> | Same as <code>/A</code> but it automatically assigns wave names of the form <code>baseName0</code> , <code>baseName1</code> .                                                              |
| <code>/D</code>          | Creates double-precision waves. If omitted, JCAMPLoadWave creates single-precision waves.                                                                                                  |
| <code>/H</code>          | Reads header information from JCAMP file. If you include <code>/W</code> , this information is stored in the wave note. If you include <code>/V</code> , it is stored in header variables. |
| <code>/I</code>          | Forces JCAMPLoadWave to display an Open File dialog even if the file is fully specified via <code>/P</code> and <code>fileNameStr</code> .                                                 |
| <code>/N</code>          | Same as <code>/A</code> except that, instead of choosing names that are not in use, it overwrites existing waves.                                                                          |
| <code>/N=baseName</code> | Same as <code>/N</code> except that it automatically assigns wave names of the form <code>baseName0</code> , <code>baseName1</code> .                                                      |
| <code>/O</code>          | Overwrite existing waves in case of a name conflict.                                                                                                                                       |
| <code>/P=pathName</code> | Specifies the folder to look in for <code>fileNameStr</code> . <code>pathName</code> is the name of an existing symbolic path.                                                             |
| <code>/Q</code>          | Suppresses the normal messages in the history area.                                                                                                                                        |
| <code>/R</code>          | Reads data from file and creates Igor waves.                                                                                                                                               |
| <code>/V</code>          | Set variables from header information if <code>/H</code> is also present                                                                                                                   |
| <code>/W</code>          | Stores header information in the wave note if <code>/R</code> and <code>/H</code> are also present.                                                                                        |

## Details

The `/N` flag instructs Igor to automatically name new waves "wave", or `baseName` if `/N=baseName` is used, plus a number. The number starts from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten.

The `/A` flag is like `/N` except that Igor skips names already in use.

## Output Variables

JCAMPLoadWave sets the following output variables:

|                          |                                                                       |
|--------------------------|-----------------------------------------------------------------------|
| <code>V_flag</code>      | Number of waves loaded or -1 if an error occurs during the file load. |
| <code>S_fileName</code>  | Name of the file being loaded.                                        |
| <code>S_path</code>      | File system path to the folder containing the file.                   |
| <code>S_waveNames</code> | Semicolon-separated list of the names of loaded waves.                |

`S_path` uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon.

When JCAMPLoadWave presents an Open File dialog and the user cancels, `V_flag` is set to 0 and `S_fileName` is set to "".

In addition, if the `/V` flag is used, variables are created corresponding to JCAMP-DX labels in the header. See **Variables Set By JCAMPLoadWave** on page II-159 for details.

## Example

```
Function LoadJCAMP(pathName, fileName)
 String pathName // Name of Igor symbolic path or ""
 String fileName // Full path, partial path or simple file name

 JCAMPLoadWave/P=$pathName fileName
```

## JacobiCn

---

```
if (V_Flag == 0)
 Print "No waves were loaded"
 return -1
endif

NVAR VJC_NPOINTS
Printf "Number of points: %d\r", VJC_NPOINTS

SVAR SJC_YUNITS
Printf "Y Units: %s\r", SJC_YUNITS

return 0
End
```

## JacobiCn

### JacobiCn(x, k)

The JacobiCn function returns the Jacobian elliptic function  $\text{cn}(x,k)$  for real  $x$  and modulus  $k$  with

$$0 < k^2 < 1.$$

The JacobiCn function was added in Igor Pro 7.00.

## JacobiSn

### JacobiSn(x, k)

The JacobiSn function returns the Jacobian elliptic function  $\text{sn}(x,k)$  for real  $x$  and modulus  $k$  with

$$0 < k^2 < 1.$$

The JacobiSn function was added in Igor Pro 7.00.

## jlim

### jlim

The jlim function returns the ending loop count for the 2nd inner most iterate loop. Not to be used in a function. iterate loops are archaic and should not be used.

## JointHistogram

### JointHistogram [flags] wave1, wave2 [, wave3, wave4]

The JointHistogram computes 2D, 3D and 4D joint histograms of data provided in the input waves. The input waves must be 1D real numeric waves having the same number of points. The result of the operation is stored in the multidimensional wave M\_JointHistogram in the current data folder or in the wave specified via the /DEST flag.

This operation was added in Igor Pro 7.00.

**Flags**

|                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/BINS={nx, ny, nz, nt}</i>                                                                    | Specifies the number of bins along each axis. Set the number of bins for unused axes to zero. If the number of bins is non-zero, then the flags <i>/XBMT</i> , <i>/YBMT</i> , <i>/ZBMT</i> , and <i>/TBMT</i> are overridden.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>/C</i>                                                                                        | Sets the output wave scaling so that the values in each axis are centered in the bins. By default, wave scaling of the output wave is set with values at the left bin edges. This flag has no effect on axes where bins are specified by using <i>/XBWV</i> , <i>/YBWV</i> , <i>/ZBWV</i> or <i>/TBWV</i> .                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>/E</i>                                                                                        | Excludes outliers. This flag is relevant only if there are one or more bin waves specified by using <i>/XBWV</i> , <i>/YBWV</i> , <i>/ZBWV</i> or <i>/TBWV</i> . By default values that might fall below the first bin or above the last bin are folded into the first and last bin respectively. These values (outliers) are excluded from the joint histogram when you use <i>/E</i> . See <i>/P</i> below for the way outliers affect the probability calculation.                                                                                                                                                                                                                                                            |
| <i>/DEST=destWave</i>                                                                            | Specifies the output wave created by the operation. If you omit <i>/DEST</i> then the output wave is <i>M_JointHistogram</i> in the current data folder.<br><br>It is an error to specify a destination which is the same as one of the input waves.<br><br>When used in a user-defined function, the <i>JointHistogram</i> operation by default creates a real wave reference for the destination wave. See <b>Automatic Creation of WAVE References</b> on page IV-71 for details.                                                                                                                                                                                                                                             |
| <i>/P=mode</i>                                                                                   | Normalizes the histogram to a probability density.<br><br>Use <i>mode=0</i> to count all points, including possible outliers but excluding non-finite values, in the probability calculation. This is the default setting.<br><br>Use <i>mode=1</i> if you want to completely exclude outliers from the normalization.<br><br>When outliers are excluded the output wave sums to 1. When they are included the sum of the output wave is smaller by the ratio of the number of outliers to the total number of points in the histogram.                                                                                                                                                                                          |
| <i>/W=weightWave</i>                                                                             | Creates a weighted histogram. Instead of adding a single count to the appropriate bin, the corresponding value from <i>weightWave</i> is added to the bin. <i>weightWave</i> may be any real number type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>/XBMT=method</i><br><i>/YBMT=method</i><br><i>/ZBMT=method</i><br><i>/TBMT=method</i>         | These flags specify which method is used to set the bins. By default <i>method=0</i> . **Details**

The input waves must be 1D real numeric waves. If one or more waves contain a non-finite value (a NaN or INF) the corresponding row of all waves are not counted in the joint histogram.

## JulianToDate

---

The optional waves that define user-specified bins must be real numeric waves and contain a monotonically increasing values. Using non-finite values in user-specified bin waves may lead to unpredictable results.

### JointHistogram Binning Methods

The /XBMT, /YBMT, /ZBMT and /TBMT flags set the binning method for the X, Y, Z and T dimensions respectively.

These flags are overridden by /BINS if a non-zero value is specified for a given axis and by /XBWV, /YBWV, /ZBWV and /TBWV.

The *method* parameter is defined as follows:

- method*=0: 128 equally spaced bins between the minimum and maximum of the input data. This is the default setting.
- method*=1: The number of bins is computed using Sturges' method where  
 $numBins=1+\log_2(N)$ .  
N is the number of data points in each wave. The bins are distributed so that they include the minimum and maximum values.
- method*=2: The number of bins is computed using Scott's method where the optimal bin width is given by  
 $binWidth=3.49*\sigma*N^{-1/3}$ .  
 $\sigma$  is the standard deviation of the distribution and N is the number of points. The bins are distributed so that they include the minimum and maximum values.
- method*=3: Freedman-Diaconis method where  
 $binWidth=2*IQR*N^{-1/3}$ ,  
where IQR is the interquartile distance (see **StatsQuantiles**) and the bins are evenly distributed between the minimum and maximum values.

Bin selection methods are described at: <http://en.wikipedia.org/wiki/Histogram>

### Example: 2D Joint Histogram

```
Make/O/N=(1000) xwave=gnoise(10), ywave=gnoise(5)
JointHistogram/BINS={20,30} xwave,ywave
NewImage M_JointHistogram
```

### Example: 2D Joint Histogram using one bins wave

```
Make/O/N=(1000) xwave=gnoise(10), ywave=gnoise(5)
Make/O/N=3 xBinsWave={-8,0,14}
JointHistogram/BINS={0,30}/XBWV=xBinsWave/E xwave,ywave
Display; AppendImage/T M_JointHistogram vs {xBinsWave,*}
```

### Example: 3D Joint Histogram

```
Make/O/N=(1000) xwave=gnoise(10), ywave=gnoise(5), zwave=ennoise(4)
JointHistogram/BINS={15,15,20,0} xwave,ywave,zwave
NewImage M_JointHistogram
ModifyImage M_JointHistogram plane=10
```

## JulianToDate

**JulianToDate**(*julianDay*, *format*)

The JulianToDate function returns a date string containing the day, month, and year. The input *julianDay* is truncated to an integer.

### Parameters

*julianDay* is the Julian day to be converted.

*format* specifies the format of the returned date string.

| <i>format</i> | Date String               |
|---------------|---------------------------|
| 0             | mm/dd/year                |
| 1             | dd/mm/year                |
| 2             | Tuesday November 15, 2002 |
| 3             | year mm dd                |
| 4             | year/mm/dd                |

**See Also**

The **dateToJulian** function.

For more information about the Julian calendar see:

<<http://www.tondering.dk/claus/calendar.html>>.

## KillBackground

**KillBackground**

The KillBackground operation kills the unnamed background task.

KillBackground works only with the unnamed background task. New code should use named background tasks instead. See **Background Tasks** on page IV-316 for details.

**Details**

You can not call KillBackground from within the background function itself. However, if you return 1 from the background function, instead of the normal 0, Igor will terminate the background task.

**See Also**

The **BackgroundInfo**, **CtrlBackground**, **CtrlNamedBackground**, **SetBackground**, and **SetProcessSleep** operations; and **Background Tasks** on page IV-316.

## KillControl

**KillControl** [/W=*winName*] *controlName*

The KillControl operation kills the named control in the top or specified graph or panel window or subwindow.

If the named control does not exist, KillControl does not complain.

**Flags**

*/W=winName* Looks for the control in the named graph or panel window or subwindow. If */W* is omitted, KillControl looks in the top graph or panel window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**See Also**

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

### KillDataFolder

**KillDataFolder** [/Z] *dataFolderSpec*

The KillDataFolder operation kills the specified data folder and everything in it including other data folders. However, if *dataFolderSpec* is the name of a data folder reference variable that refers to a free data folder, the variable is cleared and the data folder is killed only if this is the last reference to that free data folder.

#### Flags

/Z                      No error reporting (except for setting V\_flag). Does not halt function execution.

#### Parameters

*dataFolderSpec* can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

#### Details

If specified data folder is the current data folder or contains the current data folder then Igor makes its parent the new current data folder.

For legacy reasons, a null data folder is taken to be the current data folder. This can happen when using a \$ expression where the string might possibly evaluate to "".

It is legal to kill the root data folder. In this case the root data folder itself is not killed but everything in it is killed.

KillDataFolder generates an error if any of the waves involved are in use. In this case, nothing is killed.

KillDataFolder generates an error if any of the waves involved are in use. In this case, nothing is killed. Execution ceases unless /Z is specified.

The variable V\_flag is set to 0 when there is no error, otherwise it is an error code.

#### Examples

```
KillDataFolder foo // Kills foo in the current data folder.
KillDataFolder :bar:foo // Kills foo in bar in current data folder.
String str= "root:foo"
KillDataFolder $str // Kills foo in the root data folder.
```

#### See Also

Chapter II-8, **Data Folders** and the **KillStrings**, **KillVariables**, and **KillWaves** operations.

### KillFIFO

**KillFIFO** *FIFOName*

The KillFIFO operation discards the named FIFO.

#### Details

FIFOs are used for data acquisition.

If there is an output or review file associated with the FIFO, KillFIFO closes the file. If the FIFO is used by an XOP, you should call the XOP to release the FIFO before killing it.

#### See Also

See **FIFOs and Charts** on page IV-310 for information about FIFOs and data acquisition.

### KillFreeAxis

**KillFreeAxis** [/W=*winName*] *axisName*

The KillFreeAxis operation removes a free axis specified by *axisName* from a graph window or subwindow.

**Flags**

*/W=winName* Kills the free axis in the named graph window or subwindow. If */W* is omitted, it acts on the top graph window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Details**

Only an axis created by **NewFreeAxis** can be killed and only if no traces or images are attached to the axis.

**See Also**

The **NewFreeAxis** operation.

**KillPath**

**KillPath** [*/A/Z*] *pathName*

The KillPath operation removes a path from the list of symbolic paths. KillPath is a newer name for the **RemovePath** operation.

**Flags**

*/A* Kills all symbolic paths in the experiment except for the built-in paths. Omit *pathName* if you use */A*.

*/Z* Does not generate an error if a path to be killed is a built-in path or does not exist or is in use. To kill all paths in the experiment, use **KillPath/A/Z**.

**Details**

You can't kill the built-in paths "home" and "Igor".

A symbolic path is "in use" if the current experiment contains shared waves or notebooks loaded from the associated disk folder.

Prior to Igor Pro 9.00, the KillPath operation prevented killing a symbolic path used to load a shared wave if the shared wave file was in the current data folder. It now prevents killing a symbolic path used to load a shared wave in any data folder. Use the */Z* flag to suppress error reporting if this change creates problems for you.

**See Also**

**Symbolic Paths** on page II-22, **NewPath**

**KillPICTs**

**KillPICTs** [*/A/Z*] [*PICTName* [, *PICTName*]...]

The KillPICTs operation removes one or more named pictures from the current Igor experiment.

**Flags**

*/A* Kills all pictures in the experiment.

*/Z* Does not generate an error if a picture to be killed is in use or does not exist. To kill all pictures in the experiment, use **KillPICTs/A/Z**.

**Details**

You can not kill a picture that is used in a graph or page layout.

**Warning:** You *can* kill a picture that is referenced from a graph or layout recreation macro. If you do, the graph or layout can not be completely recreated. Use the Find dialog (Edit menu) to locate references in the procedure window to a named picture you want to kill.

**See Also**

See **Pictures** on page III-509 for general information on how Igor handles pictures.

### KillStrings

**KillStrings** [/A/Z] [*stringName* [, *stringName*]...]

The KillStrings operation discards the named global strings.

#### Flags

- /A        Kills all global strings in the current data folder. If you use /A, omit *stringName*.
- /Z        Does not generate an error if a global string to be killed does not exist. To kill all global strings in the current data folder, use KillStrings/A/Z.

### KillVariables

**KillVariables** [/A/Z] [*variableName* [, *variableName*]...]

The KillVariables operation discards the named global numeric variables.

#### Flags

- /A        Kills all global variables in the current data folder. If you use /A, omit *variableName*.
- /Z        Does not generate an error if a global variable to be killed does not exist. To kill all global variables in the current data folder, use KillVariables/A/Z.

### KillWaves

**KillWaves** [*flags*] *waveName* [, *waveName*]...

The KillWaves operation destroys the named waves.

#### Flags

- /A        Kills all waves in the current data folder. If you use /A, omit *waveNames*.
- /F        Deletes the Igor binary wave file from which *waveName* was loaded.
- /Z        Does not generate an error if a wave to be killed is in use or does not exist.

#### Details

The memory the waves occupied becomes available for other uses. You can't kill a wave used in a graph or table or which is reserved by an XOP.

XOPs reserve a wave by sending the OBJINUSE message.

For functions compiled with the obsolete `rtGlobals=0` setting, you also can't kill a wave referenced from a user-defined function.

#### Examples

```
KillWaves/A/Z // kill waves not in use in current data folder
```

### KillWindow

**KillWindow** [*flags*] *winName*

The KillWindow operation kills or closes a specified window or subwindow without saving a recreation macro.

#### Parameters

*winName* is the name of an existing window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

#### Flags

- /Z        Does not generate an error if the specified window does not exist.

#### See Also

The **DoWindow** operation.

## KMeans

**KMeans** [*flags*] *populationWave*

The KMeans operation analyzes the clustering of data in *populationWave* using an iterative algorithm. The result of KMeans is a specification of the classes which is saved in the wave M\_KMClasses in the current data folder. Optional results include the distribution of class members (W\_KMMembers) and the inter-class distances. *populationWave* is a 2D wave in which columns correspond to members of the population and rows contain the dimensional information.

### Flags

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/CAN</i>         | Analyzes the clustering by computing Euclidean distances between the means of the resulting classes. The resulting distances are stored in an NxN square matrix where N is the number of classes. Self distances (along the diagonal) or distances involving classes that did not survive the iterations are filled with NaN. Also saves the wave W_KMDispersion, which contains the sum of the distances between the center of each class and all its members. Distances are evaluated using the method specified by <i>/DIST</i> . |
| <i>/DEAD=method</i> | Specifies how the algorithm should handle "dead" classes, which are those that lose all members in a given iteration. <ul style="list-style-type: none"> <li><i>method=1:</i> Remove the class if it loses all members.</li> <li><i>method=2:</i> Default; keeps the last value of the mean vector in case the class might get new members in a subsequent iteration.</li> <li><i>method=3:</i> Assigns the class a random mean vector.</li> </ul>                                                                                   |
| <i>/DIST=mode</i>   | Specifies how the class distances are evaluated. <ul style="list-style-type: none"> <li><i>mode=1:</i> Distance is evaluated as the sum of the absolute values (also known as Manhattan distance).</li> <li><i>mode=2:</i> Default; distance is evaluated as Euclidean distance.</li> </ul>                                                                                                                                                                                                                                          |
| <i>/INIT=method</i> | Specifies the initialization method. <ul style="list-style-type: none"> <li><i>method=1:</i> Random assignment of members of the population to a class.</li> <li><i>method=2:</i> User-specified mean values (<i>/INW</i>).</li> <li><i>method=3:</i> Default; initialize classes using values of a random selection from the population.</li> </ul>                                                                                                                                                                                 |
| <i>/INW=iWave</i>   | Sets the initial classes. The number of rows of <i>iWave</i> equals the dimensionality of the class and the number of columns of <i>iWave</i> is the number of classes. For example, if we want to initialize 5 classes in a problem that involves position in two dimensions then <i>iWave</i> must have 2 rows and 5 columns. The number of rows must also match the number of rows in <i>populationWave</i> .                                                                                                                     |
| <i>/NCLS=num</i>    | Sets the number of classes in the data. If the initialization method uses specific means ( <i>/INIT=2</i> ) then the number of columns of <i>iWave</i> (see <i>/INW</i> ) must match <i>num</i> . The default number of classes is 2.                                                                                                                                                                                                                                                                                                |

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/OUT=<i>format</i></code> | Specifies the format for the results.<br><br><code>format=1:</code> Output only the specification of the classes in the 2D wave <code>M_KMClasses</code> (default). Each column in <code>M_KMClasses</code> represents a class. The number of rows in <code>M_KMClasses</code> is equal to the number of rows in <code>populationWave+1</code> . The last row contains the number of class members. The remaining rows represent the center of the class. For example, if <code>populationWave</code> has two rows then the dimensionality of the problem is 2 and <code>M_KMClasses</code> has 3 rows with the first row containing the first components of each class center, the second row containing the second components of each class center and the third row containing the number of elements in each class.<br><br><code>format=2:</code> Output (in addition to <code>M_KMClasses</code> ) the class membership in the wave <code>W_KMMembers</code> . The rows in this 1D wave correspond to sequential members of <code>populationWave</code> and the entries correspond to the (zero based) column number in <code>M_KMClasses</code> . |
| <code>/SEED=<i>val</i></code>   | Sets the seed for a new sequence in the pseudo-random number generator that is used by the operation. <i>val</i> must be an integer greater than zero.<br><br>By changing the sequence you may be able to find new solutions or just make the process converge at a different rate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>/TER=<i>method</i></code> | Determines when the iterations stop.<br><br><code>method=1:</code> User-specified number of iterations ( <code>/TERN</code> ).<br><code>method=2:</code> Default; continue iterating until no more than a fixed number of elements change classes in one iteration ( <code>TERN</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>/TERN=<i>num</i></code>   | Specifies the termination number. The meaning of the number is determined by <code>/TER</code> above. By default, the termination <code>method=2</code> and the default value of the maximum number of elements that change classes in one iteration is 5% of the size of the population.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>/Z</code>                 | No error reporting. If an error occurs, sets <code>V_flag</code> to -1 but does not halt function execution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### Details

KMeans uses an iterative algorithm to analyze the clustering of data. The algorithm is not guaranteed to find a global optimum (maximum likelihood solution) so the operation provides various flags to control when the iterations terminate. You can determine if the operation iterates a fixed number of times or loops until at most a specified maximum number of elements change class membership in a single iteration. If you are computing KMeans in more than one dimension you should pay attention to the relative magnitudes of the data in each dimension. For example, if your data is distributed on the interval [0,1] in the first dimension and on the interval [0,1e7] in the second dimension, the operation will be biased by the much larger magnitude of values in the second dimension.

### Examples

Create data with 3 classes:

```
Make/O/N=(1,128) jack=4+gnoise(1)
jack[0][15,50]+=10
jack[0][60,]+=20
```

Perform KMeans looking for 5 classes:

```
KMeans/init=1/out=1/ter=1/dead=1/tern=1000/ncls=5 jack
Print M_KMClasses
M_KMClasses[0][0]= {24.1439, 68}
M_KMClasses[0][1]= {14.1026, 36}
M_KMClasses[0][2]= {4.01537, 24}
```

## Label

**Label** [/W=*winName*/Z] *axisName*, *labelStr*

The Label operation labels the named axis with *labelStr*.

### Parameters

*axisName* is the name of an existing axis in the top graph. It is usually one of "left", "right", "top" or "bottom", though it may also be the name of a free axis such as "VertCrossing".

*labelStr* contains the text that labels the axis.

### Flags

- /W=winName* Adds axis label in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
- When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.
- /Z* No errors generated if the named axis doesn't exist. Used for style macros.

### Details

*labelStr* can contain escape codes which affect subsequent characters in the text. An escape code is introduced by a backslash character. In a literal string, you must enter two backslashes to produce one. See **Backslashes in Annotation Escape Sequences** on page III-58 for details.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See **Annotation Escape Codes** on page III-53 for details.

Some escape codes insert text based on axis properties. See **Axis Label Escape Codes** on page III-57 for details.

The characters "<??>" in an axis label indicate that you specified an invalid escape code or used a font that is not available.

## laguerre

**laguerre**(*n*, *x*)

The laguerre function returns the Laguerre polynomial of degree *n* (positive integer) and argument *x*. The polynomials satisfy the recurrence relation:

$$(n + 1)\text{Laguerre}(n + 1, x) = (2n + 1 - x)\text{Laguerre}(n, x) - n\text{Laguerre}(n - 1, x),$$

with the initial conditions

$$\text{Laguerre}(0, x) = 1$$

and

$$\text{Laguerre}(1, x) = 1 - x.$$

## laguerreA

**laguerreA**(*n*, *k*, *x*)

The laguerreA function returns the associated Laguerre polynomial of degree *n* (positive integer), index *k* (non-negative integer) and argument *x*. The associated Laguerre polynomials are defined by

$$L_n^k(x) = (-1)^k \frac{d^k}{dx^k} [L_{n+k}(x)],$$

where  $L_{n+k}(x)$  is the Laguerre polynomial.

## laguerreGauss

**laguerreGauss**(*p*, *m*, *r*)

The laguerreGauss function returns the normalized product of the associated Laguerre polynomials and a Gaussian. This function is typically encountered in solutions to physical problems where it represents the radial solution with an additional factor  $\exp(i*m*\phi)$  which is not included in this case. The LaguerreGauss is given by

$$U_{pm}(r) = \sqrt{\frac{2p!}{\pi(m+p)!}} (r\sqrt{2})^m L_p^m(2r^2) \exp(-r^2).$$

The **laguerre**, **laguerreA**, and **hermiteGauss** functions.

## LambertW

**LambertW**(*z*, *branch*)

The LambertW function returns the complex value of Lambert's W function for complex *z* and integer index *branch*. The function can be defined through its inverse,

$$z = w e^w.$$

Since *w* is multivalued, the branch parameter is used to differentiate between solutions for the equation.

The LambertW function was added in Igor Pro 7.00.

### Details

IGOR's LambertW uses complex input and output. You can use LambertW in real expressions but you must make sure that you are not calling the function in a range where its imaginary part is non-zero.

The average accuracy of the function defined by  $\text{cabs}(z-w*\exp(w))$  in the region  $|\text{real}(z)| < 10$ ,  $|\text{imag}(z)| < 10$  is  $5e-14$ . In general the accuracy decreases with increasing  $|\text{branch}|$  and with increasing distance from the origin in the *z*-plane.

IGOR uses a hybrid algorithm to compute the function which requires longer computation times in the presence of numerical instabilities.

## Layout

**Layout** [*flags*] [*objectSpec* [, *objectSpec*]...] [*as titleStr*]

The Layout operation creates a page layout.

**Note:** The Layout operation is antiquated and can not be used in user-defined functions. For new programming, use the **NewLayout** operation instead.

### Parameters

All of the parameters are optional.

Each *objectSpec* parameter identifies a graph, table, textbox or picture to be added to the layout. An object specification can also specify the location and size of the object, whether the object should have a frame or not, whether it should be transparent or opaque, and whether it should be displayed in high fidelity or not. See **Details**.

*titleStr* is a string expression containing the layout's title. If not specified, Igor will provide one which identifies the objects displayed in the graph.

### Flags

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/A=(rows,cols)</i>                | Specifies rows and columns for tiling or stacking.                                                                                                                                                                                                                                                                                                                                              |
| <i>/B=(r,g,b[,a])</i>                | Specifies the background color for the layout. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> . The default is opaque white.                                                                                                                                                                                                        |
| <i>/C=colorOnScreen</i>              | Obsolete. In ancient times, this flag switched the screen display of the layout between black and white and color. It is still accepted but has no effect.                                                                                                                                                                                                                                      |
| <i>/G=g</i>                          | Specifies grout, the spacing between tiled objects. Units are points unless <i>/I</i> , <i>/M</i> , or <i>/R</i> are specified.                                                                                                                                                                                                                                                                 |
| <i>/HIDE=h</i>                       | Hides ( <i>h</i> = 1) or shows ( <i>h</i> = 0, default) the window.                                                                                                                                                                                                                                                                                                                             |
| <i>/I</i>                            | Specifies that coordinates are in inches. This affects subsequent <i>/G</i> , <i>/W</i> , and <i>objectSpec</i> coordinates. Coordinates are relative to the top/left corner of the paper.                                                                                                                                                                                                      |
| <i>/K=k</i>                          | Specifies window behavior when the user attempts to close it.<br><i>k</i> =0: Normal with dialog (default).<br><i>k</i> =1: Kills with no dialog.<br><i>k</i> =2: Disables killing.<br><i>k</i> =3: Hides the window.<br>If you use <i>/K</i> =2 or <i>/K</i> =3, you can still kill the window using the <b>KillWindow</b> operation.                                                          |
| <i>/M</i>                            | Specifies that coordinates are in centimeters. This affects subsequent <i>/G</i> , <i>/W</i> , and <i>objectSpec</i> coordinates. Coordinates are relative to the top/left corner of the paper.                                                                                                                                                                                                 |
| <i>/P=orientation</i>                | <i>orientation</i> is either Portrait or Landscape (e.g., <i>Layout/P= Landscape</i> ). This controls the orientation of the page in the layout. See <b>Details</b> .<br>If you use the <i>/P</i> flag, you should make it the first flag in the Layout operation. This is necessary because the orientation of the page affects the behavior of other flags, such as <i>/T</i> and <i>/G</i> . |
| <i>/R</i>                            | Specifies that coordinates are in percent. This affects subsequent <i>/G</i> , <i>/W</i> , and <i>objectSpec</i> coordinates. For <i>/W</i> , coordinates are as a percent of the main screen. For <i>/G</i> and <i>objectSpec</i> , coordinates are relative to the top/left corner of the printing part of the page.                                                                          |
| <i>/S</i>                            | Stacks objects.                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>/T</i>                            | Tiles objects.                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>/W=(left, top, right, bottom)</i> |                                                                                                                                                                                                                                                                                                                                                                                                 |

Gives the layout window a specific location and size on the screen. Coordinates for */W* are in points unless */I* or */M* are specified.

### Details

When you create a new page layout window, if preferences are enabled, the page size is determined by the preferred page size as set via the Capture Layout Prefs dialog. If preferences are disabled, as is usually the case when executing a procedure, the page is set to the factory default size.

If you use the */P* flag, you should make it the first flag in the Layout operation. This is necessary because the orientation of the page affects the behavior of other flags, such as */T* and */G*.

The form of an *objectSpec* is:

```
objectName [(objLeft, objTop, objRight, objBottom)] [/O=objType] [/F=frame]
[/T=trans] [/D=fidelity]
```

*objectName* can be the name of an existing graph, table or picture. It can also be the name of an object that does not yet exist. In this case it is called a "dummy object".

*objectSpec* can be specified using a string by using the \$ operator, but the entire *objectSpec* must be in the string.

Here are some examples of valid usage:

```
Layout Graph0
Layout/I Graph0(1, 1, 6, 5)/F=1
String s = "Graph0"
Layout/I $s

String s = "Graph0(1, 1, 6, 5)/F=1"
Layout/I $s // Entire object spec is in string.
```

The object's coordinates are determined as follows:

- If *objectName* is followed by a coordinates specification in (*objLeft*, *objTop*, *objRight*, *objBottom*) form then this sets the object's coordinates. The units for the coordinates are points unless the */I* or */M* flag was present in which case the units are inches or centimeters respectively.
- If the object coordinates are not specified explicitly but the Layout/S flag was present then the object is stacked. If the Layout/T flag was present then the object is tiled, and if the Layout/A=(*rows,cols*) flag is present, tiling is performed using that number of rows and columns.
- If the object's coordinates are not determined by these rules then the object is set to a default size and is stacked.

Each object has a type (graph, table, textbox or picture) determined as follows:

|                     |                                                                                          |
|---------------------|------------------------------------------------------------------------------------------|
| <i>O=objType</i>    | If the <i>objectName/O=objType</i> flag is present then it determines the object's type: |
| <i>objType</i> =1:  | Graph.                                                                                   |
| <i>objType</i> =2:  | Table.                                                                                   |
| <i>objType</i> =8:  | Picture.                                                                                 |
| <i>objType</i> =32: | Textbox.                                                                                 |

If there is no */O* flag and *objectName* is the name of an existing graph, table or picture, then the object type is graph, table or picture.

If the object's type is not determined by the above rules and *objectName* contains "Table", "PICT", or "TextBox", then the object type is table, picture or textbox.

If the object's type is not specified by any of the above rules, it is taken to be a graph type object.

The remaining flags have the following meanings:

|                     |                                            |
|---------------------|--------------------------------------------|
| <i>/D=fidelity</i>  | Controls the drawing of the layout object: |
| <i>fidelity</i> =0: | Low fidelity display.                      |
| <i>fidelity</i> =1: | High fidelity display (default).           |

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/F=frame</i> | Controls the object frame:<br><i>frame=0</i> : No frame.<br><i>frame=1</i> : Single frame (default).<br><i>frame=2</i> : Double frame.<br><i>frame=3</i> : Triple frame.<br><i>frame=4</i> : Shadow frame.                                                                                                                                                                                                                            |
| <i>/T=trans</i> | Controls the transparency of the layout object:<br><i>trans=0</i> : Opaque (default).<br><i>trans=1</i> : Transparent. For this to be effective, the object itself must also be transparent. Annotations have their own transparent/opaque settings. Graphs are transparent only if their backgrounds are white. Pictures may have been created transparent or opaque, and Igor cannot make an inherently opaque picture transparent. |

The **NewLayout** and **LayoutInfo** operations. See Chapter II-18, **Page Layouts**.

## Layout

**Layout**

Layout is a procedure subtype keyword that identifies a macro as being a page layout recreation macro. It is automatically used when Igor creates a window recreation macro for a layout. See **Procedure Subtypes** on page IV-204 and **Killing and Recreating a Layout** on page II-465 for details.

**See Also**

See Chapter II-18, **Page Layouts**.

## LayoutInfo

**LayoutInfo**(*winNameStr*, *itemNameStr*)

The LayoutInfo function returns a string containing a semicolon-separated list of keywords and values that describe an object in the active page of a page layout or overall properties of the layout. The main purpose of LayoutInfo is to allow an advanced Igor programmer to write a procedure which formats or arranges objects.

*winNameStr* is the name of an existing page layout window or " " to refer to the top layout.

*itemNameStr* is a string expression containing one of the following:

- The name (e.g., "Graph0") of a layout object in the active page to get information about that object.
- An object instance (e.g., "Graph0#0" or "Graph0#1") to get information about a particular instance of an object in the active page. This is of use only in the unusual situation when the same object appears in the active page multiple times. "Graph0#0" is equivalent to "Graph0". "Graph0#1" is the second occurrence of Graph0 in the active page.
- An integer object index starting from zero to get information about an object referenced by its position in the active page in the layout. Zero refers to the first object going from back to front in the page.
- The word "Layout" to get overall information about the layout.

**Details**

In cases 1, 2 and 3 above, where *itemNameStr* references an object, the returned string contains the following keywords, with a semicolon after each keyword-value pair.

| Keyword  | Information Following Keyword                                                  |
|----------|--------------------------------------------------------------------------------|
| FIDELITY | Object fidelity expressed as a code usable in a ModifyLayout fidelity command. |
| FRAME    | Object frame expressed as a code usable in a ModifyLayout frame command.       |
| HEIGHT   | Object height in points.                                                       |

## LayoutInfo

---

| Keyword  | Information Following Keyword                                                                |
|----------|----------------------------------------------------------------------------------------------|
| INDEX    | Object position in back-to-front order in the active page of the layout, starting from zero. |
| LEFT     | Object left position in points.                                                              |
| NAME     | The name of the object.                                                                      |
| SELECTED | Zero if the object is not selected or nonzero if it is selected.                             |
| TOP      | Object top position in points.                                                               |
| TRANS    | Object transparency expressed as a code usable in a ModifyLayout trans command.              |
| TYPE     | Object type which is one of: Graph, Table, Picture, or Textbox.                              |
| WIDTH    | Object width in points.                                                                      |

---

In case 4 above, where *itemNameStr* is "Layout", the returned string contains the following keywords, with a semicolon after each keyword-value pair.

| Keyword        | Information Following Keyword                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| BGRGB          | Layout background color expressed as <red>, <green>, <blue> where each color is a value from 0 to 65535.                                    |
| MAG            | Layout magnification: 0.25, 0.5, 1.0, or 2.0.                                                                                               |
| NUMOBJECTS     | Total number of objects in the active page of the layout.                                                                                   |
| NUMSELECTED    | Number of selected objects in the active page of the layout.                                                                                |
| PAGE           | A rectangle defining the part of the paper that is inside the margins, expressed in points. The format is <left>, <top>, <right>, <bottom>. |
| CURRENTPAGENUM | One-based page number of the currently active page. Added in Igor Pro 7.00.                                                                 |
| NUMPAGES       | Total number of pages in the layout. Added in Igor Pro 7.00.                                                                                |
| PAPER          | A rectangle defining the bounds of the paper, expressed in points. The format is <left>, <top>, <right>, <bottom>.                          |
| SELECTED       | A comma-separated list of the names of selected objects in the active page of the layout.                                                   |
| UNITS          | Units used to display object locations and sizes. This will be one of the following: 0 for points, 1 for inches, 2 for centimeters.         |

---

LayoutInfo returns "" in the following situations:

- *winNameStr* is "" and there are no layout windows.
- *winNameStr* is a name but there are no layout windows with that name.
- *itemNameStr* is not "Layout" and is not the name or index of an existing object.

### Examples

This example sets the background color of all selected graphs in the active page of a particular page layout to the color specified by red, green, and blue, which are numbers from 0 to 65535.

```
Function SetLayoutGraphsBackgroundColor(layoutName, red, green, blue)
 String layoutName // Name of layout or "" for top layout.
 Variable red, green, blue

 Variable index
 String info
 Variable selected
 String indexStr
 String objectTypeStr
 String graphNameStr
```

```

index = 0
do
 sprintf indexStr, "%d", index
 info = LayoutInfo(layoutName, indexStr)
 if (strlen(info) == 0)
 break // No more objects
 endif

 selected = NumberByKey("SELECTED", info)
 if (selected)
 objectTypeStr = StringByKey("TYPE", info)
 if (CmpStr(objectTypeStr,"Graph") == 0)// This is a graph?
 graphNameStr = StringByKey("NAME", info)
 ModifyGraph/W=$graphNameStr wbRGB=(red,green,blue)
 ModifyGraph/W=$graphNameStr gbRGB=(red,green,blue)
 endif
 endif
endif

index += 1
while(1)
End

```

The **Layout** operation. See Chapter II-18, **Page Layouts**.

## LayoutMarquee

**LayoutMarquee**

LayoutMarquee is a procedure subtype keyword that puts the name of the procedure in the layout Marquee menu. See **Marquee Menu as Input Device** on page IV-163 for details.

**See Also**

See Chapter II-18, **Page Layouts**.

## LayoutPageAction

**LayoutPageAction** [/W=*winName*] [*keyword* = *value* [, *keyword* = *value* ...]]

The LayoutPageAction operation adds, deletes, reorders, or adjusts the sizes of layout pages.

The LayoutPageAction operation was added in Igor Pro 7.00.

**Parameters**

|                                                        |                                                                                                                                                                              |
|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| appendPage                                             | Appends a new page.                                                                                                                                                          |
| insertPage= <i>page</i>                                | Inserts a new page before <i>page</i> .<br>Page numbers start from 1. Pass 0 for <i>page</i> to insert before the first page.                                                |
| page= <i>page</i>                                      | Makes <i>page</i> the active page.<br>Page numbers start from 1.                                                                                                             |
| deletePage= <i>page</i>                                | Deletes <i>page</i> . This action cannot be undone.<br>Page numbers start from 1.                                                                                            |
| reorderPages={ <i>anchorPage</i> , <i>page1</i> , ...} | Reorders the pages so that <i>page1</i> and any others appear before <i>anchorPage</i> , in the same order as their appearance in the command.<br>Page numbers start from 1. |
| size=( <i>width</i> , <i>height</i> )                  | Sets the global page dimensions for the layout to <i>width</i> and <i>height</i> , specified in units of points.                                                             |
| size( <i>page</i> )=( <i>width</i> , <i>height</i> )   |                                                                                                                                                                              |

## LayoutSlideShow

---

Sets the dimensions of *page* to *width* and *height*, specified in units of points.

Using this keyword with *page* set to -1 modifies the global page dimensions for the layout.

`margins=(leftMargin, topMargin, rightMargin, bottomMargin)`

Sets the global page margins for the layout to the specified values, expressed in units of points.

`margins(page)=(leftMargin, topMargin, rightMargin, bottomMargin)`

Sets the margins of specified page to these values, expressed in units of points.

Page numbers start from 1.

Passing -1 for *page* sets the global margins for the layout.

### Flags

`/W=winName`      Modifies the named layout. When omitted, the actions affect the top layout.

### Details

Page numbers starts from 1. Use *page=0* to refer to the active page.

The layout as a whole has a size and margins. These are called "global" dimensions and govern all pages by default. You can set the global dimensions using the *size* and *margins* keyword without specifying a particular page.

You can override the dimensions for a given page using *size(page)* and *margins(page)* to specify custom dimensions.

Use *size(page)=(0,0)* to revert the specified page to the global layout dimensions. This reverts both the page size and its margins.

## LayoutSlideShow

`LayoutSlideShow [/W=winName] [keyword = value [, keyword = value ...]]`

The `LayoutSlideShow` operation starts, stops, or modifies a slideshow that displays the pages of a page layout.

The `LayoutSlideShow` operation was added in Igor Pro 7.00.

### Parameters

`autoMode=a`      Controls whether the presentation will advance between slides automatically (*a=1*) or manually (*a=0*). Use the `delay` keyword to control the delay between automatic transitions.

`delay=d`      *d* is the number of seconds to wait between slide transitions when running in auto mode.

`otherScreenContents=o`

Controls what is displayed on any additional screens that may be connected.

*o=0*:      Other screens show the presentation.

*o=1*:      Other screens show a presenter's view with additional information.  
Use the `presentersView` keyword to control the contents of this view.

*o=2*:      Other screens show a presenter's view with additional information.  
Use the `presentersView` keyword to control the contents of this view.

`page=p`      Causes the slideshow to start from page *p*. *p* is a page number starting from 1. This keyword has no effect unless the `start` keyword is also present.

|                          |                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| presentersView= <i>p</i> | Controls what is displayed on the screens that show the presenter's view.<br><i>p</i> is a bitfield of flags:<br>Bit 0: Show the next page.<br>Bit 1: Show the current time.<br>Bit 2: Show the elapsed time.<br><br><b>Setting Bit Parameters</b> on page IV-12 for details about bit settings.                                                                                                          |
| scaleMode= <i>s</i>      | Specifies how the pages are scaled to fit the screen.<br><i>s</i> =0: No scaling. Pages are drawn at actual size even if they are much larger or smaller than the screen size.<br><i>s</i> =1: All pages are individually scaled to the screen size.<br><i>s</i> =2: All pages are scaled by the same factor so that the largest page fits on the screen. This preserves the relative sizes of the pages. |
| screen= <i>s</i>         | Specifies the screen to be used for the main presentation. Use <i>s</i> =1 to use the primary screen. Use <b>IgorInfo</b> to determine the number of available screens.                                                                                                                                                                                                                                   |
| start                    | Starts the slideshow.                                                                                                                                                                                                                                                                                                                                                                                     |
| stop                     | Stops the slideshow. You can also stop it by pressing the escape key.                                                                                                                                                                                                                                                                                                                                     |
| wrapMode= <i>w</i>       | Controls what happens when the presentation reaches the last page in the slideshow.<br><i>w</i> =0: Advancing to the next page has no effect.<br><i>w</i> =1: Advancing to the next page causes the slideshow to wrap around to the first page.<br><i>w</i> =2: Advancing to the next page causes the slideshow to stop.                                                                                  |

## Flags

*/W=winName*      *winName* is the name of the desired layout window. If */W* is omitted or if *winName* is "\$", the top layout window is used.

## Details

A layout slide show can be used to present an Igor experiment to others, or to run an information kiosk.

Any changes to the layout window during a slide show are automatically reflected in the slides. For example you could use a background task to update a graph so that the slides always show the latest data.

You can control a running slide show by right-clicking on the slideshow. Alternatively, use the arrow keys or a mouse click to advance to the next slide.

Press the space bar to toggle between automatic and manual advancing of the slides. Press escape to end the slideshow.

## Example

```
Function DemoSlideshow() // Press escape to end the slideshow
 NewLayout
 TextBox/C/N=text0/F=0/A=LB/X=33.57/Y=70.81 "\\Z961"
 LayoutPageAction appendpage
 TextBox/C/N=text0/F=0/A=LB/X=33.57/Y=70.81 "\\Z962"
 LayoutPageAction appendpage
 TextBox/C/N=text0/F=0/A=LB/X=33.57/Y=70.81 "\\Z963"
 LayoutSlideShow autoMode=1,delay=1,page=1,wrapMode=1,start
End
```

### LayoutStyle

#### LayoutStyle

LayoutStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Layout dialog and in the Layout Macros menu. See **Page Layout Style Macros** on page II-484 for details.

#### See Also

See Chapter II-18, **Page Layouts** and **Page Layout Style Macros** on page II-484.

### leftx

#### leftx (waveName)

The leftx function returns the X value of point 0 (the first point) of the named 1D wave. The leftx function is not multidimensional aware. The multidimensional equivalent of this function is **DimOffset**.

#### Details

Point 0 contains a wave's *first* value, which is usually the leftmost point when displayed in a graph. Leftx returns the value elsewhere called *x0*. The function DimOffset returns any of x0, y0, z0, or t0, for dimensions 0, 1, 2, or 3.

#### See Also

The **deltax** and **rightx** functions.

For multidimensional waves, see **DimDelta**, **DimOffset**, and **DimSize**.

For an explanation of waves and X scaling, see **Changing Dimension and Data Scaling** on page II-68.

### Legend

#### Legend [flags] [legendStr]

The Legend operation puts a legend on a graph or page layout.

#### Parameters

*legendStr* contains the text that is printed in the legend.

If *legendStr* is missing or is an empty string (" "), the text needed for a default legend is automatically generated. Legends are automatically updated when waves are appended to or removed from the graph or when you rename a wave in the graph.

*legendStr* can contain escape codes which affect subsequent characters in the text. An escape code is introduced by a backslash character. In a literal string, you must enter two backslashes to produce one. See **Backslashes in Annotation Escape Sequences** on page III-58 for details.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See **Annotation Escape Codes** on page III-53 for details. However normally you leave it to Igor to automatically manage the legend.

See **Legend Text** on page III-42 for a discussion of what *legendStr* may contain.

#### Flags

/H=*legendSymbolWidth*

Sets the width in points of the area in which to draw the wave symbols. A value of 0 means "default". This results in a width that is based on the text size in effect when the symbol is drawn. A value of 36 gives a 0.5 inch (36 points) width which is nice in most cases.

/H={*legendSymbolWidth*, *minThickness*, *maxThickness*}

This is an additional form of the /H flag. The *legendSymbolWidth* parameter works the same as described above.

The *minThickness* and *maxThickness* parameters allow you to create a legend whose line and marker thicknesses are different from the thicknesses of the associated traces in the graph. This can be handy to make the legend more readable when you use very thin lines or markers for the traces.

*minThickness* and *maxThickness* are values from 0.0 to 10.0. Also, setting *minThickness* to 0.0 and *maxThickness* to 0.0 (default) uses the same thicknesses for the legend symbols as for the traces.

- /J Disables the default legend mechanism so that a default legend is not created even if *legendStr* is an empty string (" ") or omitted.  
Window recreation macros use /J in case *legendStr* is too long to fit on the same command line as the Legend operation itself. In this case, an AppendText command appears after the Legend command to append *legendStr* to the empty legend. For really long values of *legendStr*, there may be multiple AppendText commands.
- /M[=*saMeSize*] /M or /M=1 specifies that legend markers should be the same size as the marker in the graph.  
/M=0 turns same-size mode off so that the size of the marker in the legend is based on text size.

See the **TextBox** operation for documentation for all other flags.

### Examples

The command Legend (with no parameters) creates a default legend. A default legend in a layout contains a line for each wave in each of the graphs in the layout, starting from the bottom graph and working toward the front.

The command:

```
Legend/C/N=name " "
```

changes the named existing legend to a default legend.

You can put a legend in a page layout with a command such as:

```
Legend "\s(Graph0.wave0) this is wave0"
```

This creates a legend in the layout that shows the symbol for wave0 in Graph0. The graph named in the command is usually in the layout but it doesn't have to be.

## legendreA

**legendreA**(*n*, *m*, *x*)

The legendreA function returns the associated Legendre polynomial:

$$P_n^m(x)$$

where *n* and *m* are integers such that  $0 \leq m \leq n$  and  $|x| \leq 1$ .

### References

Arfken, G., *Mathematical Methods for Physicists*, Academic Press, New York, 1985.

## limit

`limit(num, low, high)`

The limit function returns *num*, limited to the range from *low* to *high*:

*num* if  $low \leq num \leq high$ .

*low* if  $num < low$ .

*high* if  $num > high$ .

Since all comparisons with NaN return false, limit will not work as expected with NaNs. If a parameter may be NaN, use `numtype` to test it before calling limit.

## LinearFeedbackShiftRegister

`LinearFeedbackShiftRegister [flags]`

The LinearFeedbackShiftRegister operation implements a, well, linear feedback shift register, or LFSR. A LFSR is a way to produce a sequence of very bad pseudorandom numbers, or a random bit stream (that is, a random sequence of zeroes or ones that over time are nearly equal in number).

If it produces bad random numbers, why would I want to use a LFSR? A properly-configured LFSR will create a “maximal-length sequence”: a LFSR of  $N$  bits will produce  $2^N - 1$  numbers in a quasi-random sequence without repeating. That is, it will produce all the  $N$ -bit numbers except zero. This gives the sequence good spectral properties for certain applications, and, taking the least-significant bit as the output, it creates a pseudorandom bit stream with nearly equal numbers of zeroes and ones (*nearly* means one more one than zeroes).

The LinearFeedbackShiftRegister operation generates either a wave full of the sequential states of the shift register or a wave full of ones and zeroes representing the least significant bit of the shift register.

### Linear Feedback Shift Registers

A LFSR is a shift register with taps. The tap bits are XOR’ed together and the result, after the register is shifted, becomes the new most significant bit. Here is a diagram of a 7-bit LFSR:

Each successive number is generated by shifting the contents of the register (boxes 1-7) to the right, while shifting in the output of the XOR node. The XOR node samples specified bits of the register contents, generating its output ready to be shifted in. Thus, the inputs of the XOR are bits sampled *before* a shift; the output of the XOR becomes the leading bit in the register *after* a shift.

In many applications the output of interest is the stream of bits that appear in the last position. This stream of bits is a pseudorandom sequence of ones and zeroes (or ones and minus ones, or whatever other binary sequence you need).

The bits fed into the XOR node are referred to as *taps*. The taps illustrated here would be specified with the tap list 7,6,4,1. As implemented in Igor Pro, the output tap (tap 7 in the illustration) is the least significant bit, so an alternate way to express the tap list is as the binary number  $1001011_2$  ( $77_{10}$ ).

With the right taps, a LFSR produces a maximal-length sequence. The list of sequential states in a maximal-length sequence has length  $2^N - 1$  without repeating a state. That means that every possible  $N$ -bit nonzero number appears exactly once in the maximal-length sequence.

Maximal-length tap lists always have an even number of taps.

If you have a tap list that gives a maximal-length sequence, you can generate another tap list from it. If your tap list is (n, A, B, C) the new tap list is (n, n-C, n-B, n-A). This new tap list will generate a bit stream that is the mirror image in time of the bit stream produced by the first tap list.

**Flags**

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/DEST=wavename</i>      | <p>Specifies a wave to receive the generated sequence. With <i>/MODE=0</i>, the number type of the wave must have at least <i>nbits</i> bits for an integer wave, or at least an <i>nbit</i> mantissa if it is a floating-point wave. That is, <i>/N=25</i> requires a double-precision wave or a 32-bit integer wave. <i>/N=18</i> requires any floating-point wave or a 16- or 32-bit integer wave. If you use an integer wave, we recommend an unsigned integer wave for <i>/N=8, 16, or 32</i>.</p> <p>If <i>/MODE=1</i> is used, any number type is acceptable. See the Details for what happens if you don't use <i>/DEST</i>.</p> <p>If <i>wavename</i> doesn't exist, a suitable integer wave will be made.</p> <p>If <i>wavename</i> already exists, LinearFeedbackShiftRegister will use it as-is. The sequence length will be taken from the wave. If the number type of the wave is not suitable, an error is issued. If the sequence length is less than the number of points in your wave, it will be truncated to match.</p> |
| <i>/FREE</i>               | <p>In a user-defined function, makes a free wave. See <b>Free Waves</b> on page IV-90 for details.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>/INIT=initialValue</i>  | <p>Sets the initial value of the shift register to <i>initialValue</i>. This will also be the first value in the output for <i>/MODE=0</i>, or the least-significant bit of <i>initialValue</i> will be the first output for <i>/MODE=1</i>. You can use this initial value to restart a very long sequence from the last state of a previous run.</p> <p>Default is a single 1 bit in the first position (bit <i>nbits-1</i> for <i>/N=nbits</i>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>/LEN=length</i>         | <p>Sets the length of sequence to generate. If the sequence repeats before <i>length</i> states are generated, the sequence is terminated early. If <i>length</i> is larger than the number of states in a maximal-length sequence, you will get a maximal-length sequence, or a shorter sequence if the initial value is seen again (that is, your sequence is not a maximal-length sequence).</p> <p>You can specify <i>length</i> greater than the maximal-length sequence length, but it will be truncated to the maximal length.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>/MAX=index</i>          | <p>An internal table of tap lists gives maximal-length sequences. This table has up to 32 tap lists for each value of <i>nbits</i>. You select a tap list by setting <i>index</i> to a number from 0 to 31. For values of <i>nbits</i> that do not have 32 maximal-length tap lists, the table repeats. Most <i>nbits</i> values have many more than 32 possible maximal-length sequences. For each tap list in the table, another tap list can be accessed using the <i>/MROR</i> flag.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>/MODE=doBitStream</i>   | <p>Sets the output stream format.</p> <p><i>doBitStream=0</i>: Succession of bit register states (default).</p> <p><i>doBitStream=1</i>: Stream of ones and zeroes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>/MROR [=doMirror]</i>   | <p>Transforms the tap list into its complementary tap list, creating a mirror-image bit stream, when you use <i>/MROR</i> or <i>doMirror=1</i>. Specify the tap list using <i>/TAPS</i>, <i>/TAPB</i>, or <i>/MAX</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>/N=nbits</i>            | <p>Determines the number of bits in the shift register. A maximal-length sequence will have <math>2^{nbits}-1</math> states. <i>nbits</i> must be in the range of 1-32. Note that <i>nbits = 1 or 2</i> is not very interesting.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>/STOP=stopValue</i>     | <p>Terminates the sequence when <i>stopValue</i> is the next shift register value. You can use this flag to generate long sequences using multiple calls to LinearFeedbackShiftRegister by storing the initial value of the first call, and setting <i>stopValue</i> to that initial value in subsequent calls.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>/TAPB=tapbits</i>       | <p>An alternate way to express the tap list. <i>tapbits</i> is a number in which each bit represents a tap, with bit 0 representing the tap with tap number <i>nbits</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>/TAPS={t1, t2, ...}</i> | <p>Specifies the tap list. Tap numbers are in the range from 1 to <i>nbits</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Details

If the /TAPS, /TAPB, or /MAX flags are absent, the maximal-length sequence corresponding to /MAX=0 is generated.

If you omit the /DEST flag, a wave named W\_LFSR will be generated for you. W\_LFSR is an unsigned integer wave with number type set to the minimum size for the shift register size and /MODE setting. Thus, if you set /N=10/MODE=0, W\_LFSR will be an unsigned 16-bit integer wave.

Because W\_LFSR is an unsigned integer wave, you will need to redimension the wave to a floating-point wave for many purposes. Use the **Redimension** operation or the Redimension Waves item in the Data menu.

Up to /N=18, W\_LFSR will initially be created large enough to hold a maximal-length sequence, unless you request a shorter sequence using the /LEN flag. If the initial value is seen again before a maximal-length sequence is generated, it means that the tap list specified was not one that generates a maximal-length sequence, and generation is terminated. The wave is shortened to the generated sequence length.

If you set a register size greater than /N=18 and you do not use /LEN, the generated sequence will stop after  $2^{18}-1$  (262143) states. Note that beyond some N, it will be impossible to create a wave large enough to hold a maximal-length sequence.

Some tap lists do not generate maximal-length sequences but also do not repeat the initial value. In that case, the generated sequence will be of maximal length but will contain repeated subsequences. The V\_flag variable will be set to 0 if the sequence was not a maximal-length sequence, or 1 if it was. If /LEN=length values were generated, V\_flag is set to 2.

If you specify your own wave using /DEST, the sequence length will be the same as the length of your wave. Your wave will be resized if a shorter sequence is generated.

### Generating Long Sequences in Smaller Segments

Very long maximal-length sequences will not fit in the largest wave you can make. It may also be more convenient to make multiple, small fragments of a longer sequence. You can do this using the /INIT, /STOP, and /LEN flags, along with the V\_nextValue variable. Here is an example of making 1000-point subsequences from a 16-bit maximal-length sequence:

```
// Start with the first 1000 states, with initial value of 1
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=1
// Restart using the V_nextValue variable to continue the sequence
// /STOP=1 sets the stopping value to the first initial value
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=(V_nextValue)/STOP=1
// Continue...
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=(V_nextValue)/STOP=1
```

### Variables

The LinearFeedbackShiftRegister operation returns information in the following variables:

|             |                                                                                                                                                                                                                                                                                                      |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_flag      | Set to zero when a nonmaximal-length sequence was detected. This occurs if the initial value is seen again before a maximal-length sequence was generated, or if a maximal-length sequence was generated but the final state was not the same as the initial state.                                  |
|             | Set to 1 when a maximal-length sequence was generated.                                                                                                                                                                                                                                               |
|             | Set to 2 when the sequence was limited by /LEN=length or by the default limit of $2^{18}-1$ (262143) states.                                                                                                                                                                                         |
| V_tapValue  | Set to the binary representation of the tap sequence used. That is, you can generate the same sequence using /TAPB=V_tapValue. If you use /MROR=1, V_tapValue reflects that setting. It will also give the actual tap value used when you specify the a maximal-length sequence using the /MAX flag. |
| V_nextValue | Set to the next value beyond the last generated register state. This can be used to restart a truncated sequence.                                                                                                                                                                                    |

### Examples

Generate a 16-bit maximal-length sequence and reprocess the output values to be centered on zero and normalized to a maximum value of 1:

```
LinearFeedbackShiftRegister/N=16
Redimension/D W_LFSR
```

```
W_LFSR -= 2^15
W_LFSR /= 2^15-1
```

Another way to do the same thing that avoids the Redimension operation, which could lead to fragmentation of memory:

```
Make/D/N=(2^16-1) LFSR_output
LinearFeedbackShiftRegister/N=16/DEST=LFSR_output
LFSR_output -= 2^15
LFSR_output /= 2^15-1
```

Make a bit stream with random +1 and -1 instead of 0 and 1:

```
LinearFeedbackShiftRegister/N=16/MODE=1
Redimension/B W_LFSR
W_LFSR = W_LFSR*2-1
```

### See Also

If you really need random numbers, we provide high-quality RNG's that return random deviates from a number of distributions. See **noise**, **gnoise**, and others.

### References

A discussion of LFSR's can be found in "Generation of Random Bits" (Section 7.4) in Press, William H., *et al.*, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992. They refer to "primitive polynomials modulo 2" and do not use the name Linear Feedback Shift Register, but it is the same thing. We use an implementation equivalent to their Method I.

## ListBox

```
ListBox [/Z] ctrlName [keyword = value [, keyword = value ...]]
```

The ListBox operation creates or modifies the named control that displays, in the target window, a list from which the user can select any number of items.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*ctrlName* is the name of the ListBox control to be created or changed.

The following keyword=value parameters are supported:

*align=alignment* Sets the alignment mode of the control. The alignment mode controls the interpretation of the *leftOrRight* parameter to the *pos* keyword. The *align* keyword was added in Igor Pro 8.00.

If *alignment=0* (default), *leftOrRight* specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.

If *alignment=1*, *leftOrRight* specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

*appearance={kind [, platform]}*

Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.

*kind* can be one of *default*, *native*, or *os9*.

*platform* can be one of *Mac*, *Win*, or *All*.

See **Button** and **DefaultGUIControls** for more appearance details.

*clickEventModifiers=modifierSelector*

Selects modifier keys to ignore when processing clicks to start editing a cell or when toggling a checkbox. That is, use this keyword if you want to prevent a shift-click (for instance) from toggling checkbox cells. Allows the action procedure to receive mousedown events with those modifiers without interfering actions on the part of the listbox control.

*modifierSelector* is a bit pattern with a bit for each modifier key; sum these values to get the desired combination of modifiers:

*modifierSelector*=1: Control key (Macintosh only)  
*modifierSelector*=2: Option (Macintosh) or Alt (Windows)  
*modifierSelector*=4: Context click  
(right click on Windows, control-click on Macintosh)  
*modifierSelector*=8: Shift key  
*modifierSelector*=16: Cmd key (Macintosh) or Ctrl key (Windows)  
*modifierSelector*=32: Caps lock key

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

|                        |                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>col=c</i>           | Sets the left-most visible column (user scrolling will change this). The list is scrolled horizontally as far as possible. Sometimes this won't be far enough to actually make column <i>c</i> the first column, but it will at least be visible. Use <i>c</i> =1 to put the left edge of column 1 (the <i>second</i> column) at the left edge of the list.        |
| <i>colorWave=cw</i>    | Specifies a 3-column (RGB) or 4-column (RGBA) numeric wave. Used in conjunction with planes in <i>selWave</i> to define foreground and background colors for individual cells. Values range from 65535 (full on) to 0.                                                                                                                                             |
| <i>disable=d</i>       | Sets user editability of the control.<br><i>d</i> =0: Normal.<br><i>d</i> =1: Hide.<br><i>d</i> =2: Draw in gray state; disable control action.                                                                                                                                                                                                                    |
| <i>editStyle=e</i>     | Sets the style for cells designated as editable (see <i>selWave</i> , bit 1).<br><i>e</i> =0: Uses a light blue background (default).<br><i>e</i> =1: Draws a frame around the cell with a white background.<br><i>e</i> =2: Combines the frame with the blue background. The background in all cases can be overridden using the <i>colorWave</i> parameter.      |
| <i>focusRing=fr</i>    | Enables or disables the drawing of a rectangle indicating keyboard focus:<br><i>fr</i> =0: Focus rectangle will not be drawn.<br><i>fr</i> =1: Focus rectangle will be drawn (default).<br><br>On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences. |
| <i>font="fontName"</i> | Sets the font used for the list box items, e.g., <i>font="Helvetica"</i> .                                                                                                                                                                                                                                                                                         |
| <i>frame=f</i>         | Specifies the list box frame style.<br><i>f</i> =0: No frame.<br><i>f</i> =1: Simple rectangle.<br><i>f</i> =2: 3D well.<br><i>f</i> =3: 3D raised.<br><i>f</i> =4: Text well style.                                                                                                                                                                               |
| <i>fsize=s</i>         | Sets list box font size.                                                                                                                                                                                                                                                                                                                                           |

| <i>mode=m</i>                | <p>List selection mode specifying how many list selections can be made at a time.</p> <ul style="list-style-type: none"> <li><i>m</i>=0:     No selection allowed.</li> <li><i>m</i>=1:     One or zero selection allowed.</li> <li><i>m</i>=2:     One and only one selection allowed.</li> <li><i>m</i>=3:     Multiple, but not disjoint, selections allowed.</li> <li><i>m</i>=4:     Multiple and disjoint selections allowed.</li> </ul> <p>When multiple columns are used, you can enable individual cells to be selected using modes 5, 6, 7, and 8 in analogy to <i>m</i>=1-4. When using <i>m</i>=3 or 4 with multiple columns, only the first column of the <code>selWave</code> is used to indicate selections. Checkboxes and editing mode, however, use all cells even in modes 0-4.</p> <p>Modes 9 and 10 are the same as modes 4 and 8 except they use different selection rules and require testing bit 3 as well as bit 0 in <code>selWave</code>. In modes 4 and 8, a shift click toggles individual cells or rows, but in modes 9 and 10, the Command (<i>Macintosh</i>) or Ctrl (<i>Windows</i>) key toggles individual cells or rows whereas Shift defines a rectangular selection. To determine if a cell is selected, perform a bitwise AND with <code>0x09</code>.</p> |
| <i>proc=p</i>                | <p>Set name of user function proc to be called upon certain events. See discussion below.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <code>selRow=s</code>                              | <p>Defines the selected row when mode is 1 or 2; when no <code>selWave</code> is used, it is defined by modes 5 or 6. Use -1 for no selection.</p> <p>To read this value, use <b>ControlInfo</b> and the <code>V_value</code> variable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>selWave=sw</code>                            | <p><code>sw</code> is a numeric wave with the same dimensions as <code>listWave</code>. It is optional for modes 0-2, 5 and 6 and required in all other modes.</p> <p>In modes greater than 2, <code>sw</code> indicates which cells are selected. In modes 1 and 2 use <b>ControlInfo</b> to find out which row is selected.</p> <p>In all modes <code>sw</code> defines which cells are editable or function as checkboxes or disclosure controls.</p> <p>Numeric values are treated as integers with individual bits defined as follows:</p> <ul style="list-style-type: none"><li>Bit 0 (0x01): Cell is selected.</li><li>Bit 1 (0x02): Cell is editable.</li><li>Bit 2 (0x04): Cell editing requires a double click.</li><li>Bit 3 (0x08): Current shift selection.</li><li>Bit 4 (0x10): Current state of a checkbox cell.</li><li>Bit 5 (0x20): Cell is a checkbox.</li><li>Bit 6 (0x40): Cell is a disclosure cell. Drawn as a disclosure triangle (<i>Macintosh</i>) or a treeview expansion node (<i>Windows</i>).</li><li>Bit 7 (0x80): Cell is disabled. Clicks on the cell are ignored and it is drawn with a grayed appearance. Added in Igor Pro 8.00.</li></ul> <p>Because of technical issues, this bit currently does not prevent the selection of the cell using the arrow keys.</p> <p>In modes 3 and 4 bit 0 is set only in column zero of a multicolumn listbox.</p> <p>Other bits are reserved. Additional dimensions are used for color info. See the discussion for <code>colorWave</code>. <code>selWave</code> is not required for modes 5 and 6.</p> |
| <code>setEditCell={row,col,selStart,selEnd}</code> | <p>Initiates edit mode for the cell at <code>row</code>, <code>col</code>. An error is reported if <code>row</code> or <code>col</code> is less than zero. Nothing happens and no error is reported if <code>row</code>, <code>col</code> is beyond the limits of the listbox, or if the cell has not been made editable by setting bit 1 of <code>selWave</code>.</p> <p><code>selStart</code> and <code>selEnd</code> set the range of bytes that are selected when editing is initiated; 0 is the start of the text. If there are N bytes in the listbox cell, setting <code>selStart</code> or <code>selEnd</code> to N or greater moves the start or end of the selection to the point after the last character. Setting <code>selStart</code> and <code>selEnd</code> to the same value selects no characters and the insertion point is set to <code>selStart</code>. Setting <code>selStart</code> to -1 always causes all characters to be selected.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>size={width,height}</code>                   | Sets list box size in <b>Control Panel Units</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>special={kind,height,style}</code>           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Specifies special cell formatting or contents.

*kind=0*: Normal text but with specified *height* (if nonzero). Use a *style* of 1 to autocalculate widths based on the entire list contents. In this case, user widths are taken to be minimums and the last is not repeated.

*kind=1*: Text taken to be the names of graphs or tables. Images of the graphs or tables are displayed in the cells. Use a *style* of 0 to display just the presentation portion of the graph or 1 to display it entirely. For tables, only the presentation portion is displayed.

*kind=2*: Text taken to be the names of pictures. Images are displayed in the cells.

*kind=3*: Displays a PNG, TIFF, or JPEG image. You can obtain binary picture data using SavePICT.

*kind=4*: Displays raw text without any escape code processing. Added in Igor Pro 8.00 to allow display of LaTeX expressions which make heavy use of backslashes.

For *kind=1* or *2*, *height* may be zero to auto-set cell height to same as width or a specific value.

*titleWave=w* Specifies a text wave containing titles for the listbox columns, instead of using the list wave dimension labels. Each row is the title for one column; if you have N columns you must have a wave with N rows.

*userColumnResize=u* Enables resizing the list columns using the mouse.

*u=0*: Columns are not resizable (default). The widths parameter still works, though.

*u=1*: User can resize columns by dragging the column dividers.  
When resizing a column without Option, Alt, or Shift modifiers (a "normal" resizing), any width added to the column is subtracted from the following column (if any).

When resizing while pressing Option (*Macintosh*) or Alt (*Windows*), only columns following the dragged divider will move (the same way table columns are resized).

When pressing Shift, all columns are set to the same width as the column being resized. If the total widths of all columns is less than the width of the listbox, then each column expands to fill the available width.

*userdata=UDStr* Sets the unnamed user data to *UDStr*.

*userdata(UDName)=UDStr*  
Sets the named user data, *UDName*, to *UDStr*.

*userdata+=UDStr* Appends *UDStr* to the current unnamed user data.

*userdata(UDName)+=UDStr*  
Appends *UDStr* to the current named user data, *UDName*.

*widths={w1,w2,...}* Optional list of minimum column widths in screen pixels. If more columns than widths, the last is repeated. If total of widths is greater than list box width then a horizontal scroll bar will appear. If total is less than available width then each expands proportionally.

|                                  |                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>widths+={w1,w2,...}</code> | Additional column widths. Because only 2500 bytes fit on a command line, lists with many columns may require multiple <code>widths+=</code> parameters to define all the column widths. However if all the widths are the same, <code>widths+=</code> is not needed; just use:<br><br><code>ListBox ctrlName widths={sameWidth}</code> |
| <code>win=winName</code>         | Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.<br><br>When identifying a subwindow with <code>winName</code> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.                                 |

### Flags

`/Z` No error reporting.

### Details

If the list wave has column dimension labels (see **SetDimLabel**), then those will be used as column titles. Note that a 1D wave is subtly different from a 1 column 2D wave. The former does not have any columns and therefore no column dimension labels.

Alternately, use a text wave with the `titleWave` keyword to specify column titles.

Using escape codes you can change the font, size, style, and color of the title. See **Annotation Escape Codes** on page III-53 or details.

For instance, to make a title bold use the `\f01` escape sequence:

```
SetDimLabel 1, columnNum, $"\\f01My Label", textWave
```

If you can't fit title text within the 255 byte limit (styled text can be especially long), use the `titleWave` keyword with a text wave. The wave must have as many rows as the list wave has columns. When using a title wave, there are no restrictions on the number of bytes or on what characters you can use.

This example uses a title wave to add a red up-arrow graph marker to the end of a centered title:

```
Make/O/T/N=(numColumns) columnTitles
columnTitles[colNum]="\\JCThis is the title\\K(65535,0,0)\\k(65535,0,0)\\W523"
ListBox list0 titleWave=columnTitles
```

That's a 51-byte title that results in 19 characters or symbols that you actually see. `\JC` requests centered text, `\K` sets the text color (which colors the inside of the graph marker), `\k` sets the marker stroke color, and `\W523` inserts a down-pointing triangular graph marker.

When using modes that allow multiple selections, use Shift to extend or add to the selection.

You can specify individual cells as being editable by setting bit 1 (counting from zero on the right) in `selWave`. The user can start editing a cell by either clicking in it or, if the cell is selected, by pressing Enter (or Return). When finished, the user can press Enter to accept the changes or can press Escape to reject changes. The user may also press Up or Down Arrow to accept changes and begin editing the next editable cell in a column. Likewise, Tab and Shift-Tab moves to the next or previous column in a row. If bit 2 of `selWave` is set then a double click will be required rather than a single click. **Note:** in edit mode, Tab and Shift-Tab are used to move left and right because the Left and Right Arrow keys are used to move the text entry cursor left and right.

When the listbox has keyboard focus (either by tabbing to the list box or by clicking in the box), the keyboard arrow keys move a cell selection (or row depending on mode). When not in cell edit mode, Tab and Shift-Tab move the keyboard focus to other objects in the window. The Home, End, Page Up, and Page Down keys affect the vertical scroll bar.

When the listbox has focus, the user may type the first few chars of an entry in the list to select that entry. Only the first column is used. If a match is not found then nothing is done. The search is case insensitive.

### Listbox Help

You can provide a text wave with help strings to show a tooltip for individual cells or rows of a listbox in place of the generic help string provided by the help keyword. In general, the string in `helpWave[listbox row][listbox column]` is used. If your help wave is a 1D wave, then the listbox column is ignored, and `helpWave[listbox row]` is used in all columns.

Note that a 1D wave (Make/N=*rows*) is not the same as a 2D wave with one column (Make/N=(*rows*,1)). A 2D wave with one column provides help for column 0 only and the generic help string is shown for column 1 and beyond. A 1D wave provides help for all columns.

If the help wave has an empty string for a given row and column then the generic help string is shown for the corresponding listbox cell. If the help wave has too few rows or columns, then the generic help string is shown for the cells outside the range of the help wave.

### ListBox Action Procedure

The action procedure for a ListBox control takes a predefined structure `WMListboxAction` as a parameter to the function:

```
Function ActionProcName(LB_Struct) : ListboxControl
 STRUCT WMListboxAction &LB_Struct
 ...
 return 0
End
```

The “: ListboxControl” designation tells Igor to include this procedure in the Procedure pop-up menu in the List Box Control dialog.

See **WMListboxAction** for details on the `WMListboxAction` structure.

Although the return value is not currently used, action procedures should always return zero.

You may see an old format listbox action procedure in old code:

```
Function MyListboxProc(ctrlName,row,col,event) : ListboxControl
 String ctrlName // name of this control
 Variable row // row if click in interior, -1 if click in title
 Variable col // column number
 Variable event // event code
 ...
 return 0 // other return values reserved
End
```

This old format should not be used in new code.

### Specifying Cell Color

The background and foreground (text) color of individual cells may be defined by providing `colorWave` in conjunction with specific planes in `selWave`. The planes in `selWave` are taken to be integer indexes into `colorWave`. The planes are defined by specific dimension labels and not by specific plane numbers. To provide foreground colors, define a plane labeled “foreColors” that contains the desired index values. Likewise define and fill a plane labeled “backColors” for background colors. The value 0 is special and indicates that the default colors should be used. Note that if you have a one column list for which you want to supply colors, the `selWave` needs to be three dimensional but with just one column. Here is an example:

```
Make/T/N=(5,1) tw= "row "+num2str(p) // 5 row, 1 col text wave (2D)
Make/B/U/N=(5,1,2) sw // 5 row, 1 col, 2 plane byte wave
Make/O/W/U myColors={0,0,0},{65535,0,0},{0,65535,0},{0,0,65535},{0,65535,65535}
MatrixTranspose myColors // above was easier to enter as 3 rows, 5 cols

NewPanel
ListBox lb,mode=3,listWave= tw,selWave= sw,size={200,100},colorWave=myColors
sw[][][1]= p // arbitrary index values into plane 1
```

Now, execute the following commands one at a time and observe the results:

```
SetDimLabel 2,1,backColors,sw // define plane 1 as background colors
SetDimLabel 2,1,foreColors,sw // redefine plane 1 as foreground colors
sw[][][%foreColors]= 4-p // change the color index values
```

In the above example, the `selWave` was defined as unsigned byte. If you need more than 254 colors, you will have to use a larger number size.

The color wave may have four columns instead of three, with the fourth specifying transparency (65535=fully opaque, 0=fully transparent). Transparency of the background color is of limited utility as it just shows the white background color through the cell color, resulting in pastel shades. Transparency of the foreground color permits the cell background color to show through the text color.

### Checkboxes in Cells

You can cause a cell to contain a checkbox by setting bit 5 in selWave. The title (if any) is taken from listWave and the results (selected/deselected) is bit 4 of selWave. If a checkbox cell is selected then the space bar will toggle the checkbox. (Clicking a checkbox cell does not select it — use the arrow keys.)

### Errors

Your listbox may be drawn with a red X and an error code. The error codes are:

| Error | Meaning                                                                          |
|-------|----------------------------------------------------------------------------------|
| E1    | The listbox is too small                                                         |
| E2    | The listWave is invalid (missing, not text or no rows)                           |
| E3    | The listWave and selWave do not match in dimensions                              |
| E4    | Mode is greater than 2 but no selWave was specified                              |
| E5    | The number of rows in titleWave does not match the number of columns in listWave |
| E6    | The titleWave is not a textWave                                                  |

### Event Queue

It is possible for a single user action to produce more than one event. For instance, pressing the up arrow key while editing to select a cell that is not visible generates event codes 4, 8, and 6. Igor calls your action procedure separately for each code.

If your code tests for a nonzero value in eventCode2, and uses it only if it is nonzero, then the event queue method will not break your code. If you have determined empirically when you need to use eventCode2 and you do not test, your code will break.

### Scroll Event Warnings

Events 8, 9, and 10 report to you that the listbox has been scrolled vertically or horizontally. These events are envisioned as allowing you to keep two listboxes synchronized (you may find other uses for these events). You might use an action procedure like this one to keep two listboxes (named list0 and list1) in sync:

```
Function ListBoxProc2(LB_Struct) : ListBoxControl
 STRUCT WMListboxAction &LB_Struct

 if (LB_Struct.eventCode == 8)
 String listname
 if (CmpStr(LB_Struct.ctrlName, "list1") == 0)
 listname = "list0"
 else
 listname = "list1"
 endif
 ControlInfo $listname
 if (V_startRow != LB_Struct.row)
 listbox $listname,row=LB_Struct.row
 ControlUpdate $listname
 endif
 endif

 return 0
End
```

It is very easy to create an infinite cascade of events feeding back between the two listboxes, especially if you use event 10. When this happens, you will see your listboxes jiggling up and down endlessly. The test using ControlInfo is intended to make this unlikely.

The slow response of the old-style, nonstructure action procedure can defeat the ControlInfo test by delaying the action procedure execution. If you use events 8, 9, or 10, we recommended that you use the new-style action procedure.

### Note on Keystroke Event

In a keystroke event passed to a listbox action procedure the eventCode is 12. A character code is stored in the row field of the WMListboxAction structure. This works only for ASCII characters and a few special

characters such as delete (8), forward delete (127) and escape (27). It does not work for non-ASCII characters such as accented characters which are represented as UTF-8 and require multiple bytes.

As explained below, many keystroke events are not sent to the listbox action procedure because they are consumed by the internal listbox code in Igor. For this reason the keystroke event for a listbox is of limited use.

The architecture of Igor controls is such that events are passed to an action procedure only after the control has used them. In the case of a keystroke event, that means that other uses of the keystroke may consume the event before the action procedure gets a chance at it. In particular, a listbox editable cell that is actively being edited consumes keystroke events, and the action procedure is not called. The only editing-related events your action procedure will get are event codes 6 and 7.

If an arrow key is pressed, and this results in the selected row or cell changing, your action procedure will not get a keystroke event. Instead, your action procedure will receive event code 4 or 5. If the arrow key causes scrolling to occur, the action procedure will also get event code 8 or 9.

### Examples

Here is a simple Listbox example:

```
Make/O/T/N=30 tjack="this is row "+num2str(p)
Make/O/B/N=30 sjack=0
NewPanel /W=(19,61,319,261)
ListBox lb1,pos={42,9},size={137,94},listWave=tjack,selWave=sjack,mode= 3
Edit/W=(367,61,724,306) tjack,sjack
ModifyTable width(tjack)=148
```

Make selections in the list and note changes in the table and vice versa. Edit one of the list text values in the table and note update of the list.

Here is an example using a titleWave and styled text in the title cells. Note that the last title isn't very long when rendered, but requires a 63 byte specification.

```
Make/O/T/N=(4,3) ListWave="row "+num2str(p)+" col "+num2str(q)
Make/O/T/N=3 titles // three rows to match 3-column ListWave
titles[0] = "\f01Bold Title"
titles[1] = "title with semicolon;"
titles[2] = "Marker in Gray: \K(40000,40000,40000)\k(40000,40000,40000)\W517"
NewPanel /W=(515,542,1011,794)
ListBox list0,pos={1,2},size={391,120},listWave=ListWave
ListBox list0,titleWave=titles
```

An example experiment that lets you easily experiment with ListBox settings is available in "Examples:Feature Demos 2:ListBox Demo.pxp".

### See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

**Control Panel Units** on page III-444 for a discussion of the units used for controls.

The **GetUserData** function for retrieving named user data.

The **ControlInfo** operation for information about the control.

**Setting Bit Parameters** on page IV-12 for further details about bit settings.

## ListBoxControl

### ListBoxControl

ListBoxControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined listbox control. See **Procedure Subtypes** on page IV-204 for details. See **ListBox** for details on creating a listbox control.

## ListMatch

**ListMatch(listStr, matchStr [, listSepStr])**

The ListMatch function returns each list item in *listStr* that matches *matchStr*.

*listStr* should contain items separated by *listSepStr* which typically is ";".

You may include asterisks in *matchStr* as a wildcard character. Note that matching is case-insensitive. See **StringMatch** for wildcard details.

## ListToTextWave

---

*ListSepStr* is optional. If omitted it defaults to ";".

### See Also

The **GrepList**, **StringMatch**, **StringFromList**, and **WhichListItem** functions.

## ListToTextWave

**ListToTextWave**(*listStr*, *separatorStr*)

The ListToTextWave function returns a free text wave containing the individual list items in *listStr*.

See **Free Waves** on page IV-90 for details on free waves.

The ListToTextWave function was added in Igor Pro 7.00.

### Parameters

*listStr* is a string that contains any number of substrings separated by a common string separator.

*separatorStr* is the separator string that separates one item in the list from the next. It is usually a single semicolon character but can be any string.

### Details

The ListToTextWave function returns a free wave so it can't be used on the command line or in a macro. If you need to convert the free wave to a global wave use MoveWave.

For lists with a large number of items, using ListToTextWave and then retrieving the substrings sequentially from the returned text wave is much faster than retrieving the substrings using StringFromList.

The reverse operation, converting the contents of a text wave into a string list, can be accomplished using **wfprintf** like this:

```
WAVE/T tw
String list
wfprintf list, "%s\r", tw // Carriage-return separated list
```

### Example

```
Function Test(num, separator)
 Variable num
 String separator // Usually ";"

 // Build a string list using separator
 String list = ""
 Variable i
 for(i=0; i<num; i+=1)
 list += "item_" + num2str(i) + separator
 endfor

 // Convert to a text wave and print its elements
 Wave/T w = ListToTextWave(list, separator)
 Print numpts(w)
 for(i=0; i<num; i+=1)
 Print i, w[i]
 endfor
End
```

### See Also

Using Strings as Lists on page IV-172, **StringFromList**, **MoveWave**, **Free Waves** on page IV-90

## ListToWaveRefWave

**ListToWaveRefWave**(*stringList* [, *options*])

The ListToWaveRefWave function returns a free wave containing a wave reference for each entry in *stringList* that corresponds to an existing wave.

The ListToWaveRefWave function was added in Igor Pro 7.00.

**Parameters**

*stringList* is a semicolon-separated string list of waves specified using full paths or partial paths relative to the current data folder.

*options* is a bit field that is 0 by default. Set bit 0 to if you want the function to generate an error (see **GetRTError**) if any of the list elements does not specify an existing wave. Other bits are reserved for future use and must be cleared.

**Example**

```
Function Test()
 NewDataFolder/O/S root:TestDF // Create empty data folder as current DF
 Make/O aaa // aaa will be the first wave in list
 Make/O bbb
 String strList = WaveList("a", ";", "b")
 Wave/WAVE wr = ListToWaveRefWave(strList, 0) // Returns a free wave
 Wave w = wr[0]
 Print GetWavesDataFolder(w, 2)
 Wave w = wr[1]
 Print GetWavesDataFolder(w, 2)
End
```

**See Also**

**WaveRefWaveToList**, **ListToTextWave**, **Wave References** on page IV-70

**ln****ln (*num*)**

The ln function returns the natural logarithm of *num*, -INF if *num* is 0, or NaN if *num* is less than 0. In complex expressions, *num* is complex, and ln(*num*) returns a complex value.

To compute a logarithm base n use the formula:

$$\log_n(x) = \frac{\log(x)}{\log(n)}$$

**See Also**

The **log** function.

**LoadData****LoadData** [*flags*] *fileOrFolderNameStr*

The LoadData operation loads data from the named file or folder. "Data" means Igor waves, numeric and string variables and data folders containing them. The specified file or folder must be an Igor packed experiment file or a folder containing Igor binary data, such as an Igor unpacked experiment folder or a folder in which you have stored Igor binary wave files.

In Igor Pro 9.00 or later, LoadData can load data from a standard packed experiment file (.pxp) or from an HDF5 packed experiment file (.h5xp). Previous versions support .pxp only. The term "packed experiment file" below refers to either .pxp or .h5xp.

LoadData loads data objects into memory and they become part of the current Igor experiment, disassociated from the file from which they were loaded.

If loading from a file-system folder, the data (waves, variables, strings) in the folder, including any subfolders if /R is specified, is loaded into the current Igor data folder.

If loading from a packed Igor experiment file, the data in the file, including any packed sub-data folders if /R is specified, is loaded into the current Igor data folder.

Use LoadData to load experiment data using Igor procedures. To load experiment data interactively, use the Data Browser (Data menu).

**Parameters**

If you use a full or partial path for *fileOrFolderNameStr*, see **Path Separators** on page III-453 for details on forming the path.

## LoadData

---

If *fileOrFolderNameStr* is omitted you get to locate the file (if /D is omitted) or the folder (if /D is present) via a dialog.

### Flags

/D If present, loads from a file-system folder (a directory). If omitted, LoadData loads from an Igor packed experiment file.

/GREP={*regExpStr*, *grepMode*, *objectTypeMask*, *grepFlags*}

Applies a regular expression to determine what objects are loaded. /GREP was added in Igor Pro 8.00.

See **Using Regular Expressions With LoadData** on page V-500 for details.

/I Interactive. Forces LoadData to present a dialog.

/J=*objectNamesStr* Loads only the objects named in the semicolon-separated list of object names.

/L=*loadFlags* Controls what kind of data objects are loaded with a bit for each data type:

| <i>loadFlags</i> | Bit Number | Loads this Object Type |
|------------------|------------|------------------------|
| 1                | 0          | Waves                  |
| 2                | 1          | Numeric Variables      |
| 4                | 2          | String Variables       |

To load multiple data types, sum the values shown in the table. For example, /L=1 loads waves only, /L=2 loads numeric variables only, and /L=3 loads both waves and numeric variables. See **Setting Bit Parameters** on page IV-12 for further details about bit settings.

If no /L is specified, all object types are loaded. This is equivalent to /L=7. All other bits are reserved and should be set to zero.

/O[=*overwriteMode*] If /O alone is used, overwrites existing data objects in case of a name conflict.

*overwriteMode* is defined as follows:

- 0: No overwrite, as if there were no /O.
- 1: Normal overwrite. In the event of a name conflict, objects in the incoming file replace the conflicting objects in memory. Incoming data folders completely replace any conflicting data folders in memory.
- 2: Mix-in overwrite. In the event of a name conflict, objects in the incoming file replace the conflicting objects in memory but nonconflicting objects in memory are left untouched.

See **Details** for more about overwriting.

/P=*pathName* Specifies folder to look in for the specified file or folder. *pathName* is the name of an existing Igor symbolic path. See **Symbolic Paths** on page II-22 for details.

/Q Suppresses the normal messages in the history area.

/R Recursively loads sub-data folders.

/S=*subDataFolderStr* Specifies a sub-data folder within a packed experiment file to be loaded. See **Loading a Specific Data Folder from a Packed Experiment** on page V-499 for details.

/T[=*topLevelName*] If /T=*topLevelName* is specified, it creates a new data folder in the current data folder with the specified name and places the loaded data in the new data folder.

If just /T is specified, it creates a new data folder in the current data folder with a name derived from the name of the unpacked experiment folder, packed experiment file or packed sub-data folder being loaded.

## Details

If /T is present, LoadData loads the top level data folder and its contents. If /T is omitted, it loads just the contents of the top level data folder and not the data folder itself. This distinction has an analogy in the desktop. You can drag the contents of disk folder A into folder B or you can drag folder A itself into folder B.

Because LoadData can load from a complex packed Igor experiment file or from a complex hierarchy of file-system folders, it does not set the variables normally set by a file loader: S\_path, S\_fileName, and S\_waveNames. The variable V\_flag is set to the total number of objects loaded, or to -1 if the user cancelled the open file dialog. To find what objects were created by LoadData, you can use the **CountObjects** and **GetIndexedObjName** functions.

## Overwriting Existing Data

If you do a load of a data folder, overwriting an existing data folder of the same name, the behavior of LoadData depends on whether you use /J. If you do not use /J, the entire data folder and all of its contents are replaced. If you do use /J, just the specified objects in the data folder are replaced, leaving any other preexisting objects in the data folder unchanged.

If you do not use the /O (overwrite) flag or if you use /O=0 and there is a conflict between objects or data folders in the current data folder and objects or data folders in the file or folder being loaded, LoadData presents a dialog to ask you if you want to replace the existing data. However, LoadData can not replace an object with an object of a different type and will refuse to do so.

You can overwrite an object that is in use, such as a wave that is displayed in a graph or table. You can also overwrite a data folder that contains objects that are in use. This is a powerful feature. Imagine that you define a data structure consisting of waves, variables and possibly sub-data folders. You can display the data in graphs and tables and you can display these in a layout. You can then overwrite the data with an analogous data structure from a packed experiment file and Igor will automatically update any graphs, tables or layouts that need to be updated.

## Controlling Which Objects Are Loaded

LoadData provides several ways to control whether a given object is loaded or is skipped. These methods, which are described in the following sections, include:

- Using /L to control whether waves, numeric variables, and string variables are loaded
- Specifying a sub-data folder using /S
- Specifying object names using /J
- Applying a regular expression using /GREG. /GREG requires Igor Pro 8.00 or later.

You can use more than one of these flags. For example, if you use /S and /J, then LoadData loads only objects in the data folder specified by /S with names listed using /J. In most cases, if you use /GREG, you will not need to combine it with /S or /J.

## Loading a Specific Data Folder from a Packed Experiment

If present, /S=*subDataFolderStr* specifies the sub-data folder within the packed experiment file from which the load is to start. For example:

```
LoadData/P=Path1/S="root:Folder A:Folder B" "aPackedExpFile.pxp"
```

This starts loading from data folder "root:Folder A:Folder B" in the packed experiment file. *subDataFolderStr* is the full data folder path to the desired data folder. A trailing semicolon is allowed but not required. Since this parameter is specified as a string, you must not use single quotes to quote liberal names.

Prior to Igor Pro 7.00, the "root:" part of the data folder path was implicit and you had to omit it from *subDataFolderStr*. Now you can provide the full path including "root:" and this is recommended for clarity. For backward compatibility, if *subDataFolderStr* does not start with "root:", LoadData automatically prepends it.

/S has no effect if you are loading from an unpacked file system folder rather than from a packed experiment file.

Specifying /S="" acts like no /S at all.

## Loading Specific Objects Based on Object Name

If /J=*objectNamesStr* is used, then only the objects named in *objectNamesStr* are loaded into the current experiment. For example, /J="wave0;wave1;" will load only the two named waves, ignoring any other data in the file or folder being loaded.

Assume that you have an experiment that contains 5 runs where each run, stored in a separate data folder in a packed experiment file, consists of data acquired from four channels from an ADC card. Using the `/J` flag, you can load just one specific channel from each run. You can use this to compare that channel's data from all runs without loading the other channels.

The list of object names used with `/J` must be semicolon-separated. A semicolon after the last object name in the list recommended but optional. Since `objectNamesStr` is specified as a string, you must not use single quotes to quote liberal names.

`objectNamesStr` is limited to 2000 bytes.

Specifying `/J=""` acts like no `/J` at all.

If you load a hierarchy of data folders, using the `/R` flag, with `/J` in effect, `LoadData` will create each data folder in the hierarchy even if it contains none of the named objects. This behavior is necessary to avoid loading a sub-data folder without loading its parent, as well as other such complications.

### Using Regular Expressions With LoadData

If you include the `/GREP={regExpStr,grepMode,objectTypeMask,grepFlags}` flag, `LoadData` applies a regular expression (see **Regular Expressions** on page IV-175) to determine if a given object is to be loaded.

Before we get into the details, here are some simple examples. These examples assume that we are loading a packed experiment file named "Packed.pxp" and have an Igor symbolic path named `Data`.

```
// Load waves named wave1 from all data folders
LoadData/P=Data/Q/R/L=1/GREP={"(?i)^wave1$",1,1,0} "Packed.pxp"

// Load root:DataFolder0B and all objects in it
LoadData/P=Data/Q/R/L=7/GREP={"(?i)^root:DataFolder0B:$",3,8,0} "Packed.pxp"

// Load all data folders whose paths are of the form root:DataFolder<suffix>
LoadData/P=Data/Q/R/L=7/GREP={"(?i)^root:DataFolder.+.*$",3,8,0} "Packed.pxp"
```

See the **Examples** on page V-501 for more examples.

`regExpStr` is the regular expression.

GREP is by default case-sensitive but Igor names are case-insensitive. For this reason, we recommend that you start `regExpStr` with `"(?i)"` which turns GREP's case-sensitivity off.

When looking for the appropriate value for `regExpStr`, you may find it helpful to test if a given name or path is matched by a given regular expression using **GrepString**. For example:

```
Print GrepString("root:DataFolder0A:str0", "(?i).*0$") // Prints 1 if path is matched
```

The `grepMode` parameter selects one of three modes of using the regular expression.

If `grepMode` is 1, `LoadData` matches the name of each object of types specified by `objectTypeMask` against the specified regular expression. If there is a match, the object passes this test.

If `grepMode` is 2, `LoadData` matches the full data folder path to the object's parent data folder for objects of types specified by `objectTypeMask` against the regular expression. The full data folder path starts from "root:" and includes a trailing colon. If there is a match, the object passes this test. By definition, the parent of the root: data folder is "" (empty string) which can be expressed using the regular expression `"^$"`.

If `grepMode` is 3, `LoadData` matches the full data folder path to the object against the regular expression. The full data folder path starts from "root:" and includes a trailing colon for data folder objects only. If there is a match, the object passes this test.

When loading unpacked data, modes 2 and 3 are not supported and are ignored. They apply when loading data from a packed experiment file only.

`objectTypeMask` is a bitwise parameter with each bit controlling whether the regular expression is applied to a given object type. Bits 0, 1, 2, and 3 control whether the regular expression is applied against waves, numeric variables, string variables and data folders respectively. You can apply a given regular expression to more than one type of object by setting more than one bit in `objectTypeMask`. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

`grepFlags` is a bitwise parameter. Currently only bit 0 is used so its value must be 0 or 1. Normally, when `grepFlags=0`, objects that do not match the regular expression are skipped by `LoadData`. If `grepFlags=1`, the meaning of a match is reversed and objects that do match the regular expression are skipped by `LoadData`. For example:

```
// Load all objects whose name ends with "2"
LoadData/P=Data/Q/R/L=7/GREP={"(?i)[2]$",1,7,0} "Packed.pxp" // Normal mode

// Load all objects except those whose name ends with "2"
LoadData/P=Data/Q/R/L=7/GREP={"(?i)[2]$",1,7,1} "Packed.pxp" // Reverse mode
```

It is often not necessary, but you can use /GREP more than once in a given LoadData command, each time with a different combination of *grepMode*, object type, and reverse mode. A given object is loaded only if it passes all tests as well as any tests specified by /L, /J and /S. For example:

```
// Load root:DataFolder0B and all objects in it, except objects whose name ends with "2"
LoadData/P=Data/Q/R/L=7/GREP={"(?i)^root:DataFolder0B:$",3,8,0}/GREP={"(?i)[2]$",1,7,1} "Packed.pxp"
```

In this example, the first /GREP flag restricts which data folders are loaded and the second /GREP flag restricts which waves and variables are loaded.

If no test is applied to a particular kind of object then all objects of that type are loaded. For example, this command

```
LoadData/P=<pathName>/GREP={"(?i)^wave1$",1,1,0} <file name>
```

specifies that only waves named "wave1" should be loaded but it says nothing about numeric variables, string variables, or data folders so they are all loaded regardless of name. If you want to exclude all numeric and string variables, add the /L flag:

```
LoadData/P=<pathName>/L=1/GREP={"(?i)^wave1$",1,1,0} <file name>
```

As LoadData progresses through the data folders of the source, it has to create each data folder before it applies regular expression tests to objects in that data folder and its descendants. Consequently, it would be possible to end up with empty data folders because no data objects were loaded into them or their descendants. To eliminate the clutter that this would create, if you use /GREP, after loading all of the data, LoadData deletes any empty data folders that it created along the way. Data folders that existed before LoadData ran are not deleted even if they are empty. For backward compatibility, this pruning of empty data folders is done only if you use /GREP.

For each combination of *grepMode*, object type, and reverse mode, only one regular expression is applied. If you specify, for example, /GREP={"(?i)first",1,1,0} /GREP={"(?i)second",1,1,0}, the second /GREP flag overrides the first because they both apply a name test (*grepMode*=1) to wave objects (*objectTypeMask*=1) using normal mode (*grepFlags*=0). By contrast, /GREP={"(?i)first",1,1,0} /GREP={"(?i)second",1,2,0} results in no overriding because the first /GREP flag applies to waves (*objectTypeMask*=1) while the second applies to numeric variables (*objectTypeMask*=2). Similarly, /GREP={"(?i)first",1,1,0} /GREP={"(?i)second",1,1,1} results in no overriding because the first /GREP flag uses normal mode (*grepFlags*=0) while the second uses reverse mode (*grepFlags*=1).

## Examples

These examples assume that we are loading a packed experiment file named "Packed.pxp" and have an Igor symbolic path named Data. The file contains this data hierarchy:

```
root:
 wave0, wave1, wave2, var0, var1, var2, str0, str1, str2
 DataFolder0A
 wave0, wave1, wave2, var0, var1, var2, str0, str1, str2
 DataFolder0B
 wave0, wave1, wave2, var0, var1, var2, str0, str1, str2

// Load everything
LoadData/P=Data/Q/R "Packed.pxp"

// Load all objects named wave1
LoadData/P=Data/Q/R/J="wave1;" "Packed.pxp"

// Load all objects whose name ends with "2"
LoadData/P=Data/Q/R/L=7/GREP={"(?i)[2]$",1,7,0} "Packed.pxp"

// Load all numeric variables whose name starts with "var"
LoadData/P=Data/Q/R/L=2/GREP={"(?i)^var",1,2,0} "Packed.pxp"

// Load all string variables whose name starts with "str" and ends with "2"
LoadData/P=Data/Q/R/L=4/GREP={"(?i)^str.*2$",1,4,0} "Packed.pxp"

// Load all objects whose path contains "DataFolder", case-insensitive
LoadData/P=Data/Q/R/L=7/GREP={"(?i)DataFolder",2,7,0} "Packed.pxp"

// Load root:DataFolder0B and all objects in it using /S
LoadData/P=Data/Q/R/L=7/S="root:DataFolder0B"/T "Packed.pxp"
```

## LoadPackagePreferences

---

```
// Load root:DataFolder0B and all objects in it using /GREP
LoadData/P=Data/Q/R/L=7/GREP={"(?i)^root:DataFolder0B:$",3,8,0} "Packed.pxp"

// Load all objects whose path contains "DataFolder" and whose name ends with "1"
LoadData/P=Data/Q/R/L=7/GREP={"(?i)DataFolder",2,7,0}/GREP={"(?i).*1$",1,7,0} "Packed.pxp"

// Load all objects in root:DataFolder0B and whose name ends with "0"
LoadData/P=Data/Q/R/L=7/GREP={"(?i)root:DataFolder0B:.*0$",3,7,0} "Packed.pxp"
```

## LoadPackagePreferences

**LoadPackagePreferences** [/MIS=*mismatch* /P=*pathName*] *packageName*, *prefsFileName*, *recordID*, *prefsStruct*

The LoadPackagePreferences operation loads preference data previously stored on disk by the SavePackagePreferences operation. The data is loaded into the specified structure.

**Note:** The package preferences structure must not use fields of type Variable, String, WAVE, NVAR, SVAR or FUNCREF because these fields refer to data that may not exist when LoadPackagePreferences is called.

The structure can use fields of type char, uchar, int16, uint16, int32, uint32, int64, uint64, float and double as well as fixed-size arrays of these types and substructures with fields of these types.

If the /P flag is present then the location on disk of the preference file is determined by *pathName* and *prefsFileName*. However in the usual case the /P flag will be omitted and the preference file is located in a file named *prefsFileName* in a directory named *packageName* in the Packages directory in Igor's preferences directory.

**Note:** You must choose a very distinctive name for *packageName* as this is the only thing preventing collisions between your package and someone else's package. If you use a name longer than 31 bytes, your package will require Igor Pro 8.00 or later.

See **Saving Package Preferences** on page IV-249 for background information and examples.

### Parameters

*packageName* is the name of your package of Igor procedures. It is limited to 255 bytes and must be a legal name for a directory on disk. This name must be very distinctive as this is the only thing preventing collisions between your package and someone else's package. If you use a name longer than 31 bytes, your package will require Igor Pro 8.00 or later.

*prefsFileName* is the name of a preference file to be loaded by LoadPackagePreferences. It should include an extension, typically ".bin".

*prefsStruct* is the structure into which data from disk, if it exists, will be loaded.

*recordID* is a unique positive integer that you assign to each record that you store in the preferences file. If you store more than one structure in the file, you would use distinct *recordIDs* to identify which structure you want to load. In the simple case you will store just one structure in the preference file and you can use 0 (or any positive integer of your choice) as the *recordID*.

### Flags

|                       |                                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /MIS= <i>mismatch</i> | Controls what happens if the number of bytes in the file does not match the size of the structure:                                                                                               |
| 0:                    | Returns an error. Default behavior if /MIS is omitted.                                                                                                                                           |
| 1:                    | Returns the smaller of the size of the structure and the number of bytes in the file. Does not return an error. Use this if you want to read and update old versions of a preferences structure. |

*/P=pathName* Specifies the directory to look in for the file specified by *prefsFileName*.  
*pathName* is the name of an existing symbolic path. See **Symbolic Paths** on page II-22 for details.  
*/P=\$<empty string variable>* acts as if the */P* flag were omitted.

### Details

LoadPackagePreferences sets the following output variables:

*V\_flag* Set to 0 if no error occurred or to a nonzero error code.  
 If the preference file does not exist, *V\_flag* is set to zero so you must use *V\_bytesRead* to detect that case.

*V\_bytesRead* Set to the number of bytes read from the file. This will be zero if the preference file does not exist.

*V\_structSize* Set to the size in bytes of *prefsStruct*. This may be useful in handling structure version changes.

After calling LoadPackagePreferences if *V\_flag* is nonzero or *V\_bytesRead* is zero then you need to create default preferences as illustrated by the example referenced below.

*V\_bytesRead*, in conjunction with the */MIS* flag, makes it possible to check for and deal with old versions of a preferences structure as it loads the version field (typically the first field) of an older or newer version structure. However in most cases it is sufficient to omit the */MIS* flag and treat incompatible preference data the same as missing preference data.

### Example

See the example under **Saving Package Preferences in a Special-Format Binary File** on page IV-250.

### See Also

SavePackagePreferences.

## LoadPICT

**LoadPICT** [*flags*] [*fileNameStr*] [, *pictName*]

The LoadPICT operation loads a picture from a file or from the Clipboard into Igor. Once you have loaded a picture, you can append it to graphs and page layouts.

### Parameters

The file to be loaded is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

If you want to force a dialog to select the file, omit the *fileNameStr* parameter.

If *fileNameStr* is "Clipboard" and */P=pathName* is omitted, LoadPICT loads its data from the Clipboard rather than from a file.

*pictName* is the name that you want to give to the newly loaded picture. You can refer to the picture by its name to append it to graphs and page layouts. LoadPICT generates an error if the name conflicts with some other type of object (e.g., wave or variable) or if the name conflicts with a built-in name (e.g., the name of an operation or function).

If you omit *pictName*, LoadPICT automatically names the picture as explained in **Details**.

### Flags

*/M=promptStr* Specifies a prompt to use if LoadPICT needs to put up a dialog to find the file.

## LoadPICT

---

|                    |                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>/O</b>          | Overwrites an existing picture with the same name.<br>If /O is omitted and there is an existing picture with the same name, LoadPICT displays a dialog in which you can resolve the name conflict. |
| <b>/P=pathName</b> | Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.                                                                                            |
| <b>/Q</b>          | Quiet: suppresses the insertion of picture info into the history area.                                                                                                                             |
| <b>/Z</b>          | Doesn't load the picture, just checks for its existence.                                                                                                                                           |

### Details

If the picture file is not fully specified then LoadPICT presents a dialog from which you can select the file. "Fully specified" means that LoadPICT can determine the name of the file (from the *fileNameStr* parameter) and the folder containing the file (from the flag */P=pathName* flag or from the *fileNameStr* parameter). If you want to force a dialog, omit the *fileNameStr* parameter.

If you use */P=pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-22 for details.

If you omit *pictName*, LoadPICT automatically names the picture as follows:

If the picture was loaded from a file, LoadPICT uses the file name. If necessary, it makes it into a legal name by replacing illegal characters or shortening it.

Otherwise, LoadPICT uses a name of the form "PICT\_#".

If the resulting name is in conflict with an existing picture name, Igor puts up a name conflict resolution dialog.

LoadPICT sets the variable *V\_flag* to 1 if the picture exists and fits in available memory or to 0 otherwise.

It also sets the string variable *S\_info* to a semicolon-separated list of values:

| <b>Keyword</b> | <b>Information Following Keyword</b>                                                                                                                                          |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME           | Name of the loaded PICT, often "PICT_0", etc.                                                                                                                                 |
| SOURCE         | "Data fork" or "Clipboard".                                                                                                                                                   |
| RESOURCENAME   | Obsolete - always "".                                                                                                                                                         |
| RESOURCEID     | Obsolete - always 0.                                                                                                                                                          |

| BYTES          | Amount of memory used by the picture.                                                                                                                                         |
| WIDTH          | Width of the picture in pixels.                                                                                                                                               |

---

| Keyword    | Information Following Keyword             |
|------------|-------------------------------------------|
| HEIGHT     | Height of the picture in pixels.          |
| PHYSWIDTH  | Physical width of the picture in points.  |
| PHYSHEIGHT | Physical height of the picture in points. |

**See Also**

See **Pictures** on page III-509 for general information on how Igor handles pictures.

The **ImageLoad** operation for loading PICT and other image file types into waves, and the **PICTInfo** function.

## LoadWave

**LoadWave** [*flags*] [*fileNameStr*]

The LoadWave operation loads data from the named Igor binary, Igor text, delimited text, fixed field text, or general text file into waves. LoadWave can load 1D and 2D data from delimited text, fixed field text and general text files, or data of any dimensionality from Igor binary and Igor text files.

**Parameters**

The file to be loaded is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If LoadWave can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

If *fileNameStr* is "Clipboard" and */P=pathName* is omitted, LoadWave takes its data from the Clipboard rather than from a file. This is not implemented for binary loads.

If *fileNameStr* is omitted or is "", or if the */I* flag is used, LoadWave presents an Open File dialog from which you can choose the file to load.

**Flags**

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/A</i>               | "Auto-name and go" option (used with <i>/G</i> , <i>/F</i> or <i>/J</i> ).<br><br>This skips the dialog in which you normally enter wave names. Instead it automatically assigns names of the form <i>wave0</i> , <i>wave1</i> , choosing names that are not already in use. When used with <i>/W</i> , it reads wave names from the file instead of automatically assigning names and <i>/A</i> just skips the wave name dialog. The <i>/B</i> flag can also override names specified by <i>/A</i> . |
| <i>/A=baseName</i>      | Same as <i>/A</i> but it automatically assigns wave names of the form <i>baseName0</i> , <i>baseName1</i> .                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>/B=columnInfoStr</i> | Specifies the name, format, numeric type, and field width for columns in the file. See <b>Specifying Characteristics of Individual Columns</b> .                                                                                                                                                                                                                                                                                                                                                      |
| <i>/C</i>               | This is used in experiment recreation commands generated by Igor to force experiment recreation to continue if an error occurs in loading a wave.                                                                                                                                                                                                                                                                                                                                                     |
| <i>/D</i>               | Creates double precision waves. (Used with <i>/G</i> , <i>/F</i> or <i>/J</i> .) The <i>/B</i> flag can override the numeric precision specified by the <i>/D</i> flag.                                                                                                                                                                                                                                                                                                                               |
| <i>/E=editCmd</i>       | Controls table creation:<br><i>editCmd=1</i> : Makes a new table containing the loaded waves.<br><i>editCmd=2</i> : Appends the loaded waves to the top table. If no table exists, a new table is created.<br><i>editCmd=0</i> : Same as if <i>/E</i> had not been specified (loaded waves are not put in any table).                                                                                                                                                                                 |

`/ENCG=textEncoding`

`/ENCG={textEncoding, tecOptions}`

Specifies the text encoding of the plain text file being loaded.

This flag was added in Igor Pro 7.00.

This flag is ignored when loading an Igor binary wave file.

See **Text Encoding Names and Codes** on page III-492 for a list of accepted values for *textEncoding*.

For most purposes the default value for *tecOptions*, 3, is fine and you can use `/ENCG=textEncoding` instead of `/ENCG={textEncoding, tecOptions}`.

*tecOptions* is an optional bitwise parameter that controls text encoding conversion. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

*tecOptions* is defined as follows:

- Bit 0:        If cleared, the presence of null bytes causes LoadWave to consider the text invalid in all byte-oriented text encodings. This makes it easier for LoadWave to identify UTF-16 and UTF-32 text which usually contains null bytes.
- If set (default), null bytes are allowed in byte-oriented text encodings.
- Bit 1:        If cleared LoadWave does not validate text if the specified text encoding is UTF-8.
- If set (default), LoadWave validates text even if the text encoding is UTF-8.
- Bit 2:        If cleared (default) LoadWave validates the text in the specified text encoding except that validation for UTF-8 is skipped if bit 1 is cleared.
- If set, LoadWave assumes that the text is valid in the specified text encoding and does not validate it. Setting this bit makes LoadWave slightly faster but it is usually inconsequential.
- Bit 3:        If cleared (default), LoadWave presents the Choose Text Encoding dialog if the specified text encoding is not valid for the text in the file.
- If set, LoadWave does not present the Choose Text Encoding dialog if the text is not valid in the specified text encoding and instead returns an error. Set this bit if you are running an automated procedure and do not want it interrupted by a dialog.

See **LoadWave Text Encoding Issues** on page V-514 for further discussion.

`/F={numColumns, defaultFieldWidth, flags}`

Indicates that the file uses the fixed field file format. Most FORTRAN programs generate files in this format.

*numColumns* is the number of columns of data in the file.

*defaultFieldWidth* is the default number of bytes in each column. If the columns do not all have the same number of bytes, you need to use the `/B` flag to provide more information to LoadWave.

*flags* is a bitwise parameter that controls the conversion of text to values. The bits are defined as follows:

- Bit 0 :        If set, any field that consists entirely of the digit "9" is taken to be blank. A field that consists entirely of the digit "9" except for a leading "+" or "-" is also taken to be blank.

All other bits are reserved and must be cleared.

`/G`

Indicates that the file uses the general text format.

- /H** Loads the wave into the current experiment and severs the connection between the wave and the file. When the experiment is saved, the wave copy will be saved as part of the experiment. For a packed experiment this means it is saved in the packed experiment file. For an unpacked experiment this means it is saved in the experiment's home folder.
- See **Sharing Versus Copying Igor Binary Wave Files** on page II-147.
- /I** Forces LoadWave to display an Open File dialog even if the file is fully specified via */P* and *fileNameStr*.
- /J** Indicates that the file uses the delimited text format.
- /K=k** Controls how to determine whether a column in the file is numeric or text (only for delimited text and fixed field text files).
- k=0*: Deduces the nature of the column automatically.
- k=1*: Treats all columns as numeric.
- k=2*: Treats all columns as text.
- This flag as well as the ability to load text data into text waves were added in Igor Pro 3.0. The default for the LoadWave operation is */K=1*, meaning that it will treat all columns as numeric. We did this so that existing procedures would behave the same in Igor Pro 3.0 as before. Use */K=0* when you want to load text columns into text waves. */K=2* may have use in a text-processing application.
- For finer control, the */B* flag specifies the format of each column in the file individually.
- /L={nameLine, firstLine, numLines, firstColumn, numColumns}**
- Affects loading delimited text, fixed field text, and general text files only (*/J*, */F* or */G*). */L* is accepted no matter what the load type but is ignored for Igor binary and Igor text loads. Line and column numbers start from 0.
- nameLine* is the number of the line containing column names. For general text loads, 0 means auto. See **Loading General Text Files** on page II-138 for details.
- firstLine* is the number of the first line to load into a wave. For general text loads, 0 means auto. See **Loading General Text Files** on page II-138 for details.
- numLines* is the number of lines that should be treated as data. 0 means auto which loads until the end of the file or until the end of the block of data in general text files. The *numLines* parameter can also be used to make loading very large files more efficient. See **Loading Very Large Files**.
- firstColumn* is the number of the first column to load into a wave. This is useful for skipping columns.
- numColumns* is the number of columns to load into a wave. 0 means auto, which loads all columns.
- /M** Loads data as matrix wave. If */M* is used then it ignores the */W* flag (read wave names) and follows the */U* flags instead.
- The wave is autonamed unless you provide a specific wave name using the */B* flag.
- The type of the wave (numeric or text) is determined by an assessment of the type of the first loaded column unless you override this using the */K* flag or the */B* flag.
- See **The Load Waves Dialog for Delimited Text — 2D** on page II-133 for further information.
- /N** Same as */A* except that, instead of choosing names that are not in use, it overwrites existing waves.
- /N=baseName** Same as */N* except that it automatically assigns wave names of the form *baseName0*, *baseName1*.

*/O* Overwrite existing waves in case of a name conflict.

*/P=pathName* Specifies the folder to look in for *fileNameStr*. *pathName* is the name of an existing symbolic path.

*/Q* Suppresses the normal messages in the history area.

*/R={languageName, yearFormat, monthFormat, dayOfMonthFormat, dayOfWeekFormat, layoutStr, pivotYear}*

Specifies a custom date format for dates in the file. If the */R* flag is used, it overrides the date setting that is part of the */V* flag.

*languageName* controls the language used for the alphabetic date components, namely the month and the day-of-week. *languageName* is one of the following:

Default

|            |                   |         |           |
|------------|-------------------|---------|-----------|
| Chinese    | ChineseSimplified | Danish  | Dutch     |
| English    | Finnish           | French  | German    |
| Italian    | Japanese          | Korean  | Norwegian |
| Portuguese | Russian           | Spanish | Swedish   |

Default means the system language on Macintosh or the user default language on Windows.

*yearFormat* is one of the following codes:

- 1: Two digit year.
- 2: Four digit year.

*monthFormat* is one of the following codes:

- 1: Numeric, no leading zero.
- 2: Numeric with leading zero.
- 3: Abbreviated alphabetic (e.g., Jan).
- 4: Full alphabetic (e.g., January).

*dayOfMonthFormat* is one of the following codes:

- 1: Numeric, no leading zero.
- 2: Numeric with leading zero.

*dayOfWeekFormat* is one of the following codes:

- 1: Abbreviated alphabetic (e.g., Mon).
- 2: Full alphabetic (e.g., Monday).

*layoutStr* describes which components appear in the date in what order and what separators are used. *layoutStr* is constructed as follows (but with no line break):

```
"<component keyword><separator>
<component keyword><separator>
<component keyword><separator>
<component keyword>"
```

where *<component keyword>* is one of the following:

```
Year
Month
DayOfMonth
DayOfWeek
```

and *<separator>* is a string of zero to 15 bytes.

Starting from the end, parts of the layout string must be omitted if they are not used.

Extraneous spaces are not allowed in *layoutStr*. Each separator must be no longer than 15 bytes. No component can be used more than once. Some components may be used zero times.

*pivotYear* determines how LoadWave interprets two-digit years. If the year is specified using two digits, *yy*, and is less than *pivotYear* then the date is assumed to be 20*yy*. If the two digit year is greater than or equal to *pivotYear* then the year is assumed to be 19*yy*. *pivotYear* must be between 4 and 40.

See **Loading Custom Date Formats** on page V-510 for further discussion of date formats.

*/T* Indicates that the file uses the Igor text format.

Although LoadWave is generally thread-safe, it is not thread-safe to load an Igor text file containing an Igor command (e.g., "X <command>").

*/U={readRowLabels, rowPositionAction, readColLabels, colPositionAction}*

These parameters affect loading a matrix (*/M*) from a delimited text (*/J*) or a fixed field text (*/F*) file. They are accepted no matter what the load type is but are ignored when they don't apply.

If *readRowLabels* is nonzero, it reads the first column of data in the file as the row labels for the matrix wave.

*rowPositionAction* has one of the following values:

- 0: The file has no row position column.
- 1: Uses the row position column to set the row scaling of the matrix wave.
- 2: Creates a 1D wave containing the values in the row position column. The name of the 1D wave will be the same as the matrix wave but with the prefix "RP\_".

The *readColumnLabels* and *columnPositionAction* parameters have analogous meanings. The prefix used for the column position wave is "CP\_".

See Chapter II-9, **Importing and Exporting Data** for further details.

*/N={delimsStr, skipCharsStr, numConversionFlags, loadFlags}*

These parameters affect loading delimited text (*/J*) and fixed field text (*/F*) data and column names. They do not affect loading general text (*/G*). They are accepted no matter what the load type is but are ignored when they don't apply. These parameters should rarely be needed.

*delimsStr* is a string expression containing the characters that should act as delimiters for delimited file loads. (When loading data as general text, the delimiters are always tab, comma and space.) The default is "\t," for tab and comma. You can specify the space character as a delimiter, but it is always given the lowest priority behind any other delimiters contained in *delimsStr*. The low priority means that if a line of text contains any other delimiter besides the space character, then that delimiter is used rather than the space character.

*skipCharsStr* is a string expression containing characters that should always be treated as garbage and skipped when they appear before a number. The default is "\$" for space and dollar sign. This parameter should rarely be needed.

*numConversionFlags* is a bitwise parameter that controls the conversion of text to numbers. The bits are defined as follows:

- Bit 0: If set: dates are dd/mm/yy.  
If cleared: dates are mm/dd/yy.
- Bit 1: If set: decimal character is comma.  
If cleared: it is period.
- Bit 2: If set: thousands separators in numbers are ignored when loading delimited text only (LoadWave/J).

The thousands separator is the comma in 1,234 or, if comma is the decimal character, the dot in 1.234.

Most numeric data files do not use thousands separators and searching for them slows loading down so this bit should usually be 0.

This bit has no effect if the thousands separator (e.g., comma) is also a delimiter character as specified by *delimsStr*.

All other bits are reserved and must be cleared.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

If the /R flag is used to specify the date format, this overrides the setting of bit 0.

*loadFlags* is a bitwise parameter that controls the overall load. The bits are defined as follows:

- Bit 0: If set, ignores blanks at the end of a column. This is appropriate if the file contains columns of unequal length. Set *loadFlags* = 1 to set bit 0.
- Bit 1: If set, when the /W flag is specified and the line containing column labels starts with one or more space characters, the spaces are taken to be a blank column name. The resulting column will be named Blank. Use this if both the line containing column labels and the lines containing data start with leading spaces in a space-delimited file. Set *loadFlags* = 2 to set bit 1.
- Bit 2: If set: Disables pre-counting of lines of data. See **Loading Very Large Files** below.
- Bit 3: If set: Disables unescaping of backslash characters in text columns. See **Escape Sequences** below.
- Bit 4: If set: Disables support for quoted strings.

Setting this bit improves compatibility with Igor7. It applies to delimited text only and should rarely be needed. See **Quoted Strings in Delimited Text Files** on page II-135 and **Delimited Text Compatibility With Igor7** on page II-136 for background information.

/W Looks for wave names in a file. (With /G, /F, and /J.)

LoadWave cleans up column names to create standard, not liberal, wave names. See **Object Names** on page III-503 and **CleanupName** for details.

Use /W/A to read wave names from the file and then continue the load without displaying the normal wave name dialog.

### Details

Without the /G, /F, /J, or /T flags, LoadWave loads Igor binary wave files.

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-22 for details.

When loading a general text file, the delimiters are always tab, comma and space.

### Loading Custom Date Formats

Here are some examples showing custom date formats and how you would specify them using the /R flag:

| Date Format      | Specification                                          |
|------------------|--------------------------------------------------------|
| October 11, 1999 | /R={English, 2, 4, 1, 1, "Month DayOfMonth, Year", 40} |
| Oct 11, 1999     | /R={English, 2, 3, 1, 1, "Month DayOfMonth, Year", 40} |
| 11 October 1999  | /R={English, 2, 4, 1, 1, "DayOfMonth Month Year", 40}  |
| 11 Oct 1999      | /R={English, 2, 3, 1, 1, "DayOfMonth Month Year", 40}  |
| 10/11/99         | /R={English, 1, 2, 1, 1, "Month/DayOfMonth/Year", 40}  |
| 11-10-99         | /R={English, 1, 2, 2, 1, "DayOfMonth-Month-Year", 40}  |
| 11-Jun-99        | /R={English, 1, 3, 2, 1, "DayOfMonth-Month-Year", 40}  |
| 991011           | /R={English, 1, 2, 2, 1, "YearMonthDayOfMonth", 40}    |
| 19991011         | /R={English, 2, 2, 2, 1, "YearMonthDayOfMonth", 40}    |

When loading data as delimited text, if you use a date format containing a comma, such as "October 11, 1999", you must use the /V flag to make sure that LoadWave will not treat the comma as a delimiter.

When loading a date format that consists entirely of digits, such as 991011, you must use the LoadWave/B to specify that the data is a date. Otherwise, LoadWave will treat it as a regular number.

### Loading Very Large Files

The number of waves (columns) or points (rows) that LoadWave can handle when loading a text file is limited only by available memory.

You can improve the speed and efficiency of loading very large files (i.e., more than 50,000 lines of data) using the *numLines* parameter of the /L flag. Normally this parameter is used to load a section of the file instead of the whole file. However, in delimited, general text and fixed field text loads, the *numLines* parameter also specifies how many rows the waves should initially have. Thus all of the required memory is allocated at the start of the load, rather than increasing the number of wave rows over and over as more lines of data are loaded. When loading very large files, if you know the exact number of lines of data in the file, use the *numLines* parameter of the /L flag. If you don't know the exact number of lines, you can provide a number that is guaranteed to be larger.

If you omit the /L flag or if the *numLines* parameter is zero, and if you are loading a file greater than 500,000 bytes, LoadWave automatically counts the lines of data in the file so that the entire wave can be allocated before data loading starts. This acts as if you used /L and set *numLines* to the exact correct value which normally speeds the loading process considerably. You can disable this feature by using the /V flag and setting bit 2 of the *loadFlags* parameter to 1.

### Escape Sequences

An escape sequence is a two-character sequence used to represent special characters in plain text. Escape sequences are introduced by a backslash character.

By default, in a text column, LoadWave interprets the following escape sequences: \t (tab), \n (linefeed), \r (carriage-return), \\ (backslash), \" (double-quote) and \' (single-quote). This works well with Igor's **Save** operation which uses escape sequences to encode the first four of these characters.

If you are loading a file that does not use escape sequences but which does contain backslashes, you can disable interpretation of these escape sequences by setting bit 3 of the *loadFlags* parameter of the /V flag. This is mainly of use for loading a text file that contains unescaped Windows file system paths.

### Generating Wave Names

The /N flag automatically names new waves "wave" (or *baseName* if *=baseName* is used) plus a digit. The digit starts from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten.

The /A flag is like /N except that it skips names already in use.

## Specifying Characteristics of Individual Columns

The `/B=columnInfoStr` flag provides information to LoadWave for each column in a delimited text (`/J`), fixed field text (`/F`) or general text (`/G`) file. The flag overrides LoadWave's normal behavior. In most cases, you will not need to use it.

`columnInfoStr` is constructed as follows:

```
"<column info>;<column info>; ... ;<column info>";
```

where `<column info>` consists of one or more of the following:

- C=<number>**      The number of columns controlled by this column info specification. `<number>` is an integer greater than or equal to one.
- F=<format>**      A code that specifies the data type of the column or columns. `<format>` is an integer from -2 to 10. The meaning of the `<format>` is:
- 2:      Text. The column will be loaded into a text wave.
  - 1:      Format unknown. It will deduce the format.
  - 0 to 5:    Numeric.
  - 6:      Date.
  - 7:      Time.
  - 8:      Date/Time.
  - 9:      Octal number.
  - 10:     Hexadecimal number.
- The `F=` flag is used for delimited text and fixed field text files only. It is ignored for general text files.
- N=<name>**      A name to use for the column. `<name>` can be a standard name (e.g., `wave0`) or a quoted liberal name (e.g., `'Heart Rate'`). If `<name>` is `'_skip_'` (including single quotation marks) then LoadWave will skip the column.
- The `N=` flag works for delimited text, fixed field text and general text files.
- T=<numtype>**    A number that specifies what the numeric type for the column should be. This flag overrides the `LoadWave/D` flag. It has no effect on columns whose format is text. `<numtype>` must be one of the following:
- 2:      32-bit float.
  - 4:      64-bit float.
  - 8:      8-bit signed integer.
  - 16:     16-bit signed integer.
  - 32:     32-bit signed integer.
  - 72:     8-bit unsigned integer.
  - 80:     16-bit unsigned integer.
  - 96:     32-bit unsigned integer.
- W=<width>**      The column field width for fixed field files. `<width>` is an integer greater than or equal to one. Fixed width files are FORTRAN-style files in which a fixed number of bytes is allocated for each column and spaces are used as padding.
- The `W=` flag is used for fixed field text only.

Here is an example of the `/B=columnInfoStr` flag:

```
/B="C=1,F=-2,T=2,W=20,N=Factory; C=1,F=6,W=16,T=4,N=MfgDate;
C=1,F=0,W=16,T=2,N=TotalUnits; C=1,F=0,W=16,T=2,N=DefectiveUnits; "
```

This example is shown on two lines but in a real command it would be on a single line. In a procedure, it could be written as:

```
String columnInfoStr = "
columnInfoStr += "C=1,F=-2,T=2,W=20,N=Factory; "
columnInfoStr += "C=1,F=6,T=4,W=16,N=MfgDate; "
```

```
columnInfoStr += "C=1,F=0,T=2,W=16,N=TotalUnits;"
columnInfoStr += "C=1,F=0,T=2,W=16,N=DefectiveUnits;"
```

Note that each flag inside the quoted string ends with either a comma or a semicolon. The comma separates one flag from the next within a particular column info specification. The semicolon marks the end of a column info specification. The trailing semicolon is required. Spaces and tabs are permitted within the string.

This example provides information about a file containing four columns.

The first column info specification is "C=1;F=-2,T=2,W=20,N=Factory;". This indicates that the specification applies to one column, that the column format is text, that the numeric format is single-precision floating point (but this has no effect on text columns), that the column data is in a fixed field width of 20 bytes, and that the wave created for this column is to be named Factory.

The second column info specification is "C=1;F=6,T=4,W=16,N=MfgDate;". This indicates that the specification applies to one column, that the column format is date, that the numeric format is double-precision floating point (double precision should always be used for dates), that the column data is in a fixed field width of 16 bytes, and that the wave created for this column is to be named MfgDate.

The third column info specification is "C=1;F=0,T=2,W=16,N=TotalUnits;". This indicates that the specification applies to one column, that the column format is numeric, that the numeric format is single-precision floating point, that the column data is in a fixed field width of 16 bytes, and that the wave created for this column is to be named TotalUnits.

The fourth column info specification is the same as the third except that the wave name is DefectiveUnits.

All of the items in a column specification are optional. The default value for each item in the column info specification is as follows:

|             |                                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| C=<number>  | C=1. Specifies that the column info describes one column.                                                                                                                  |
| F=<format>  | F=-1. Determines the format as dictated by the /K flag. If /K=0 is used, LoadWave will automatically determine the column format.                                          |
| N=<name>    | N=_auto_. Generates the wave name as it would if the /B flag were omitted.                                                                                                 |
| T=<numtype> | Defaults to T=4 (double precision) if the LoadWave/D flag is used or to T=2 (single precision) if the /D flag is omitted.                                                  |
| W=<width>   | W=0. For a fixed width file, LoadWave will use the default field width specified by the /F flag unless you provide an explicit field width greater than 0 using W=<width>. |

Taking advantage of the default values, we could abbreviate the example as follows:

```
/B="F=-2,W=20,N=Factory; F=6,T=4,W=16,N=MfgDate;
W=16,N=TotalUnits; W=16,N=DefectiveUnits;"
```

If the file were not a fixed field text file, we would omit the W= flag and the example would become:

```
/B="F=-2,N=Factory;F=6,T=4,N=MfgDate;N=TotalUnits;N=DefectiveUnits;"
```

Here are some more examples and discussion that illustrate the use of the /B=*columnInfoStr* flag.

In this example, the /B flag is used solely to specify the name to use for the waves created from the columns in the file:

```
/B="N=WaveLength; N=Absorbance;"
```

The wave names in the previous example are standard names. If you want to use liberal names, such as names containing spaces or dots, you must use single quotes. For example:

```
/B="N='Wave Number'; N='Reflection Angle';"
```

The name that you specify via N= can not be used if overwrite is off and there is already a wave with this name or if the name conflicts with a macro, function or operation or variable. In these cases, LoadWave generates a unique name by adding one or more digits to the name specified by the N= flag for the column in question. You can avoid the problem of a conflict with another wave name by using the overwrite (/O) flag or by loading your data into a newly-created data folder. You can minimize the likelihood of a name conflict with a function, operation or variable by avoiding vague names.

If you specify the same name in two N= flags, LoadWave will generate an error, so make sure that the names are unique.

Except if the specified name is '\_skip\_', the N= flag generates a name for one column only, even if the C= flag is used to specify multiple columns. Consider this example:

## LoadWave

---

```
/B="C=10,N=Test;"
```

This ostensibly uses the name Test for 10 columns. However, wave names must be unique, so LoadWave will not do this. It will use the name Test for just the first column and the other columns will receive default names.

You can load a subset of the columns in the file using the /L flag. Even if you do this, the column info specifications that you provide via the /B flag start from the first column in the file, not from the first column to be loaded. For example, if you are using /L to skip columns 0 and 1, you must skip columns 0 and 1 in the column info specification, like this:

```
// Skip column 0 and 1 and name the successive columns
/L={0,0,0,2,0} /B="C=2;N=Column2;N=Column3;"
```

The "C=2;" part accepts default specifications for columns 0 and 1 and the subsequent specifications apply to subsequent columns.

You can achieve the same thing using /B without /L, like this:

```
/B="C=2,N='_skip_';N=Column2;N=Column3;"
```

Also, when loading data into a matrix wave, LoadWave uses only one name. If you specify more than one name, only the first is used. If you are loading data into a matrix and also skipping columns, the explanation above about skipping applies.

In this example, the /B flag solely specifies the format of each column in the file. The file in question starts with a text column, followed by a date column, followed by 3 numeric columns.

```
/B="F=-2; F=6; C=3,F=0"
```

In most cases, it is not necessary to use the F= flag because LoadWave can automatically deduce the formats. The flag is useful for those cases where it deduces the column formats incorrectly. It is also useful to force LoadWave to interpret a column as octal or hexadecimal because LoadWave can not automatically deduce these formats.

The numeric codes (0...10) used by the F= flag are the same as the codes used by the ModifyTable operation. If you create a table using the /E flag, the F= flag controls the numeric format of table columns.

The code -1 is not a real column format code. If you use F=-1 for a particular column, LoadWave will deduce the format for that column from the column text.

In this example, the /B flag is used solely to specify the width of each column in a fixed field file. This file contains a 20 byte column followed by ten 16 byte columns followed by three 24 byte columns.

```
/B="C=1,W=20; C=10,W=16; C=3,W=24"
```

The field widths specified via W= override the default field width specified by the /F flag. If all of the columns in the file have the same field width then you can use just the /F flag.

You can load a subset of the columns in the file using the /L flag. Even if you do this, the column info specifications that you provide via the /B flag start from the first column in the file, not from the first column to be loaded.

### LoadWave Text Encoding Issues

This section discusses text encoding issues of interest to advanced users. It assumes that you are familiar with the general topic of text encodings as explained under **Text Encodings** on page III-461.

Since Igor stores all text internally as UTF-8, it must convert text read from a file from the source text encoding to UTF-8. In order to do this it needs to know the source text encoding.

When loading an Igor binary wave file LoadWave ignores the /ENCG=*textEncoding* flag. The loaded wave's text encoding is determined as described under **LoadWave Text Encodings for Igor Binary Wave Files** on page III-477. The rest of this section applied to loading data from plain text files, not from Igor binary wave files.

When loading a text data file you can use the /ENCG=*textEncoding* flag to tell Igor what that text encoding is. See **Text Encoding Names and Codes** on page III-492 for a list of accepted values for *textEncoding*.

LoadWave uses the text encoding specified by /ENCG and the rules described under **Determining the Text Encoding for a Plain Text File** on page III-469 to determine the source text encoding for conversion of the text file's data to UTF-8. If you omit /ENCG or specify /ENCG=0, the specified text encoding is unknown and does not factor into the determination of the source text encoding. If following the rules does not identify a text encoding that works for converting the file's text to UTF-8, Igor displays the Choose Text Encoding dialog.

If the file contains nothing but ASCII characters, as is often the case, then any byte-oriented text encoding will work and there is no need to use the `/ENCG` flag.

When you are loading a huge file (e.g., hundreds of megabytes), finding a valid source text encoding may add a noticeable amount to the time it takes to load the file. If you know that the file is either all ASCII or is valid UTF-8, you can tell LoadWave to skip text encoding conversion altogether using an optional parameter, like this:

```
/ENCG={1,4}
```

"1" tells LoadWave that the text is valid as UTF-8, meaning that it is all ASCII or, if it contains non-ASCII characters, they are properly encoded as UTF-8.

"4" tells LoadWave to assume that the text is valid as UTF-8 and skip all validation and conversion.

In testing with a 200 MB delimited text file containing 1 million rows and 20 columns, we found that using `/ENCG={1,4}` saved about 10% of the time.

**NOTE:** If you use this flag but the file is not valid UTF-8 and you are loading data into text wave, the text waves will wind up with invalid data which will result in errors when you use the waves later.

As noted above, if following the rules does not identify a text encoding that works for converting the file's text to UTF-8, Igor displays the Choose Text encoding dialog. If you are loading many files using an unattended, automated procedure, displaying this dialog will cause your procedure to grind to a halt. You can prevent this by using another optional flag, like this:

```
/ENCG={1,8}
```

If you use this flag and LoadWave can not determine the source text encoding for a file, it will return an error. If you want your procedure to continue with other files you must check for and handle the error using **GetRTError** on page V-310.

### Output Variables

LoadWave sets the following variables:

|                          |                                                        |
|--------------------------|--------------------------------------------------------|
| <code>V_flag</code>      | Number of waves loaded.                                |
| <code>S_fileName</code>  | Name of the file being loaded.                         |
| <code>S_path</code>      | File system path to the folder containing the file.    |
| <code>S_waveNames</code> | Semicolon-separated list of the names of loaded waves. |

`S_path` uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon. If LoadWave is loading from the Clipboard, `S_path` is set to "".

When LoadWave presents an Open File dialog and the user cancels, `V_flag` is set to 0 and `S_fileName` is set to "".

### See Also

The **ImageLoad** operation.

See **Importing Data** on page II-126 for further information on loading waves, including loading multidimensional data from HDF, PICT, TIFF and other graphics files. Check the "More Extensions:File Loaders" folder other file-loader extensions.

**Setting Bit Parameters** on page IV-12 for further details about bit settings.

## Loess

```
Loess [flags] srcWave = srcWaveName [, factors = factorWaveName1
[, factorWaveName2 ...]
```

The Loess operation smooths `srcWaveName` using locally-weighted regression smoothing. This algorithm is sometimes classified as a "nonparametric regression" procedure. The regression can be constant, linear, or quadratic. A robust option that ignores outliers is available. See **Basic Algorithm**, **Robust Algorithm**, and **References** for additional details and terminology.

This implementation works with waveforms, XY pairs of waves, false-color images, matrix surfaces, and multivariate data (one dependent data wave with multiple independent variable data waves).

Unlike the **FilterFIR** operation, Loess discards any NaN input values and will not generate a result that is wholly NaN.

**Parameters**

*srcWaveName* is the input data to be smoothed. It may be a one-dimensional or a two-dimensional wave, and it may contain NaNs.

When no /DEST flag is specified, Loess will overwrite *srcWaveName* with the smoothed result.

If *srcWaveName* is one-dimensional and no factors are provided, X values are derived from the X scaling of *srcWaveName*.

If *srcWaveName* is two-dimensional, the factors keyword is not permitted and the X and Y values are derived from the X and Y scaling of *srcWaveName*.

Higher dimensions of *srcWaveName* are not supported.

The optional factors parameter(s) provide the independent variable value(s) that correspond to the observed value in *srcWaveName*.

**Note:** Cleveland et al. (1992) use the term “multiple factors” instead of “multivariate”, hence the keyword name “factors” is used to denote these waves.

Use one factors wave when *srcWaveName* is the one-dimensional Y wave of an XY data pair:

*srcWaveName*[i] = someFunction(*factorWaveName1*[i])

Use multiple factors waves when *srcWaveName* contains the values of a multivariate function.

“Multivariate” means that *srcWaveName* contains the observed results of a process that combines multiple independent input variables:

*srcWaveName*[i] = someFunction(*factorWaveName1*[i], *factorWaveName2*[i], ...)

A maximum of 10 factors waves is supported.

All factors wave(s) must be numeric, noncomplex, one-dimensional and have the same number points as *srcWaveName*.

Any NaN values in *srcWaveName*[i], *factorWaveName1*[i], *factorWaveName2*[i], ... cause all corresponding values to be ignored. Factors waves may contain NaN values only when /DFCT is specified.

Loess does not support NaNs in any of *destFactorWaveName1*, *destFactorWaveName2*, ... and the results are undefined.

**Flags**

/CONF={*confInt*, *ciPlusWaveName* [,*ciMinusWaveName*]}

*confInt* specifies the confidence interval (a probability value from 0 to 1).  
*ciPlusWaveName* and the optional *ciMinusWaveName* are the names of new or overwritten output waves to hold the fitted value ± the confidence interval.

**Note:** /CONF uses large memory allocations, approximately N\*N\*8 bytes, where N is the number of points in *srcWaveName* (see **Memory Details**).

/DEST=*destWaveName* Specifies the name of the wave to hold the smoothed data. It creates *destWaveName* if it does not already exist or overwrites it if it does. The x (and possibly y) scaling of *destWave* determines the independent (factor) coordinates unless /DFCT={*destFactorWaveName1* [,*destFactorWaveName2*...]} is also specified.

/DFCT Specifies that the /DEST wave's x (and possibly y) scaling determines the independent (factor) coordinates at which to compute the smoothed data.

/DFCT={*destFactorWaveName1* [,*destFactorWaveName2*...]}

Specifies the names of one-dimensional waves providing the independent coordinates at which to compute the smoothed data.

If `/DFCT={...}` is used, the same number of waves must be specified for `/DFCT` and for factors = `{factorWaveName1 [, factorWaveName2...]}`, though their lengths may (and usually will) be different. The length of `destFactorWaveName` waves must be the same as that of the `destWaveName` wave.

All destination factor waves must be numeric, noncomplex, and one-dimensional. The number of destination factor waves must match the number of source factor waves (if specified), or match the dimensionality of `srcWaveName` (one destination factor wave if `srcWaveName` is one-dimensional, two destination factors waves if `srcWaveName` is two-dimensional.)

The values in the destination factor waves may not be NaN.

`/E=extrapolate`

Set `extrapolate` to nonzero to use a slower fitting method that computes values beyond the domain defined by the source factors. This is the “surface” parameter named “direct” in Cleveland et al. (1992). The default is `extrapolate = 0`, which uses the “interpolate” surface parameter, instead.

`/N=neighbors`

Specifies the number of values in the smoothing window.

If `neighbors` is even, the next larger odd number is used. When `neighbors` is less than two, no smoothing is done.

The default is  $0.5 * \text{numpts}(\text{srcWaveName})$  rounded up to the next odd integer or 3, whichever is larger.

Use either `/N` or `/SMTH`, but not both.

`/NORM [=norm]`

Set `norm` to 0 when specifying multiple factors and they all have the same scale and meaning, for example multiple factors all in units of meters.

The default is `norm = 1`, which normalizes each factor independently when computing the weighting function. This is appropriate when the factors are not dimensionally related, for example one factor measures wavelength and another measures temperature.

`/ORD=order`

Specifies the regression (fitting) order, the  $d$  parameter in Cleveland (1979):

`order=0`: Fits a constant to the locally-weighted neighbors around each point.

`order=1`: Fits a line to the locally-weighted neighbors around each point (Lowess smoothing).

`order=2`: Default; fits a quadratic (Loess smoothing).

`/PASS=passes`

The number of iterations of local weighting and regression fitting performed. The minimum is 1 and the default is 4. The `passes` parameter corresponds to the  $t$  parameter in Cleveland (1979).

`/R [=robust]`

Set `robust` to nonzero to use a robust fitting method that uses a bisquare weight function instead of the normal tricube weight function. This corresponds to the “symmetric” family in Cleveland et al. (1992). The robust method is less affected by outliers. The default is `robust = 0`, which is the “gaussian” family in Cleveland et al. (1992).

`/SMTH=sf`

Another way to express the number of values in the smoothing window,  $0 \leq sf \leq 1$ . The default is 0.5.

To compute `neighbors` from `sf`, use:

`neighbors = 1 + floor(sf * numpts(srcWaveName))`.

Use either `/N` or `/SMTH`, but not both.

- /TIME=secs*                      *secs* is the number of seconds allowed to complete the calculation before either warning (default) or stopping.
- If the stop bit (4) of */V=verbose* is set, the calculation stops after the allotted time. If the diagnostic bit of */V=verbose* is also set, warnings about the calculation exceeding the allotted time are printed to the history area.
- As an example, use */TIME=30/V=6* to abort calculations longer than 30 seconds and print the warning to the history area.
- /V [=verbose]*                      Controls how much information to print to the history area. *verbose* is a bitwise parameter with each bit controlling one aspect:
- verbose=0*:    Prints nothing to the history area (default).
  - verbose=1*:    Prints the number of observations, equivalent number of parameters, and residual standard error.
  - verbose=2*:    Prints diagnostic information and error messages.
  - verbose=4*    Use with */TIME*. If this bit is set, calculations that exceed *secs* seconds are aborted.
- Set *verbose* to 6 to both limit the time and print diagnostic and error messages.
- /V* alone is the same as */V=3*, which prints all information.
- S\_info* contains all the informational messages regardless of the value of
- /Z[=z]*                              Set *z* to nonzero to prevent an error from stopping execution. Use the *V\_flag* variable to see if the smoothing succeeded.

**Basic Algorithm**

The basic locally-weighted regression algorithm fits a constant, line, or quadratic to each point of the source data, using data that falls within the given span of neighbors over the factor data. Data outside of the span is ignored (given a weight of zero), and data inside the span is given a weight that depends on the distance of the data from the point being evaluated: data closer to the point being evaluated have higher weights and have a greater affect on the fit.

The basic algorithm uses the “tricube” weighting function to emphasize near values and deemphasize far values. For the one-factor case (simple XY data), the weighting function can be expressed as:

$$w_i = \left( 1 - \left| \frac{x - x_i}{\max_q (x - x_i)} \right|^3 \right)^3,$$

where  $\max_q (x - x_i)$  is the maximum Euclidean distance of the q factor values within the given span from the factor point (x) whose observation (y) value is being evaluated.

The weights are applied to the factor values in the span to compute the constant, linear, or quadratic regression at x.

When multiple factors are used, the Euclidean distance is computed using one dimension per factor. The default is to normalize each factor’s range by the standard deviation of that factor’s values before computing the Euclidean distances. When factors are dimensionally equal, use the */NORM=0* option to skip this normalization. (See */NORM*, about “dimensionally equal”.)

**Robust Algorithm**

The robust algorithm adds to the basic algorithm a method to identify and remove outliers by rejecting values that exceed a threshold related to the “median absolute deviation” of the basic regression’s residuals. The remaining values are used to compute robust “bisquare” weighting values:

$$r_i = \begin{cases} \left( 1 - \left| \frac{e_i}{6 \cdot \text{median}(|e_i|)} \right|^2 \right)^2 & \text{for } 0 \leq |e_i| < 6 \cdot \text{median}(|e_i|) \\ 0 & \text{for } |e_i| > 6 \cdot \text{median}(|e_i|) \end{cases}$$

where  $e_i$  is the difference between the observed value and the regression's fitted value, and  $\text{median}(|e_i|)$  is evaluated for all the observed values.

These robust weighting values are multiplied with the original weighting values and a new regression (with new residuals) is computed. This process repeats 4 times by default. Use the /PASS flag to specify a different number of repetitions.

### Details

Loess sets the variable `V_flag` to 0 if the smoothing was successful, or to an error code if not. Unlike other operations, the /Z flag allows execution to continue even if input parameters are in error.

Information printed to the history area when /V is set is always stored in the `S_info` string, even if /V=0 (the default). `S_Info` also contains the error message text if `V_flag` is an error code.

The error messages are described in Cleveland et al. (1992). They are often more dire than they seem.

The error message "Span too small. Fewer data values than degrees of freedom" usually means that the /SMTH or /N values are too small. The error code returned in `V_Flag` for this case is 1106.

The "Extrapolation not allowed with blending" (`V_Flag` = 1115) error usually means that the destination factors are trying to compute observations outside of the source factors domain without specifying /E=1. This happens if the /DEST *destWaveName* already exists and has X scaling that extends beyond the X scaling of *srcWaveName*. The solution is either kill the /DEST wave, limit the X scaling to the domain of the source wave, or use /E=1.

### Memory Details

Loess requires a lot of memory, especially with the /CONF flag. Even without /CONF, the memory allocations exceed this approximation:

Number of bytes allocated = number of points in *srcWaveName* \* 216

With /CONF, Loess can allocate large amounts of memory, approximately  $N*N*8$  bytes, where N is the number of points in *srcWaveName*. The 2GB memory limit of 32-bit addressing limits *srcWaveName* to approximately 10,000 points when using /CONF.

More precisely, the memory allocation may be approximated by this function:

```
Function ComputeLoessMemory(srcPoints, numFactorsWaves, doConfidence)
 Variable srcPoints // number of points in srcWave, aka N
 Variable numFactorsWaves // 1 or number of factors (independent variables)
 Variable doConfidence // true if /CONF is specified

 Variable doubles= 9 * srcPoints // 9 allocated double arrays
 doubles += 5 * numFactorsWaves * srcPoints // 5 more arrays
 doubles += (1+numFactorsWaves) * srcPoints // another array
 doubles += (1+numFactorsWaves) * srcPoints // another array
 doubles += (4+5) * srcPoints // two more arrays
 if(doConfidence)
 doubles += srcPoints*srcPoints // one HUGE array
 endif
 Variable bytes= doubles * 8
 return bytes
End

Macro DemoLoessMemory()
 Make/O wSrcPoints={10,100,1000,2000,3000,5000,7500,10000,12500,15000,20000}
 Duplicate/O wSrcPoints, loessMemory, loessMemory3, loessMemoryConf
 SetScale d, 0,0, "Points", wSrcPoints
 SetScale d, 0,0, "Bytes", loessMemory, loessMemory3, loessMemoryConf
 loessMemory= ComputeLoessMemory(wSrcPoints[p],1, 0) // 1 factor (X) no /CONF
```

```

loessMemory3= ComputeLoessMemory(wSrcPoints[p],3, 0)// 3 factors (X,Y,Z) no /CONF
loessMemoryConf= ComputeLoessMemory(wSrcPoints[p],1, 1)// 1 factor (X)with /CONF

```

### Examples

1-D, factors are X scaling, output in new wave:

```

Make/O/N=200 wv=2*sin(x/8)+gnoise(1)
KillWaves/Z smoothed // ensure Loess creates a new wave
Loess/DEST=smoothed srcWave=wv // 21-point loess.
Display wv; ModifyGraph mode=3,marker=19
AppendtoGraph smoothed; ModifyGraph rgb(smoothed)=(0,0,65535)

```

1-D, output in existing wave with more points than original data:

```

Make/O/N=100 short=2*cos(x/4)+gnoise(1)
Make/O/N=300 out; SetScale/I x, 0, 99, "" out // same X range
Loess/DEST=out/DFCT/N=30 srcWave=short
Display short; ModifyGraph mode=3,marker=19
AppendtoGraph out
ModifyGraph rgb(out)=(0,0,65535),mode(out)=2,lsize(out)=2

```

1-D Y vs X wave data interpolated to waveform (Y vs X scaling) with 99% confidence interval outputs:

```

// NOx = f(EquivRatio)
// Y wave
// Note: The next 2 Make commands are wrapped to fit on the page.
Make/O/D NOx = {4.818, 2.849, 3.275, 4.691, 4.255, 5.064, 2.118, 4.602, 2.286, 0.97,
3.965, 5.344, 3.834, 1.99, 5.199, 5.283, 3.752, 0.537, 1.64, 5.055, 4.937, 1.561};

// X wave (Note that the X wave is not sorted)
Make/O/D EquivRatio = {0.831, 1.045, 1.021, 0.97, 0.825, 0.891, 0.71, 0.801, 1.074,
1.148, 1, 0.928, 0.767, 0.701, 0.807, 0.902, 0.997, 1.224, 1.089, 0.973, 0.98, 0.665};

// Interpolate to dense waveform over X range
Make/O/D/N=100 fittedNOx
WaveStats/Q EquivRatio
SetScale/I x, V_Min, V_Max, "", fittedNOx
Loess/CONF={0.99,cp,cm}/DEST=fittedNOx/DFCT/SMTH=(2/3) srcWave=NOx, factors={EquivRatio}
Display NOx vs EquivRatio; ModifyGraph mode=3,marker=19
AppendtoGraph fittedNOx, cp,cm // fit and confidence intervals
ModifyGraph rgb(fittedNOx)=(0,0,65535)
ModifyGraph mode(fittedNOx)=2,lsize(fittedNOx)=2

```

Interpolate X, Y, Z waves as a 3D surface.

```

// Note: The next 3 Make commands are wrapped to fit on the page.

## log

### log (num)

The log function returns the log base 10 of *num*.

It returns -INF if *num* is 0, and returns NaN if *num* is less than 0.

To compute a logarithm base n use the formula:

$$\log_n(x) = \frac{\log(x)}{\log(n)}.$$

### See Also

The **ln** function.

## logNormalNoise

### logNormalNoise (m, s)

The logNormalNoise function returns a pseudo-random value from the lognormal distribution function whose probability distribution function is

$$f(x, m, s) = \frac{1}{xs\sqrt{2\pi}} \exp\left\{-\frac{[\ln(x) - m]^2}{2s^2}\right\},$$

with a mean  $\exp\left(m + \frac{1}{2}s^2\right)$ ,

and variance  $\exp(2m^2 + s^2)[\exp(s^2) - 1]$ .

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable "random" numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

### LombPeriodogram

**LombPeriodogram** [*flags*] *srcTimeWave*, *srcAmpWave* [, *srcFreqWave* ]

The LombPeriodogram is used in spectral analysis of signal amplitudes specified by *srcAmpWave* which are sampled at possibly random sampling times given by *srcTimeWave*. The only assumption about the sampling times is that they are ordered from small to large time values. The periodogram is calculated for either a set of frequencies specified by *srcFreqWave* (slow method) or by the flags /FR and /NF (fast method). Unless you specify otherwise, the results of the operation are stored by default in W\_LombPeriodogram and W\_LombProb in the current data folder.

#### Flags

*/DESP=datafolderAndName*

Saves the computed P-values in a wave specified by *datafolderAndName*. The destination wave will be created or overwritten if it already exists. *dataFolderAndName* can include a full or partial path with the wave name.

Creates by default a wave reference for the destination wave in a user function. See **Automatic Creation of WAVE References** on page IV-71 for details.

If this flag is not specified, the operation saves the P-values in the wave W\_LombProb in the current data folder.

*/DEST=datafolderAndName*

Saves the computed periodogram in a wave specified by *datafolderAndName*. The destination wave will be created or overwritten if it already exists. *datafolderAndName* can include a full or partial path with the wave name (*/DEST=root:bar:destWave*).

Creates by default a wave reference for the destination wave in a user function. See **Automatic Creation of WAVE References** on page IV-71 for details.

If this wave is not specified the operation saves the resulting periodogram in the wave W\_LombPeriodogram in the current data folder.

*/FR=fRes*

Use /FR to specify the frequency resolution of the output. This flag is used together with /NF to specify the range of frequencies for which the periodogram is computed. Note that *fRes* is also the lowest frequency in the output.

*/NF=numFreq*

Use /NF to specify the number of frequencies at which the periodogram is computed. The range of frequencies of the periodogram is then [*fRes*, (*numFreq*-1)\**fRes*].

*/Q*

Quiet mode; suppresses printing results in the history area.

*/Z*

Do not report any errors.

#### Details

The LombPeriodogram (sometimes referred to as "Lomb-Scargle" periodogram) is useful in detection of periodicities in data. The main advantage of this approach over Fourier analysis is that the data are not required to be sampled at equal intervals. For an input consisting of N points this benefit comes at a cost of an  $O(N^2)$  computations which becomes prohibitive for large data sets. The operation provides the option of computing the periodogram at equally spaced (output) frequencies using /FR and /NF or at completely arbitrary set of frequencies specified by *srcFreqWave*. It turns out that when you use equally spaced output frequencies the calculation is more efficient because certain parts of the calculation can be factored.

The Lomb periodogram is given by

$$LP(\omega) = \frac{1}{2\sigma^2} \left\{ \frac{\left[ \sum_{i=0}^{N-1} (y_i - \bar{y}) \cos[\omega(t_i - \tau)] \right]^2}{\sum_{i=0}^{N-1} \cos^2[\omega(t_i - \tau)]} + \frac{\left[ \sum_{i=0}^{N-1} (y_i - \bar{y}) \sin[\omega(t_i - \tau)] \right]^2}{\sum_{i=0}^{N-1} \sin^2[\omega(t_i - \tau)]} \right\}$$

Here  $y_i$  is the  $i$ th point in *srcAmpWave*,  $t_i$  is the corresponding point in *srcTimeWave*,

$$\bar{y} = \frac{1}{N} \sum_{i=0}^{N-1} y_i,$$

$$\tan(2\omega\tau) = \frac{\sum_{i=0}^{N-1} \sin(2\omega t_i)}{\sum_{i=0}^{N-1} \cos(2\omega t_i)}.$$

and

$$p = 1 - \{1 - \exp[LP(w)]\}^{N_{ind}}.$$

In the absence of a Nyquist limit, the number of independent frequencies that you can compute can be estimated using:

$$N_{ind} = -6.362 + 1.193N + 0.00098N^2.$$

This expression was given by Horne and Baliunas derived from least square fitting.  $N_{ind}$  is used to compute the P-values as:

$$p = 1 - \{1 - \exp[LP(w)]\}^{N_{ind}}.$$

Note that you can invert the last expression to determine the value of  $LP(w)$  for any significance level.

**Noise Functions** on page III-390.

Chapter III-12, **Statistics** for a function and operation overview.

## LowerStr

### LowerStr(*str*)

The LowerStr function returns a string expression identical to *str* except that all upper-case ASCII characters are converted to lower-case.

### See Also

The **UpperStr** function.

## Macro

### Macro *macroName*( [*parameters*] ) [ :*macro type* ]

The Macro keyword introduces a macro. The macro will appear in the Macros menu unless the procedure file has an explicit Macros menu definition. See Chapter IV-4, **Macros** and **Macro Syntax** on page IV-118 for further information.

## MacroList

### MacroList(*matchStr*, *separatorStr*, *optionsStr*)

The MacroList function returns a string containing a list of the names of user-defined procedures that start with the Proc, Macro, or Window keywords that also satisfy certain criteria. Note that if the procedures need to be compiled, then MacroList may not list all of the procedures.

### Parameters

Only macros having names that match *matchStr* string are listed. See **WaveList** for examples.

*separatorStr* is appended to each macro name as the output string is generated. *separatorStr* is usually “;” for list processing (See **Processing Lists of Waves** on page IV-198 for details on list processing).

*optionsStr* is used to further qualify the macros. It is a string containing keyword-value pairs separated by commas. Available options are:

|                           |                                                                                                                                                                                                                                                                                                                   |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| KIND: <i>nk</i>           | Determines the kind of procedure returned.<br><i>nk</i> =1: List Proc procedures.<br><i>nk</i> =2: List Macro procedures.<br><i>nk</i> =4: List Window procedures.<br><br><i>nk</i> can be the sum of these values to match multiple procedure kinds. For example, use 3 to list both Proc and Macro procedures.  |
| NPARAMS: <i>np</i>        | Restricts the list to macros having exactly <i>np</i> parameters. Omitting this option lists macros having any number of parameters.                                                                                                                                                                              |
| SUBTYPE: <i>typeStr</i>   | Lists macros that have the type <i>typeStr</i> . That is, you could use ButtonControl as <i>typeStr</i> to list only macros that are action procedures for buttons.                                                                                                                                               |
| WIN: <i>windowNameStr</i> | Lists macros that are defined in the named procedure window. “Procedure” is the name of the built-in procedure window.<br><br><b>Note:</b> Because <i>optionsStr</i> keyword-value pairs are comma separated and procedure window names can have commas in them, the WIN: keyword must be the last one specified. |

**Examples**

To list all Macros with three parameters:

```
Print MacroList ("*", ";", "KIND:2,NPARAMS:3")
```

To list all Macro, Proc, and Window procedures in the main procedure window whose names start with b:

```
Print MacroList ("b*", ";", "WIN:Procedure")
```

**See Also**

The **DisplayProcedure** operation and the **FunctionList**, **OperationList**, **StringFromList**, and **WinList** functions.

For details on procedure subtypes, see **Procedure Subtypes** on page IV-204, as well as **Button**, **CheckBox**, **SetVariable**, and **PopupMenu**.

**magsqr****magsqr (z)**

The magsqr function returns the sum of the squares of the real and imaginary parts of the complex number *z*, that is, the magnitude squared.

**Examples**

Assume waveCmplx is complex and waveReal is real.

```
waveReal = sqrt(magsqr(waveCmplx))
```

sets each point of waveReal to the magnitude of the complex points in waveCmplx.

You may get unexpected results if the number of points in waveCmplx differs from the number of points in waveReal because of interpolation. See **Mismatched Waves** on page II-83 for details.

**See Also**

The **cabs** function.

WaveMetrics provides Igor Technical Note 006, "DSP Support Macros" which uses the magsqr function to compute the magnitude of FFT data, and Power Spectral Density with options such as windowing and segmenting. See the Technical Notes folder. Some of the techniques discussed there are available as Igor procedure files in the "WaveMetrics Procedures:Analysis:" folder.

**Make**

```
Make [flags] waveName [, waveName]...
```

```
Make [flags] waveName [= {n0, n1, ...}] ...
```

```
Make [flags] waveName [= {{n0, n1, ...}, {n0, n1, ...}, ...}] ...
```

The Make operation creates the named waves. Use braces to assign data values when creating the wave.

**Flags**

**/B** Makes 8-bit signed integer waves or unsigned waves if **/U** is present.

**/C** Makes complex waves.

**/D** Makes double precision waves.

**/DF** Wave holds data folder references.

See **Data Folder References** on page IV-78 for more discussion.

**/FREE[=*nm*]** Creates a free wave. Allowed only in functions and only if a simple name or wave reference structure field is specified.

See **Free Waves** on page IV-90 for further discussion.

If *nm* is present and non-zero, then *waveName* is used as the name for the free wave, overriding the default name **'\_free\_'**. The ability to specify the name of a free wave was added in Igor Pro 9.00 as a debugging aid - see **Free Wave Names** on page IV-94 and **Wave Tracking** on page IV-207 for details.

**/I** Makes 32-bit signed integer waves or unsigned waves if **/U** is present.

## Make

|                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/L</code>                                              | Makes 64-bit signed integer waves or unsigned waves if <code>/U</code> is present. Requires Igor Pro 7.00 or later.                                                                                                                                                                                                                                                                                                                 |
| <code>/N=<i>n</i></code>                                     | <i>n</i> is the number of points each wave will have. If <i>n</i> is an expression, it must be enclosed in parentheses: <code>Make/N=(myVar+1) aNewWave</code>                                                                                                                                                                                                                                                                      |
| <code>/N=(<i>n1</i>, <i>n2</i>, <i>n3</i>, <i>n4</i>)</code> | <i>n1</i> , <i>n2</i> , <i>n3</i> , <i>n4</i> specify the number of rows, columns, layers and chunks each wave will have. Trailing zeros can be omitted (e.g., <code>/N=(<i>n1</i>, <i>n2</i>, 0, 0)</code> can be abbreviated as <code>/N=(<i>n1</i>, <i>n2</i>)</code> ).                                                                                                                                                         |
| <code>/O</code>                                              | Overwrites existing waves in case of a name conflict. After an overwrite, you cannot rely on the contents of the waves and you will need to reinitialize them or to assign appropriate values.                                                                                                                                                                                                                                      |
| <code>/R</code>                                              | Makes real value waves (default).                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>/T</code>                                              | Makes text waves.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>/T=<i>size</i></code>                                  | Makes text waves with pre-allocated storage.<br><i>size</i> is the number of bytes preallocated by Igor for each element in each text wave. The waves are not initialized - it is up to you to initialize them.<br>Preallocation can dramatically speed up text wave assignment when the wave has a very large number of points but only when all strings assigned to the wave are exactly the same size as the preallocation size. |
| <code>/U</code>                                              | Makes unsigned Integer waves.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>/W</code>                                              | Makes 16-bit signed integer waves or unsigned waves if <code>/U</code> is present.                                                                                                                                                                                                                                                                                                                                                  |
| <code>/WAVE</code>                                           | Wave holds wave references.<br>See <b>Wave References</b> on page IV-70 for more discussion.                                                                                                                                                                                                                                                                                                                                        |
| <code>/Y=<i>type</i></code>                                  | See <b>Wave Data Types</b> below.                                                                                                                                                                                                                                                                                                                                                                                                   |

### Wave Data Types

You can use `/Y=(numType)` to set the data type instead of the `/B`, `/C`, `/D`, `/I`, `/L`, `/R`, `/T`, `/U`, and `/W` data type flags. See **WaveType** function for *numType* values. The `/Y` flag overrides other type flags. You still need to use the explicit data type flags to control the automatic wave reference created by the compiler if you use the wave in an assignment statement in the same function; see **WAVE Reference Types** on page IV-73 for details.

### Details

Unless overridden by the flags, the created waves have the default length, type, precision, units and scaling. The factory defaults are:

**Note:** The *preferred* precision set by the Miscellaneous Settings dialog only presets the Make Waves dialog checkbox and determines the precision of imported waves. It does not affect the Make operation.

| Property               | Default                             |
|------------------------|-------------------------------------|
| Number of points       | 128                                 |
| Precision              | Single precision floating point     |
| Type                   | Real                                |
| dimensions             | 1                                   |
| x, y, z, and t scaling | offset=0, delta=1 ("point scaling") |

| Property             | Default     |
|----------------------|-------------|
| x, y, z, and t units | " " (blank) |
| Data Full Scale      | 0, 0        |
| Data units           | " " (blank) |

**See Also**

The **SetScale**, **Duplicate**, and **Redimension** operations.

**MakeIndex**

**MakeIndex** [/A/C/R] *sortKeyWaves*, *indexWave*

The **MakeIndex** operation sets the data values of *indexWave* such that they give the ordering of *sortKeyWaves*.

For simple sorting problems, **MakeIndex** is not needed. Just use the **Sort** operation.

**Parameters**

*sortKeyWaves* is either the name of a single wave, to use a single sort key, or the name of multiple waves in braces, to use multiple sort keys.

*indexWave* must specify an existing numeric wave.

All waves must be of the same length and must not be complex.

**Flags**

- /A      Alphanumeric. When *sortKeyWaves* includes text waves, the normal sorting places "wave1" and "wave10" before "wave9". Use /A to sort the number portion numerically, so that "wave9" is sorted before "wave10".
- /C      Case-sensitive. When *sortKeyWaves* includes text waves, the ordering is case-insensitive unless you use the /C flag which makes it case-sensitive.
- /LOC    Performs a locale-aware sort.  
When *sortKeyWaves* includes text waves, the text encoding of the text waves' data is taken into account and sorting is done according to the sorting conventions of the current system locale. This flag is ignored if the text waves' data encoding is unknown, binary, Symbol, or Dingbats. This flag cannot be used with the /A flag. See Details for more information.  
The /LOC flag was added in Igor Pro 7.00.
- /R      Reverse the index so that ordering is from largest to smallest.

**Details**

**MakeIndex** is used in preparation for a subsequent **IndexSort** operation. If /R is used the ordering is from largest to smallest. Otherwise it is from smallest to largest.

When the /LOC flag is used, the bytes stored in the text wave at each point are converted into a Unicode string using the text encoding of the text wave data. These Unicode strings are then compared using OS specific text comparison routines based on the locale set in the operating system. This means that the order of sorted items may differ when the same sort is done with the same data under different operating systems or different system locales.

When /LOC is omitted the sort is done on the raw text without regard to the waves' text encoding.

### MandelbrotPoint

**MandelbrotPoint(x, y, maxIterations, algorithm)**

The MandelbrotPoint function returns a value between 0 and *maxIterations* based on the Mandelbrot set complex quadratic recurrence relation  $z[n] = z[n-1]^2 + c$  where *x* is the real component of *c*, *y* is the imaginary component of *c* and  $z[0] = 0$ .

The returned value is the number of iterations the equation was evaluated before  $|z[n]| > 2$  (the escape radius of the Mandelbrot set), or *maxIterations*, whichever is less.

#### Parameters

- algorithm=0*      The "Escape Time" algorithm returns the integer *n* which is the number of iterations until  $|z[n]| > 2$ .
- algorithm=1*      The "Renormalized Iteration Count Algorithm" algorithm returns a floating point value which is a refinement of the number of iterations *n* by adding the quantity:  
 $5 - \ln(\ln(|z[n+4]|)) / \ln(2)$   
(which requires four more iterations of the recurrence relation). The returned value is clipped to *maxIterations*.

### MarcumQ

**MarcumQ(m, a, b)**

The MarcumQ function returns the generalized Q-function defined by the integral

$$Q_m(a,b) = \int_b^{\infty} u \left(\frac{u}{a}\right)^{m-1} \exp\left(-\frac{(a^2 + u^2)}{2}\right) I_{m-1}(au) du$$

where  $I_k$  is the modified Bessel function of the first kind and order *k*.

Its applications have been primarily in the fields of communication and detection theory. However, an interesting interpretation of its result with *m=1* and appropriate parameter scaling is the fractional power of a two-dimensional circular Gaussian function within a displaced circular aperture.

Depending on the input arguments, the MarcumQ function may be computationally intensive but you can abort the calculation at any time.

### MarkPerfTestTime

**MarkPerfTestTime idval**

Use the MarkPerfTestTime operation for performance testing of user-defined functions in conjunction with SetIgorOption DebugTimer. When used between SetIgorOption DebugTimer, Start and SetIgorOption DebugTimer, Stop, MarkPerfTestTime stores the ID value and the time of the call in a buffer. When SetIgorOption DebugTimer, Stop is called the contents of the buffer are dumped to a pair of waves: W\_DebugTimerIDs will contain the ID values and W\_DebugTimerVals will contain the corresponding times of the calls relative to the very first call. The timings use the same high precision mechanism as the StartMSTimer and StopMSTimer calls.

By default, `SetIgorOption DebugTimer, Start` allocates a buffer for up to 10000 entries. You can allocate a different sized buffer using `SetIgorOption DebugTimer, Start=bufsize`.

Additional documentation can be found in an example experiment, `PerformanceTesting.pxp`, and a `WaveMetrics` procedure file, `PerformanceTestReport.ipf`.

## MatrixBalance

**MatrixBalance [flags] srcWave**

The `MatrixBalance` operation permutes and/or scales an NxN real or complex matrix to obtain a similar matrix that is more stable for subsequent calculations such as eigenvalues and eigenvectors. Balancing a matrix is useful when some matrix elements are much smaller than others.

`MatrixBalance` saves the resulting matrix in the wave specified by the `/DSTM` flag. It creates a secondary output wave specified by the `/DSTS` flag containing permutation and scaling information.

`MatrixBalance` was added in Igor Pro 9.00.

### Parameters

*srcWave* must be single-precision or double-precision floating point, real or complex, and must contain no NaNs. `MatrixBalance` returns an error if these conditions are not met.

### Flags

|                         |                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/DSTM=dest</code> | Specifies the destination wave for the balanced output matrix. If you omit <code>/DSTM</code> , the output is saved in <code>M_Balanced</code> in the current data folder.                                                                                                                                                                                                   |
| <code>/DSTS=dest</code> | Specifies the destination wave for the scaling array. If you omit <code>/DSTS</code> , the scaling wave is saved as <code>W_Scale</code> in the current data folder.                                                                                                                                                                                                         |
| <code>/FREE</code>      | Creates free destination waves when they are specified via <code>/DSTM</code> or <code>/DSTS</code> .                                                                                                                                                                                                                                                                        |
| <code>/J=job</code>     | <i>job</i> is one of the following letters:<br>N <i>srcWave</i> is not permuted or scaled.<br>P <i>srcWave</i> is permuted but not scaled.<br>S <i>srcWave</i> is scaled but not permuted. The scaling applies a diagonal similarity transformation to make the norms of the various columns close to each other.<br>B <i>srcWave</i> is both scaled and permuted (default). |
| <code>/Z</code>         | Do not report any errors. <code>V_flag</code> will be set to 0 if successful or to an error code. <code>V_min</code> and <code>V_max</code> will be set to NaN in case of an error.                                                                                                                                                                                          |

### Details

Matrix balancing is usually called internally by LAPACK routines when there is large variation in the magnitude of matrix elements. The `/J` flag supports the granularity of applying only permutation, only scaling or both.

After balancing there will be a block diagonal form that could typically be handled using Schur decomposition (see `MatrixSchur`). The rows/columns corresponding to this block diagonal are saved in zero based `V_min` and `V_max`. The scaling wave `W_scale[i]` (for  $i < V\_min$ ) contains the index of the row/column that was interchanged with row/col  $i$ . For  $i \geq V\_min$  the scaling wave contains the scaling factor use to balance row and column  $i$ .

When you balance *srcWave* using this operation the resulting eigenvectors belong to the balanced matrix. Use **MatrixReverseBalance** to obtain the eigenvectors of *srcWave*.

When solving for the Schur vectors of *srcWave* after using `/J=P` for permuting only, use **MatrixReverseBalance** to transform the vectors. If you are solving for the Schur vectors do not use either `/J=S` or `/J=B` because that balancing transformation is not orthogonal.

## MatrixBalance

---

### Output Variables

|        |                                                                                                                                                                                         |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_Flag | Set to zero when the operation succeeds. Otherwise, when V_flag is positive the value is a standard error code. When V_flag is negative it is an indication of a wrong input parameter. |
| V_min  | Set to zero if $J=N$ or $J=S$ .                                                                                                                                                         |
| V_max  | Set to $N-1$ (where $N$ is the number of rows or columns) if $J=N$ or $J=S$ .                                                                                                           |

When  $J=B$  or  $J=P$  the matrix  $M\_Balanced[i][j]=0$  if  $i>j$  and  $j=0\dots V\_min-2$  or  $i=V\_max,\dots N-1$ .

### Examples

```
Function DemoMatrixBalance1()
 // Generate random unbalanced data
 Make/D/O/N=(7,7) srcWave=p+10*q+enoise(5)
 MatrixBalance srcWave
 Wave M_Balanced
 Wave W_Scale

 MatrixOP/O/FREE matD=diagonal(W_Scale)
 MatrixOP/O/FREE matDInv=inv(matD)

 // Check that W_Scale produces the correct balanced matrix
 MatrixOP/O/FREE matProd=matDInv x srcWave x matD

 // Compare with M_Balanced
 MatrixOP/O/FREE/P=1 aa=sum(abs(M_Balanced-matProd))
End

Function DemoMatrixBalance2()
 Make/O/N=(3,3) mat
 mat[0][0] = {2,88,164}
 mat[0][1] = {0,1,1}
 mat[0][2] = {1e-05,0,1}

 MatrixBalance mat
 Wave W_scale,M_Balanced
 Print "EqualWaves(input,output,-1)", EqualWaves(mat,M_Balanced,-1)

 // Calculate right eigenvectors for the original matrix
 MatrixEigenV/R mat
 Wave/Z M_R_eigenVectors
 Duplicate/O M_R_eigenVectors, origEigenVectors

MatrixReverseBalance

## MatrixCondition

**MatrixCondition** (*wave2D*, *mode*)

MatrixCondition returns the estimated reciprocal of the condition number of a 2D square matrix *wave2D*.

The condition number is the product of the norm of the matrix with the norm of the inverse of the matrix (see details below). The type of norm is determined by the value of the *mode* parameter. 1-norm is used if *mode* is 1 and infinity-norm is used otherwise.

The MatrixCondition function was added in Igor Pro 7.00.

### Details

The function uses LAPACK routines to estimate the reciprocal condition number by first obtaining the norm of the input matrix and then using LU decomposition to obtain the norm of the inverse of the matrix. The estimate returned is

$$\text{reciprocalCon} = \frac{1}{\|wave2D\| * \|wave2D^{-1}\|},$$

where the norms are selected by the choice of the *mode* parameter. The 1-norm of matrix *A* with elements *a<sub>ij</sub>* is defined as

$$\|A\|_1 = \max_{1 \leq j \leq n} \sum_{i=1}^m |a_{ij}|,$$

and the infinity-norm is defined by

$$\|A\|_\infty = \max_{1 \leq i \leq m} \sum_{j=1}^n |a_{ij}|.$$

The function returns a NaN if there is any error in the input parameters.

## MatrixConvolve

**MatrixConvolve** [/R=*roiWave*] *coefMatrix*, *dataMatrix*

The MatrixConvolve operation convolves a small coefficient matrix *coefMatrix* into the destination *dataMatrix*.

### Flags

|                   |                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/R=roiWave</i> | Modifies only data contained inside the region of interest. The ROI wave should be 8-bit unsigned with the same dimensions as <i>dataMatrix</i> . The interior of the ROI is defined by zeros and the exterior is any nonzero value. |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Details

On input *coefMatrix* contains an *N*×*M* matrix of coefficients where *N* and *M* should be odd. Generally *N* and *M* will be equal. If *N* and *M* are greater than 13, it is more efficient to perform the convolution using the Fourier transform (see FFT).

## MatrixCorr

---

The convolution is performed in place on the data matrix and is acausal, i.e., the output data is not shifted. Edges are handled by replication of edge data.

When *dataMatrix* is an integer type, the results are clipped to limits of the given number type. For example, unsigned byte is clipped to 0 to 255.

MatrixConvolve works also when both *coefMatrix* and *dataMatrix* are 3D waves. In this case the convolution result is placed in the wave *M\_Convolution* in the current data folder, and the optional */R=roiWave* is required to be an unsigned byte wave that has the same dimensions as *dataMatrix*.

This operation does not support complex waves.

**MatrixFilter** and **ImageFilter** for filter convolutions.

**Matrix Math Operations** on page III-138 for more about Igor's matrix routines.

The **Loess** operation.

## MatrixCorr

**MatrixCorr** [/COV] [/DEGC] *waveA* [, *waveB*]

The MatrixCorr operation computes the correlation or covariance or degree of correlation matrix for the input 1D wave(s).

If we denote elements of *waveA* by  $\{x_i\}$  and elements of *waveB* by  $\{y_i\}$  then the correlation matrix for these waves is the vector product of the form:

$$\begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_n \end{bmatrix} \begin{bmatrix} y_1 & y_2 & y_3 & \dots & y_n \end{bmatrix}^* = \begin{bmatrix} x_1 y_1^* & x_1 y_2^* & x_1 y_3^* & \dots & x_1 y_n^* \\ x_2 y_1^* & x_2 y_2^* & x_2 y_3^* & & x_2 y_n^* \\ x_3 y_1^* & x_3 y_2^* & x_3 y_3^* & & x_3 y_n^* \\ \vdots & & & & \\ x_n y_1^* & x_n y_2^* & x_n y_3^* & \dots & x_n y_n^* \end{bmatrix}$$

where \* denotes complex conjugation. If you use the optional *waveB* then the matrix is the cross correlation matrix. *waveB* must have the same length of *waveA* but it does not have to be the same number type.

### Flags

The flags are mutually exclusive; only one matrix can be generated at a time.

*/COV*            Calculates the covariance matrix.

The covariance matrix for the same input is formed in a similar way after subtracting from each vector its mean value and then dividing the resulting matrix elements by  $(n-1)$  where  $n$  is the number of elements of *waveA*.

Results are stored in the *M\_Corr* or *M\_Covar* waves in the current data folder.

*/DEGC*            Calculates the complex degree of correlation. The degree of correlation is defined by:

$$\text{deg } C = \frac{M\_Covar}{\sqrt{\text{Var}(waveA) \cdot \text{Var}(waveB)}},$$

where *M\_Covar* is the covariance matrix and *Var(wave)* is the variance of the wave.

The complex degree of correlation should satisfy:  $0 \leq |\text{deg } C| \leq 1$ .

**Examples**

The covariance matrix calculation is equivalent to:

```
Variable N=1/(DimSize(waveA,0)-1)
Variable ma=mean(waveA,-inf,inf)
Variable mb=mean(waveB,-inf,inf)
waveA-=ma
waveB-=mb
MatrixTranspose/H waveB
MatrixMultiply waveA,waveB
M_product*=N
```

**Matrix Math Operations** on page III-138 for more about Igor's matrix routines.

**References**

Hayes, M.H., *Statistical Digital Signal Processing And Modeling*, 85 pp., John Wiley, 1996.

**MatrixDet**

**matrixDet** (*dataMatrix*)

The MatrixDet function returns the determinant of *dataMatrix*. The matrix wave must be a real, square matrix or else the returned value will be NaN.

**Details**

The function calculates the determinant using LU decomposition. If, following the decomposition, any one of the diagonal elements is either identically zero or equal to  $10^{-100}$ , the return value of the function will be zero.

**See Also**

The **MatrixOp** operation for more efficient matrix operations.

**Matrix Math Operations** on page III-138 for more about Igor's matrix routines.

**MatrixDot**

**MatrixDot** (*waveA*, *waveB*)

The MatrixDot function calculates the inner (scalar) product for two 1D waves. A 1D wave **A** represents a vector in the sense:

$$\mathbf{A} = \sum \alpha_i \hat{e}_i, \quad \hat{e}_i \text{ is a unit vector.}$$

Given two such waves **A** and **B**, the inner product is defined as

$$ip = \sum \alpha_i \beta_i.$$

When both *waveA* and *waveB* are complex and the result is assigned to a complex-valued number MatrixDot returns:

$$ipc = \sum \alpha_i^* \beta_i.$$

If you prefer the definition where the second factor is the one that is conjugated, you can simply reverse the order of *waveA* and *waveB* in the function call.

If the result is assigned to a real number, MatrixDot returns:

$$ip = \left| \sum \alpha_i^* \beta_i \right|.$$

If either *waveA* or *waveB* is complex and the result is assigned to a real-valued number, MatrixDot returns:

$$ip = \left| \sum \alpha_i \beta_i \right|.$$

## MatrixEigenV

---

When the result is assigned to a complex-valued number MatrixDot returns:

$$ipc = \sum \alpha_i \beta_i.$$

The **MatrixOp** operation for more efficient matrix operations.

**Matrix Math Operations** on page III-138 for more about Igor's matrix routines.

## MatrixEigenV

**MatrixEigenV** [*flags*] *matrixA* [, *matrixB*]

MatrixEigenV computes the eigenvalues and eigenvectors of a square matrix using LAPACK routines.

### Flags for General Matrices

- /C* Creates complex valued output for real valued input waves. This is equivalent to converting the input to complex, with zero imaginary component, prior to computing the eigenvalues and eigenvectors. The main benefit of this format is that the output has simple packing of eigenvalues and eigenvectors. See the example in the **Details for General Matrices** section below.  
The */C* flag was added in Igor Pro 7.00.
- /B=balance* Determines how the input matrix should be scaled and or permuted to improve the conditioning of the eigenvalues.  
*balance=0* (default), 1, 2, or 3, corresponding respectively to N, P, S, or B in the LAPACK routines. Applicable only with the */X* flag.  
0: Do not scale or permute.  
1: Permute.  
2: Do diagonal scaling.  
3: Scale and permute.
- /L* Calculates for left eigenvectors.
- /O* Overwrites *matrixWave*, requiring less memory.
- /R* Calculates for right eigenvectors.
- /S=sense* Determines which reciprocal condition numbers are calculated.  
*sense=0* (default), 1, 2, or 3, corresponding respectively to N, E, V, or B in the LAPACK routines. Applicable only with the */X* flag.  
0: None.  
1: Eigenvalues only.  
2: Right eigenvectors.  
3: Eigenvalues and right eigenvectors.  
If *sense* is 1 or 3 you must compute both left and right eigenvectors.  
**NOTE:** */S* is applicable only with the */X* flag or for the generalized eigenvalue problem.
- /X* Uses LAPACK expert routines, which require additional parameters (see */B* and */S* flags). The operation creates additional waves:  
The *W\_MatrixOpInfo* wave contains in element 0 the ILO, in element 1 the IHI, and in element 2 the ABNRM from the LAPACK routines.  
The wave *W\_MatrixRCONDE* contains the reciprocal condition numbers for the eigenvalues.  
The wave *W\_MatrixRCONDV* contains the reciprocal condition number for the eigenvectors.

**Flags for Symmetric Matrices**

`/SYM` Computes the eigenvalues of an NxN symmetric matrix and stores them in the wave `W_eigenValues`. You must specify this flag if you want to use the special routines for symmetric matrices. The number of eigenvalues is stored in the variable `V_npnts`. Because `W_eigenValues` has N points, only the first `V_npnts` will contain relevant eigenvalues. When using this flag with complex input the matrix is assumed to be Hermitian.

`/EVEC` Computes eigenvectors in addition to eigenvalues. Eigenvectors will be stored in the wave `M_eigenVectors`, which is of dimension NxN. The first `V_npnts` columns of the wave will contain the `V_npnts` eigenvectors corresponding to the eigenvalues in `W_eigenValues`. `/EVEC` must be preceded by `/SYM`.

`/RNG={method,low,high}`

Determines what is computed:

`method=0:` Computes all the eigenvalues or eigenvectors (default).  
`method=1:` Computes eigenvalues for *low* and *high* double precision range.  
`method=2:` Computes eigenvalues for *low* and *high* integer indices (1 based). For example, to compute the first 3 eigenvalues use: `/RNG={ 2 , 1 , 3 }`.

`/RNG` must be preceded by `/SYM`.

**Flags for Generalized Eigenvalue Problem**

These are the same flags as for general (non-symmetric) matrices above except for `/O` and `/X` which are not supported for the generalized eigenvalue solution.

**Common Flags**

`/Z` No error reporting (except for setting `V_flag`).

**Details**

There are three mutually exclusive branches for the operation. The first is designed for a square matrix input *matrixA*. The operation computes the solution to the problem

$$\mathbf{Ax} = \lambda \mathbf{x},$$

where A is the input matrix, x is an eigenvector and  $\lambda$  is an eigenvalue.

The second branch is designed for symmetric matrices A, i.e., when

$$\mathbf{A} = \mathbf{A}^T,$$

where the superscript T denotes a transpose.

The third branch of the operation is designed to solve the generalized eigenvalue problem,

$$\mathbf{Ax} = \lambda \mathbf{Bx},$$

where A and B are square matrices, x is an eigenvector and  $\lambda$  is an eigenvalue.

Each branch of the operation supports its own set of flags as shown above. All branches support input of single and double precision in real or complex waves. If you specify both *matrixA* and *matrixB* then they must have the same number type.

**Details for General Matrices**

The eigenvalues are returned in the 1D complex wave `W_eigenValues`. The eigenvectors are returned in the 2D wave `M_R_eigenVectors` or `M_L_eigenVectors`.

The calculated eigenvectors are normalized to unit length.

Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

## MatrixEigenV

---

If the  $j$ th eigenvalue is real, then the corresponding eigenvector  $u(j)=M[][j]$  is the  $j$ th column of M\_L\_eigenVectors or M\_R\_eigenVectors. If the  $j$ th and  $(j+1)$ th eigenvalues form a complex conjugate pair, then  $u(j) = M[][j] + i*M[][j+1]$  and  $u(j+1) = M[][j] - i*M[][j+1]$ .

### Example

```
Function TestMatrixEigenVReal()
 Make/D/N=(2,2)/O eee={{0,1},{-1,0}}
 MatrixEigenV/R eee
 Wave W_eigenvalues, M_R_eigenVectors
 MatrixOP/O firstEV=cplx(col(M_R_eigenVectors,0),col(M_R_eigenVectors,1))
 MatrixOP/O aa=eee x firstEV - W_eigenvalues[0]*firstEV
 Print aa
End

Function TestMatrixEigenVComplex()
 Make/D/N=(2,2)/O eee={{0,1},{-1,0}}
 MatrixEigenV/R/C eee
 Wave W_eigenvalues, M_R_eigenVectors
 MatrixOP/O aa=eee x col(M_R_eigenVectors,0) - W_eigenvalues[0]*col(M_R_eigenVectors,0)
 Print aa
End
```

### Details for Symmetric Matrices

The LAPACK routines that compute the eigenvalues and eigenvectors of symmetric matrices claim to use the Relatively Robust Representation whenever possible. If your matrix is symmetric you should use this branch of the operation (/SYM) for improved accuracy.

### Details for Generalized Eigenvalue Problem

Here the right eigenvectors (/R) are solutions to the equation

$$\mathbf{Ax} = \lambda \mathbf{Bx},$$

and the left eigenvectors (/L) are solutions to

$$\mathbf{x}^H \mathbf{A} = \lambda \mathbf{x}^H \mathbf{B},$$

where the superscript H denotes the conjugate transpose.

When both *matrixA* and *matrixB* are real valued, the operation creates the following waves in the current data folder:

|                                               |                                                                                                                      |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| W_alphaValues                                 | Contains the complex alpha values.                                                                                   |
| W_betaValues                                  | Contains the real-valued denominator such that the eigenvalues are given by $\lambda_j = \frac{\alpha_j}{\beta_j}$ . |
| M_leftEigenVectors and<br>M_rightEigenVectors | Real valued waves where columns correspond to eigenvectors of the equation.                                          |

Every point in the wave W\_alphaValues corresponds to an eigenvalue. When the imaginary part of W\_alphaValues[j] is zero, the eigenvalue is real and the corresponding eigenvector is also real e.g., M\_rightEigenVectors[][j]. When the imaginary part is positive then there are two eigenvalues that are complex-conjugates of each other with corresponding complex eigenvectors given by

```
cplx(M_rightEigenVectors[][j],M_rightEigenVectors[][j+1])
```

and

```
cplx(M_rightEigenVectors[][j],-M_rightEigenVectors[][j+1])
```

When both *matrixA* and *matrixB* are complex the operation creates the complex waves:

W\_alphaValues, W\_betaValues, M\_leftEigenVectors, M\_rightEigenVectors

with the ratio W\_alphaValues[j]/W\_betaValues[j] expressing the generalized eigenvalue. The corresponding M\_leftEigenVectors[][j] and M\_rightEigenVectors[][j] are the respective left and right

eigenvectors. The simplicity of the complex case suggests that when *matrixA* and *matrixB* are real it is best to convert them to complex waves prior to executing `matrixEigenV`.

Depending on the choice of */S* the operation also calculates the reciprocal condition number for the eigenvalues (stored in `W_reciprocalConditionE`) and the reciprocal condition number of the eigenvectors (stored in `W_reciprocalConditionV`). Note that a zero entry in `W_reciprocalConditionV` implies that the eigenvalues could not be ordered.

**Matrix Math Operations** on page III-138 for more about Igor's matrix routines and for background references with details about the LAPACK libraries.

Symmetric matrices can also be decomposed using the **MatrixSchur** operation and using **MatrixOp chol**.

## MatrixFactor

**MatrixFactor** [ *flags* ] *srcWave*

The `MatrixFactor` operation computes two real-valued output matrices, conceptually called `matA` and `matB`, whose matrix product minimizes the Frobenius norm of:

$$| \text{srcWave} - (\text{matA} \times \text{matB}) |$$

The `MatrixFactor` operation was added in Igor Pro 9.00.

### Flags

|                             |                                                                                                                                                                                                                                                                                                                        |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/COMC=cCols</code>    | Sets the common dimension in the factorization so that, for <i>srcWave</i> with <i>m</i> rows and <i>n</i> columns, the factorization will be ( <i>m</i> x <i>cCols</i> ) <code>matA</code> and ( <i>cCols</i> x <i>n</i> ) <code>matB</code> . If you omit <code>/COMC</code> , <i>cCols</i> defaults to <i>m/2</i> . |
| <code>/CORR=cRate</code>    | Sets the correction factor for the learning rate. The default value is 0.9.                                                                                                                                                                                                                                            |
| <code>/DSTA=wA</code>       | Specifies the output wave representing <code>matA</code> .                                                                                                                                                                                                                                                             |
| <code>/DSTB=wB</code>       | Specifies the output wave representing <code>matB</code> .                                                                                                                                                                                                                                                             |
| <code>/FREE</code>          | Creates output waves as free waves.                                                                                                                                                                                                                                                                                    |
| <code>/INIA=iwA</code>      | Specifies an initial solution matrix for <code>matA</code> . The wave must have the same dimensions as <code>matA</code> and the same numeric type as <i>srcWave</i> .                                                                                                                                                 |
| <code>/INIB=iwB</code>      | Specifies an initial solution matrix for <code>matB</code> . The wave must have the same dimensions as <code>matB</code> and the same numeric type as <i>srcWave</i> .                                                                                                                                                 |
| <code>/ITER=nIters</code>   | Sets the maximum number of iterations. By default <i>nIters</i> is 1E7.                                                                                                                                                                                                                                                |
| <code>/LRNR=lRate</code>    | Sets the initial learning rate of the algorithm. The default value of <i>lRate</i> is 0.01.                                                                                                                                                                                                                            |
| <code>/OUT=type</code>      | Sets restrictions on the output. The default value for <i>type</i> is 0 and there are no restrictions on the elements of the output. Set <i>type</i> =1 for non-negative output elements or <i>type</i> =2 for positive output elements.                                                                               |
| <code>/TOL=tolerance</code> | Use <code>/TOL</code> to terminate iterations when the average Frobenius norm per input point falls below the tolerance value. By default <i>tolerance</i> is 1E-9 for single precision floating point input wave and 1E-15 for double precision input.                                                                |
| <code>/Q</code>             | Quiet - do not print diagnostic information to the history area and do not display progress bar.                                                                                                                                                                                                                       |
| <code>/Z</code>             | Errors are not fatal and do not abort procedure execution. Your procedure can inspect the <code>V_flag</code> variable to see if the operation succeeded. <code>V_flag</code> will be zero if it succeeded or nonzero if it failed.                                                                                    |

### Details

*srcWave* must be a single or double precision real wave.

## MatrixFilter

---

If you specify the factorization output waves using /DSTA and /DSTB, they must have the same numeric type.

If you omit /DSTA or /DSTB, MatrixFactor produces output waves named factorAMat and factorBMat with the same numeric type as *srcWave*.

The algorithm produces a non-unique solution that may depend on the initialization of the two factors. The default initialization, used if you omit /INIA and /INIB, uses Igor's random number generator. If you want to investigate convergence you can generate your own initial values and specify them using the /INIA and /INIB flags. If you want to provide your own initial values you must provide them for both matA and matB via both /INIA and /INIB. You can run MatrixFactor once and use the outputs as initial values for a second run.

We recommend using double precision waves because the algorithm involves iterations where the Frobenius norm is computed. For large matrices or for a large number of iterations the calculation is strongly susceptible to roundoff errors which may cause it to fail to converge.

The algorithm iterates until either the tolerance is met or the number of iterations, specified by /ITER or the default value of 1E7, is exceeded. The algorithm also terminates if the the computed norm remains relatively constant:

```
(prevIterationNorm-curIterationNorm)/prevIterationNorm < 1e-16.
```

### Output Variables

MatrixFactor sets these automatically created variables:

|              |                                                                                                     |
|--------------|-----------------------------------------------------------------------------------------------------|
| V_flag       | Set to 0 if the operation succeeded or to a non-zero error code.                                    |
| V_avg        | The last average Frobenius norm (Frobenius sum divided by the number of points in <i>srcWave</i> ). |
| V_iterations | The number of iterations executed before the algorithm terminated.                                  |

### Example

```
Function DemoMatrixFactor()
 Make/O/N=(10,8)/D matA0 = 1+abs(enoise(3))
 Make/O/N=(8,12)/D matB0 = 1+abs(enoise(3))
 MatrixOP/O matX0=matA0 x matB0
 MatrixFactor/COMC=8/DSTA = biMatA/DSTB=biMatB matX0
 MatrixOP/O/P=1 aa = sum(sq(matX0- biMatA x biMatB))/120 // Check norm
End
```

## MatrixFilter

**MatrixFilter** [*flags*] **Method** *dataMatrix*

The MatrixFilter operation performs one of several standard image filter type operations on the destination *dataMatrix*.

**Note:** The parameters below are also available in ImageFilter. See **ImageFilter** for additional parameters.

### Parameters

*Method* selects the filter type. *Method* is one of the following names:

|                                                            |                                                           |
|------------------------------------------------------------|-----------------------------------------------------------|
| avg                                                        | <i>n</i> x <i>n</i> average filter.                       |
| FindEdges                                                  | 3x3 edge finding filter.                                  |
| gauss                                                      | <i>n</i> x <i>n</i> gaussian filter.                      |
| gradN, gradNW, gradW, gradSW, gradS, gradSE, gradE, gradNE | 3x3 North, NorthWest, West, ... pointing gradient filter. |

|              |                                                                                                                                                                                                                                                                                                                                    |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| median       | $n \times n$ median filter. You can assign values other than the median by specifying the desired rank using the /M flag.                                                                                                                                                                                                          |
| min          | $n \times n$ minimum rank filter.                                                                                                                                                                                                                                                                                                  |
| max          | $n \times n$ maximum rank filter.                                                                                                                                                                                                                                                                                                  |
| NanZapMedian | $n \times n$ filter that only affects data points that are NaN. Replaces them with the median of the $n \times n$ surrounding points. Unless /P is used, automatically cycles through matrix until all NaNs are gone or until $cols * rows$ iterations.                                                                            |
| point        | 3x3 point finding filter $8 * center - outer$ .                                                                                                                                                                                                                                                                                    |
| sharpen      | 3x3 sharpening $filter = (12 * center - outer) / 4$ .                                                                                                                                                                                                                                                                              |
| sharpenmore  | 3x3 sharpening $filter = (9 * center - outer)$ .                                                                                                                                                                                                                                                                                   |
| thin         | Calculates binary image thinning using neighborhood maps based on the algorithm in <i>Graphics Gems IV</i> , p. 465.<br><b>Note:</b> The thin keyword to MatrixFilter will be removed someday. The functionality will be available — just not as a part of MatrixFilter. The /R flag does not apply to the lame duck thin keyword. |

### Flags

|                    |                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /B= <i>b</i>       | Specifies value that is considered background. Used with thin. If object is black on white background, use 255. If object is white on a black background, use 0.                                                                                                            |
| /F= <i>value</i>   | Specifies the value in the ROI wave that marks excluded pixels. <i>value</i> is either 0 or 1. This flag was added in Igor Pro 7.00.<br>By default, and for compatibility with Igor Pro 6, <i>value</i> =0. Use /F=1 if your ROI wave contains 1 for pixels to be excluded. |
| /M= <i>rank</i>    | Assigns a pixel value other than the median when used with the median filter. Valid <i>rank</i> values are between 0 and $n^2 - 1$ (for the default median $rank = n^2 / 2$ ).                                                                                              |
| /N= <i>n</i>       | For any method described above as “ $n \times n$ ”, you can specify that the filtering kernel will be a square matrix of size <i>n</i> . In the absence of the /N flag, the default size is 3.                                                                              |
| /P= <i>p</i>       | Filter passes over the data <i>p</i> times. The default is one pass.                                                                                                                                                                                                        |
| /R= <i>roiWave</i> | Only the data outside the region of interest will be modified. <i>roiWave</i> should be an 8-bit unsigned wave with the same dimensions as the data matrix. The exterior of the ROI is defined by zeros and the interior is any nonzero value.                              |
| /T                 | Applies the thinning algorithm of Zhang and Suen with the thin parameter. The wave M_MatrixFilter contains the results; the input wave is not overwritten.                                                                                                                  |

### Details

This operation does not support complex waves.

### MatrixGaussJ

**MatrixGaussJ** *matrixA*, *vectorsB*

The MatrixGaussJ operation solves matrix expression  $A*x=b$  for column vector  $x$  given matrix  $A$  and column vector  $b$ . The operation can also be used to calculate the inverse of a matrix.

#### Parameters

*matrixA* is a NxN matrix of coefficients and *vectorsB* is a NxM set of right-hand side vectors.

#### Details

On output, the array of solution vectors  $x$  is placed in  $M\_x$  and the inverse of  $A$  is placed in  $M\_Inverse$ .

If the result is a singular matrix,  $V\_flag$  is set to 1 to indicate the error. All other errors result in an alert, and abort any calling procedure.

All output objects are created in the current data folder.

An error is generated if the dimensioning of the input arrays is invalid.

This routine is provided for completeness only and is not recommended for general work (use LU decomposition – see **MatrixLUD**). MatrixGaussJ does calculate the inverse matrix but that is not generally needed either.

### MatrixGLM

**MatrixGLM** [/Z] *matrixA*, *matrixB*, *waveD*

The MatrixGLM operation solves the general Gauss-Markov Linear Model problem (GLM) which minimizes the 2-norm of a vector  $y$

$$\min \|y\|_2 \quad \text{subject to} \quad d = Ax + By.$$

$A$  is *matrixA* (an NxM wave),  $B$  is *matrixB* (an NxP wave), and  $d$  is provided by *waveD* which is a 1D wave of  $N$  rows. The vectors  $x$  and  $y$  are the results of the calculation; they are stored in output waves  $Mat\_X$  and  $Mat\_Y$  in the current data folder.

#### Flags

/Z                      In the event of an error, MatrixGLM will not return the error to Igor, which would cause procedure execute to abort. Your code should use the  $V\_flag$  output variable to detect and handle errors.

#### Details

All input waves must have the same numeric type. Supported types are single-precision and double-precision floating point, both real and complex. The output waves  $Mat\_X$  and  $Mat\_Y$  have the same numeric type as the input.

The LAPACK algorithm assumes that  $M \leq N \leq M+P$  and

$$rank(A) = M,$$

$$rank(AB) = N.$$

Under these assumptions there is a unique solution  $x$  and a minimal 2-norm solution  $y$ , which are obtained using a generalized QR factorization of  $A$  and  $B$ . If the operation completes successfully the variable  $V\_Flag$  is set to zero. Otherwise it contains a LAPACK error code.

**Output Variables**

V\_flag                    Set to 0 if MatrixGLM succeeds or to a LAPACK error code.

**See Also**

**Matrix Math Operations** on page III-138 for more about Igor's matrix routines and for background references with details about the LAPACK libraries.

**MatrixInverse**

**MatrixInverse** [*flags*] *srcWave*

The MatrixInverse operation calculates the inverse or the pseudo-inverse of a matrix. *srcWave* may be real or complex.

MatrixInverse saves the result in the wave M\_Inverse in the current data folder.

**Flags**

- /D                    Creates the wave W\_W that contains eigenvalues of the singular value decomposition (SVD) for the pseudo-inverse calculation. If one or more of the eigenvalues are small, the matrix may be close to singular.
- /G                    Calculates only the direct inverse; does not affect calculation of pseudo-inverse. By default, it calculates the inverse of the matrix using LU decomposition. The inverse is calculated using Gauss-Jordan method. The only advantage in using Gauss-Jordan is that it is more likely to flag singular matrices than the LU method.
- /O                    Overwrites the source with the result.
- /P                    Calculates the pseudo-inverse of a matrix using the SVD algorithm. The calculated pseudo-inverse is a unique minimal solution to the problem:

$$\min_{\mathbf{X} \in \mathbb{R}^{n \times m}} \|\mathbf{AX} - \mathbf{I}_m\|.$$

**Examples**

```
Make/O/N=(2,2) mat0 = {{2,3},{1,7}}
MatrixInverse mat0 // Creates wave M_inverse
MatrixOp/O/T=1 mat1 = M_inverse x mat0 // Check result

Make/O/D/N=(4,6) mat1 = enoise(4)
MatrixInverse/P mat1
MatrixOP/O/T=1 aa = mat1 x M_Inverse
MatrixOP/O/P=1 avgAbsErr = sum(abs(mat1 x M_Inverse - identity(4)))/12
```

**MatrixLinearSolve**

**MatrixLinearSolve** [*flags*] *matrixA matrixB*

The MatrixLinearSolve operation solves the linear system  $\mathit{matrixA} * \mathbf{X} = \mathit{matrixB}$  where *matrixA* is an N-by-N matrix and *matrixB* is an N-by-NRHS matrix of the same data type.

| <i>/D={sub,super}</i> | Specifies a band diagonal matrix. The subdiagonal ( <i>sub</i> ) and superdiagonal ( <i>super</i> ) size must be positive integers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>/L</i>             | Uses the lower triangle of <i>matrixA</i> . <i>/L</i> and <i>/U</i> are mutually exclusive flags.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>/U</i>             | Uses the upper triangle of <i>matrixA</i> . <i>/U</i> is the default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>/O</i>             | Overwrites <i>matrixA</i> and <i>matrixB</i> with the results of the operation. This will save on the amount of memory needed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>/Z</i>             | No error reporting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### Details

If */O* is not specified, the operation also creates the n-by-n wave *M\_A* and the n-by-nrhs solution wave *M\_B*.

The variable *V\_flag* is created by the operation. If the operation completes successfully, *V\_flag* is set to zero, otherwise it is set to the LAPACK error code.

## MatrixLinearSolveTD

**MatrixLinearSolveTD** [*/Z*] *upperW, mainW, lowerW, matrixB*

The **MatrixLinearSolveTD** operation solves the linear system  $TDMatrix * X = matrixB$ . In the matrix product on the left hand side, *TDMatrix* is a tridiagonal matrix with upper diagonal *upperW*, main diagonal *mainW*, and lower diagonal *lowerW*. It solves for vector(s) *X* depending on the number of columns (NRHS) in *matrixB*.

**Flags***/DSTC=solutionWave*

Specifies the output wave when all input waves are complex. If you omit */DSTC* then the output wave is *M\_TDLinearSolution* in the current data folder. */DSTC* was added in Igor Pro 9.00.

*/DSTR=solutionWave*

Specifies the output wave when all input waves are real. If you omit */DSTR* then the output wave is *M\_TDLinearSolution* in the current data folder. */DSTR* was added in Igor Pro 9.00.

*/FREE*

Creates the solution wave as a free wave. */FREE* is allowed only in functions and only if the solution wave, as specified by */DSTC* or */DSTR*, is a simple name or wave reference structure field. */DSTC* was added in Igor Pro 9.00.

*/Z*

No error reporting.

**Details**

The input waves can be single or double precision (real or complex). Results are returned in the wave *M\_TDLinearSolution* in the current data folder. The wave *mainW* determines the size of the main diagonal (*N*). All other waves must match it in size with *upperW* and *mainW* containing one less point and *matrixB* consisting of *N*-by-*NRHS* elements of the same data type.

*MatrixLinearSolveTD* should be more efficient than *MatrixLinearSolve* with respect to storage requirements.

*MatrixLinearSolveTD* creates the variable *V\_flag*, which is zero when it finishes successfully.

**Matrix Math Operations** on page III-138; the **MatrixLinearSolve** and **MatrixOp** operations.

**MatrixLLS****MatrixLLS** [*/O/Z/M=method*] *matrixA matrixB*

The *MatrixLLS* operation solves overdetermined or underdetermined linear systems involving *M*×*N* *matrixA*, using either QR/LQ or SV decompositions. Both *matrixA* and *matrixB* must have the same number type. Supported types are real or complex single precision and double precision numbers.

**Flags***/M=method*

Specifies the decomposition method.

*method=0*: Decomposition is to QR or LQ (default). Creates the 2D wave *M\_A*, which contains details of the QR/LQ factorization.

*method=1*: Singular value decomposition. Creates the 2D wave *M\_A*, which contains the right singular vectors stored row-wise in the first  $\min(m, n)$  rows. Creates the 1D wave *M\_SV*, which contains the singular values of *matrixA* arranged in decreasing

*/O*

Overwrites *matrixA* with its decomposition and *matrixB* with the solution vectors. This requires less memory.

*/Z*

No error reporting.

**Details**

When the */O* flag is not specified, the solution vectors are stored in the wave *M\_B*, otherwise the solution vectors are stored in *matrixB*. Let *matrixA* be *m* rows by *n* columns and *matrixB* be an *m* by *NRHS* (if *NRHS*=1 it can be omitted). If  $m \geq n$ , *MatrixLLS* solves the least squares solution to an overdetermined system:

$$\text{Minimize} \left\| \text{matrixB} - \text{matrixA} \times \mathbf{X} \right\|.$$

Here the first  $n$  rows of `M_B` contain the least squares solution vectors while the remaining rows can be squared and summed to obtain the residual sum of the squares. If you are not interested in the residual you can resize the wave using, for example:

```
Redimension/N=(n,NRHS) M_B
```

If  $m < n$ , MatrixLLS finds the minimum norm solution of the underdetermined system:

$$\mathit{matrixA} \times \mathbf{X} = \mathit{matrixB}.$$

In this case, the first  $m$  rows of `M_B` contain the minimum norm solution vectors while the remaining rows can be squared and summed to obtain the residual sum of the squares for the solution. If you are not interested in the residual you can resize the wave using, for example:

```
Redimension/N=(m,NRHS) M_B
```

**Note:** Here *matrixB* consists of one or more column vectors B corresponding to one or more solution vectors X that are computed simultaneously. If *matrixB* consists of a single column, `M_B` is a 2D matrix wave that contains a single solution column.

The variable `V_flag` is set to 0 when there is no error; otherwise it contains the LAPACK error code.

### Examples

```
// Construct matrixA as a 4x4 matrix
Make/O/D/N=(4,4) matrixA
matrixA[0][0] = {-54,-27,-9,-38}
matrixA[0][1] = {13,60,-42,-26}
matrixA[0][2] = {-80,17,44,-35}
matrixA[0][3] = {98,-8,-72,7}

// Construct matrixB as a single column (1D wave)
Make/O/D/N=4 matrixB={-20,77,-79,-33}

// Solve for matrixA x vectorX = matrixB
MatrixLLS matrixA, matrixB// Output stored in M_B

// Verify the solution
MatrixOP/O/P=1 aa=sum(abs(matrixA x col(M_B,0) - matrixB)) aa={9.947598300641403e-14}

// Compute multiple solutions at once
// Construct matrixB as two columns (2D wave)
Redimension/N=(4,2) matrixB
matrixB[0][0] = {-20,77,-79,-33}
matrixB[0][1] = {-94,61,29,68}

// Perform the calculation
MatrixLLS matrixA, matrixB

// Verify the solutions
MatrixOP/O/P=1 aa=sum(abs(matrixA x col(M_B,0) - col(matrixB,0)))
aa={9.947598300641403e-14}
MatrixOP/O/P=1 aa=sum(abs(matrixA x col(M_B,1) - col(matrixB,1)))
aa={1.989519660128281e-13}

// See if we have an overdetermined system ...
Make/D/N=(5,4) matrixA
matrixA[0][0] = {-7,-62,-47,-54,-80}
matrixA[0][1] = {43,15,-9,-94,57}
matrixA[0][2] = {22,61,-95,-95,51}
matrixA[0][3] = {-54,68,81,-51,54}
Make/O/D/N=(5) matrixB
matrixB[0] = {-28,-75,-74,35,86}

// Perform the calculation
MatrixLLS matrixA, matrixB

// Remove the extra rows from M_B
Redimension/N=4 M_B

// M_B is only the least squares solution so there is no point in attempting
// to verify the solution as in the example above.
```

**MatrixLUBkSub**

**MatrixLUBkSub** *matrixL*, *matrixU*, *index*, *vectorB*

The MatrixLUBkSub operation provides back substitution for LU decomposition.

**Details**

This operation is used to solve the matrix equation  $Ax=b$  after you have performed LU decomposition (see **MatrixLUD**). Feed this routine *M\_Lower*, *M\_Upper* and *W\_LUPermutation* from MatrixLUD along with your right-hand-side vector *b*. The solution vector *x* is returned as *M\_x*. The array *b* can be a matrix containing a number of *b* vectors and the *M\_x* will contain a corresponding set of solution vectors.

Generates an error if the dimensions of the input matrices are not appropriate.

**See Also**

**Matrix Math Operations** on page III-138 for more about Igor's matrix routines.

**MatrixLUD**

**MatrixLUD** [*flags*] *matrixA*

The MatrixLUD operation computes the LU factorization of a matrix. The general form of the factorization/decomposition is expressed in terms of matrix products:

$$M\_Pt \times srcWave = M\_Lower \times M\_Upper$$

*M\_Pt*, *M\_Lower* and *M\_Upper* are outputs created by MatrixLUD.

*M\_Pt* is the transpose of the permutation matrix, *M\_Lower* is a lower triangular matrix with 1's on the main diagonal and *M\_Upper* is an upper triangular (or trapezoidal) matrix.

The MatrixLUD operation was substantially changed in Igor Pro 7.00. See the */B* flag for information about backward compatibility.

**Flags**

- |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <i>/B</i>    | This flag is provided for backward compatibility only; it is not compatible with any other flag. <i>/B</i> makes MatrixLUD behave as it did in Igor Pro 6. This flag is deprecated and will be removed in a future version of Igor.<br><br>The input is restricted to a 2D real valued, single or double precision square matrix. The outputs (all double precision) are stored in the waves <i>M_Upper</i> , <i>M_Lower</i> and <i>W_LUPermutation</i> in the current data folder.<br><br>The <i>W_LUPermutation</i> output wave was needed for solving a linear system of equations using the back substitution routine, <b>MatrixLUBkSub</b> . For better computation methods see <b>MatrixLinearSolve</b> , <b>MatrixLinearSolveTD</b> and <b>MatrixLLS</b> . |
| <i>/CMF</i>  | Uses Combined Matrix Format where the upper and lower matrix factors are combined into a single matrix saved in the wave <i>M_LUFactors</i> in the current data folder. The upper matrix factor is constructed from the main and from the upper diagonals of <i>M_LUFactors</i> . The lower matrix factor is constructed from the lower diagonals of <i>M_LUFactors</i> and setting the main diagonal to 1.                                                                                                                                                                                                                                                                                                                                                       |
| <i>/MIND</i> | Finds the minimum magnitude diagonal element of <i>M_Upper</i> and store it in <i>V_min</i> . This is useful for investigating the behavior of the determinant of the matrix when it is close to being singular.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>/PMAT</i> | Saves the transpose of the permutation matrix in a double precision wave <i>M_Pt</i> in the current data folder. Note that the permutation matrix is orthogonal and so the inverse of the matrix is equal to its transpose.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>/SUMP</i> | Computes the sum of the phases of the elements on the main diagonal of <i>M_Upper</i> and store in the variable <i>V_Sum</i> . <i>V_Sum</i> is initialized to NaN and is set only if <i>/SUMP</i> is specified and <i>M_Upper</i> is complex.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## MatrixLUDTD

---

### Details

The input matrix *srcWave* is an MxN real or complex wave of single or double precision. Use **MatrixLUDTD** if your input is tri-diagonal.

The main results of the factorization are stored in the waves *M\_Lower*, *M\_Upper* and *M\_Pt*. Alternatively the lower and upper factors can be combined and stored in the wave *M\_LUFactors* (see /CMF). The waves *M\_Lower*, *M\_Upper* and *M\_LUFactors* have the same data type as the input wave. *M\_Pt* is always double precision.

When the input matrix *srcWave* is square (NxN), the resulting matrices have the same dimensions (NxN). You can reconstruct the input using the MatrixOp expression:

```
MatrixOp/O rA=(M_Pt^t) x (M_Lower x M_Upper)
```

If the input matrix is rectangular (NxM) the reconstruction depends on the size of N and M. If N<M:

```
MatrixOp/O rA=(M_Pt^t) x (subRange(M_lower,0,N-1,0,N-1) x M_Upper)
```

If N>M:

```
MatrixOp/O rA=(M_Pt^t) x M_lower x subRange(M_Upper,0,M-1,0,M-1)
```

The variable *V\_flag* is set to zero if the operation succeeds and to 1 otherwise (e.g., if the input is singular). When you use the /B flag the polarity of the matrix is returned in the variable *V\_LUPolarity*. The variables *V\_Sum* and *V\_min* are also set by some of the flag options above.

## MatrixLUDTD

**MatrixLUDTD** [*flags*] *srcMain*, *srcUpper*, *srcLower*

The MatrixLUDTD operation computes the LU factorization of a tri-diagonal matrix. The general form of the factorization/decomposition is expressed in terms of matrix products:

```
M_Pt x triDiagonalMat = M_Lower x M_Upper
```

*triDiagonalMat* is the matrix defined by the main diagonal specified by *srcMain*, the upper diagonal specified by *srcUpper*, and the lower diagonal specified by *srcLower*.

*M\_Pt* is an output wave created when the /PMAT flag is present. *M\_Lower* and *M\_Upper* are output waves created when the /FM flag is present. *M\_Pt* is the transpose of the permutation matrix, *M\_Lower* is a lower triangular matrix with 1's on the main diagonal and *M\_Upper* is an upper triangular (or trapezoidal) matrix.

### Flags

|       |                                                                                                                                                                                                                                                                 |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /MIND | Finds the minimum magnitude diagonal element of <i>M_Upper</i> and stores it in <i>V_min</i> . This feature is useful if you want to investigate the behaviour of the determinant of the matrix when it is close to being singular.                             |
| /PMAT | Saves the transpose of the permutation matrix in the wave <i>M_Pt</i> in the current data folder. Note that the permutation matrix is orthogonal and so the inverse of the matrix is equal to its transpose.                                                    |
| /SUMP | Computes the sum of the phases of the elements on the main diagonal of <i>M_Upper</i> and store in the variable <i>V_Sum</i> . Note that the variable is initialized to NaN and that it is not set unless this flag is specified and <i>M_Upper</i> is complex. |
| /FM   | The full matrix output is stored in the waves <i>M_Lower</i> and <i>M_Upper</i> in the current data folder.                                                                                                                                                     |

### Details

You specify the tridiagonal matrix using three 1D waves of the same data type (single or double precision real or complex).

If /FM is present the output of the operation consists of two 2D waves and one 1D wave:

*M\_Lower* is a lower triangular matrix with 1's on the main diagonal.

M\_Upper is an upper triangular (or trapezoidal) matrix.

W\_PIV is 1D wave containing pivot indices.

See code example below for implementation details.

If /FM is omitted the output of the operation consists of five 1D waves:

W\_Diagonal is the main diagonal of matrixU.

W\_UDiagonal is the first upper diagonal of M\_Upper.

W\_U2Diagonal is the second diagonal of M\_Upper.

W\_LDiagonal is the first lower diagonal of M\_Lower.

W\_PIV is a vector of pivot indices.

In this case M\_Lower can be constructed (see below) from W\_LDiagonal and the pivot index wave W\_PIV.

If you are working with tridiagonal matrices you can take advantage of MatrixOp functionality to reconstruct your outputs. For example:

```
MatrixOp/O M_Upper=Diagonal(W_diagonal)
MatrixOp/O M_Upper=setOffDiag(M_Upper,1,W_UDiagonal)
MatrixOp/O M_Upper=setOffDiag(M_Upper,2,W_U2Diagonal)
```

These commands can be combined into a single command line.

The construction of M\_Lower is a bit more complicated and can be accomplished for real data using the following code:

```
Function MakeLTMatrix(W_diagonal,W_LDiagonal,W_PIV)
 Wave W_diagonal,W_LDiagonal,W_PIV

 Variable i,N=DimSize(W_diagonal,0)
 MatrixOp/O M_Lower=setOffDiag(ZeroMat(N,N,4),-1,W_LDiagonal)
 M_Lower=p==q ? 1:M_Lower[p][q] // Set the main diagonal to 1's
 MatrixOp/O index=W_PIV-1 // Convert from 1-based array
 for(i=1;i<=N-2;i+=1)
 if(index[i]!=i)
 variable j,tmp
 for(j=0;j<=i-1;j+=1)
 tmp=M_Lower[i][j]
 M_Lower[i][j]=M_Lower[i+1][j]
 M_Lower[i+1][j]=tmp
 endfor
 endif
 endfor
End
```

This code is provided for illustration only. In practice you could use the /FM flag so that the operation creates the full lower and upper matrices for you.

The variable V\_flag is set to zero if the operation succeeds and to 1 otherwise (e.g., if the input is singular). The variables V\_Sum and V\_min are also set by some of the flag options above.

## MatrixMultiply

**MatrixMultiply** *matrixA* [/T], *matrixB* [/T] [, **additional matrices**]

The MatrixMultiply operation calculates matrix expression  $matrixA * matrixB$  and puts the result in a matrix wave named M\_product generated in the current data folder. The /T flag can be included to indicate that the transpose of the specified matrix should be used.

If any of the source matrices are complex, then the result is complex.

### Parameters

If *matrixA* is an NxP matrix then *matrixB* must be a PxM matrix and the product is an NxM matrix. Up to 10 matrices can be specified although it is unlikely you will need more than three. The inner dimensions must be the same. Multiplication is performed from right to left.

It is legal for M\_product to be one of the input matrices. Thus MatrixMultiply A,B,C could also be done as:

## MatrixMultiplyAdd

---

MatrixMultiply B,C  
MatrixMultiply A,M\_product

### Details

Supports multiplication of complex matrices.

An error is generated if the dimensioning of the input arrays is invalid.

**Matrix Math Operations** on page III-138 for more about Igor's matrix routines.

**FastOp** for additional efficient non-matrix operations.

## MatrixMultiplyAdd

**MatrixMultiplyAdd** [/ZC or /DC] [/A=*alpha*] [/B=*beta*] *matA*[/T], *matB*[/T] *matC*

The MatrixMultiplyAdd operation calculates the matrix expression:

$matC = alpha * matA \times matB + beta * matC$

where \* indicates scalar multiplication and x indicates matrix multiplication.

MatrixMultiplyAdd uses the LAPACK library for fast computation. It was added in Igor Pro 9.00.

Use /B=0 for just matrix multiply with no addition. In this case, the *beta\*matC* term is not evaluated.

### Parameters

*matA*, *matB* and *matC* must be of the same number type and must be single or double precision real or complex.

If *matA* is an NxP matrix then *matB* must be a PxM matrix and the product is an NxM matrix. If these conditions are violated MatrixMultiplyAdd generates an error.

Include the /T flag after *matA* and/or *matB* to indicate that the transpose of *matA* and/or *matB* should be used.

If *matC* is a NULL wave reference, then a free wave is created and a reference to it is stored in the wave reference *matC*.

### Flags

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /A= <i>alpha</i> | <i>alpha</i> is the scalar value multiplied with <i>matA</i> . It defaults to 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| /B= <i>beta</i>  | <i>beta</i> is the scalar value multiplied with <i>matB</i> . It defaults to 1. Use /B=0 to omit the <i>beta*matC</i> term.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| /DC              | Duplicates the wave referenced by <i>matC</i> as a free wave, performs the calculation with the duplicate as the destination, and stores a reference to the free wave in <i>matC</i> .<br><br>/DC is allowed only when calling MatrixMultiplyAdd from a user-defined function. It is an error to use /DC from the command line or in a macro.                                                                                                                                                                                                                   |
| /T               | Used after <i>matA</i> and/or <i>matB</i> , /T indicates tells MatrixMultiplyAdd to use the transform of <i>matA</i> and/or <i>matB</i> in the calculation.                                                                                                                                                                                                                                                                                                                                                                                                     |
| /ZC              | Clears the input wave reference <i>matC</i> . This guarantees that <i>matC</i> is NULL which causes MatrixMultiplyAdd to create a free output wave and store a reference to it in <i>matC</i> .<br><br>When using MatrixMultiplyAdd in a loop, use /ZC to clear the input wave reference to ensure that a new free wave is created each time through the loop rather than re-using the same output wave.<br><br>/ZC is allowed only when calling MatrixMultiplyAdd from a user-defined function. It is an error to use /ZC from the command line or in a macro. |

### Details

*matA* and *matB* must exist but, when running in a user-defined function, *matC* may or may not exist. If it does not exist, MatrixMultiplyAdd creates a free output wave, creates a wave reference named *matC*, and stores a reference to the free output wave in *matC*.

Both *alpha* and *beta* must be real and default to 1.

Use */B=0* to omit the *beta\*matC* term.

### Example

```
Function Demo() // Demonstrates various ways to call MatrixMultiplyAdd
 // Create input waves
 Make/O/N=(3,3) matA = p + 10*q
 Make/O/N=(3,3) matB = p == q

 Print "=== matC = matA x matB ==="
 Make/O/N=(3,3) matC = 0
 MatrixMultiplyAdd /B=0 matA, matB, matC
 Print matC

 Print "=== matC = 2*matA x matB ==="
 Make/O/N=(3,3) matC = 0
 MatrixMultiplyAdd /A=2 /B=0 matA, matB, matC
 Print matC

 Print "=== Free Wave Using WaveClear = matA x matB ==="
 Make/O/N=(3,3) matC = 0 // matC wave ref is cleared by WaveClear
 WaveClear matC // MatrixMultiplyAdd creates a free output wave
 MatrixMultiplyAdd /B=0 matA, matB, matC
 Print matC

 Print "=== Free Wave Using /ZC = matA x matB ==="
 Make/O/N=(3,3) matC = 0 // matC wave ref is cleared by /ZC
 MatrixMultiplyAdd /B=0 /ZC matA, matB, matC
 Print matC

 Print "=== Create dest wave using string variable ==="
 String dest = "matDest1"
 Make/O/N=(3,3) $dest = 0
 WAVE destWave = $dest
 MatrixMultiplyAdd /B=0 matA, matB, destWave
 Print destWave
End
```

**FastOp** for additional efficient non-matrix operations.

## MatrixOp

**MatrixOp** [*/C /FREE /NTHR=n /O /S*] *destwave = expression*

The MatrixOp operation evaluates *expression* and stores the result in *destWave*.

*expression* may include literal numbers, numeric variables, numeric waves, and the set of operators and functions described below. MatrixOp does not support text waves, strings or structures.

MatrixOp is faster and in some case more readable than standard Igor waveform assignments and matrix operations.

See **Using MatrixOp** on page III-140 for an introduction to MatrixOp.

### Parameters

*destWave*

Specifies a destination wave for the assignment expression. *destWave* is created at runtime. If it already exists, you must use the /O flag to overwrite it or the operation returns an error.

When the operation is completed, *destWave* has the dimensions and data type implied by *expression*. In particular, it may be complex if *expression* evaluates to a complex quantity. If *expression* evaluates to a scalar, *destWave* is a 1x1 wave.

If you include the /FREE flag then *destWave* is created as a free wave.

By default the data type of *destWave* depends on the data types of the operands and the nature of the operations on the right-hand side of the assignment. If *expression* references integer waves only, *destWave* may be an integer wave too but most operations with a scalars convert *destWave* into a double precision wave. See **MatrixOp Data Promotion Policy** on page III-145 for further discussion.

Even if *destWave* exists before the operation, MatrixOp may change its data type and dimensionality as implied by *expression*.

You can force the number type using MatrixOp functions such as `uint16` and `fp32`.

*expression*

*expression* is a mathematical expression referencing waves, local variables, global variables and literal numbers together with MatrixOp functions and MatrixOp operators as listed in the following sections.

You can use any combination of data types for operands. In particular, you can mix real and complex types in *expression*. MatrixOp determines data types of inputs and the appropriate output data type at runtime without regard to any type declaration such as `Wave/C`.

## Operators

|    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| +  | Addition between scalars, matrix addition or addition of a scalar (real or complex) to each element of a matrix.                                                                                                                                                                                                                                                                                                                                                                                       |
| -  | Subtraction of one scalar from another, matrix subtraction, or subtracting a scalar from each element of a matrix. Subtraction of a matrix from a scalar is not defined.                                                                                                                                                                                                                                                                                                                               |
| *  | Multiplication between two scalars, multiplication of a matrix by a scalar, or element-by-element multiplication of two waves of the same dimensions.                                                                                                                                                                                                                                                                                                                                                  |
| /  | Division of two scalars, division of a matrix by a scalar, or element-by-element division between two waves of the same dimensions.<br><br>Division of a scalar by a matrix is not supported but you can use the <code>rec</code> function with multiplication instead.                                                                                                                                                                                                                                |
| x  | Matrix multiplication (lower case x symbol only).<br><br>This operator <i>must</i> be preceded and followed by a space. Matrix multiplication requires that the number of columns in the matrix on the left side be equal to the number of rows in the matrix on the right.                                                                                                                                                                                                                            |
| .  | Generalized form of a dot product. In an expression $a.b$ it is expected that $a$ and $b$ have the same number of points although they may be of arbitrary numeric type. The operator returns the sum of the products of the sequential elements as if both $a$ and $b$ were 1D arrays.<br><br>For complex binary operand waves $a$ and $b$ , this operator returns the MatrixOp equivalent of $\text{sum}(a*\text{conj}(b))$ . The <b>MatrixDot</b> function returns $\text{sum}(b*\text{conj}(a))$ . |
| ^t | Matrix transpose. This is a postfix operator meaning that ^t appears after the name of a matrix wave.                                                                                                                                                                                                                                                                                                                                                                                                  |
| ^h | Hermitian transpose. This is a postfix operator meaning that ^h appears after the name of a matrix wave.                                                                                                                                                                                                                                                                                                                                                                                               |
| && | Logical AND operator supports all real data types and results in a signed byte numeric token with the value of either 0 or 1. The operation acts on an element by element basis and is performed for each element of the operand waves.                                                                                                                                                                                                                                                                |
|    | Logical OR operator supports all real data types and results in a signed byte numeric token with the value of either 0 or 1. The operation acts on an element by element basis and is performed for each element of the operand waves.                                                                                                                                                                                                                                                                 |

MatrixOp does not support operator combinations such as +=.

This table shows the precedence of MatrixOp operators:

| MatrixOp Operator | Precedence     |
|-------------------|----------------|
| ^h    ^t          | <b>Highest</b> |
| x    .            |                |
| *    /            |                |
| +    -            |                |
| &&                | <b>Lowest</b>  |

You can use parentheses to force evaluation order.

Operators that have the same precedence associate from right to left. This means that  $a * b / c$  is equivalent to  $a * (b / c)$ .

## Functions

These functions are available for use with MatrixOp.

|                        |                                                                       |
|------------------------|-----------------------------------------------------------------------|
| <code>abs ( w )</code> | Absolute value of a real number or the magnitude of a complex number. |
|------------------------|-----------------------------------------------------------------------|

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>acos(w)</code>             | Arc cosine of $w$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>acosh(w)</code>            | Inverse hyperbolic cosine of $w$ . Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>addCols(w, dc)</code>      | Returns a matrix where elements of the 1D wave $dc$ are added to the corresponding column in $w$ :<br>$\text{out} = w + dc[q]$ Added in Igor Pro 9.00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <code>axisToQuat(ax)</code>      | See <b>Functions Using Quaternions</b> on page V-572.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>backwardSub(U, c)</code>   | Returns a column vector solution for the matrix equation $Ux=c$ , where $U$ is an (NxN) wave representing an upper triangular matrix and $c$ is a column vector of $N$ rows. If $c$ has additional columns they are ignored. Ideally, $U$ and $c$ should be either SP or DP waves (real or complex). Other numeric data types are supported with a slight performance penalty.<br><br>This function is typically used in solving linear equations following a matrix decomposition into lower and upper triangular matrices (e.g., Cholesky), with an expression of the form:<br>$\text{MatrixOp/O solVector}=\text{backwardSub}(U, \text{forwardSub}(L, b))$ where $U$ and $L$ are the upper and lower triangular factors.<br>Added in Igor Pro 7.00.                                                  |
| <code>beam(w, row, col)</code>   | When $w$ is a 3D wave the beam function returns a 1D array corresponding to the data in the beam defined by $w[\text{row}][\text{col}][]$ . In other words, it returns a 1D array consisting of all elements in the specified row and column from all layers. See also <b>ImageTransform</b> <code>getBeam</code> .<br><br>When $w$ is a 4D wave it returns a 2D array containing $w[\text{row}][\text{col}][][]$ . In other words, it returns a matrix consisting of all elements in the specified row and column from all layers and all chunks.<br><br>The beam function belongs to a special class in that it does not operate on a layer by layer basis. It therefore does not permit compound expressions in place of any of its parameters.<br><br>The beam function has the highest precedence. |

| <code>bitReverseCol(w, c, order)</code> | <p>Returns the matrix <math>w</math> with the entries of column <math>c</math> reordered.</p> <p><code>bitReverseCol</code> was added in Igor Pro 9.00.</p> <p><i>order</i> is one of the following values:</p> <ul style="list-style-type: none"> <li>0: Direct binary reversal of the index</li> <li>1: Hadamard order</li> <li>2: Dyadic/Paley/Gray order</li> <li>3: Unchanged order</li> </ul> <p><code>bitReverseCol</code> can be used for changing the order of entries in fast transform algorithms such as FFT and the fast Walsh-Hadamard transform. The number of rows in <math>w</math> must be a power of 2.</p> <p>See <i>Examples</i> below for an example using <code>bitReverseCol</code>.</p> |
| <code>bitShift(w1, w2)</code>           | <p>Returns an array of the same dimensions and number type as <math>w1</math> shifted by the amount specified in <math>w2</math>. When <math>w2</math> is positive the shifting is to the left. When it is negative the shifting is to the right.</p> <p><math>w2</math> can be either a single number or a matrix of the same dimensions as <math>w1</math>. Both <math>w1</math> and <math>w2</math> must be real integer numeric types.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                    |
| <code>bitXor(w1, w2)</code>             | <p>Returns an array of the same dimensions and number type as <math>w1</math> where each element corresponds to the bitwise XOR operation between <math>w1</math> and <math>w2</math>.</p> <p><math>w2</math> can be either a single number or a matrix of the same dimensions as <math>w1</math>. Both <math>w1</math> and <math>w2</math> must be real integer numeric types.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                                               |
| <code>bitNot(w)</code>                  | <p>Returns an array of the same dimensions and number type as <math>w</math> where each element is the bitwise complement of the corresponding element in <math>w</math>.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>catCols(w1, w2)</code>            | <p>Concatenates the columns of <math>w2</math> to those of <math>w1</math>. <math>w1</math> and <math>w2</math> must have the same number of rows and the same number type.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>catRows(w1, w2)</code>            | <p>Concatenates the rows of <math>w2</math> to those of <math>w1</math>. <math>w1</math> and <math>w2</math> must have the same number of columns and the same number type.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>cbrt(w)</code>                    | <p>Returns the cube root of the elements of <math>w</math>. When <math>w</math> is complex <code>cbrt</code> returns the principal cube root (the root with a positive imaginary number).</p> <p>Added in Igor Pro 8.00.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ceil (z)</code>                   | Smallest integer larger than $z$ .                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>chirpZ (data, A, W, M)</code>     | <p>Chirp Z Transform of the 1D wave data calculated for the contour defined by</p> $z_k = AW^{-k},$ $k = 0, 1, \dots, M - 1.$ <p>Here both <math>A</math> and <math>W</math> are complex and the standard <math>z</math> transform for a sequence <math>\{x(n)\}</math> is defined by</p> $X(z) = \sum_{k=0}^{N-1} x(n)z^{-k}.$ <p>The phase of the output is inverted to match the result of the ChirpZ transform on the unit circle with that of the FFT.</p> |
| <code>chirpZf (data, f1, f2, df)</code> | <p>Chirp Z Transform except that the transform parameters are specified by real-valued starting frequency <math>f1</math>, end frequency <math>f2</math> and frequency resolution <math>df</math>. The transform is confined to the unit circle because both <math>A</math> and <math>W</math> have unit magnitude.</p>                                                                                                                                         |
| <code>chol (w)</code>                   | Returns the Cholesky decomposition $U$ of a positive definite symmetric matrix $w$ such that $w=U^t \times U$ . Note that only the upper triangle of $w$ is actually used in the computation.                                                                                                                                                                                                                                                                   |
| <code>chunk (w, n)</code>               | Returns chunk $n$ from 4D wave $w$ .<br>Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>clip (w, low, high)</code>        | Returns the values in the wave $w$ clipped between the <i>low</i> and the <i>high</i> parameters. If $w$ contains NaN or INF values, they are not modified. The result retains the same number type as the input wave $w$ irrespective of the range of the <i>low</i> and <i>high</i> input parameters.                                                                                                                                                         |
| <code>cmplx (re, im)</code>             | Returns a complex token from two real tokens. <i>re</i> and <i>im</i> must have the same dimensionality.<br>Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                             |
| <code>col (w, c)</code>                 | Returns column $c$ from matrix wave $w$ .                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>colRepeat (w, n)</code>           | Returns a matrix that consists of $n$ identical columns containing the data in the wave $w$ . If $w$ is a 2D wave, it is treated as if it were a single column containing all the data. Higher dimensions are supported on a layer-by-layer basis. MatrixOp returns an error if $n < 2$ .<br>Added in Igor Pro 7.00.                                                                                                                                            |
| <code>conj (matrixWave)</code>          | Complex conjugate of the input expression.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>const (r, c, val)</code>          | Returns an $(r \times c)$ matrix where all elements are equal to <i>val</i> . The data type of the returned matrix is the same as that of <i>val</i> . See also <code>zeroMat</code> below.<br>Added in Igor Pro 7.00.                                                                                                                                                                                                                                          |

`convolve(w1, w2, opt)` Convolution of  $w1$  with  $w2$  subject to options  $opt$ . The dimensions of the result are determined by the largest dimensions of  $w1$  and  $w2$  with the number of rows padded (if necessary) so that they are even. Supported options include  $opt=0$  for circular convolution and  $opt=4$  for acausal convolution.

For fast 2D convolutions where where  $w1$  is an image and  $w2$  is a square kernel of the same numeric type, you can use  $opt=-1$  or  $opt=-2$ . When  $opt=-1$  the convolution at the boundaries is evaluated using zero padding. When  $opt=-2$  the padding is a reflection of  $w1$  about the boundaries. When working with integer waves the kernel is internally normalized by the sum of its elements. The kernel for floating point waves remain unchanged.

To convolve an image in  $w1$  with a smaller point spread function in  $w2$  you can use:

$opt=-1$  if you want to pad the image boundaries with zeros or

$opt=-2$  if you want to pad the boundaries by reflecting image values about each boundary.

The negative options are designed for a very optimized convolution calculation which requires that  $w1$  and  $w2$  have the same numeric type. If the size of the point spread function is larger than about 13x13 it may become more efficient to compute the convolution using the positive options.

`correlate(w1, w2, opt)` Correlation of  $w1$  with  $w2$  subject to options  $opt$ . The dimensions of the result are determined by the largest dimensions of  $w1$  and  $w2$  with the number of rows padded (if necessary) so that they are even. Supported options include  $opt=0$  for circular correlation and  $opt=4$  for acausal correlation.

`cos(w)`

Cosine of  $w$ .

`cosh(w)`

Hyperbolic cosine of  $w$ . Added in Igor Pro 7.00.

`covariance(w)`

Returns the sample covariance matrix. Added in Igor Pro 8.00.

If  $w$  is a rows x cols real matrix then the returned value is the cols x cols matrix  $Q$  with elements

$$q_{ij} = \frac{1}{rows-1} \sum_{i=0}^{rows-1} (w_{ij} - \bar{w}_j)(w_{ik} - \bar{w}_k),$$

where

$$\bar{w}_k = \frac{1}{rows} \sum_{i=0}^{rows-1} w_{ik}.$$

`crossCovar(w1, w2, opt)` Returns the cross-covariance for 1D waves  $w1$  and  $w2$ . The options parameter  $opt$  can be set to 0 for the raw cross-covariance or to 1 if you want the results to be normalized to 1 at zero offset. If  $w1$  has  $N$  rows and  $w2$  has  $M$  rows then the returned vector is of length  $N+M-1$ . The cross-covariance is computed by subtracting the mean of each input followed by correlation and optional normalization. See also **Correlate** with the /NODC flag.

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>decimateMinMax(w, N)</code>  | <p>Decimates the matrix <math>w</math> on a column by column basis. Each column is divided into <math>N</math> bins and each bin is represented by its minimum and maximum values.</p> <p>For an <math>R \times C</math> real valued input <math>w</math>, the output is an array of dimensions <math>2N \times C</math> and the extrema are ordered as in <math>\{\min_0, \max_0, \min_1, \max_1, \dots\}</math>.</p> <p>Because of roundoff, sequential bins may not represent the same number of elements when <math>R</math> is not an integer multiple of <math>N</math>. In this case you not count on the exact form of the bin size roundoff.</p> <p>The <code>decimateMinMax</code> keyword was added in Igor Pro 9.00.</p> |
| <code>det(w)</code>                | Returns a scalar corresponding to the determinant of matrix $w$ , which must be real.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>diagonal(w)</code>           | Creates a square matrix that has the same number of rows as $w$ . All elements are zero except for the diagonal elements which are taken from the first column in $w$ . Use <code>DiagRC</code> if the input is not an existing wave (such as a result from another function).                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>diagRC(w, rows, cols)</code> | 2D matrix of dimensions $rows$ by $cols$ . All matrix elements are set to zero except those of the diagonal which are filled sequentially from elements of $w$ . The dimensionality of $w$ is unimportant. If the total number of elements in $w$ is less than the number of elements on the diagonal then all elements will be used and the remaining diagonal elements will be set to zero.                                                                                                                                                                                                                                                                                                                                        |
| <code>e</code>                     | Returns the base of the natural logarithm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>equal(w1, w2)</code>         | <p>Returns unsigned byte result with 1 for equality and zero otherwise. The dimensionality of the result matches the dimensionality of the largest parameter.</p> <p>Either or both <math>w1</math> and <math>w2</math> can be constants (i.e., one row by one column).</p> <p>If <math>w1</math> and <math>w2</math> are not constants, they must have the same number of rows and columns. If <math>w1</math> or <math>w2</math> have multiple layers, they must either have the same number of layers or one of them must have a single layer.</p> <p>Both parameters can be either real or complex. A comparison of a real with a complex parameter returns zero.</p>                                                            |
| <code>erf(w)</code>                | <p>Returns the error function (see <b>erf</b>) for real values in <math>w</math>.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>erfc(w)</code>               | <p>Returns the complementary error function (see <b>erfc</b>) for real values in <math>w</math>.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>exp(w)</code>                | Exponential function for $w$ which can be real or complex, scalar or a matrix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>expIntegralE1(w)</code>      | Returns the exponential integral for real arguments $w$ . See also <b>ExpIntegralE1</b> . Added in Igor Pro 9.00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>expm(w)</code>               | Returns the matrix exponential of a real-valued square matrix $w$ . Added in Igor Pro 9.00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>FCT(w, dir)</code>           | See <b>Trigonometric Transform Functions</b> on page V-570.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>fft(w, options)</code>       | <p>FFT of <math>w</math>.</p> <p><math>w</math> must have an even number of rows.</p> <p><i>options</i> contains a binary field flag. Set bit 1 to 1 if you want to disable the zero centering (see <code>/Z</code> flag in the <b>FFT</b> operation). Other bits are reserved.</p> <p>MatrixOp does not support wave scaling and therefore it does not produce the same wave scaling changes as the <b>FFT</b> operation.</p>                                                                                                                                                                                                                                                                                                       |

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <code>integrate(w, opt)</code>                          | <p>Returns a running sum of <math>w</math>.</p> <p>If <math>opt=0</math> the sum runs over the entire input wave treating the columns of 2D waves as if they were part of one big column.</p> <p>If <math>opt=1</math> the running sum is computed separately for each column of a 2D wave.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                          |

`intMatrix(w)` Returns a double-precision matrix of the same dimensions as  $w$ .  
 Each element of the returned matrix is the sum of all the corresponding elements of  $w$  that are above and to the left of it, i.e.,

$$out_{ij} = \sum_{m=0}^i \sum_{n=0}^j w_{mn}.$$

The utility of this function is apparent in the following relationship:

$$\sum_{i=x_1}^{x_2} \sum_{j=y_1}^{y_2} w_{ij} = out[x_2, y_2] - out[x_2, y_1 - 1] - out[x_1 - 1, y_2] + out[x_1 - 1, y_1 - 1].$$

`intMatrix` was added in Igor Pro 7.00.

`inv(w)` Returns the inverse of the square matrix  $w$ .  
 If  $w$  is not invertible, the operation returns a matrix of the same dimensions where all elements are set to NaN.

`inverseErf(w)` Returns the inverse error function (see **inverseErf**) for the real values in  $w$ .  
 Added in Igor Pro 7.00.

`inverseErfc(w)` Returns the inverse complementary error function (see **inverseErfc**) for the real values in  $w$ .  
 Added in Igor Pro 7.00.

`kronProd(u, v)` Returns the Kronecker product of matrices  $u$  and  $v$ .  
`kronProd` was added in Igor Pro 9.00.  
 If  $u$  has dimensions  $M \times N$  and  $v$  has dimensions  $P \times Q$  then the returned block matrix has dimensions  $M \times P \times N \times Q$ . It is given by

$$u \otimes v = \begin{bmatrix} u_{11}v_{11} & u_{11}v_{112} & \cdots & u_{11}v_{1q} & \cdots & \cdots & u_{1n}v_{11} & u_{1n}v_{12} & \cdots & u_{1n}v_{1q} \\ u_{11}v_{21} & u_{11}v_{22} & \cdots & u_{11}v_{2q} & \cdots & \cdots & u_{1n}v_{21} & u_{1n}v_{22} & \cdots & u_{1n}v_{2q} \\ \vdots & \vdots & \ddots & \vdots & & & \vdots & \vdots & \ddots & \vdots \\ u_{11}v_{p1} & u_{11}v_{p2} & \cdots & u_{11}v_{pq} & \cdots & \cdots & u_{1n}v_{p1} & u_{1n}v_{p2} & \cdots & u_{1n}v_{pq} \\ \vdots & \vdots & & \vdots & & & \vdots & \vdots & & \vdots \\ \vdots & \vdots & & \vdots & & & \vdots & \vdots & & \vdots \\ u_{m1}v_{11} & u_{m1}v_{12} & \cdots & u_{m1}v_{1q} & \cdots & \cdots & u_{mn}v_{11} & u_{mn}v_{12} & \cdots & u_{mn}v_{1q} \\ u_{m1}v_{21} & u_{m1}v_{22} & \cdots & u_{m1}v_{2q} & \cdots & \cdots & u_{mn}v_{21} & u_{mn}v_{22} & \cdots & u_{mn}v_{2q} \\ \vdots & \vdots & \ddots & \vdots & & & \vdots & \vdots & & \vdots \\ u_{m1}v_{p1} & u_{m1}v_{p2} & \cdots & u_{m1}v_{pq} & & & u_{mn}v_{p1} & u_{mn}v_{p2} & & u_{mn}v_{pq} \end{bmatrix}$$

See *Examples* below for an example using `kronProd`.

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>layer(w, n, chunk)</code>   | <p>Returns a layer of a 3D or 4D wave.</p> <p>The layer function was added in Igor Pro 7.00.</p> <p>The optional <i>chunk</i> parameter was added in Igor Pro 9.00.</p> <p>If you omit <i>chunk</i> and <i>w</i> is a 3D wave, the layer function returns layer <i>n</i> from <i>w</i>.</p> <p>If you omit <i>chunk</i> and <i>w</i> is a 4D wave, the layer function returns layer <i>n</i> of chunk 0 from <i>w</i>.</p> <p>If you include <i>chunk</i>, <i>w</i> must be a 4D wave and the layer function returns layer <i>n</i> of the specified chunk from <i>w</i>.</p> <p>In all cases <i>w</i> must be a an actual wave and not an expression.</p> |
| <code>layerStack(w, n)</code>     | <p>The layerStack function takes a 4D input wave <i>w</i> and a layer number <i>n</i> and returns a 3D wave (stack) that contains sequentially the data in layer <i>n</i> of each chunk of <i>w</i>. <i>w</i> must be a wave and not a derived token.</p> <p>layerStack was added in Igor Pro 9.00.</p> <p>Example:</p> <pre>// Create 3D stack from red channel of 4D RGB movie wave MatrixOP/O redChannelStack=layerStack(myRGBMovie, 0)</pre>                                                                                                                                                                                                           |
| <code>limitProduct(w1, w2)</code> | <p>Returns a partial element-by-element multiplication of waves <i>w1</i> and <i>w2</i>.</p> <p>It is assumed that the dimensions of <i>w1</i> are greater or equal to that of <i>w2</i>. If <i>w2</i> is of dimensions NxM then the function returns a matrix of the same dimensions as <i>w1</i> with the first NxM elements contain the product of the corresponding elements in <i>w1</i> and <i>w2</i> and the remaining elements set to zero.</p> <p>The function is designed to be used in filtering applications where the size of the kernel <i>w2</i> is much smaller than the size of the input <i>w1</i>.</p> <p>Added in Igor Pro 7.00.</p>   |
| <code>log(w)</code>               | <p>Returns the log base 10 of a token <i>w</i> which can be real or complex, scalar or a matrix.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>log2(w)</code>              | <p>Returns the log base 2 of a token <i>w</i> which can be real or complex, scalar or a matrix. log2 was added in Igor Pro 9.00.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>ln(w)</code>                | <p>Returns the natural logarithm of a token <i>w2</i> which can be real or complex, scalar or a matrix.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>mag(w)</code>               | <p>Returns a real valued wave containing the magnitude of each element of <i>w</i>. This is equivalent to the abs function.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>magSqr(w)</code>            | <p>Returns a real value wave containing the square of a real <i>w</i> or the squared magnitude of complex <i>w</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>maxAB(a, b)</code>          | <p>Returns the larger of the two real numbers <i>a</i> and <i>b</i>.</p> <p>maxAB does not support NaN or complex inputs.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>maxMagAB(a, b)</code>       | <p>For each data point in the tokens <i>a</i> and <i>b</i>, maxMagAB returns the one with the larger absolute value.</p> <p>maxMagAB does not support complex numbers.</p> <p>Added in Igor Pro 9.00.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                       |                                                                                                                                                                                                                                    |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mod ( w , b )</code>            | Returns the remainder after dividing $w$ by $b$ . $b$ can be a scalar or a matrix of the same dimensions as $w$ .<br>Added in Igor Pro 7.00.                                                                                       |
| <code>nan ( )</code>                  | Returns NaN.<br>Added in Igor Pro 7.00.                                                                                                                                                                                            |
| <code>normalize ( w )</code>          | Normalized version of a vector or a matrix. Normalization is such that the returned token should have a unity magnitude except if all elements are zero, in which case output is unchanged.                                        |
| <code>normalizeCols ( w )</code>      | Divides each column of the real wave $w$ by the square root of the sum of the squares of all elements of the column.                                                                                                               |
| <code>normalizeRows ( w )</code>      | Divides each row of the real wave $w$ by the square root of the sum of the squares of all the elements in that row.                                                                                                                |
| <code>normP ( w , pn )</code>         | Returns the p-norm of matrix $w$ defined by<br>$\ w\ _p = \left( \sum_{j=0}^{cols} \sum_{i=0}^{rows}  w[i][j] ^p \right)^{1/p}$<br>The case of $pn=2$ is equivalent to the MatrixOp Frobenius function.<br>Added in Igor Pro 9.00. |
| <code>numCols ( w )</code>            | Returns the number of columns in the wave $w$ . When $w$ is 1D the function returns 1.                                                                                                                                             |
| <code>numPoints ( w )</code>          | Returns the number of points in a layer of $w$ .                                                                                                                                                                                   |
| <code>numRows ( w )</code>            | Returns the number of rows in $w$ .                                                                                                                                                                                                |
| <code>numType ( w )</code>            | Number the number type of $w$ :<br>0: $w$ is a normal number<br>1: $w$ is +/-INF<br>2: $w$ is NaN                                                                                                                                  |
| <code>oneNorm ( w )</code>            | Returns the 1-norm of matrix $w$ defined as the maximum absolute column sum<br>$\ w\ _1 = \max_{0 \leq j < cols} \left( \sum_{i=0}^{rows}  w[i][j]  \right)$<br>Added in Igor Pro 9.00.                                            |
| <code>outerProduct ( w1 , w2 )</code> | For a 1D wave $w1$ containing M points and a 1D wave $w2$ containing N points, <code>outerProduct</code> returns an M by N matrix where the (i,j) element is:<br>$out[i,j] = w1[i] * conj(w2[j])$<br>Added in Igor Pro 8.00.       |
| <code>p2Rect ( w )</code>             | Converts each element of $w$ from polar to rectangular representation.                                                                                                                                                             |
| <code>phase ( w )</code>              | Returns a real valued wave containing the phase of each element of $w$ calculated using <code>phase=atan2 ( y , x )</code> .                                                                                                       |
| <code>Pi</code>                       | Returns $\pi$ .                                                                                                                                                                                                                    |
| <code>powC ( w1 , w2 )</code>         | Complex valued $w1^{w2}$ where $w1$ and $w2$ can be real or complex.                                                                                                                                                               |
| <code>powR ( x , y )</code>           | Returns $x^y$ for real $x$ and $y$ .                                                                                                                                                                                               |

---

|                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>productCol (w, c)</code>                    | Returns the a (1 x 1) wave containing the product of the elements in column <i>c</i> of wave <i>w</i> . The output is double precision real or complex.<br>Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                   |
| <code>productCols (w)</code>                      | Returns a (1 x cols) wave where each entry is the product of all the elements in the corresponding column. The output is double precision real or complex.<br>Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                |
| <code>productDiagonal (w, d)</code>               | Returns a (1 x 1) wave containing the product of the elements on the specified diagonal of wave <i>w</i> . <i>d</i> =0 is the main diagonal, <i>d</i> >0 correspond to upper diagonals and <i>d</i> <0 to lower diagonals. The output is double precision real or complex.<br>Added in Igor Pro 7.00.                                                                                                                                                                                                                                                |
| <code>productRow (w, r)</code>                    | Returns the a (1 x 1) wave containing the product of the elements in row <i>r</i> of wave <i>w</i> . The output is double precision real or complex.<br>Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                      |
| <code>productRows (w)</code>                      | Returns a (1 x rows) wave where each entry is the product of all the elements in the corresponding row. The output is double precision real or complex.<br>Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                   |

| <code>quatToMatrix (qIn)</code>                   | See <b>Functions Using Quaternions</b> on page V-572.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>r2Polar (w)</code>                          | Performs the equivalent of the <b>r2polar</b> function on each element of <i>w</i> , i.e., each complex number (x+iy) is converted into the polar representation r,theta with $x+iy=r*\exp(i*theta)$                                                                                                                                                                                                                                                                                                                                                 |
| <code>real (w)</code>                             | Returns the real part of <i>w</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>rec (w)</code>                              | Returns the reciprocal of each element in <i>w</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>redimension (w, nr, nc)</code>              | Returns an (nr x nc) matrix from the data in the wave <i>w</i> . The data in <i>w</i> are moved contiguously (column by column regardless of dimensionality) into the output. If the output size is larger than <i>w</i> the remaining points are set to zero. If <i>w</i> contains more than one layer the new dimensions apply on a layer by layer basis. For example:<br><pre>Make/N=(10,20,30) ddd = p + 10*q + 100*r MatrixOp/O aa = redimension(ddd,25,1)</pre> creates a wave <i>aa</i> with dimensions (25,1,30).<br>Added in Igor Pro 7.00. |
| <code>replace (w, findVal, replacementVal)</code> | Replace in wave <i>w</i> every occurrence of <i>findVal</i> with <i>replacementVal</i> . The wave <i>w</i> retains its dimensionality and number type. <i>replacementVal</i> is converted to the same number type as <i>w</i> which may cause truncation.                                                                                                                                                                                                                                                                                            |
| <code>replaceNaNs (w, replacementVal)</code>      | Replaces every occurrence of NaN in the wave <i>w</i> with <i>replacementVal</i> . The wave <i>w</i> retains its dimensionality. <i>replacementVal</i> is converted to the same number type as <i>w</i> which may cause truncation.                                                                                                                                                                                                                                                                                                                  |

## MatrixOp

| <code>reverseRows (w)</code>      | Returns array $w$ with all rows in reverse order.<br>Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                       |
| <code>rotateChunks (w, n)</code>  | Returns a matrix where the last $n$ chunks of $w$ are moved to chunks $[0, n-1]$ . If $n$ is negative then the first $\text{abs}(n)$ chunks are moved to the end of the data. It is an error to pass NaN for $n$ .<br>Added in Igor Pro 7.00.                                                                                                                                                                      |
| <code>rotateCols (w, nc)</code>   | Rotates the columns of a 2D wave $w$ so that the last $nc$ columns are moved to columns $[0, nc - 1]$ of the data. If $nc$ is negative the first $\text{abs}(nc)$ columns are moved to columns $[n-1-nc, n-1]$ . Here $n$ is the total number of columns. It is an error to pass NaN for $nc$ . If $nc$ is greater than the number of columns then the effective rotation is $\text{mod}(nc, \text{actualCols})$ . |
| <code>rotateLayers (w, n)</code>  | Returns a matrix where the last $n$ layers of $w$ are moved to layers $[0, n-1]$ . If $n$ is negative then the first $\text{abs}(n)$ layers are moved to the end of the data. It is an error to pass NaN for $n$ .<br>Added in Igor Pro 7.00.                                                                                                                                                                      |
| <code>rotateRows (w, nr)</code>   | Rotates the rows of a 2D wave $w$ so that the last $nr$ rows are moved to rows $[0, nr - 1]$ of the data. If $nr$ is negative the first $\text{abs}(nr)$ rows are moved to rows $[n-1-nr, n-1]$ where $n$ is the total number of rows. It is an error to pass NaN for $nr$ . If $nr$ is greater than the number of rows then the effective rotation is $\text{mod}(nr, \text{actualRows})$ .                       |
| <code>round (z)</code>            | Rounds $z$ to the nearest integer. The rounding method is "away from zero".                                                                                                                                                                                                                                                                                                                                        |
| <code>row (w, r)</code>           | Returns row $r$ from matrix wave $w$ . The returned row is a $(1 \times C)$ wave where $C$ is the number of columns in $w$ . To convert it to a 1D wave use <code>Redimension/N=(C)</code> . See also <b>ImageTransform</b> <code>getRow</code> .                                                                                                                                                                  |
| <code>rowRepeat (w, n)</code>     | Returns a matrix that consists of $n$ identical rows containing the data in the wave $w$ . If $w$ is a 2D wave, it is treated as if it were a single column containing all the data. Higher dimensions are supported on a layer-by-layer basis. MatrixOp returns an error if $n < 2$ .<br>Added in Igor Pro 7.00.                                                                                                  |
| <code>scale (w, low, high)</code> | Returns the values in the wave $w$ scaled between the <i>low</i> and the <i>high</i> parameters. If $w$ contains NaN or INF values, they are not modified. The result retains the same number type as that of $w$ irrespective of the range of the <i>low</i> and <i>high</i> input parameters.                                                                                                                    |
| <code>scaleCols (w1, w2)</code>   | Returns a matrix of the same dimensions as $w1$ where each column of $w1$ is scaled by the value in the corresponding row of the 1D wave $w2$ . The number of rows in $w2$ must equal the number of columns in $w1$ .<br>Added in Igor Pro 7.00.                                                                                                                                                                   |
| <code>scaleRows (w1, w2)</code>   | Returns a matrix of the same dimensions as $w1$ where each row of $w1$ is scaled by the value in the corresponding row of the 1D wave $w2$ . The number of rows in $w2$ must equal the number of rows in $w1$ .<br>Added in Igor Pro 7.00.                                                                                                                                                                         |

---

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>select (w, sr, sc)</code>          | Returns a matrix consisting of the elements of matrix <i>w</i> for which the row index satisfies $(p\%sr)=0$ and the column index satisfies $(q\%sc)=0$ . The first row and column are always selected.<br><br><i>sr</i> and <i>sc</i> must be real, finite, and non-negative.<br><br>Added in Igor Pro 9.00.                                                                                                                                                                 |
| <code>setCol (w2d, c, w1d)</code>        | Returns the data in the <i>w2d</i> with the contents of <i>w1d</i> stored in column <i>c</i> .<br><br><i>w1d</i> must have at least as many elements as the number of rows of <i>w2d</i> . <i>w2d</i> and <i>w1d</i> must be either both real or both complex.<br><br>Added in Igor Pro 7.00.                                                                                                                                                                                 |
| <code>setColsRange (w, low, high)</code> | Returns a matrix in which each column of <i>w</i> is scaled to the range $[low,high]$ . <i>w</i> must be real-valued.<br><br><code>setColsRange</code> was added in Igor Pro 9.00.                                                                                                                                                                                                                                                                                            |
| <code>setNaNs (w, mask)</code>           | Returns the data in the wave <i>w</i> with NaNs stored where the mask wave is non-zero. The wave <i>w</i> can be of any numeric type.<br><br><i>mask</i> must have the same dimensions as <i>w</i> and must be real. It is usually the result of another expression. For example, to set all values in the destination to NaN where <i>w</i> is greater than 5:<br><br><code>MatrixOp/ou = setNaNs (w, greater (w, 5))</code><br><br>Added in Igor Pro 7.00.                  |
| <code>setOffDiag (w, d, w1)</code>       | Returns the data in the <i>w</i> with the contents of <i>w1</i> stored in diagonal <i>d</i> .<br><br><i>d=0</i> is the main diagonal of <i>w</i> , <i>d&gt;0</i> correspond to upper diagonals and <i>d&lt;0</i> to lower diagonals. <i>w</i> and <i>w1</i> can either be both real or both complex.<br><br>Added in Igor Pro 7.00.                                                                                                                                           |
| <code>setRow (w2d r, w1d)</code>         | Returns the data in the <i>w2d</i> with the contents of <i>w1d</i> stored in row <i>r</i> .<br><br><i>w1d</i> must have at least as many elements as the number of columns in <i>w2d</i> . <i>w2d</i> and <i>w1d</i> must be either both real or both complex.<br><br>Added in Igor Pro 7.00.                                                                                                                                                                                 |
| <code>sgn (w)</code>                     | Returns the sign of each element in <i>w</i> . It returns -1 for negative numbers and 1 otherwise. It does not accept complex numbers.                                                                                                                                                                                                                                                                                                                                        |
| <code>shiftVector (w, n, val)</code>     | Shifts the element of a 1D row-vector <i>w</i> by <i>n</i> elements and fills the displaced elements with <i>val</i> , which must match the data type of <i>w</i> and should be expressed as <code>cmplx (a, b)</code> for complex <i>w</i> .                                                                                                                                                                                                                                 |
| <code>sin (z)</code>                     | Sine of <i>z</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>sinh (z)</code>                    | Hyperbolic sine of <i>z</i> . Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>slerp (qIn1, qIn2, frac)</code>    | See <b>Functions Using Quaternions</b> on page V-572.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>spliceCols (w, c, d, ic)</code>    | Returns a matrix where <i>ic</i> columns from matrix <i>d</i> are spliced into matrix <i>w</i> starting at column <i>c</i> of <i>w</i> . Matrix <i>d</i> must have the same number of rows as matrix <i>w</i> and they must both have the same number type. <i>ic</i> must be non-negative integer. If <i>ic</i> is greater than the number of columns in the matrix <i>d</i> , the function repeats as many columns of <i>d</i> as necessary.<br><br>Added in Igor Pro 9.00. |
| <code>sq (w)</code>                      | Returns the square of each element of the matrix <i>w</i> .<br><br>For complex elements <i>z</i> the returned value is $z*z$ , not <code>magsqr(z)</code> .<br><br>Added in Igor Pro 9.00.                                                                                                                                                                                                                                                                                    |

|                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <code>sqrt (z)</code>                             | Square root of $z$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>subRange (w, rs, re, cs, ce)</code>         | <p>Returns a contiguous subset of the wave <math>w</math> from starting row <math>rs</math> through ending row <math>re</math> and from starting column <math>cs</math> through ending column <math>ce</math>. This is similar to Duplicate/R except that dimension scaling and labels not preserved.</p> <p>Added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>subtractMean (w, opt)</code>                | Computes the mean of the real wave $w$ and returns the values of the wave minus the mean value ( $opt=0$ ). Computes the mean of each column and subtracts it from that column ( $opt=1$ ). Subtracts the mean of each row from row values ( $opt=2$ ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>subWaveC (w, r, c, count [, stride])</code> | <p>Returns a subset of the data that is sampled along columns of the wave <math>w</math>, containing count elements starting with the element at row <math>r</math> and column <math>c</math>. By default <math>stride=1</math> and the sampling is continuous.</p> <p>You can specify a negative stride to sample backwards from the starting element.</p> <p>The operation returns an error if the sampling would exceed the array bounds in either direction.</p> <p>For example:</p> <pre>Make/O/N=(22,33) ddd=x MatrixOP/O/P=1 aa=subWaveC(ddd,4,5,10,2) // aa={4,6,8,10,12,14,16,18,20,0} MatrixOP/O/P=1 aa=subWaveC(ddd,4,5,5,-4) // aa={4,0,18,14,10}</pre>                                                                 |
| <code>subWaveR (w, r, c, count [, stride])</code> | <p>Returns a subset of the data that is sampled along rows of the wave <math>w</math>, containing count elements starting with the element at row <math>r</math> and column <math>c</math>. By default <math>stride=1</math> and the sampling is continuous.</p> <p>You can specify a negative stride to sample backwards from the starting element.</p> <p>The operation returns an error if the sampling would exceed the array bounds in either direction.</p> <p>Examples:</p> <pre>Make/O/N=(10,20) ddd=y // Forward sampling across right boundary MatrixOP/O/P=1 aa=subWaveR(ddd,4,15,6,2) // aa={15,17,19,1,3,5} // Reverse sampling across left boundary MatrixOP/O/P=1 aa=subWaveR(ddd,2,3,5,-1) // aa={3,2,1,0,19}</pre> |
| <code>sum (z)</code>                              | Returns the sum of all the elements in expression $z$ .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

`sumBeams (w)` Returns an (n x m) matrix containing the sum over all layers of all the beams of the 3D wave  $w$ :

$$out_{ij} = \sum_{k=0}^{nLayers-1} w_{ijk}.$$

A beam is a 1D array in the Z-direction.

`sumBeams` is a non-layered function which requires that  $w$  be a proper 3D wave and not the result of another expression.

`sumCols (w)` Returns a (1 x m) matrix containing the sums of the m columns in the nxm input wave  $w$ :

$$out_j = \sum_{i=0}^{nRows-1} w_{ij}.$$

`sumND (w)` Returns a 1-point wave containing the sum of the token  $w$  regardless of its dimensionality.

`sumND` was added in Igor Pro 9.00.

This example illustrates the difference between `sumND` and the `sum` function which operates on a layer-by-layer basis:

```
Make/O/N=(5,6,3) w3D = z
MatrixOP/O/P=1 sumOut=sum(w3D) // Prints 3 layer sums
MatrixOP/O/P=1 sumNDOut=sumND(w3D) // Prints single sum
```

`sumRows (w)` Returns an (n x 1) matrix containing the sums of the n rows in the nxm input wave  $w$ :

$$out_i = \sum_{j=0}^{nCols-1} w_{ij}.$$

`sumSqr (w)` Sum of the squared magnitude of all elements in  $w$ .

`syncCorrelation (w)` Synchronous spectrum correlation matrix for a real valued input matrix wave  $w$ . See also `asyncCorrelation`.

The correlation matrix is computed by subtracting from each column of  $w$  its mean value, multiplying the resulting matrix by its transpose, and finally dividing all elements by (nrows-1) where nrows is the number of rows in  $w$ .

`tan (w)` Tangent of  $w$ .

`tanh (w)` Hyperbolic tangent of  $w$ . Added in Igor Pro 7.00.

`tensorProduct (w1, w2)` Returns a 2D matrix that is the tensor product of the 2D matrices  $w1$  and  $w2$ . For example, the tensor product of two (2 x 2) matrices is given by:

$$\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} \otimes \begin{pmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{pmatrix} = \begin{pmatrix} a_{11}b_{11} & a_{11}b_{12} & a_{12}b_{11} & a_{12}b_{12} \\ a_{11}b_{21} & a_{11}b_{22} & a_{12}b_{21} & a_{12}b_{22} \\ a_{21}b_{11} & a_{21}b_{12} & a_{22}b_{11} & a_{22}b_{12} \\ a_{21}b_{21} & a_{21}b_{22} & a_{22}b_{21} & a_{22}b_{22} \end{pmatrix}$$

Added in Igor Pro 7.00.

| <code>Trace (w)</code>                 | Returns a real or complex scalar which is the sum of the diagonal elements of $w$ . If $w$ is not a square matrix, the sum is over the elements for which the row and column indices are the same.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                      |                                |                      |                                |                      |                                |                      |                                |                      |                                |

| <code>triDiag (w1, w2, w3)</code>      | Returns a tri-diagonal matrix where $w1$ is the upper diagonal, $w2$ the main diagonal and $w3$ the lower diagonal. If $w2$ has $n$ points then $w1$ and $w3$ are expected to have $n-1$ points. The waves can be of any numeric type and the returned wave has a numeric type that accommodates the input.                                                                                                                                                                                                                                                                                                                                                                                                                       |                      |                                |                      |                                |                      |                                |                      |                                |                      |                                |
| <code>uint8 (w)</code>                 | Converts $w$ to 8-bit unsigned integer representation. See also the <code>/NPRM</code> flag below for more information. Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                      |                                |                      |                                |                      |                                |                      |                                |                      |                                |
| <code>uint16 (w)</code>                | Converts $w$ to 16-bit unsigned integer representation. See also the <code>/NPRM</code> flag below for more information. | <code>waveIndexSet (w1, w2, w3)</code> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                      |                                |                      |                                |                      |                                |                      |                                |                      |                                |

Returns a matrix of the same dimensions as  $w1$  with values taken either from  $w1$  or from  $w3$  depending on values in  $w2$  using:

$$out[i][j] = \begin{cases} w1[i][j] & \text{if } w2[i][j] < 0 \\ w3[w2[i][j]] & \text{otherwise} \end{cases} .$$

$w1$  and  $w2$  must have the same number of rows and columns.  $w1$  and  $w3$  must match in number type.  $w2$  cannot be unsigned.

Values from  $w2$  are used as point number indices into  $w3$  which is treated like a 1D wave regardless of its actual dimensionality.

An index value from  $w2$  is out-of-bounds if it is greater than or equal to the number of points in  $w3$ . In this case, the output value is taken from  $w1$  as if the index value were negative.

|                                   |                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>waveMap(w1, w2)</code>      | Returns an array of the same dimensions as $w2$ containing the values $w1[w2[i][j]]$ . The data type of the output is the same as that of $w1$ . Values of $w2$ are taken as 1D integer indices into the $w1$ array. See also <b>IndexSort</b> .                                                                                                                                         |
| <code>waveChunks(w)</code>        | Returns the number of chunks in the wave $w$ . Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                   |
| <code>waveLayers(w)</code>        | Returns the number of layers in the wave $w$ . Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                   |
| <code>wavePoints(w)</code>        | Returns the number of points in the wave $w$ . Added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                   |
| <code>within(w, low, high)</code> | Returns an array of the same dimensions as $w$ with the value 1 where the corresponding element of $w$ is between low and high ( $low \leq w[i][j] < high$ ). Added in Igor Pro 7.00.<br>All parameters must be real. It is an error to pass a NaN as either <i>low</i> or <i>high</i> . It is also an error if $low \geq high$ . If $w$ contains NaNs, the corresponding outputs are 0. |
| <code>zapINFs(w)</code>           | Returns a one-column wave containing the sequential data of $w$ with all INF elements removed. The input $w$ can be 1D or 2D but higher dimensions are not supported.<br>Added in Igor Pro 9.00.                                                                                                                                                                                         |
| <code>zapNaNs(w)</code>           | Returns a one-column wave containing the sequential data of $w$ with all NaN elements removed. The input $w$ can be 1D or 2D but higher dimensions are not supported.<br>Added in Igor Pro 9.00.                                                                                                                                                                                         |
| <code>zeroMat(r, c, nt)</code>    | Returns an ( $r \times c$ ) matrix of number type $nt$ where all entries are set to zero. See <b>WaveType</b> for supported types. See also <code>const</code> above.<br>Added in Igor Pro 7.00.                                                                                                                                                                                         |

**Trigonometric Transform Functions**

FCT(*w*, *dir*) Computes the fast, real to real cosine transform on 1D wave *w*.  
 Added in Igor Pro 8.00.  
 The forward transform (*dir*=1) is defined by:

$$F(k) = \frac{1}{n} \left[ f(0) + f(n) \cos(k\pi) \right] + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos\left(\frac{ik\pi}{n}\right), \quad k = 0, \dots, n$$

The number of intervals is  $n = \text{numpts}(w) - 1$ .  
 The inverse transform (*dir*=-1) is defined by:

$$f(i) = \frac{1}{2} \left[ F(0) + F(n) \cos(i\pi) \right] + \sum_{k=1}^{n-1} F(k) \cos\left(\frac{ik\pi}{n}\right), \quad i = 0, \dots, n$$

See **Trigonometric Transforms** on page V-575 below for more information.

FST(*w*, *dir*) Computes the fast, real to real sine transform on 1D wave *w*.  
 Added in Igor Pro 8.00.  
 The forward transform (*dir*=1) is defined by:

$$F(k) = \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin\left(\frac{ik\pi}{n}\right), \quad k = 1, \dots, n-1$$

where  $n = \text{numpts}(w)$ .  
 The inverse transform (*dir*=-1) is defined by:

$$f(i) = \sum_{k=1}^{n-1} F(k) \sin\left(\frac{ik\pi}{n}\right), \quad i = 1, \dots, n-1$$

See **Trigonometric Transforms** on page V-575 below for more information.

FSST(*w*, *dir*) Computes the fast, real to real staggered sine transform on 1D wave *w*.  
 Added in Igor Pro 8.00.  
 The forward direction (*dir*=1) is defined by:

$$F(k) = \frac{1}{n} \sin\left(\frac{(2k-1)\pi}{2}\right) f(n) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin\left(\frac{i(2k-1)\pi}{2n}\right), \quad k = 1, \dots, n$$

where  $n = \text{numpts}(w)$ .  
 The inverse transform (*dir*=-1) is defined by:

$$f(i) = \sum_{k=1}^n F(k) \sin\left(\frac{i(2k-1)\pi}{2n}\right), \quad i = 1, \dots, n$$

See **Trigonometric Transforms** on page V-575 below for more information.

FSCT( $w, dir$ ) Computes the fast, real to real, staggered cosine transform on 1D wave  $w$ .  
 Added in Igor Pro 8.00.  
 The forward direction ( $dir=1$ ) is defined by:

$$F(k) = \frac{1}{n} f(0) + \frac{2}{n} \sum_{j=1}^{n-1} f(j) \cos\left(\frac{j\pi(2k+1)}{2n}\right), \quad k = 0, \dots, n-1$$

The inverse transform ( $dir=-1$ ) is defined by:

$$f(i) = \sum_{k=0}^{n-1} F(k) \cos\left(\frac{(2k+1)i\pi}{2n}\right), \quad i = 0, \dots, n-1$$

See **Trigonometric Transforms** on page V-575 below for more information.

FSST2( $w, dir$ ) Computes the fast, real to real, staggered2 sine transform on 1D wave  $w$ .  
 Added in Igor Pro 8.00.  
 The forward direction ( $dir=1$ ) is defined by:

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \sin\left(\frac{(2k-1)(2i-1)\pi}{4n}\right), \quad k = 1, \dots, n$$

The inverse transform ( $dir=-1$ ) is defined by:

$$f(i) = \sum_{k=1}^n F(k) \cos\left(\frac{(2k-1)(2i-1)\pi}{4n}\right), \quad i = 1, \dots, n$$

See **Trigonometric Transforms** on page V-575 below for more information.

FSCT2( $w, dir$ ) Computes the fast, real to real, staggered2 cosine transform on 1D wave  $w$ .  
 Added in Igor Pro 8.00.  
 The forward direction ( $dir=1$ ) is defined by:

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \cos\left(\frac{(2k-1)(2i-1)\pi}{4n}\right), \quad k = 1, \dots, n$$

The inverse transform ( $dir=-1$ ) is defined by:

$$f(i) = \sum_{k=1}^n F(k) \cos\left(\frac{(2k-1)(2i-1)\pi}{4n}\right), \quad i = 1, \dots, n$$

See **Trigonometric Transforms** on page V-575 below for more information.

### Functions Using Quaternions

These functions create and manipulate quaternion tokens or return quaternion results. They were added in Igor Pro 8.00. See **MatrixOp Quaternion Data Tokens** on page III-146 for background information on quaternions in MatrixOp.

`quat (arg)` Converts *arg* into a quaternion token.

*arg* can be:

- A scalar which is converted to a real quaternion
- A 1x3 or 3x1 wave which is converted to a pure imaginary quaternion
- The output from another `quat` call

Arithmetic on quaternion tokens obeys quaternion arithmetic rules.

*arg* must not be complex. The resulting quaternion token is not normalized by the `quat` function.

See **MatrixOp Quaternion Data Tokens** on page III-146 for details.

`quatToMatrix (qIn)`

Converts *qIn* into a quaternion token, if not already a quaternion token, normalizes it, and returns the equivalent 4x4 homogeneous rotation matrix.

`quatToAxis (qIn)`

Converts *qIn* into a quaternion token, if not already a quaternion token, normalizes it, and returns the equivalent axis of rotation and rotation angle. The result is a 4-element wave in which the first three elements define the rotation axis and the last element is the rotation angle in radians.

`quatToEuler (qIn, mode)`

Converts *qIn* into a quaternion token, if not already a quaternion token, and returns a 3x1 wave containing equivalent Euler angles expressed in radians.

The returned Euler angles are phi (rotation about the X axis), theta (rotation about the Y axis), and psi (rotation about the Z axis).

The *mode* parameter defines the rotation sequence. The supported modes are: 121, 123, 131, 132, 212, 213, 231, 232, 312, 313, 321 and 323. 1 designates the X axis, 2 the Y axis and 3 the Z axis. See, for example:

[https://www.euclideanspace.com/maths/geometry/rotations/conversions/quaternionToEuler/quat\\_2\\_euler\\_paper\\_ver2-1.pdf](https://www.euclideanspace.com/maths/geometry/rotations/conversions/quaternionToEuler/quat_2_euler_paper_ver2-1.pdf)

`axisToQuat (ax)` *ax* is a 4-element wave with the axis of rotation in the first 3 elements and the rotation angle in radians as the last element. Returns a 4-element wave containing the quaternion components representing this rotation.

`slerp (qIn1, qIn2, frac)`

Performs spherical linear interpolation between quaternion *qIn1* and quaternion *qIn2*. *frac* is a value between 0 and 1 representing the amount of desired rotation from *qIn1* to *qIn2*.

The function returns a 4-element wave containing the quaternion components that represent the rotated quaternion. This is useful, for example, in animating a sequence of rotations.

### Wave Parameters

MatrixOp was designed to work with 2D waves (matrices) but also works with 1D, 3D and 4D waves. A 1D wave is treated like a 1-column matrix. 3D and 4D waves are treated on a layer-by-layer basis, as if each layer were a matrix>

You can reference subsets of waves in *expression*. Only two types of subsets are supported: those that evaluate to a single element, which are treated as scalars, and those that evaluate to one or more layers. For example:

```

wave1d [a] Scalar
wave2d [a] [b] Scalar
wave3d [a] [b] [c] Scalar
wave3d [] [] [a] Layer a from 3D wave
wave3d [] [] [a, b] Layers a through b from 3D wave
wave3d [] [] [a, b, c] Layers a through b stepping by c from 3D wave

```

You can pass waves of any dimensions as parameters to MatrixOp functions. For example:

```

Make/O/N=128 wave1d = x
MatrixOp/O outWave = powR(wave1d, 2)

```

MatrixOp does not allow using the same 3D wave on both sides of the assignment:

```

MatrixOp/O wave3D = wave3D + 3 // Not allowed

```

See **MatrixOp Wave Data Tokens** on page III-141 for further discussion.

## Flags

*/AT=allocationType*

*/AT* lets you control the method used to allocate memory in MatrixOP. It was added in Igor Pro 9.00.

Use *allocationType=0* for generic memory allocation.

Use *allocationType=1* for Intel scalable allocation.

Use *allocationType=2* for Intel scalable and aligned allocation.

By default MatrixOP uses scalable and aligned allocation.

*/C* Provides a complex wave reference for *destWave*. If omitted, MatrixOp creates a real wave reference for *destWave*. The wave reference allows you to refer to the output wave in a subsequent statement of a user-defined function.

*/FREE* Creates *destWave* as a free wave. Allowed only in functions and only if a simple name or wave reference structure field is specified.

Requires Igor Pro 6.1 or later. For advanced programmers only.

See **Free Waves** on page IV-90 for more discussion.

*/NTHR=*n** Sets the number of threads used to compute the results for 3D waves. Each thread computes the results for a single layer of the input.

By default (*/NTHR* omitted) the calculations are performed by the main thread only.

If *n=0* the operation uses as many threads you have processors on your computer.

If *n>0*, *n* specifies the number of threads to use. More threads may or may not improve performance.

## MatrixOp

---

- /NPRM** Use `/NPRM` to restrict the automatic promotion of numeric data types in MatrixOp expressions.
- By default, MatrixOp promotes numeric data types so that operations result in reasonable accuracy. In some situations you may want to keep the results as a particular data type even at the risk of truncation or overflow. If you include the `/NPRM` flag, MatrixOp creates the destination wave using the highest precision data type in the expression. For example, an expression `A=B+C` where B is 16-bit wave and C is an 8-bit wave results in a 16-bit wave A. Unsigned number types can result only when all operands are unsigned.
- `/NPRM` is ignored when data promotion is required. For example:
- ```
Make/B/U wave2
MatrixOp/O/NPRM wave1 = -wave2
```
- You can use MatrixOp functions such as `int8`, `int16`, etc., to precisely control the number type of any token.
- /NV=mode** Controls use of Intel MKL vectorized functions. `/NV` was added in Igor Pro 9.00.
- By default, `mode=1`, which uses vectorized functions where possible.
- Set `mode` to 0 to request non-vectorized execution. This may improve speed when MatrixOP is called in a preemptive thread by preventing spawning additional threads.
- /O** Overwrites `destWave` if it already exists.
- /P=printMode**
- Controls printing of the result of the MatrixOp evaluation. `/P` was added in Igor Pro 8.00. `/P` is ignored if MatrixOp is not running in the main thread.
- `printMode` is a value between 0 and 2:
- 0: No printing is done (default).
 - 1: Prints the result from evaluating expression in layer-by-layer order to the history area of the command window and stores the result in the destination wave.
 - 2: Prints the result from evaluating expression in layer-by-layer order to the history area of the command window but does create or store the resulting values in the destination wave. If the destination wave may already exist, you must include the `/O` flag, even though the destination wave is not changed by the operation.
- Use `/P=1` if you want MatrixOp to work normally and then to print the destination wave. Use `/P=2` if you want MatrixOp to print its result without creating or affecting any waves. Values are printed sequentially using 16-digit precision. Output is not formatted to represent rows and columns.
- When the operation's result is a 3D or 4D wave, the results are printed on a layer-by-layer basis.
- See **MatrixOp Printing Examples** on page V-576 below.
- /S** Preserves the dimension scaling, units and wave note of a pre-existing destination wave in a MatrixOp/O command.
- /T=k** Displays results in a table. `k` specifies the behavior when the user attempts to close it.
- 0: Normal with dialog (default).
 - 1: Kills with no dialog.
 - 2: Disables killing.

Details

MatrixOp has the general form:

```
MatrixOp [flags] destWave = expression
```

destWave specifies the wave created by MatrixOp or overwritten by MatrixOp/O.

From the command line, *destWave* can be a simple wave name, a partial data folder path or a full data folder path. In a user-defined function it can be a simple wave name or, if /O is present, a wave reference pointing to an existing wave.

expression is a mathematical expression that consists of one or more data tokens combined with the built-in MatrixOp functions and MatrixOp operators listed above. MatrixOp does not support the p, q, r, s, or x, y, z, t symbols that are used in waveform assignment statements.

Data tokens include waves, variables and literal numbers.

You can use any combination of data types for operands. In particular, you can mix real and complex types in *expression*. MatrixOp determines data types of inputs and the appropriate output data type at runtime without regard to any type declaration such as Wave/C.

See **Using MatrixOp** on page III-140 for more information.

Trigonometric Transforms

The trigonometric transform functions were added in Igor Pro 8.00.

FST, FCT, FSST, FSCT, FSST2 and FSCT2 are implemented using INTEL MKL library functions. The transforms may automatically execute in multiple threads.

The equations for the definitions of the forward and reverse transforms follow Intel's documentation (see <https://software.intel.com/en-us/mkl-developer-reference-c-trigonometric-transforms-implemented>).

In MatrixOP's implementation, all input and output arrays are zero based. This is illustrated by the following example for the staggered2 cosine:

```
Function DoStaggered2Cosine(inWave)
  Wave inWave

  Variable n = dimsize(inWave,0)
  Make/O/N=(n)/D outStaggered2CosTransform=0
  Variable i, k, theSum, frontFactor=2/n

  for(k=1; k<=n; k+=1)
    theSum=0
    for(i=1; i<=n; i+=1)
      theSum += inWave[i-1] * cos((2*k-1) * (2*i-1) * pi/(4*n))
    endfor
    outStaggered2CosTransform[k-1] = frontFactor * theSum
  endfor
End
```

Examples

In addition to these examples, see **MatrixOp Optimization Examples** on page III-148.

The following matrices are used in these examples:

```
Make/O/N=(3,3) r1=x, r2=y
```

Matrix addition and matrix multiplication by a scalar:

```
MatrixOp/O outWave = r1+r2-3*r1
```

Using the matrix Identity function:

```
MatrixOp/O outWave = Identity(3) x r1
```

Create a persisting identity matrix for another calculation:

```
MatrixOp/O id4 = Identity(4)
```

Using the Trace function:

```
MatrixOp/O outWave = (Trace(r1)*identity(3) x r1)-3*r1
```

Using matrix inverse function Inv() with matrix multiplication:

```
MatrixOp/O outWave = Inv(r2) x r2
```

Using the determinant function Det():

```
MatrixOp/O outWave = Det(r1)+Det(r2)
```

Using the Transpose postfix operator:

```
MatrixOp/O outWave = r1^t+(r2-r1)^t-r2^t
```

Using a mix of real and complex data:

MatrixOp

```
Variable/C complexVar = cmplx(1,2)
MatrixOp/O outWave = complexVar*r2 - Cmplx(2,4)*r1

Hermitian transpose operator:
MatrixOp/O outWave = Trace(complexVar*r2)^h -Trace(cmplx(2,4)*r1)^h

In-place operation and conversion to complex:
MatrixOp/O r1 = r1*cmplx(1,2)

Image filtering using 2D spatial filter filterWave:
MatrixOp/O filteredImage=IFFT(FFT(srcImage,2)*filterWave,3)

Positive shift:
Make/O w={0,1,2,3,4,5,6}
MatrixOp/O w=shiftVector(w,2,77)
Print w
// w[0]= {77,77,0,1,2,3,4}

Negative shift:
Make/O w={0,1,2,3,4,5,6}
MatrixOp/O w=shiftVector(w,(-2),77)
Print w
// w[0]= {2,3,4,5,6,77,77}

// Using KronProd function to generate Hadamard matrices
Function HadamardMatrix(int N) // N must be >= 2
    Make/FREE/N=(2,2) H2={{1,1},{1,-1}}
    Duplicate/FREE H2, tmp
    int i
    for(i=2; i<N; i+=1)
        MatrixOP/O/FREE tmp=KronProd(H2,tmp)
    endfor
    Duplicate/O tmp, Hadamard
End

// bitReverseCol
Make/N=8 index = p
MatrixOP/O/P=1 out = bitReverseCol(index,0,0) // Direct binary reversal
// Prints: out = {0,4,2,6,1,5,3,7}
MatrixOP/O/P=1 out = bitReverseCol(index,0,1) // Hadamard order
// Prints: out = {0,4,6,2,3,7,5,1}
MatrixOP/O/P=1 out = bitReverseCol(index,0,2) // Dyadic/Paley/Gray order
// Prints: out = {0,1,3,2,6,7,5,4}
```

MatrixOp Printing Examples

```
// Print a single-valued result
Make/O/N=(10,5) m2D=(p+1)*(q+1)
MatrixOP/O/P=1 aa=sum(m2D)
aa={825}

// Print a real 2D result
Make/O/N=(1,4) ddd=enoise(3)
MatrixOp/O/P=1 aa=ddd
aa={-2.273916482925415,-2.327789783477783,1.286988377571106,-0.8658701777458191}

// Print higher-dimension result layer-by-layer
Make/O/N=(3,4,3) ddd=z+1
MatrixOP/O/P=1 aa=mean(ddd)
aa={1} // Each layer results in a 1x1 value
aa={2}
aa={3}
```

Matrix Math Operations on page III-138 for more about Igor's matrix routines

FastOp

MatrixRank

matrixRank(matrixWaveA [, conditionNumberA])

The matrixRank function returns the rank of *matrixWaveA* subject to the specified condition number.

The matrix is not considered to have full rank if its condition number exceeds the specified *conditionNumberA*.

If the optional parameter *conditionNumberA* is not specified, Igor Pro uses the value 10^{20} .

matrixRank supports real and complex single precision and double precision numeric wave data types.

The value of *conditionNumberA* should be large enough but taking into account the accuracy of the numerical representation given the numeric data type.

If there are any errors the function returns NaN.

See Also

Matrix Math Operations on page III-138 for more about Igor's matrix routines.

MatrixReverseBalance

MatrixReverseBalance [flags] scaleWave, eigenvectorsWave

MatrixReverseBalance inverse-transforms left or right eigenvectors contained in *eigenvectorsWave* that were computed for a matrix that was balanced using MatrixBalance. The results are the eigenvectors of the pre-balanced matrix. *scaleWave* is *W_scale* as returned by MatrixBalance.

MatrixBalance was added in Igor Pro 9.00.

Parameters

eigenvectorsWave must be single-precision or double-precision floating point, real or complex, and must contain no NaNs. MatrixReverseBalance returns an error if these conditions are not met.

Flags

<i>/DSTM=dest</i>	Specifies the destination wave for the inverse-transformed eigenvectors. If you omit <i>/DSTM</i> , the output is saved in <i>M_RBEigenvectors</i> in the current data folder.
<i>/FREE</i>	Create free destination wave when it is specified via <i>/DSTM</i> .
<i>/J=job</i>	<i>job</i> is the type of backward transformation required. It is one of the following letters: N <i>srcWave</i> is not permuted or scaled. P <i>srcWave</i> is permuted but not scaled. S <i>srcWave</i> is scaled but not permuted. The scaling applies a diagonal similarity transformation to make the norms of the various columns close to each other. B <i>srcWave</i> is both scaled and permuted (default). You should use the same value for <i>job</i> as was used in the original balancing.
<i>/LH={low,high}</i>	Specifies the zero-based low and high indices that were returned by MatrixBalance in <i>V_min</i> and <i>V_max</i> respectively.
<i>/Z</i>	Suppresses error reporting. If you use <i>/Z</i> , check the <i>V_Flag</i> output variable to see if the operation succeeded.

MatrixSchur

Details

Matrix balancing is usually called internally by LAPACK routines when there is large variation in the magnitude of matrix elements. Following matrix balancing the computed eigenvalues are expected to be more accurate but the resulting eigenvectors are not the correct eigenvectors of the original pre-balanced matrix. MatrixReverseBalance is then applied to the balanced eigenvectors in order to obtain the eigenvectors of the original matrix.

The operation uses outputs from MatrixBalance as inputs. Pass the *W_scale* output from MatrixBalance as the *scaleWave* parameter. Pass the *V_min* and *V_max* outputs from MatrixBalance as the */LH low* and *high* parameters. See **MatrixBalance** for an example.

Output Variables

V_Flag Set to zero when the operation succeeds. Otherwise, when *V_flag* is positive the value is a standard Igor error code. When *V_flag* is negative it is an indication of an invalid input parameter.

References

The operation uses the following LAPACK routines: *sgebak*, *dgebak*, *cgebak*, and *zgebak*.

See Also

MatrixBalance

MatrixSchur

MatrixSchur [*/Z*] *srcMatrix*

The MatrixSchur operation computes for an NxN nonsymmetric *srcMatrix*, the eigenvalues, the real Schur form *A* and the matrix of Schur vectors *V*.

The Schur factorization has the form: $S = V \times A \times (V^T)$, where V^T is the transpose (use V^H if *S* is complex) and \times denotes matrix multiplication.

Flags

/Z No error reporting.

Details

The operation creates:

M_A Upper triangular matrix containing the Schur form *A*.
M_V Unitary matrix containing the orthogonal matrix *V* of the Schur vectors.
W_REigenValues Waves containing the real and imaginary parts of the eigenvalues when *srcMatrix* is a real wave. If *srcMatrix* is complex, the eigenvalues are stored in *W_eigenValues*.
W_IEigenValues

The variable *V_flag* is set to 0 when there is no error; otherwise it contains the LAPACK error code.

Examples

You can test this operation for an N-by-N source matrix:

```
Make/D/C/N=(5,5) M_S=cplx(enoise(1),enoise(1))
MatrixSchur M_S
MatrixOp/O unitary=(M_V^h) x M_V // Check unitary
MatrixOp/O diff=abs(M_S-M_V x M_A x (M_V^H)) // Check decomposition
```

See Also

Matrix Math Operations on page III-138 for more about Igor's matrix routines and for background references with details about the LAPACK libraries.

MatrixSolve

MatrixSolve *method*, *matrixA*, *vectorB*

The MatrixSolve operation was superseded by MatrixLLS and is included for backward compatibility only.

Used to solve matrix equation $Ax=b$ using the method of your choice. Choices for *method* are:

<i>method</i>	Solution Method
GJ	Gauss Jordan.
LU	LU decomposition.
SV	Singular Value decomposition.

Details

The array *b* can be a matrix containing a number of *b* vectors and the output matrix *M_x* will contain a corresponding set of solution vectors.

V_flag is set to zero if success, 1 if singular matrix using GJ or LU and 1 if SV fails to converge.

For normal problems you should use LU. GJ is provided only for completeness and has no practical use.

When using SV, singular values smaller than 10^{-6} times the largest singular value are set to zero before back substitution.

Generates an error if the dimensions of the input matrices are not appropriate.

See Also

The **MatrixLLS** operation. **Matrix Math Operations** on page III-138 for more about Igor's matrix routines.

MatrixSparse

MatrixSparse [*flags*] **keyword=value**

The MatrixSparse operation provides support for basic matrix operations on sparse matrices. The MatrixSparse operation was added in Igor Pro 9.00.

The following sections use terms and concepts explained under Sparse Matrices. You will need to understand those terms and concepts to understand the following material.

Flags

<i>/LM</i>	Limited memory hint. Specifies that the operation can allocate limited memory proportional to vector size. If this flag is omitted, the operation allocates memory aggressively up to the size of the sparse matrix.
<i>/Q</i>	Quiet - do not print diagnostic information to the history area.
<i>/Z</i>	Errors are not fatal and do not abort procedure execution. Your procedure can inspect the <i>V_flag</i> variable to see if the operation succeeded. <i>V_flag</i> will be zero if it succeeded or nonzero if it failed.

Keywords

<i>alpha=value</i>	Specifies the real part of the alpha value for the MM, MV, and TRSV operations. The default value is 1.
<i>alphai=value</i>	Specifies the imaginary part of the alpha value for the MM, MV, and TRSV operations on complex matrices. The default value is 0. alphai should be specified only when operating on complex matrices.
<i>beta=value</i>	Specifies the real part of the beta value for the MM and MV operations. The default value is 0.
<i>betai=value</i>	Specifies the imaginary part of the beta value for the MM and MV operations. The default value is 0. betai should be specified only when operating on complex matrices.
<i>colsA=nCols</i>	Specifies the number of columns of the sparse matrix A. colsA is a required keyword for all MatrixSparse commands even in the rare cases where neither cooA, cscA, nor csrA are used.

- `colsG=nCols` Specifies the number of columns of the sparse matrix G.
`colsG` is a required keyword for operations involving sparse matrix G.
- `cooA={valuesWave, rowsWave, colsWave}`
Specifies sparse matrix A in COO format using three 1D waves. See **Sparse Matrix Formats** on page III-151 for background information on `cooA` format.
The COO format is used only for conversion operations, not for math operations which always use CSR format.
valuesWave is an wave of length *nnz* (number of non-zero values) containing the non-zero values of A. The wave must be single or double precision real or complex and must not contain any NaNs or INFs.
rowsWave and *colsWave* are 64-bit integer 1D waves created with Make/L that contain *nnz* row and column indices respectively.
When using `cooA`, you must also specify the `rowsA` and `colsA` keywords.
- `cscA={valuesWave, rowsWave, ptrWave}`
Specifies sparse matrix A in CSC format A using three 1D waves. See **Sparse Matrix Formats** on page III-151 for background information on `cscA` format.
The CSC format is used only for conversion operations, not for math operations which always use CSR format.
valuesWave is an wave of length *nnz* (number of non-zero values) containing the non-zero values of A. The wave must be single or double precision real or complex and must not contain any NaNs or INFs.
rowsWave and *ptrWave* are 64-bit integer 1D waves created with Make/L.
rowsWave consists of *nnz* entries that specify the zero-based row index of each entry in *valuesWave*.
ptrWave contains *nCols* or *nCols*+1 entries the first of which must be zero. *ptrWave*[*j*] gives the index in *valuesWave* of the first non-zero value in column *j*. The optional longer version of *ptrWave* stores *nnz* in the last wave point.
When using `cscA`, you must also specify the `rowsA` and `colsA` keywords.
- `csrA={valuesWave, colsWave, ptrWave}`
Specifies sparse matrix A in CSR format using three 1D waves. See **Sparse Matrix Formats** on page III-151 for background information on `csrA` format.
The CSR format is used for conversion operations and for math operations.
valuesWave is an wave of length *nnz* (number of non-zero values) containing the non-zero values of A. The wave must be single or double precision real or complex and must not contain any NaNs or INFs.
colsWave and *ptrWave* are 64-bit integer 1D waves created with Make/L.
colsWave consists of *nnz* entries that specify the zero-based column index of each entry in *valuesWave*.
ptrWave contains *nRows* or *nRows*+1 entries the first of which must be zero. *ptrWave*[*i*] gives the index in *valuesWave* of the first non-zero value of row *i*. The optional longer version of *ptrWave* stores *nnz* in the last wave point.
When using `csrA`, you must also specify the `rowsA` and `colsA` keywords.
- `cooG={valuesWave, rowsWave, colsWave}`
Similar to `cooA` but applies to sparse matrix G.
- `cscG={valuesWave, rowsWave, ptrWave}`
Similar to `cscA` but applies to sparse matrix G.

<code>csrG={valuesWave, colsWave, ptrWave}</code>	Similar to <code>csrA</code> but applies to sparse matrix G.																		
<code>matrixB=wb</code>	Designates the 2D wave <i>wb</i> as matrix B for the MM operation. The wave <i>wb</i> must be of the same data type as sparse matrix A and must not contain INFs or NaNs.																		
<code>matrixC=wc</code>	Designates the 2D wave <i>wc</i> as matrix C for the MM operation. The wave <i>wc</i> must be of the same data type as sparse matrix A and must not contain INFs or NaNs.																		
<code>opA=opName</code>	Specifies a transformation that is applied to sparse matrix A. <i>opName</i> is a single letter: T: Transpose H: Hermitian N: No transformation (default) See MatrixSparse Transformations on page III-156 for details.																		
<code>opG=opName</code>	Specifies a transformation that is applied to sparse matrix G. <i>opName</i> is a single letter: T: Transpose H: Hermitian N: No transformation (default) See MatrixSparse Transformations on page III-156 for details.																		
<code>operation=opN</code>	Specifies the operation name. This is a required keyword. <i>opN</i> is one of the following: <table> <tr> <td>ADD</td> <td>Adds sparse matrices. See MatrixSparse ADD on page III-157 for details.</td> </tr> <tr> <td>MM</td> <td>Computes the product of a sparse matrix and a dense matrix. See MatrixSparse MM on page III-157 for details.</td> </tr> <tr> <td>MV</td> <td>Computes the product of a sparse matrix and a vector. See MatrixSparse MV on page III-158 for details.</td> </tr> <tr> <td>SMSM</td> <td>Computes the product of two sparse matrices. See MatrixSparse SMSM on page III-158 for details.</td> </tr> <tr> <td>TOCOO</td> <td>Creates a sparse matrix in COO format from a sparse matrix or dense matrix. See MatrixSparse TODENSE on page III-160 for details.</td> </tr> <tr> <td>TRSV</td> <td>Solves a system of linear equations for a triangular sparse matrix. See MatrixSparse TRSV on page III-161 for details.</td> </tr> </table>	ADD	Adds sparse matrices. See MatrixSparse ADD on page III-157 for details.	MM	Computes the product of a sparse matrix and a dense matrix. See MatrixSparse MM on page III-157 for details.	MV	Computes the product of a sparse matrix and a vector. See MatrixSparse MV on page III-158 for details.	SMSM	Computes the product of two sparse matrices. See MatrixSparse SMSM on page III-158 for details.	TOCOO	Creates a sparse matrix in COO format from a sparse matrix or dense matrix. See MatrixSparse TOCOO on page III-159 for details.	TOCSC	Creates a sparse matrix in CSC format from a sparse matrix or dense matrix. See MatrixSparse TOCSC on page III-159 for details.	TOCSR	Creates a sparse matrix in CSR format from a sparse matrix or dense matrix. See MatrixSparse TOCSR on page III-160 for details.	TODENSE	Creates a dense matrix from a sparse matrix. See MatrixSparse TODENSE on page III-160 for details.	TRSV	Solves a system of linear equations for a triangular sparse matrix. See MatrixSparse TRSV on page III-161 for details.
ADD	Adds sparse matrices. See MatrixSparse ADD on page III-157 for details.																		
MM	Computes the product of a sparse matrix and a dense matrix. See MatrixSparse MM on page III-157 for details.																		
MV	Computes the product of a sparse matrix and a vector. See MatrixSparse MV on page III-158 for details.																		
SMSM	Computes the product of two sparse matrices. See MatrixSparse SMSM on page III-158 for details.																		
TOCOO	Creates a sparse matrix in COO format from a sparse matrix or dense matrix. See MatrixSparse TOCOO on page III-159 for details.																		
TOCSC	Creates a sparse matrix in CSC format from a sparse matrix or dense matrix. See MatrixSparse TOCSC on page III-159 for details.																		
TOCSR	Creates a sparse matrix in CSR format from a sparse matrix or dense matrix. See MatrixSparse TOCSR on page III-160 for details.																		
TODENSE	Creates a dense matrix from a sparse matrix. See MatrixSparse TODENSE on page III-160 for details.																		
TRSV	Solves a system of linear equations for a triangular sparse matrix. See MatrixSparse TRSV on page III-161 for details.																		
<code>rowsA=nRows</code>	Specifies the number of rows of the sparse matrix A. <code>rowsA</code> is a required keyword for all MatrixSparse commands even in the rare cases where neither <code>cooA</code> , <code>cscA</code> , nor <code>csrA</code> are used.																		
<code>rowsG=nRows</code>	Specifies the number of rows of the sparse matrix G. <code>rowsG</code> is a required keyword for operations involving sparse matrix G.																		

MatrixSVBkSub

sparseMatrixType={*smType,smMode,smDiag*}

Provides optional information to describe both sparse matrix A and sparse matrix G. All of the parameters are keywords.

smType: GENERAL, SYMMETRIC, HERMITIAN, TRIANGULAR, DIAGONAL, BLOCK_TRIANGULAR, or BLOCK_DIAGONAL.

smMode: LOWER or UPPER.

smDiag: DIAG or NON_DIAG.

See **Optional Sparse Matrix Information** on page III-156 for details.

vectorX=*wx*

Designates the 1D wave *wx* as vector X for the MV and TRSV operations.

The wave *wx* must be of the same data type as the sparse matrix data and it must not contain INFs or NaNs.

vectorY=*wy*

Designates the 1D wave *wy* as vector Y for the MV operation.

The wave *wy* must be of the same data type as the sparse matrix data and it must not contain any INFs or NaNs.

Details

MatrixSparse supports data waves with single-precision and double-precision floating point real and complex data types. See **MatrixSparse Operation Data Type** on page III-155 for details.

Index waves must be signed 64-bit integer. See **MatrixSparse Index Data Type** on page III-156 for details.

MatrixSparse does not support waves containing NaNs or INFs.

MatrixSparse math operations (ADD, MV, MM, SMSM, TRSV) require that input sparse matrices be in CSR format. The math operations that return sparse matrices (ADD, SMSM) create output sparse matrices in CSR format.

The conversion operations (TOCOO, TOCSC, TOCSR, TODENSE) accept inputs in COO, CSC, CSR, or dense formats.

Output Variables

MatrixSparse sets these automatically created variables:

V_flag Set to 0 if the operation succeeded or to a non-zero error code.

Examples

You can find examples using MatrixSparse under **MatrixSparse Operations** on page III-156.

See Also

Sparse Matrices on page III-151 for background information about Igor's sparse matrix support.

MatrixSparse Operations on page III-156 for details on each supported operation and examples.

Matrix Math Operations on page III-138 for discussion of non-sparse Igor matrix routines.

MatrixSVBkSub

MatrixSVBkSub *matrixU, vectorW, matrixV, vectorB*

The MatrixSVBkSub operation does back substitution for SV decomposition.

Details

Used to solve matrix equation $Ax=b$ after you have performed an SV decomposition.

Feed this routine the M_U, W_W and M_V waves from **MatrixSVD** along with your right-hand-side vector b. The solution vector x is returned as M_x.

The array b can be a matrix containing a number of b vectors and the M_x will contain a corresponding set of solution vectors.

Generates an error if the dimensions of the input matrices are not appropriate.

See Also

Matrix Math Operations on page III-138 for more about Igor's matrix routines.

MatrixSVD**MatrixSVD** [*flags*] *matrixWave*

The MatrixSVD operation uses the singular value decomposition algorithm to decompose an MxN *matrixWave* into a product of three matrices. The default decomposition is into MxM wave M_U, min(M,N) wave W_W and NxN wave M_VT.

Flags

- /B** Use this flag for backwards compatibility with Igor Pro 3. This option applies only to real valued input waves. Note that no other flag can be combined with /B. Here the decomposition is such that:
- $$U*W*V^T = \text{matrixWave}$$
- U: MxN column-orthonormal matrix.
 W: NxN diagonal matrix of positive singular values.
 V: NxN orthonormal matrix.
- /DACA** Replaces the standard LAPACK algorithm with one that is based on a divide and conquer approach. For a typical 1000x1000 matrix this provides a 6x speed improvement.
 Added in Igor Pro 7.00.
- /INVW** Saves the inverse of the elements in W_W. The results are then stored in wave W_InvW.
- /O** Overwrites *matrixWave* with the first columns of U. Use this flag to if you need to conserve memory. See also related settings of /U and /V.
- /PART =nVals** Performs a partial SVD computing only *nVals* singular values (stored in W_W) and the associated vectors in the matrix M_U and M_V. If you use this flag the operation ignores all other flags except /PDEL. The partial SVD is computed using the Power method of Nash and Shlien.
 The /PART flag was added in Igor Pro 7.00.
- /PDEL=del** Sets the convergence threshold which defaults to 1e-6. Larger positive values result in faster execution but may lead to less accurate results.
 The /PDEL flag was added in Igor Pro 7.00.
- /U =UMatrixOptions** *UMatrixOptions* can have the following values:
- 0: All columns of U are returned in the wave M_U (default).
 - 1: The first min(m,n) columns of U are returned in the wave M_U.
 - 2: The first min(m,n) columns of U overwrite *matrixWave* (/O must be specified).
 - 3: No columns of U are computed.
- /V=VMatrixOptions** *VMatrixOptions* can have the following values:
- 0: All rows of V^T are returned in the wave M_VT (default).
 - 1: The first min(m,n) rows of V^T are returned in the wave M_VT.
 - 2: The first min(m,n) rows of V^T are overwritten on *matrixWave* (/O must be specified)
 - 3: No rows of V^T are computed.
- /Z** No error reporting.

MatrixTrace

Details

The singular value decomposition is computed using LAPACK routines. The diagonal elements of matrix *W* are returned as a 1D wave named *W_W*. If /B is used *W_W* will have *N* elements. Otherwise the number of elements in *W_W* is $\min(M,N)$.

The matrix *V* is returned in a matrix wave named *M_V* if /B is used otherwise the transpose V^T is returned in the wave *M_VT*.

All output objects are created in the current data folder.

The variable *V_flag* is set to zero if the operation succeeds. It is set to 1 if the algorithm fails to converge.

The variable *V_SVConditionNumber* is set to the condition number of the input matrix. The condition number is the ratio of the largest singular value to the smallest.

Example

```
Make/O/D/N=(10,20) A=gnoise(10)
MatrixSVD A
MatrixOp/O diff=abs(A-(M_U x DiagRC(W_W,10,20) x M_VT))
Print sum(diff,-inf,inf)
```

The **MatrixOp** operation for more efficient matrix operations.

Matrix Math Operations on page III-138 for more about Igor's matrix routines and for background references with details about the LAPACK libraries.

MatrixTrace

matrixTrace (*dataMatrix*)

The **matrixTrace** function calculates the trace (sum of diagonal elements) of a square matrix. *dataMatrix* can be of any numeric data type.

If the matrix is complex, it returns the sum of the magnitudes of the diagonal elements.

See Also

Matrix Math Operations on page III-138 for more about Igor's matrix routines.

MatrixTranspose

MatrixTranspose [/H] *matrix*

The **MatrixTranspose** operation Swaps rows and columns in *matrix*.

Does not take complex conjugate if data are complex. You can do that as a follow-on step.

Swaps row and column labels, units and scaling.

This works with text as well as numeric waves. If the matrix has zero data points, it just swaps the row and column scaling.

Flags

/H Computes the Hermitian conjugate of a complex wave.

See Also

The **MatrixOp** operation for more efficient matrix operations.

Matrix Math Operations on page III-138 for more about Igor's matrix routines.

max

```
max(num1, num2 [, num3, ... num200])
```

The max function returns the greatest value of *num1*, *num2*, ... *num200*.

If any parameter is NaN, the result is NaN.

Details

In Igor7 or later, you can pass up to 200 parameters. Previously max was limited to two parameters.

See Also

min, **limit**, **WaveMin**, **WaveMax**, **WaveMinAndMax**

mean

```
mean(waveName [, x1, x2])
```

The mean function returns the arithmetic mean of the wave for points from $x=x1$ to $x=x2$.

Details

If *x1* and *x2* are not specified, they default to $-\infty$ and $+\infty$, respectively.

The wave values from *x1* to *x2* are summed, and the result divided by the number of points in the range.

The X scaling of the wave is used only to locate the points nearest to $x=x1$ and $x=x2$. To use point indexing, replace *x1* with `pnt2x(waveName, pointNumber1)`, and a similar expression for *x2*.

If the points nearest to *x1* or *x2* are not within the point range of 0 to `numpts(waveName)-1`, mean limits them to the nearest of point 0 or point `numpts(waveName)-1`.

If any values in the point range are NaN, mean returns NaN.

The function returns NaN if the input wave has zero points.

Unlike the area function, reversing the order of *x1* and *x2* does *not* change the sign of the returned value.

Examples

```
Make/O/N=100 data; SetScale/I x 0,Pi,data
data=sin(x)
Print mean(data,0,Pi)           // the entire point range, and no more
Print mean(data)                // same as -infinity to +infinity
Print mean(data,Inf,-Inf)       // +infinity to -infinity
```

The following is printed to the history area:

```
Print mean(data,0,Pi)           // the entire point range, and no more
0.630201
Print mean(data)                // same as -infinity to +infinity
0.630201
Print mean(data,Inf,-Inf)       // +infinity to -infinity
0.630201
```

See Also

Variance, **WaveStats**, **median**, **APMath**

The figure "Comparison of area, faverage and mean functions over interval (12.75,13.32)", in the **Details** section of the **faverage** function.

median

```
median(waveName [, x1, x2])
```

The median function returns the median value of the wave for points from $x=x1$ to $x=x2$.

The median function was added in Igor Pro 7.00.

Details

If you omit *x1* and *x2*, they default to $-\text{INF}$ and $+\text{INF}$, respectively.

The X scaling of the wave is used only to locate the points nearest to $x=x1$ and $x=x1$. To use point indexing, replace *x1* with `"pnt2x(waveName,pointNumber1)"`, and a similar expression for *x2*.

MeasureStyledText

If the points nearest to $x1$ or $x2$ are outside the point range of 0 to `numpts(waveName)-1`, median limits them to the nearest of point 0 or point `numpts(waveName)-1`.

If the wave contains NaNs they are skipped.

The function returns NaN if the input wave has zero non-NaN points.

mean, **Variance**, **StatsMedian**, **StatsQuantiles**, **WaveStats**

MeasureStyledText

MeasureStyledText [/W=*winName* /A=*axisName* /F=*fontName* /SIZE=*fontSize* /STYL=*fontStyle*] [*styledTextStr*]

The MeasureStyledText operation takes as input a string optionally containing style codes such as are used in graph annotations and the DrawText operation. It sets various variables with information about the dimensions of the string.

In Igor Pro 9.00, the styledTextStr parameter was made optional, the /B flag was added, and several output variables (all but V_width and V_height) were added.

Flags

<i>/W=winName</i>	Takes default text information from the window <i>winName</i> . If you omit /W, MeasureStyledText works on the top graph window.
<i>/A=axisName</i>	Takes default text information from the axis named <i>axisName</i> in the top graph or in the window specified by /W.
<i>/B=baseLineMode</i>	Selects which baseline offset is returned in V_baseline if the text contains multiple lines (separated by carriage returns). If you omit /B or specify /B=0, V_baseline is set to the offset to the last line of the text. If you specify /B=1, V_baseline is set to the offset to the first line of the text. The /B flag was added in Igor Pro 9.00.
<i>/F=fontNameStr</i>	The name of the default font. In Igor Pro 9.00 and later, /F="default" and /F="" are the same as omitting /F in which case the default font is defined by /W, /A, or by the overall default font specified by the DefaultFont operation.
<i>/SIZE=size</i>	Sets default font size.
<i>/STYL=fontStyle</i>	Sets default font style: Bit 0: Bold Bit 1: Italic Bit 2: Underline Bit 4: Strikethrough <i>/STYLE=0</i> specifies plain text. See Setting Bit Parameters on page IV-12 for details about bit settings.

Parameters

styledTextStr is the styled text to be measured.

In Igor Pro 9.00 and later, *styledTextStr* is an optional parameter. Previously it was required.

If you include *styledTextStr*, the default font and styled text output variables are set.

If you omit *styledTextStr*, only the default font output variables are set.

See **Default Font Output Variables** and **Styled Text Output Variables** below.

styledTextStr can contain escape codes to set the font, size, style, color and other properties. See **Annotation Escape Codes** on page III-53 for details. The text may contain multiple lines separated with carriage returns ("`\r`").

Details

In the absence of formatting codes within the text that set the font, font size and font style, some mechanism must be provided that sets them.

The `/W` flag tells MeasureStyledText to get the default font name and font size from the specified window. If `/W` is omitted, defaults come from the top graph window.

The `/A` flag specifies that the default font name and font size come from the specified axis in the graph window specified by `/W` or in the top graph if `/W` is omitted.

The `/F`, `/SIZE` and `/STYL` flags set defaults that override any defaults from a window or axis. If you don't use any flags, the defaults are Igor's overall defaults.

If you omit all flags, the font specified by the **DefaultFont** operation is used, the default font size is 12 points, and the style is plain.

Default Font Output Variables

In the descriptions of these variables, "default font" refers to the font, size, and style defined by `/W`, `/A`, `/SIZE`, and `/STYLE`, and not any escape codes in styledTextStr.

MeasureStyledText returns information about the default font via the following output variables:

<code>S_font</code>	The name of the default font (before escape codes in <i>styledTextStr</i> take effect). If a substitute font would be used, the name of the substitute font is returned.
<code>V_ascent</code>	Height above the baseline of the default font. This will include some blank space above even the tallest characters.
<code>V_descent</code>	Height below the baseline of the default font.
<code>V_fontSize</code>	The default font size in points.
<code>V_fontStyle</code>	The default font style.
<code>V_subscriptExtraHeight</code>	Extra height needed to accomodate any subscript when using the default font.
<code>V_superscriptExtraHeight</code>	Extra height needed to accomodate any superscript when using the default font.

Styled Text Output Variables

The MeasureStyledText operation returns information in the following variables:

<code>V_width</code>	The width in points of the text.
<code>V_height</code>	The height in points of the text.
<code>V_baseline</code>	The offset to the baseline of the styled text in points, as measured from the bottom of the text. If you omit <code>/B</code> or specify <code>/B=0</code> , this is the offset to the last line's baseline. If you specify <code>/B=1</code> , this is the offset to the first line's baseline.

MeasureStyledText Diagrams

These diagrams illustrate the meanings of the various output variables:

Menu

Example

See the Example section of the documentation for MeasureStyledText in the Igor Reference help file.

See Also

Annotation Escape Codes on page III-53 for a list of text formatting codes.

DefaultFont

Menu

Menu *menuNameStr* [, **hideable**, **dynamic**, **contextualmenu**]

The Menu keyword introduces a menu definition. You can use this to create your own menu, or to add items to a built-in Igor menu.

Use the optional *hideable* keyword to make the menu hideable using **HideIgorMenus**.

Use the optional *dynamic* keyword to cause Igor to re-evaluate the menu definition when the menu is used. This is helpful when the menu item text is provided by a user-defined function. See **Dynamic Menu Items** on page IV-129.

Use the optional *contextualmenu* keyword for menus invoked by **PopupContextualMenu/N**.

See Chapter IV-5, **User-Defined Menus** for further information.

min

min(*num1*, *num2* [, *num3*, ... *num200*])

The min function returns the least value of *num1*, *num2*, ... *num200*.

If any parameter is NaN, the result is NaN.

Details

In Igor7 or later, you can pass up to 200 parameters. Previously min was limited to two parameters.

See Also

max, **limit**, **WaveMin**, **WaveMax**, **WaveMinAndMax**

MMLoadWave

MMLoadWave [*flags*] *fileNameStr*

The MMLoadWave operation loads data from the named Matlab MAT file into single 1D waves (vectors), multidimensional waves (matrices), numeric variables or string variables.

For background information, including configuration instructions, see **Loading Matlab MAT Files** on page II-154.

Parameters

The file to be loaded is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If LoadWave can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

If *fileNameStr* is omitted or is "" or the */I* flag is used, MMLoadWave displays an Open File dialog in which you locate the file to be loaded.

Flags

/A[= <i>name</i>]	Assign wave names using "wave" or <i>name</i> , if present, as the name or base name. Skips names already in use.
/B	This flag is obsolete and is ignored. Previously it was required to tell MLLoadWave the byte order of the data in the file. MLLoadWave now determines the byte order automatically.
/C	Loads columns from a Matlab matrix into an Igor 1D wave. Use /R to load rows.
/E	Skips empty Matlab matrices.
/G	Tells Igor to make numeric and string variables global when called from a macro. When called from a user-defined function or from the command line, variables are always created as globals.
/I	Interactive. Displays the Open File dialog to get the path to the file.
/M= <i>m</i>	<p><i>m</i>=1: Loads an entire Matlab matrix into an Igor 1D wave. This is the default if you omit /M.</p> <p><i>m</i>=2: Loads an entire Matlab matrix into an Igor multidimensional wave.</p> <p><i>m</i>=3: Loads an entire Matlab matrix into a transposed Igor multidimensional wave.</p> <p>/M by itself is equivalent to /M=1.</p> <p>Starting with Igor Pro 8.00, after loading a matrix that results in an Mx1 2D wave, MLLoadWave automatically redimensions the wave as an M-row 1D wave.</p>
/N[= <i>name</i>]	Assign wave names using "wave" or <i>name</i> , if present, as the name or base name. Overwrites existing waves if the name is already in use.
/O	Overwrites existing waves and variables in case of a name conflict. If /O is omitted, MLLoadWave chooses names that don't conflict with existing objects.
/P= <i>pathName</i>	Specifies the folder to look in for the specified file or folder. <i>pathName</i> is the name of an existing Igor symbolic path.
/Q	Be quiet. Suppresses normal diagnostic messages.
/R	Loads rows from a Matlab matrix into an Igor 1D wave. Use /C to load columns.
/S= <i>s</i>	<p>Controls how Matlab string data is loaded:</p> <p><i>s</i>=1 Skips Matlab string matrices.</p> <p><i>s</i>=2 Loads Matlab string matrices into Igor string variables. This is the default if /S is omitted.</p> <p><i>s</i>=3 Loads Matlab string matrices into Igor text waves.</p> <p>/S by itself is equivalent to /S=1.</p>
/T	Displays the loaded waves in a new table.
/V	Skips Matlab numeric variables (numeric matrices with one element).

<code>/Y=y</code>	Specifies the number type of the numeric waves to be created. The allowed codes for y are: 2: Single-precision floating point 4: Double-precision floating point 32: 32-bit signed integer 16: 16-bit signed integer 8: 8-bit signed integer 96: 32-bit signed integer 80: 16-bit signed integer 72: 8-bit signed integer
<code>/Z</code>	Interactive load. Displays a dialog presenting options for each Matlab matrix in the file.

MLLoadWave Wave Naming

If neither `/A`, `/A[=name]`, `/N`, or `N[=name]` is used then the waves names are taken from the matrix name, as stored in the Matlab file.

When loading 1D waves, the `/N` flag instructs MLLoadWave to automatically name new waves "wave" (or *baseName* if `/N=baseName` is used) plus a number. The number starts from zero and increments by one for each wave loaded from the file. When loading multidimensional waves, *name* is used without an appended number.

The `/A` flag is like `/N` except that MLLoadWave skips names already in use.

If you specify `/M=2` (load matrix into matrix) or `/M=3` (load matrix into transposed matrix), MLLoadWave uses the name without appending any digits. For example, if you have a 5x3 matrix in a file and you tell MLLoadWave to load it as a matrix using the name "mat", MLLoadWave will name the matrix "mat". However, if you tell MLLoadWave to load the matrix as 3 1D waves, it will use "mat0", "mat1" and "mat2".

If the name that MLLoadWave would use when creating a wave or variable is in use for an object of the same type and if you use the overwrite flag, then it will overwrite the existing object. If you do not tell MLLoadWave to overwrite, it will choose a non-conflicting name. If the conflict is with an object of a different type or with an operation or function, MLLoadWave will also choose a non-conflicting name.

Loading Strings from Matlab Files

When loading Matlab strings into Igor, you can tell MLLoadWave to create Igor string variables or Igor text waves. For example, if you have a 2x8 string matrix, MLLoadWave can create two string variables (`/S=2`) or one text wave (`/S=3`) containing two elements.

When loading Matlab string data into an Igor wave, the Igor wave will be of dimension one less than the Matlab data set. This is because each element in a Matlab string data set is a single byte whereas each element in an Igor string wave is a string (any number of bytes).

Loading Numeric Variables from Matlab Files

MLLoadWave loads numeric matrices with one element into Igor numeric variables. It loads all other numeric matrices into Igor waves.

When called from a macro, MLLoadWave creates local numeric and string variables unless you use the `/G` flag which tells it to create global variables. When called from the command line or from a user-defined function, MLLoadWave always creates global variables. Macros should be avoided in new programming.

Automatic Redimensioning from 2D to 1D

Starting with Igor Pro 8.00, after loading a matrix that results in an Mx1 2D wave, MLLoadWave automatically redimensions the wave as an M-row 1D wave.

This automatic redimensioning not affect the naming of the wave. It is still named using the 2D rules explained above under MLLoadWave Wave Naming.

Loading 3D and 4D Data from Matlab Files

For a discussion of how MLLoadWave handles 3D and 4D Matlab data, see Numeric Data Loading Modes.

Specifying Loading Options for Each Matlab Matrix

The /Z flag instructs MLoadWave to load each Matlab object (matrix, vector, variable, string) step by step. MLoadWave presents a dialog for each Matlab object in the file. You can choose to load or skip the object. If you omit the /Z flag, MLoadWave will load all objects in the file without presenting any dialogs.

Output Variables

MLoadWave sets the following output variables:

S_path	File system path to the folder containing the file. This is a system file path (e.g., "hd:FolderA:FolderB:"), not an Igor symbolic path. The path uses Macintosh path syntax, even on Windows, and has a trailing colon.
S_fileName	Name of the loaded file.
V_flag	Number of waves created.
V_flag1	Number of Matlab data sets (2D, 3D, or 4D) loaded.
V_flag2	Number of waves created.
V_flag3	Number of numeric variables created.
V_flag4	Number of string variables created.
S_waveNames	Semicolon-separated list of the names of loaded waves.

Prior to MLoadWave 5.50, the variables V_Flag1, V_Flag2, V_Flag3 and V_Flag4 were named V1_Flag, V2_Flag, V3_Flag and V4_Flag.

See Also

Symbolic Paths on page II-22

See **Loading Matlab MAT Files** on page II-154 for background information, including configuration instructions.

mod

mod(num, div)

The mod function returns the remainder when *num* is divided by *div*.

The mod function may give unexpected results when *num* or *div* is fractional because most fractional numbers can not be precisely represented by a finite-precision floating point value.

See Also

trunc, gcd

ModDate

ModDate(waveName)

The ModDate function returns the modification date/time of the wave.

Details

The returned value is a double precision Igor date/time value, which is the number of seconds from 1/1/1904. It returns zero for waves created by versions of Igor prior to 1.2, for which no modification date/time is available.

See Also

WaveModCount, Secs2Date, Secs2Time

Modify

Modify

We recommend that you use **ModifyGraph**, **ModifyTable**, **ModifyLayout**, or **ModifyPanel** rather than **Modify**. When interpreting a command, Igor treats the **Modify** operation as **ModifyGraph**, **ModifyTable**, **ModifyLayout** or **ModifyPanel**, depending on the target window. This does not work when executing a user-defined function.

ModifyBoxPlot

```
ModifyBoxPlot [/W=winName] [keyword=value, keyword=value, ...]
```

The **ModifyBoxPlot** operation modifies a box plot trace in the target or named graph. To create a box plot trace, see **AppendBoxPlot**. For a detailed discussion of box plots and the parts of a box plot, see **Box Plots** on page II-319.

ModifyBoxPlot was added in Igor Pro 8.00.

Parameters

ModifyBoxPlot parameters consist of keyword=value pairs. The trace keyword specifies the trace targeted by the subsequent keywords. For example, the command:

```
ModifyBoxPlot trace=trace0, boxFill=(49151,60031,65535) // Light blue
```

sets the box fill for all datasets of the trace0 trace to light blue.

As of Igor Pro 9.00, you can modify a setting for a specific dataset of a specific trace by adding a zero-based dataset index in square brackets after the keyword. For example:

```
ModifyBoxPlot trace=trace0, boxFill[1]=(49151,65535,49151) // Light green
```

This sets the box fill for the second dataset (index=1) to light green leaving the box fill for other datasets unchanged.

General Parameters

<code>trace=traceName</code>	Specifies the name of a box plot trace to be modified. An error results if the named trace is not a box plot trace. Without the trace keyword, ModifyBoxPlot uses the first trace in the graph, whether it is a box plot trace or not. But, see the instance keyword for an exception.
<code>instance=instanceNum</code>	The combination of trace and instance works the same as (<code>traceName#instanceNum</code>) for a ModifyGraph keyword. The instance keyword without trace keyword accesses the <i>instanceNum</i> 'th trace in the graph, just like [<i>traceNum</i>] used with a ModifyGraph keyword. See Trace Names on page II-270 and Object Indexing on page IV-20.
<code>medianIsMarker[=v]</code>	If <i>v</i> is omitted or is non-zero, the median is shown using a marker instead of with a line across the box part of the box plot.
<code>notched[=n]</code>	If <i>n</i> omitted or is non-zero, a notched box plot is drawn. The notches represent the 95 percent confidence limits of the median value.
<code>outlierMethod=m</code>	
<code>outlierMethod={m, p1, p2, p3, p4}</code>	

When the raw data values are drawn on the box plot, they are classified as normal data points, outliers and far outliers. There are four methods for classifying the values. Method 0 and 1 require no parameters and can use the outlierMethod=*m* format. Method 2 and 3 require extra parameters and require the extended format that uses curly braces:

- m*=0: Tukey's method (default): outliers are values outside of the inner fences and far outliers are values outside the outer fences. For details including the definition of the fences, see **Box Plots** on page II-319.
- m*=1: Outliers are any data values beyond the ends of the whiskers. With this method, there are no far outliers.
- m*=2: Outliers are values beyond the mean +- factor1*SD. Far outliers are values beyond the mean +- factor2*SD, where SD is the standard deviation. The factor1 is given by *p*1 and factor2 is given by *p*2. The parameters *p*3 and *p*4 are not used.
- m*=3: Outliers and far outliers are completely specified by the parameters. *p*1 sets the boundary for lower far outliers, *p*2 for lower outliers, *p*3 for upper outliers, and *p*4 for upper far outliers. All four parameters are required.

The outlierMethod keyword was added in Igor Pro 9.00.

quartileMethod=*m* Selects the method to be used in computing the quartiles (top and bottom of the boxes):

- m*=0: Tukey's method (default)
- m*=1: Minitab method
- m*=2: Moore and McCabe method
- m*=3: Mendenhall and Sincich method

See the discussion of **StatsQuantiles** /QM flag for details.

showData=*whatData* Selects a subset of the raw data for each box plot in a trace to be displayed using markers. The value of *whatData* is a name:

- All: Show all data points (default)
- None: Show no data points
- Outliers: Show only outliers and far outliers
- FarOutliers: Show only far outliers

See **Box Plots** on page II-319 for more information about outliers.

By default, the marker for normal data points is a hollow circle 0.7 times the size of a normal trace marker, outliers are shown by a full-size filled circle, and far outliers are shown using a full-size filled box.

showFences[=*v*] If *v* is omitted or non-zero, the fences are shown as dotted lines the same width as the boxes. See **Box Plots** on page II-319 for a discussion of fences. *v* defaults to 0.

showMean[=*v*] If *v* is omitted or non-zero, the mean of the data is shown as a marker. *v* defaults to 0.

whiskerMethod=*m*

whiskerMethod={*m* [, *p*1, *p*2]}

The whiskers are drawn from the quartiles (top and bottom of the box) to some extreme value, as determined by whiskerMethod. Methods 0-5 do not take extra parameters, and can be specified using the whiskerMethod=*m* format. Methods 6 and 7 take extra parameters and require the extended format with curly braces.

The extended format was added in Igor Pro 9.00.

- m*=0: The extreme data values (default)
- m*=1: The inner fences
- m*=2: The "adjacent" points - the last data points inside the inner fences
- m*=3: One standard deviation away from the mean value
- m*=4: The 9th and 91st percentiles
- m*=5: The 2nd and 98th percentiles
- m*=6: The lower whisker is drawn from the box to a percentile given by *p1*. The upper whisker is drawn from the box to a percentile given by *p2*. This method requires both *p1* and *p2*. Added in Igor Pro 9.00.
- m*=7: Whisker ends are at values given by mean data value +- a factor times the standard deviation. The factor is given by *p1*. *p2* is not used for this method. Added in Igor Pro 9.00.

See **Box Plots** on page II-319 for a discussion of fences and percentiles.

Appearance Parameters

- boxWidth=*w*** For a non-category X axis, boxWidth sets the width of the box showing the quartiles. If *w* is between zero and one, it is taken to be a fraction of the width of the plot rectangle. If *w* is greater than one, it is in points.
- If the box plot is displayed using a category X axis, boxWidth is ignored. The box width is set the same as a category plot box and is affected by ModifyGraph barGap and catGap.
- A new non-category box plot has box width set as $\text{boxWidth} = 1/(2*n)$ where *n* is the number of datasets (the number of boxes) on the trace.
- capWidth=*w*** The whiskers may optionally be terminated with a horizontal line of width controlled by the capWidth keyword. If *w* is between zero and one, it is a fraction of the box width. If *w* is greater than one, it is in points. If *w* is zero (default), no cap is drawn.
- jitter=*j*** Applies a horizontal offset to each displayed data point in order to make it easier to see dense datasets. *j* controls the maximum offset applied to any data point, expressed as a fraction of the box width. The value of *j* may be greater than 1, but in general values less than 1 look better. The default is 0.7.
- lineStyles={*boxStyle, whiskerStyle, medianStyle[, capStyle]*}**
- Set the line style used to draw the box, the whiskers, the median line, and optionally the whisker caps. See **Dashed Lines** on page III-498 for a description of line styles.
- A line style of -1 uses the line style set by ModifyGraph lstyle.
- All parameters default to -1.
- lineThickness={*boxThickness, whiskerThickness, medianThickness[, capThickness]*}**

Sets the line thickness used to draw the box, the whiskers, the median line, and optionally the whisker caps. A thickness less than zero uses the thickness set by the `ModifyGraph lsize` keyword. A zero thickness hides the corresponding element of the box plot.

All parameters default to -1.

`markers={dataMarker, outlierMarker, farOutlierMarker[, medianMarker, meanMarker]}`

Sets the marker number to be used for ordinary data points, outliers, far outliers, the median value if the `medianIsMarker` keyword was specified and the mean value if the `showMean` keyword was specified. See **Markers** on page II-279 for a complete list.

These parameters default to `markers={8, 19, 16, 26, 27}` (hollow circle, filled circle, filled square, X, horizontal diamond). Setting any of the parameters to -1 uses the corresponding default marker.

`markersOnTop={dataOnTop, medianOnTop, meanOnTop}`

By default, the data markers, median marker if enabled by `medianIsMarker`, and mean marker if enabled by `showMean`, are drawn below the box and whisker lines so that they don't obscure the lines. But some special effects require the markers to be on top.

Setting `dataOnTop` to 1 causes all raw data points (normal data points, outliers and far outliers) to be drawn above the box and whisker lines. `medianOnTop` and `meanOnTop` similarly control the drawing of median and mean markers.

The `markersOnTop` keyword was added in Igor Pro 9.00.

`markerSizes={dataSize, outlierSize, farOutlierSize[, medianSize, meanSize]}`

Sets the marker size for ordinary data points, outliers, far outliers, the median value if the `medianIsMarker` keyword has been specified and the mean value if the `showMean` keyword has been specified. A marker size of zero uses the marker size set by `ModifyGraph msiz` times a scaling factor: the scaling factor is 2/3 for non-outlier points, 1 for outliers and the median and mean markers, and 4/3 for far outliers.

All parameters default to 0.

`opaqueMarkers={opaqueData, opaqueOutliers, opaqueFarOutliers, opaqueMedian, opaqueMean}`

Causes the interior of hollow markers to be drawn opaque, covering up items underneath. This keyword has a separate settings for normal data points, outliers, far outliers, the median marker (if `medianIsMarker` is enabled) and the mean marker (if `showMean` is enabled). Markers of a given type are opaque if the corresponding parameter is set to 1.

The `opaqueMarkers` keyword was added in Igor Pro 9.00.

Color Parameters

All colors are specied as $(r,g,b[a])$ **RGBA Values**. Specify `color=(0,0,0,0)` to use the color set by `ModifyGraph rgb`.

<code>boxColor=(r,g,b[a])</code>	Sets the outline color of the box part. The default color is black.
<code>boxFill=(r,g,b[a])</code>	Sets the fill color of the box.
<code>capColor=(r,g,b[a])</code>	Sets the color of the cap line, if present. The default color is black.
<code>dataColor=(r,g,b[a])</code>	Sets the color of non-outlier data points. The default color is the trace color.

ModifyBoxPlot

<code>dataStrokeColor=(r,g,b[,a])</code>	Sets the stroke color of non-outlier data points. The default color is black. The <code>dataStrokeColor</code> keyword was added in Igor Pro 9.00.
<code>dataFillColor=(r,g,b[,a])</code>	Sets the fill color of non-outlier data points when the markers are hollow. The default color is white. The <code>dataFillColor</code> keyword was added in Igor Pro 9.00.
<code>farOutlierColor=(r,g,b[,a])</code>	Sets the color of far outlier points. The default color is the trace color.
<code>farOutlierStrokeColor=(r,g,b[,a])</code>	Sets the stroke color of far outlier data points. The default color is black. The <code>farOutlierStrokeColor</code> keyword was added in Igor Pro 9.00.
<code>farOutlierFillColor=(r,g,b[,a])</code>	Sets the fill color of far outlier data points when the markers are hollow. The default color is white. The <code>farOutlierFillColor</code> keyword was added in Igor Pro 9.00.
<code>meanColor=(r,g,b[,a])</code>	Sets the color of the mean marker. The default color is the trace color.
<code>meanStrokeColor=(r,g,b[,a])</code>	Sets the stroke color of the mean marker, if <code>showMean</code> is enabled. The default color is black. The <code>meanStrokeColor</code> keyword was added in Igor Pro 9.00.
<code>meanFillColor=(r,g,b[,a])</code>	Sets the fill color of the mean marker, if <code>showMean</code> is enabled. Applies when the marker is hollow. The default color is white. The <code>meanFillColor</code> keyword was added in Igor Pro 9.00.
<code>medianLineColor=(r,g,b[,a])</code>	Sets the color of the median line. You can see the effect only if <code>medianIsMarker</code> is not set. The default color is black.
<code>medianMarkerColor=(r,g,b[,a])</code>	Sets the color of the median marker. You can see the effect only if <code>medianIsMarker</code> is set. The default color is the trace color.
<code>medianStrokeColor=(r,g,b[,a])</code>	Sets the stroke color of the median marker which is displayed if <code>medianIsMarker</code> is enabled. The default color is black. The <code>medianStrokeColor</code> keyword was added in Igor Pro 9.00.
<code>medianFillColor=(r,g,b[,a])</code>	Sets the fill color of the median marker which is displayed if <code>medianIsMarker</code> is enabled. Applies when the marker is hollow. The default color is white. The <code>medianFillColor</code> keyword was added in Igor Pro 9.00.
<code>outlierColor=(r,g,b[,a])</code>	Sets the color of the markers for normal outliers. The default color is the trace color.
<code>outlierStrokeColor=(r,g,b[,a])</code>	Sets the stroke color of outlier data points. The default color is black. The <code>outlierStrokeColor</code> keyword was added in Igor Pro 9.00.
<code>outlierFillColor=(r,g,b[,a])</code>	Sets the fill color of outlier data points when the markers are hollow. The default color is white. The <code>outlierFillColor</code> keyword was added in Igor Pro 9.00.
<code>whiskerColor=(r,g,b[,a])</code>	Sets the color the whisker lines. The default color is black.

Box Plot Per-Data-Point Marker Settings

You can override the basic settings for data point marker color, marker style and marker size using marker settings waves containing per-data-point settings. This feature was added in Igor Pro 9.00.

You can apply per-data-point marker settings to an entire trace (to all datasets comprising a trace) or to a specific dataset of a trace. For example:

```
Function DemoBoxPlotPerPointMarkerSettings()
  Make/O box0={1,2,3,4,5}, box1={2,3,4,5,6}, box2={3,4,5,6,7}
  String title = "Box Plot Per Point Marker Settings"
  Display/W=(557,99,948,310)/N=BoxPlotPerPointPlot as title

  // Create a trace named trace0 with three datasets: box0, box1, box2
  AppendBoxPlot/TN=trace0 box0,box1,box2

  // Set the marker and marker size for all datasets of trace trace0
  ModifyBoxPlot trace=trace0, markers={18,-1,-1} // 18=Diamond
  ModifyBoxPlot trace=trace0, markerSizes={5,5,5}

  // Set the per-data-point marker for all datasets of trace0
  Make/O boxMarkers = {15,16,17,18,19}
  ModifyBoxPlot trace=trace0, dataMarkerWave=boxMarkers

  // Set the per-data-point marker for dataset box1 only
  Make/O boxMarkersForBox1 = {32,33,34,35,36}
  ModifyBoxPlot trace=trace0, dataMarkerWave[1]=boxMarkersForBox1
End
```

Usually a marker settings wave will have the same number of rows as there are data points in a given dataset, but that is not required. If there are fewer rows in the settings wave than in the dataset, the extra data points retain their basic settings. If there are more rows in the settings wave than in the dataset, the extra settings wave points are not used.

See **Making Each Data Point Look Different** on page II-331 for more information and examples.

`dataColorWave [=colorWave]` Sets *colorWave* to override data point marker color on a point-by-point basis. The wave must be a 3 or 4 column wave containing red, green, blue and optionally alpha values.

If you omit "*=colorWave*", any previous marker color wave setting is cleared.

The `dataColorWave` keyword was added in Igor Pro 9.00.

`dataMarkerWave [=markerWave]` Sets *markerWave* to override data point markers on a point-by-point basis. The values in *markerWave* are standard graph marker numbers. See **Markers** on page II-279 for a table of the markers and the associated marker numbers. The marker numbers are clipped to a valid range.

If you omit "*=markerWave*", any previous marker wave setting is cleared.

The `dataMarkerWave` keyword was added in Igor Pro 9.00.

`dataSizeWave [=markerSizeWave]` Sets *markerSizeWave* to override data point marker size on a point-by-point basis. The values in *markerSizeWave* are clipped to the range [0,200].

If you omit "*=markerSizeWave*", any previous marker size wave setting is cleared.

The `dataSizeWave` keyword was added in Igor Pro 9.00.

Example

```
Make/O/N=(25,3) multicol // A three-column wave with 25 rows
SetRandomSeed(.4) // For reproducible "randomness"
multicol = gnoise(1) // Three normally-distributed datasets
multicol[20][1] = 5 // A "far" outlier
multicol[13][2] = -4 // An outlier
Display; AppendBoxPlot multicol
ModifyGraph lSize=2
ModifyBoxPlot markers={8,19,19}
ModifyBoxPlot markerSizes={3,5,9}
ModifyBoxPlot capWidth=0.5
ModifyBoxPlot boxColor=(0,0,65535)
ModifyBoxPlot medianLineColor=(0,0,65535)
ModifyBoxPlot whiskerColor=(40000,40000,65535)
ModifyBoxPlot capColor=(40000,40000,65535)
```

ModifyBoxPlot

```
ModifyBoxPlot boxFill=(0,0,65535,20000)  
ModifyBoxPlot dataColor=(0,0,0)  
ModifyBoxPlot outlierColor=(0,0,0)  
ModifyBoxPlot farOutlierColor=(0,0,0)  
ModifyBoxPlot jitter=0.75
```

```
ModifyBoxPlot trace=multicol,markerThick={1,0,0},markersFilled={1,0,0,0,0}  
ModifyBoxPlot trace=multicol,markerThick={1,0,0},dataFillColor=(2,39321,1)
```

```
ModifyBoxPlot trace=multicol,dataFillColor[1]=(0,65535,0)
```

[AppendBoxPlot](#), [AddWavesToBoxPlot](#), [ModifyGraph \(traces\)](#)

[Box Plots](#) on page II-319

ModifyBrowser

ModifyBrowser [/M] [*keyword = value* [, *keyword = value* ...]]

The ModifyBrowser operation modifies the state of the Data Browser according to the specified keywords.

Documentation for the ModifyBrowser operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "ModifyBrowser"
```

ModifyCamera

ModifyCamera [*flags*] [*keywords*]

The ModifyCamera operation modifies the properties of a camera window.

Documentation for the ModifyCamera operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "ModifyCamera"
```

ModifyContour

ModifyContour [/W=*winName*] *contourInstanceName*, *keyword=value*
[, *keyword=value*...]

The ModifyContour operation modifies the number, Z value and appearance of the contour level traces associated with *contourInstanceName*.

contourInstanceName is a name derived from the name of the wave that provides the Z data values. It is usually just the name of the wave, but may have #1, #2, etc. added to it in the unlikely event that the same Z wave is contoured more than once in the same graph.

contourInstanceName can also take the form of a null name and instance number to affect the instanceth contour plot. That is,

```
ModifyContour ''#1
```

modifies the appearance of the second contour plot in the top graph, no matter what the contour plot names are. Note: Two single quotes, not a double quote.

The number of contour level traces and their Z values are set by the *autoLevels*, *manLevels*, and *moreLevels* keywords, described in the **Parameters** section. Normally, you will use either *autoLevels* or *manLevels*, and then optionally generate additional levels using *moreLevels*.

Parameters

Each parameter has the syntax

```
keyword = value
```

and is applied to all of the contour level traces associated with *contourInstanceName*.

To modify an individual contour level trace, use **ModifyGraph**.

*allocationFactor=**factor* In rare situations that usually involve spatial degeneracy, the Voronoi interpolation algorithm may need additional memory. You can use the *allocationFactor* keyword with an integer factor greater than 1 to increase the memory allocation.

allocationFactor was added in Igor Pro 9.00.

autoLevels= {*minLevel*, *maxLevel*, *numLevels*}

Controls automatic determination of contour levels.

If *numLevels* is zero, no automatic levels are generated. If it is nonzero, it specifies the desired number of automatic contour levels.

minLevel specifies the minimum contour level and *maxLevel* specifies the maximum contour level. The values that you specify are an approximate guide for Igor to use in determining the actual levels.

However, if *minLevel* or *maxLevel* is * (asterisk symbol), Igor uses the minimum or maximum value of the Z data for the corresponding contour level.

Using the *autoLevels* keyword cancels the effect of any previous *autoLevels* or *manLevels* keyword.

When you first append a contour plot to a graph, default contour levels are generated by the default setting `autoLevels={*,*,11}`.

boundary=b

Draws an outline around the XY domain of the contour data. For a matrix, this draws a rectangle showing the minimum and maximum X and Y values. For XYZ triples, the outline is a polygon enclosing the outside edges of the Delaunay Triangulation. Like the contour lines, the boundary is drawn using a graph trace, whose name is usually something like "`contourInstanceName = boundary`".

b=0: Hides the data boundary (default).

b=1: Shows the data boundary.

cIndexFill= matrixWave Sets contour fills to use a color index wave when automatic fill is on (see the fill keyword).

cIndexFill works the same as the *cIndexLines* keyword which controls the colors of the contour level traces.

See **Contour Fills** on page II-361 for more information.

cIndexFill was added in Igor Pro 7.00.

cIndexLines= matrixWave

Sets the Z value mapping mode such that contour line colors are determined by doing a lookup in the specified matrix wave.

matrixWave is a 3 column wave that contains red, green, and blue values from 0 to 65535. (The matrix can actually have more than three columns. Any extra columns are ignored.)

The color for a the contour line at $Z=z$ is determined by finding the RGB values in the row of *matrixWave* whose scaled X index is z . In other words, the red value is `matrixWave(z)[0]`, the green value is `matrixWave(z)[1]` and the blue value is `matrixWave(z)[2]`.

If *matrixWave* has default X scaling, where the scaled X index equals the point number, then row 0 contains the color for $Z=0$, row 1 contains the color for $Z=1$, etc.

If you use *cIndexLines*, you must not use *ctabLines* or *rgbLines* in the same command.

cTabFill= {zMin, zMax, ctName, mode}

Sets contour fills to use a color table when automatic fill is on (see the fill keyword).

cTabFill works the same as the *ctabLines* keyword which controls the colors of the contour level traces.

See **Contour Fills** on page II-361 for more information.

cTabFill was added in Igor Pro 7.00.

`ctabLines={zMin, zMax, ctName, mode}`

Sets the Z value mapping mode such that contour line colors are determined by doing a lookup in the specified color table. *zMin* is mapped to the first color in the color table. *zMax* is mapped to the last color. Z values between the min and max are linearly mapped to the colors between the first and last in the color table.

You can enter * (an asterisk) for *zMin* and *zMax*, which uses the minimum and maximum Z values of the data. The default is {*,*,Rainbow}.

Set parameter *mode* to 1 to reverse the color table; zero or missing does not reverse the color table.

ctName can be any color table name returned by the **CTabList** function, such as Grays or Rainbow (see **Image Color Tables** on page II-380) or the name of a 3 column or 4 column color table wave (see **Color Table Waves** on page II-387).

A color table wave name supplied to `ctabLines` must not be the name of a built-in color table (see **CTabList**). A 3 column or 4 column color table wave must have values that range between 0 and 65535. Column 0 is red, 1 is green, and 2 is blue. In column 3 a value of 65535 is opaque, and 0 is fully transparent.

If you use `ctabLines`, you must not use `cIndexLines` or `rgbLines` in the same command.

`equalVoronoiDistances=e`

Normally the x range and y range of the data are each normalized to a 0-1 range separately to generate the Voronoi triangulation. Voronoi triangulation is a distance-based ("nearest neighbor") algorithm that may benefit from scaling the X and Y ranges together to avoid numerical problems that occur when the triangles become very thin because of widely differing x and y ranges.

e=0: The x and y ranges are scaled individually to the 0-1 range (default).

e=1: The x and y ranges are scaled so that that maximum range of x or y is scaled to the 0-1 range, and the other is proportionally smaller. For example, if $y_{Max}-y_{Min} = 1000$ and $x_{Max}-x_{Min} = 5$, then the y range is scaled to 0-1 and the x range is scaled to $5/1000 = 0 - 0.005$.

The `equalVoronoiDistances` keyword is allowed only for XYZ contour plots.

`fill=f`

Controls the automatic filling of contour levels.

f=0: Turns automatic fill off. Default.

f=1: Turns automatic fill on.

See **Contour Fills** on page II-361 for more information.

`fill` was added in Igor Pro 7.00.

<code>interpolate=<i>i</i></code>	<p>XYZ contours can be interpolated to increase the apparent resolution, resulting in smoother contour lines.</p> <p>This keyword is allowed only for XYZ contours, created by AppendXYZContour.</p> <p><i>i</i>=0: Linear interpolation (default). This means that only the original Delaunay triangulation generates contour lines.</p> <p><i>i</i>=1: Four times the resolution generates a smoother set of contour lines. As expected, this takes longer than Linear interpolation.</p> <p><i>i</i>=2: Sixteen times the resolution generates a much smoother set of contour lines. This is rather slow.</p> <p>The interpolate parameter can be up to 8. Each time you increase <i>i</i> by one, you quadruple the apparent resolution and get smoother contour lines at the expense of computation time. Values of <i>i</i> greater than two are impractical because of the computation time required.</p>
<code>labelBkg=(<i>r,g,b[,a]</i>)</code>	Sets the background color for all contour level labels to the specified color. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as RGBA Values .
<code>labelBkg=<i>b</i></code>	Controls the background color of contour labels.
	<p><i>b</i>=0: Uses each label's individual background color, as set via the Modify Annotation dialog.</p> <p><i>b</i>=1: Makes all contour level labels transparent.</p> <p><i>b</i>=2: Uses the plot area background color as the label background color (default).</p> <p><i>b</i>=3: Uses the window background color as the label background color.</p>
<code>labelDigits=<i>d</i></code>	<i>d</i> is the number of digits after the decimal point when using <code>labelFormat=3</code> or <code>labelFormat=5</code> .
<code>labelFont=<i>fontName</i></code>	Default; specifies the font to use for contour level labels. If you pass "" for <i>fontName</i> , it will use the graph font (set via the Modify Graph dialog) for contour labels.
<code>labelFormat=<i>l</i></code>	Controls the formatting of contour labels. See the printf operation for a discussion of formatting.
	<p><i>l</i>=0: Uses general format that is suitable for most data. This is equivalent to "%<sigDigits>g".</p> <p><i>l</i>=1: Uses integer format, equivalent to "%<sigDigits>d". This rounds fractional values.</p> <p><i>l</i>=3: Uses fixed point format, equivalent to "%<decimalDigits>f".</p> <p><i>l</i>=5: Uses exponential format, equivalent to "%<decimalDigits>e".</p>
<code>labelFSize=<i>s</i></code>	Specifies the font size of contour labels in points. For example, use <code>labelSize=12</code> for 12 point type. The default value is 0, which chooses the size automatically based on the size of the graph.
<code>labelFStyle=<i>n</i></code>	<p><i>n</i> is a bitwise parameter with each bit controlling one aspect of the font style for the contour level labels. The default is 0, plain text.</p> <p>Bit 0: Bold</p> <p>Bit 1: Italic</p> <p>Bit 2: Underline</p> <p>Bit 4: Strikethrough</p> <p>See Setting Bit Parameters on page IV-12 for details about bit settings.</p>

labelHV= <i>hv</i>	<p>Specifies the contour label orientation.</p> <p>If <i>hv</i> is 3, 4, 5, or 6, the contour label's text rotates whenever it is redrawn, usually when the underlying contour data changes, the graph is resized, or the label is reattached to a new contour trace point.</p> <p><i>hv</i>=0: Horizontal contour level labels. <i>hv</i>=1: Vertical contour level labels. <i>hv</i>=2: Horizontal or vertical contour level labels, depending on the slope of the contour line. <i>hv</i>=3: Tangent to the contour line. <i>hv</i>=4: Tangent to the contour line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal (default). <i>hv</i>=5: Perpendicular to the contour line. <i>hv</i>=6: Perpendicular to the contour line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal.</p>
labelRGB=(<i>r,g,b[,a]</i>)	<p>Sets the text color for all contour level labels. <i>r</i>, <i>g</i>, <i>b</i>, and <i>a</i> specify the color and optional opacity as RGBA Values. The default is opaque black.</p>
labels= <i>l</i>	<p>Controls the display of contour labels.</p> <p><i>l</i>=0: Hides contour level labels. <i>l</i>=1: Leaves any contour level labels in place but stops updating them and stops generation of new labels. <i>l</i>=2: Generates or updates labels for the existing contour levels and window size when the command executes, but disables further updating of labels when window size or contour plot changes. This is the recommended setting if updating the labels takes long enough to annoy you. <i>l</i>=3: Default; generates labels for all contour levels whenever the contoured data changes but not when the window size changes. If you resize the graph, the labels may overlap or be too sparse. <i>l</i>=4: Generates labels for all contour levels whenever the contoured data, contour levels, axis range, or the graph size changes. (Actually, there are too many causes to list here. If all this update annoys you, use labels=2 "update once, now".)</p>
labelSigDigits= <i>d</i>	<p><i>d</i> is the number of significant digits when labelFormat=0 is used.</p>
logLines= 1 or 0	<p>0 sets the default linearly-spaced contour line colors. 1 turns on logarithmically-spaced line colors. This requires that the contour levels values be greater than 0 to display correctly. Affects line color only when the cIndexLines or ctabLines parameter is used. logLines does not affect the contour levels. To assign logarithmically-spaced contour levels, use the moreLevels parameter and disable autoLevels, for example:</p> <pre>ModifyContour '#0, autoLevels={*,*,0} // No auto levels ModifyContour '#0, moreLevels=0 ModifyContour '#0, moreLevels={1e-07,1e-06,1e-05,1e-04}</pre>
manLevels= { <i>firstLevel, increment, numLevels</i> }	<p>Explicitly specifies contour levels. ModifyContour will generate <i>numLevels</i> contour levels, evenly spaced starting from <i>firstLevel</i> and stepping by <i>increment</i>. manLevels cancels the effect of any previous manLevels or autoLevels settings.</p>
manLevels= <i>manLevelsWave</i>	

	Explicitly specifies contour levels. ModifyContour will generate contour levels at the values in <i>manLevelsWave</i> .
	manLevels cancels the effect of any previous manLevels or autoLevels settings.
moreLevels= {level, level ...}	Explicitly specifies contour levels. ModifyContour will generate a contour trace for each of the listed levels. The maximum number of levels that you can specify in a single command is the 50. However, you can concatenate any number of ModifyContour moreLevels commands. moreLevels adds levels in addition to any specified by manLevels or autoLevels. It does not override other parameters. moreLevels=0: Removes all levels generated by previous moreLevels settings.
nullValue=zValue	This keyword only affects the behavior of the ContourZ function. It is allowed only for XYZ contours, created by AppendXYZContour . By default, ContourZ treats data outside the domain of the contour as NaN and so returns NaN if you ask for a contour value outside that domain. The nullValue keyword allows you to change the default behavior to make ContourZ treat values outside the domain as the specified zValue.
nullValueAuto	This keyword only affects the behavior of the ContourZ function. It is allowed only for XYZ contours, created by AppendXYZContour . nullValueAuto acts like nullValue=zValue with zValue automatically set to the minimum value in the Z wave minus 1. See the nullValue keyword for details. To turn nullValueAuto off and return the contour to the default state, execute: ModifyContour <contourInstanceName>, nullValue=NaN
perturbation=p	Enable or disable perturbation (alteration) of the x and y values by a miniscule amount to improve the natural neighbor triangulation of XYZ contours. <i>p=0</i> : Disables perturbation, preserving the original x and y values unchanged. <i>p=1</i> : Enables x/y perturbation (default). The values are shifted by random values less than +/-0.000005 times the x and y domain extents. You can observe the perturbed x/y coordinates in the triangulation trace added by ModifyContour triangulation=1. The perturbation keyword is allowed only for XYZ contour plots.
rgbFill=(r,g,b[,a])	Specifies red, green, and blue values for all contour fills. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as RGBA Values . If you use rgbFill, you must not use cIndexFill or ctabFill in the same command.
rgbLines=(r,g,b[,a])	Specifies red, green, and blue values for all contour lines. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as RGBA Values . If you use rgbLines, you must not use cIndexLines or ctabLines in the same command.
triangulation=t	Draws the Delaunay Triangulation. As part of the XYZ contouring algorithm, the XY domain is subdivided into triangles in a process called Delaunay Triangulation. Like the contour lines, the triangulation is drawn using a graph trace, whose name is usually something like "contourInstanceName =triangulation". The triangulation keyword is allowed only for XYZ contours, created by AppendXYZContour . <i>t=0</i> : Hides the Delaunay triangulation (default). <i>t=1</i> : Shows the Delaunay triangulation.

`update=u` Sets the type of updating of contour traces when the data or contour settings change.

- `u=0:` Turns off dynamic updates, which might be advisable if updates take a long time.
- `u=1:` Updates the contours only once, or until you next execute an `update=1` command.
- `u=2:` Updates are automatic (default).
- `u=3` Marks the contour plot as having been updated once (`u=1`) already. This option is used in recreation macros to prevent an extra redraw of a graph saved with `u=1` update mode in effect.

If you use it in a command, the result is similar to `u=0`, but the Modify Contour Appearance dialog will automatically select “update once, now” from the Update Contours pop-up menu.

`xymarkers=x` Controls the visibility of XY markers.

- `x=0:` Hides markers showing XY coordinates of the Z data (default).
- `x=1:` Displays markers showing XY coordinates of Z data. Initially, this uses marker number zero. You can change this using the Modify Trace Appearance dialog.

Flags

`/W=winName` Applies to contours in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See Also

AppendMatrixContour and **AppendXYZContour**.

ModifyControl

ModifyControl [/Z] *ctrlName* [*keyword* = *value* [, *keyword* = *value* ...]]

The ModifyControl operation modifies the named control. ModifyControl works on any kind of existing control. To modify multiple controls, use **ModifyControlList**.

Parameters

ctrlName specifies the name of the control to be created or changed. The control must exist.

Keywords

The following keyword=value parameters are supported:

<code>activate</code>	<code>align</code>	<code>appearance</code>	<code>bodywidth</code>	<code>disable</code>	<code>fColor</code>
<code>focusRing</code>	<code>font</code>	<code>fSize</code>	<code>fStyle</code>	<code>help</code>	<code>labelBack</code>
<code>noproc</code>	<code>pos</code>	<code>proc</code>	<code>rename</code>	<code>size</code>	<code>title</code>
<code>userdata</code>	<code>valueBackColor</code>	<code>valueColor</code>	<code>win</code>		

Coordinates are in **Control Panel Units**.

For details on these keywords, see the documentation for **SetVariable** on page V-852.

The following keywords are not supported:

ModifyControl

mode popmatch popvalue value variable

Flags

/Z No error reporting.

Details

Use ModifyControl to move, hide, disable, or change the appearance of a control without regard to its kind

Example

Here is a **TabControl** procedure that shows and hides all controls in the tabs appropriately, without knowing what kind of controls they are.

The “trick” here is that all controls that are to be shown within particular tab *n* have been assigned names that end with “_tab*n*” such as “_tab0” and “_tab1”:

```
Function TabProc(ctrlName,tabNum) : TabControl
  String ctrlName
  Variable tabNum

  String curTabMatch= "*_tab"+num2istr(tabNum)
  String controls= ControlNameList("")
  Variable i, n= ItemsInList(controls)
  for(i=0; i<n; i+=1)
    String control= StringFromList(i, controls)
    Variable isInATab= stringmatch(control,"*_tab*")
    if( isInATab )
      Variable show= stringmatch(control,curTabMatch)
      ControlInfo $control                    // gets V_disable
      if( show )
        V_disable= V_disable & ~0x1        // clear the hide bit
      else
        V_disable= V_disable | 0x1        // set the hide bit
      endif
      ModifyControl $control disable=V_disable
    endif
  endfor
  return 0
End

// Action procedures which enable or disable the buttons
Function Tab1CheckBoxProc(ctrlName,enableButton) : CheckBoxControl
  String ctrlName
  Variable enableButton

  ModifyControl button_tab1, disable=(enableButton ? 0 : 2 )
End

Function Tab0CheckBoxProc(ctrlName,enableButton) : CheckBoxControl
  String ctrlName
  Variable enableButton

  ModifyControl button_tab0, disable=(enableButton ? 0 : 2 )
End

// Panel macro that creates a TabControl using TabProc
Window TabbedPanel() : Panel
  PauseUpdate; Silent 1                    // building window...
  NewPanel /W=(381,121,614,237) as "Tab Demo"
  TabControl tab, pos={12,9},size={205,91},proc=TabProc,tabLabel(0)="Tab 0"
  TabControl tab, tabLabel(1)="Tab 1",value= 0
  Button button_tab0, pos={54,39},size={110,20},disable=2
  Button button_tab0, title="Button in Tab0"
  Button button_tab1, pos={54,63},size={110,20},disable=1
  Button button_tab1, title="Button in Tab1"
  CheckBox check1_tab1, pos={51,41}, size={117,14}, disable=1, value= 1
  CheckBox check1_tab1, proc=Tab1CheckBoxProc, title="Enable Button in Tab 1"
  CheckBox check0_tab0, pos={51,73}, size={117,14}, proc=Tab0CheckBoxProc
  CheckBox check0_tab0, value= 0, title="Enable Button in Tab 0"
EndMacro
```

Run TabbedPanel to create the panel. Then click on “Tab 0” and “Tab 1” to run TabProc.

See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

Control Panel Units on page III-444 for a discussion of the units used for controls.

Related functions **ModifyControlList** and **ControlNameList**.

The **Button**, **Chart**, **CheckBox**, **GroupBox**, **ListBox**, **PopupMenu**, **SetVariable**, **Slider**, **TabControl**, **TitleBox**, and **ValDisplay** controls.

ModifyControlList

ModifyControlList [/Z] *listStr* [, **keyword** = *value*]...

The **ModifyControlList** operation modifies the controls named in the *listStr* string expression. **ModifyControlList** works on any kind of existing control.

Parameters

listStr is a semicolon-separated list of names in a string expression. The expression can be an explicit list of control names such as "button0;checkbox1;" or it can be any string expression such as a call to the **ControlNameList** string function:

```
ModifyControlList ControlNameList("",";","*_tab0") disable=1
```

The controls must exist.

Keywords

The following keyword=value parameters are supported:

activate	align	appearance	bodywidth	disable	fColor
focusRing	font	fSize	fStyle	help	labelBack
noproc	pos	proc	rename	size	title
userdata	valueBackColor	valueColor	win		

Coordinates are in **Control Panel Units**.

For details on these keywords, see the documentation for **SetVariable** on page V-852.

The following keywords are not supported:

mod	popmatch	popvalue	value	variable
-----	----------	----------	-------	----------

Flags

/Z	No error reporting.
----	---------------------

Details

Use **ModifyControlList** to move, hide, disable, or change the appearance of multiple controls without regard to their kind.

If *listStr* contains the name of a nonexistent control, an error is generated.

if *listStr* is "" (or any list element in *listStr* is ""), it is ignored and no error is generated.

Example

Here is the **TabControl** procedure example from **ModifyControl** rewritten to use **ModifyControlList**. It shows and hides all controls in the tabs appropriately, without knowing what kind of controls they are, but the code is simpler. This method does not, however, preserve the enable bit when a control is hidden.

The “trick” here is that all controls that are to be shown within particular tab *n* have been assigned names that end with “_tab*n*” such as “_tab0” and “_tab1”:

```
// Action procedure
Function TabProc2(ctrlName,tabNum) : TabControl
    String ctrlName
    Variable tabNum

    String controlsInATab= ControlNameList("",";","*_tab*")
```

ModifyFreeAxis

```
String curTabMatch= "*" _tab"+num2istr(tabNum)
String controlsInCurTab= ListMatch(controlsInATab, curTabMatch)
String controlsInOtherTabs=ListMatch(controlsInATab,"!" +curTabMatch)

ModifyControlList controlsInOtherTabs disable=1           // hide
ModifyControlList controlsInCurTab disable=0             // show

return 0
End

// Panel macro that creates a TabControl using TabProc2():
Window TabbedPanel2() : Panel
  PauseUpdate; Silent 1                                     // building window...
  NewPanel /W=(35,208,266,374) as "Tab Demo"
  TabControl tab,pos={12,9},size={205,140},proc=TabProc2
  TabControl tab,tabLabel(0)="Tab 0"
  TabControl tab,tabLabel(1)="Tab 1",value= 0
  Button button_tab0,pos={26,43},size={110,20},title="Button in Tab0"
  Button button2_tab0,pos={26,74},size={110,20},title="Button in Tab0"
  Button button3_tab0,pos={26,106},size={110,20},title="Button in Tab0"
  Button button_tab1,pos={85,43},size={110,20},title="Button in Tab1"
  Button button2_tab1,pos={85,75},size={110,20},title="Button in Tab1"
  Button button3_tab1,pos={84,108},size={110,20},title="Button in Tab1"
  ModifyControlList ControlNameList("",";" ,"*_tab1") disable=1
EndMacro
```

Run TabbedPanel2 and then click on "Tab 0" and "Tab 1" to run TabProc2.

The **Button**, **Chart**, **CheckBox**, **GroupBox**, **ListBox**, **PopupMenu**, **SetVariable**, **Slider**, **TabControl**, **TitleBox**, and **ValDisplay** controls.

ModifyFreeAxis

```
ModifyFreeAxis [/W=winName] axisName, master=mastName
  [, hook=funcName]
```

The **ModifyFreeAxis** operation designates the free axis (created with **NewFreeAxis**) to follow a controlling axis from which it gets axis range and units information. The free axis updates whenever the controlling axis changes. The axis limits and units can be modified by a user hook function.

Parameters

axisName is the name of the free axis (which must have been created by **NewFreeAxis**).

masterName is the name of the master axis controlling *axisName*.

funcName is the name of the user function that modifies the limits and units properties of the axis. If *funcName* is "\$", the named hook function is removed.

Flags

/W=winName Modifies *axisName* in the named graph window or subwindow. If */W* is omitted the command affects the top graph window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The free axis can also be designated to call a user-defined hook function that can modify limits and units properties of the axis. The hook function must be of the following form:

```
Function MyAxisHook(info)
  STRUCT WMAxisHookStruct &info

  <code to modify graph units or limits>
  return 0
End
```

where `WMAxisHookStruct` is a built-in structure with the following members:

WMAxisHookStruct Structure Members

Member	Description
<code>char win[MAX_WIN_PATH+1]</code>	Host (sub)window
<code>char axName[MAX_OBJ_NAME+1]</code>	Name of the axis
<code>char mastName[MAX_OBJ_NAME+1]</code>	Name of controlling axis or ""
<code>char units[MAX_UNITS+1]</code>	Axis units
<code>double min, max</code>	Axis range minimum and maximum values

The constants used to size the char arrays are internal to Igor and are subject to change in future versions.

The hook function is called when refreshing axis range information (generally early in the update of a graph). Your hook must never kill a graph or an axis.

Example

This example demonstrates how to program a free axis hook function, whose most important task is to change the values of `info.min` and `info.max` to alter the axis range of the free axis. The example free axis displays Fahrenheit values for data in Celsius.

```
Function CentigradeAndFahrenheit()
    Make/O/N=20 temperatures = -2+p/3+gnoise(0.5) // sample data
    Display temperatures// default left axis will indicate data's centigrade range
    String graphName = S_name
    Label/W=$graphName left "°C"
    ModifyGraph/W=$graphName zero(left)=1
    Legend/W=$graphName

    // make a right axis whose range will be Fahrenheit
    NewFreeAxis/R/O/W=$graphName fahrenheit
    ModifyGraph/W=$graphName freePos(fahrenheit)={0,kwFraction},lblPos(fahrenheit)=43
    Label/W=$graphName fahrenheit "°F"

    ModifyFreeAxis/W=$graphName fahrenheit, master=left, hook=CtoF_FreeAxisHook
    // NOTE master=left part which makes the "free" axis
    // actually a "slave" to the left ("master") axis.
End

Function CtoF_FreeAxisHook(info)
    STRUCT WMAxisHookStruct &info

    GetAxis/Q/W=$info.win $info.mastName // get master axis range in V_min, V_Max
    Variable minF = V_min*9/5+32
    Variable maxF = V_max*9/5+32

    // SetAxis/W=$info.win $info.axName, minF, maxF
    // SetAxis here is fruitless. These values get overwritten by Igor
    // after reading info.min and info.max, which we now set:
    info.min = minF // new min for free axis
    info.max = maxF // new max for free axis
    return 0
End
```

ModifyGizmo

ModifyGizmo [*flags*] *keyword* [=*value*]

The ModifyGizmo operation changes Gizmo properties.

Documentation for the ModifyGizmo operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "ModifyGizmo"
```

ModifyGraph (*general*)

ModifyGraph [/W=*winName/Z*] *key=value* [, *key=value*]...

The ModifyGraph operation modifies the target or named graph. This section of ModifyGraph relates to general graph window settings.

Parameters

expand= <i>e</i>	Specifies the onscreen expansion (or magnification) factor of a graph. <i>e</i> may be zero or 0.125 to 8 times expansion. Graph magnification affects only base graphs (not subwindowed graphs), and it affects only the onscreen display; it has no effect on graph exporting or printing. When magnification changes, the graph window will automatically resize except for negative values, which are used in recreation macros where the size is already correct.
frameInset= <i>i</i>	Specifies the number of pixels by which to inset the frame of the graph subwindow.
frameStyle= <i>f</i>	Specifies the frame style for a graph subwindow. <i>f</i> =0: None. <i>f</i> =1: Single. <i>f</i> =2: Double. <i>f</i> =3: Triple. <i>f</i> =4: Shadow. <i>f</i> =5: Indented. <i>f</i> =6: Raised. <i>f</i> =7: Text well. The last three styles are fake 3D and will look good only if the background color of the enclosing space and the graph itself is a light shade of gray.
gfMult= <i>f</i>	Multiplies font and marker size by <i>f</i> percent. Clipped to between 25% and 400%; it is applied after all other font and marker size calculations.
gFont= <i>fontStr</i>	Specifies the name of the default font for the graph, overriding the normal default font. The normal default font for a subgraph is obtained from its parent while a base graph uses the value set by the DefaultFont operation.
gfSize= <i>gfs</i>	Sets the default size for text in the graph. Normally, the default size for text is proportional to the graph size; gfSize will override that calculation as will the gfRelSize method. Use a value of -1 to make a subgraph get its default font size from its parent.
gfRelSize= <i>pct</i>	Specifies the percentage of the graph size to use in calculating a default size for text in the graph. This overrides the normal method for setting default font size as a function of graph size. When used, the default marker size is set to one third the font size. Use a value of 0 to revert to the default method.
gmSize= <i>gms</i>	Sets the default size for markers in the graph. Use a value of -1 to make a subgraph get its default marker size from its parent.
height= <i>heightSpec</i>	Sets the height for the graph area. See the Examples .

swapXY= <i>s</i>	<p>Sets the orientation of the X and Y axes.</p> <p><i>s</i>=0: Normal orientation of X and Y axes.</p> <p><i>s</i>=1: Swap X and Y values to plot Y coordinates versus the horizontal axes and X coordinates versus the vertical axes. The effect is similar to mirroring the graph about the lower-left to upper-right diagonal.</p>
useComma= <i>uc</i>	<p>Controls the decimal separator used in tick mark labels.</p> <p><i>uc</i>=0: Use period as decimal separator and comma as thousands separator (default) when displaying numbers in graph labels and annotations.</p> <p><i>uc</i>=1: Use comma as decimal separator and period as the thousands separator. This does not alter the presentation of numbers in $\{expression\}$ constructs in annotations.</p>
UIControl= <i>f</i>	<p>Disables certain aspects of the user interface for graphs. The UIControl keyword, added in Igor Pro 7.00, is for use by advanced Igor programmers who want to disable user actions.</p> <p>This is a bitwise setting. Setting Bit Parameters on page IV-12 for details about bit settings.</p> <p><i>f</i> is defined as follows:</p> <ul style="list-style-type: none"> Bit 0: Disable axis click. Prevents moving or otherwise modifying an axis. Bit 1: Disable cursor click. Prevents moving a graph cursor. Bit 2: Disable trace drag. Prohibits the click-and-hold action to offset a trace on the graph. Bit 3: Disable marquee. When set, you can't make a marquee on the graph, which in turn prevents changing the range of the graph using the marquee. Bit 4: Disable draw mode. Bit 5: Disable double click. Prohibits any double-click action. In general, double-clicks in a graph bring up dialogs to modify the graph's appearance. Bit 6: Disable clicks on annotations. Prevents modification of annotations. Bit 7: Disable tool tips. Bit 8: Disable contextual menus. Bit 9: Disable marquee menu. With this set, you can still have a marquee and use it for, i.e., selecting some portion of the graph, but you can't use the marquee menu to change the graph's range. Note that if bit 3 is set, this bit is moot. Bit 10: Disable mouse wheel events. This will prevent axis scaling using the mouse wheel. Bit 11: Disable option-drag. Prevents offsetting the graph by holding down the option (Macintosh) or Alt (Windows) key and then dragging in the plot area. <p>To disable items in the Graph menu use SetIgorMenuMode.</p>
useDotForX= <i>u</i>	<p>In the display of axis labels, if <i>u</i>=1 then, in instances of exponential notation such as "5x10³", the normal "x" is replaced with a dot giving "5x10³". useDotForX was added in Igor Pro 9.00.</p>
useLongMinus= <i>m</i>	<p>Uses a normal (<i>m</i>=0; default) or long dash (<i>m</i>=1) for the minus sign.</p>
width= <i>widthSpec</i>	<p>Sets the width of the graph area. See the examples.</p>

ModifyGraph (traces)

Flags

- /W=winName* Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
- When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.
- /Z* Does not generate an error if the indexed trace, named wave, or named axis does not exist in a style macro.

Examples

The following code creates a graph where all the text expands and contracts directly in relation to the window size:

```
Make jack=sin(x/8);display jack
ModifyGraph mode=4,marker=8,gfRelSize= 5.0
TextBox/N=text0/A=MC "Some \\Zr200big\\]0 and \\Zr050small\\]0\rtext"
```

The *widthSpec* and *heightSpecs* set the width and height mode for the top graph. The following examples illustrate how to specify the various modes.

- | | |
|--|---|
| <code>ModifyGraph width=0, height=0</code> | Set to auto height, width mode. The width, height of horizontal and vertical axes are automatically determined based on the overall size of the graph and other factors such as axis offset setting and effect of exterior textboxes. This is the normal, default mode. |
| <code>Variable n=72*5
ModifyGraph width=n</code> | Five inches as points absolute width mode, horizontal axis width constrained to n points. |
| <code>ModifyGraph height=n</code> | Absolute height mode, n is in points. The height of the vertical axes is constrained to n points. |
| <code>Variable n=2
ModifyGraph
width={perUnit,n,bottom}</code> | Per unit width mode. The width of the horizontal axes is n points times the range of the bottom axis. |
| <code>ModifyGraph height={Aspect,n}</code> | Aspect height mode, n = aspect ratio. The height of the vertical axes is n times the width of the horizontal axes. |
| <code>ModifyGraph
width={Plan,n,bottom,left}</code> | Plan width mode. The width of the horizontal axes is n times the height of the vertical axes times range of the bottom axis divided by the range of the left axis. |

ModifyGraph (traces)

ModifyGraph [*/W=winName/Z*] **key** [(*traceName*)] = *value*
[, **key** [(*traceName*)] = *value*]...

This section of **ModifyGraph** relates to modifying the appearance of wave “traces” in a graph. A trace is a representation of the data in a wave, usually connected line segments.

Parameters

Each *key* parameter may take an optional *traceName* enclosed in parentheses. Usually *traceName* is simply the name of a wave displayed in the graph, as in “mode (myWave) =4”. If “(*traceName*)” is omitted, all traces in the graph are affected. For instance, “ModifyGraph lSize=0.5” sets the lines size of all traces to 0.5 points.

For multiple trace instances, *traceName* is followed by the “#” character and instance number. For example, “mode (myWave#1) =4”. See **Instance Notation** on page IV-20.

A string containing a trace name can be used with the \$ operator to specify *traceName*. For example, `String MyTrace="myWave#1"; mode ($MyTrace)=4.`

Though not shown in the syntax, the optional “(*traceName*)” may be replaced with “[*traceIndex*]”, where *traceIndex* is zero or a positive integer denoting the trace to be modified. “[0]” denotes the first trace appended to the graph, “[1]” denotes the second trace, etc. This syntax is used for style macros, in conjunction with the */Z* flag.

For certain modes and certain properties, you can set the conditions at a specific point on a trace by appending the point number in square brackets after the trace name. For more information, see the **Customize at Point** on page V-624.

The parameter descriptions below omit the optional “(traceName)”. When using ModifyGraph from a user-defined function, be careful not to pass wave references to ModifyGraph. ModifyGraph expects trace names, not wave references. See **Trace Name Parameters** on page IV-87 for details.

arrowMarker=0

arrowMarker={*aWave*, *lineThick*, *headLen*, *headFat*, *posMode* [, *barbSharp*=*b*, *barbSide*=*s*, *frameThick*=*f*]}

Draws arrows instead of conventional markers at each data point in a wave. Arrows are not clipped to the plot area and will be drawn wherever a data point is within the plot area.

aWave contains arrow information for each data point. It is a two (or more) column wave containing arrow line lengths (in points) in column 0 and angles (in radians measured counterclockwise) in column 1. Zero angle is a horizontal arrow pointing to the right. If an arrow is below the minimum length of 4 points, a default marker is drawn.

You can change arrow markers into standard meteorological wind barbs by adding a column to *aWave* and giving it a column label of *windBarb*. Values are integers from 0 to 40 representing wind speeds up to 4 flags. Use positive integers for clockwise barbs and negative for the reverse. Use NaN to suppress the drawing. See **Wind Barb Plots** on page II-317 for an example.

Additional columns may be supplied in *aWave* to control parameters on a point by point basis. These optional columns are specified by dimension label and not by specific column numbers. The labels are *lineThick*, *headLen*, and *headFat* that correspond to the same parameters listed above.

lineThick is the line thickness in points.

headLen is the arrow head length in points.

headFat controls the arrow fatness. It is the width of the arrow head divided by the length.

posMode specifies the arrow location relative to the data point.

posMode=0: Start at point.

posMode=1: Middle on point.

posMode=2: End at point.

In addition to the wave specification, *aWave* can also be the literal `_inline_` to draw lines and arrows between points on the trace (see **Examples**). If *aWave* is `_inline_`, *posMode* values are:

posMode=0: Arrow at start.

posMode=1: Arrow in middle.

posMode=2: Arrow at end.

posMode=3: Arrow in middle pointing backwards.

You can also enable inline mode even if *aWave* is not `_inline_` by setting *posMode* to values between 4 and 7. These are the same as modes 0-3 above.

Optional parameters must be specified using *keyword* = *value* syntax and can only be appended after *posMode* in any order.

barbSharp is the continuously variable barb sharpness between -1.0 and 1. 0:

barbSharp=1: No barb; lines only.

barbSharp=0: Blunt (default).

barbSharp=-1: Diamond.

ModifyGraph (traces)

barbSide specifies which side of the line has barbs relative to a right-facing arrow:

barbSide=0: None.
barbSide=1: Top.
barbSide=2: Bottom.
barbSide=3: Both (default).

frameThick specifies the stroke outline thickness of the arrow in points. The default is *frameThick* = 0 for solid fill.

aWave can contain columns with data for each optional parameter using matching column names.

`barStrokeRGB=(r,g,b[,a])`

Specifies a separate color for bar strokes (outlines) if `useBarStrokeRGB` is 1. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. The default is opaque black.

Applies only to Histogram Bars drawing mode (`mode=5`).

The bar fill color continues to be set with the `rgb=(r,g,b[,a])`, `zColor={...}`, `usePlusRGB`, `plusRGB=(r,g,b[,a])`, `useNegRGB`, and `negRGB=(r,g,b[,a])` parameters.

Use `barStrokeRGB` and `useBarStrokeRGB` to put a differently-colored outline around Histogram Bars:

`useBarStrokeRGB=0`

`useBarStrokeRGB=1`

`cmplxMode=c`

Display method for complex waves.

c=0: Default mode displays both real and imaginary parts (imaginary part offset by $dx/2$).
c=1: Real part only.
c=2: Imaginary part only.
c=3: Magnitude.
c=4: Phase (radians).

`cmplxMode=0` does not work when the trace is a subrange of a multidimensional wave.

`column=n`

Changes the displayed column from a matrix. Out of bounds values are clipped.

`gaps=g`

Controls treatment of NaNs:

g=0: No gaps (ignores NaNs).
g=1: Gaps (shows NaNs as gaps).

`gradient`

See **Gradient Fills** on page III-500 for details.

`gradientExtra`

See **Gradient Fills** on page III-500 for details.

`hBarNegFill=n`

Fill kind for negative areas if `useNegPat` is true. *n* is the same as for the `hbFill` keyword.

hbFill= <i>n</i>	<p>Sets the fill pattern.</p> <p><i>n</i>=0: No fill.</p> <p><i>n</i>=1: Erase.</p> <p><i>n</i>=2: Solid black.</p> <p><i>n</i>=3: 75% gray.</p> <p><i>n</i>=4: 50% gray.</p> <p><i>n</i>=5: 25% gray.</p> <p><i>n</i>>=6: See Fill Patterns on page III-500.</p>
hideTrace= <i>h</i>	<p>Removes a trace from the graph display.</p> <p><i>h</i>=0: Shows the trace if it is hidden.</p> <p><i>h</i>=1: Hides the trace and removes it from autoscale calculations.</p> <p><i>h</i>=2: Hides the trace.</p> <p>When using <i>h</i>=1 to hide a graph trace, the hidden trace symbol and following text in annotations are also hidden. The amount of hidden text is the lesser of: the remaining text on the same line or the text up to but not including another trace symbol "\s(traceName)".</p>
lHair= <i>lh</i>	<p>Sets the hairline factor for traces printed on a PostScript® printer.</p>
lineJoin={ <i>j</i> , <i>ml</i> }	<p>Sets the line join style and miter limit.</p> <p>Line join:</p> <p><i>j</i>=0 Miter joins</p> <p><i>j</i>=1 Round joins</p> <p><i>j</i>=2 Bevel joins (default)</p> <p>Miter limit:</p> <p><i>ml</i> >= 1 Sets miter limit to <i>ml</i></p> <p><i>ml</i> = INF Sets miter limit to unlimited</p> <p><i>ml</i> = 0 Leaves miter limit unchanged</p> <p><i>ml</i> = -1 Sets miter limit to default (10)</p> <p>The miter limit applies only to miter joins (<i>j</i>=0) and is ignored otherwise. See Line Join and End Cap Styles on page III-498 for further information. The lineJoin keyword was added in Igor Pro 8.00.</p>
live= <i>lv</i>	<p><i>lv</i> is a bitwise parameter defined as follows:</p> <p>Bit 0: Live mode (see Live Mode below)</p> <p>Bit 1: Fast line drawing (see Fast Line Drawing)</p> <p>See Setting Bit Parameters on page IV-12 for details about bit settings.</p>
logZColor= <i>lzc</i>	<p>Controls the interpretation of the zColor parameter.</p> <p><i>lzc</i>=0: Sets the default linearly-spaced zColors.</p> <p><i>lzc</i>=1: Turns on logarithmically-spaced zColors. This requires that the zWave values be greater than 0 to display correctly.</p> <p>Affects trace line color only when the zColor parameter is used with a color table or color index wave - it has no effect if rgb=(<i>r,g,b</i>) parameter or zColor={...,directRGB} are used.</p>

ModifyGraph (traces)

<code>lOptions=cap</code>	Sets the line end cap style: <code>cap=0:</code> Flat caps <code>cap=1:</code> Round caps <code>cap=2:</code> Square caps (default) See Line Join and End Cap Styles on page III-498 for further information.																																				
<code>lSize=l</code>	Sets the line thickness, which can be fractional or zero, which hides the line.																																				
<code>lSmooth=ls</code>	Sets the smoothing factor for traces printed on a PostScript® printer.																																				
<code>lStyle=s</code>	Sets trace line style or dash pattern. <code>s=0</code> for solid lines. <code>s=1</code> to <code>s=17</code> for various dashed line styles. <table><tr><td>0</td><td>_____</td><td>9</td><td>- - - - -</td></tr><tr><td>1</td><td>.....</td><td>10</td><td>- - - - -</td></tr><tr><td>2</td><td>.....</td><td>11</td><td>- - - - -</td></tr><tr><td>3</td><td>- - - - -</td><td>12</td><td>_____</td></tr><tr><td>4</td><td>.....</td><td>13</td><td>_____</td></tr><tr><td>5</td><td>- - - - -</td><td>14</td><td>_____</td></tr><tr><td>6</td><td>.....</td><td>15</td><td>_____</td></tr><tr><td>7</td><td>- - - - -</td><td>16</td><td>_____</td></tr><tr><td>8</td><td>- - - - -</td><td>17</td><td>_____</td></tr></table>	0	_____	9	- - - - -	1	10	- - - - -	2	11	- - - - -	3	- - - - -	12	_____	4	13	_____	5	- - - - -	14	_____	6	15	_____	7	- - - - -	16	_____	8	- - - - -	17	_____

<code>marker=n</code>	<code>n=0</code> to 62 designates various markers if <code>mode=3</code> or 4. You can also create custom markers. See the SetWindow <code>markerHook</code> keyword. See Markers on page II-279 for a table of marker values.																																				
<code>mask={maskwave,mode,value}</code> or 0	Specifies individual points for display by comparing values in <code>maskWave</code> with <code>value</code> as specified by <code>mode</code> . <code>mode=0:</code> Exclude if equal. <code>mode=1:</code> Include if equal. <code>mode=2:</code> Include if bitwise AND is true. <code>mode=3:</code> Include if bitwise AND is false. <code>maskwave</code> can be specified using subrange notation. The length of <code>maskwave</code> (or subrange) must match the size of specified trace's wave (or subrange.) Bitwise modes should be used with integer waves with the intent of using one mask wave with multiple traces. See Examples .																																				
<code>mode=m</code>	Sets trace display mode. <code>m=0:</code> Lines between points. <code>m=1:</code> Sticks to zero. <code>m=2:</code> Dots at points. <code>m=3:</code> Markers. <code>m=4:</code> Lines and markers. <code>m=5:</code> Histogram bars. <code>m=6:</code> Cityscape. <code>m=7:</code> Fill to zero. <code>m=8:</code> Sticks and markers.																																				
<code>mrkFillRGB=(r,g,b[,a])</code>																																					

Sets the background fill color for hollow markers. r , g , b , and a specify the color and optional opacity as **RGBA Values**.

This setting takes effect only if `opaque` is set to non-zero. See the `opaque` keyword below.

The `mrkFillRGB` keyword was added in Igor Pro 9.00.

`mrkStrokeRGB=($r,g,b[,a]$)`

Specifies the color for marker stroked lines if `useMrkStrokeRGB = 1`. r , g , b , and a specify the color and optional opacity as **RGBA Values**. The default is opaque black.

The marker fill color continues to be set with the `rgb=($r,g,b[,a]$)` or `zColor={...}` parameters.

Applies only to the nontext and nonarrow marker modes.

Use `mrkStrokeRGB` and `useMrkStrokeRGB` to put a colored outline around filled markers, such as `marker=19`:

`useMrkStrokeRGB=0`

`useMrkStrokeRGB=1`

Note: The stroke color of unfilled markers such as `marker 8` is also affected by `mrkStrokeRGB`, but their fill color is only affected by the `opaque` parameter (and the opaque fill color is always white, so if you want a color-filled marker, don't use unfilled markers).

`mrkThick= t`

Sets the thickness of markers in points, which can be fractional.

`msize= m`

Specifies the marker size in points.

$m=0$: Autosize markers.

$m>0$: Sets marker size.

m can be fractional, which will only make a difference when the graph is printed because fractional points can not be displayed on the screen.

`mskip= n`

Puts a marker on only every n th data point in Lines and Markers mode (`mode=4`). Useful for displaying many data points when you want to identify the traces with markers. The maximum value for n is 32767.

`mstandoff= s`

Prevents lines from touching markers in lines and markers mode if s is greater than zero. s is in units of points. This feature was added in Igor Pro 8.00.

`muloffset={ mx,my }`

Sets the display multiplier for X (mx) and Y (my). The effective value for a given X or Y data point then becomes $muloffset * data + offset$. A value of zero means "no multiplier" — not multiply by zero.

`negRGB=($r,g,b[,a]$)`

Specifies the color for negative values represented by the trace if `useNegRGB` is 1. r , g , b , and a specify the color and optional opacity as **RGBA Values**.

`offset={ x,y }`

Sets the display offset in horizontal (X) and vertical (Y) axis units.

`opaque= o`

Displays transparent ($o=0$) or opaque ($o=1$) markers.

If o is zero (default) hollow markers such as unfilled circles and boxes have transparent backgrounds. If o is non-zero, the background is filled with color. The color defaults to white, but you can change it using the `mrkFillRGB` keyword.

`patBkgColor= 0, 1, 2 or ($r,g,b[,a]$)`

ModifyGraph (traces)

- Specifies the background color for fill patterns.
0, the default, is white, 1 is graph background, 2 is transparent.
Use $(r,g,b[,a])$ for a specific RGB color. r , g , b , and a specify the color and optional opacity as **RGBA Values**.
- `plotClip= p` $p=1$ clips the trace by the operating system (not by Igor) to the plot rectangle. This trims overhanging markers and thick lines. On Windows, this may not be supported for certain printers or by certain applications when importing.
- `plusRGB= $(r,g,b[,a])$` Specifies the color for positive values represented by the trace if `usePlusRGB` is 1. r , g , b , and a specify the color and optional opacity as **RGBA Values**.
- `quickdrag= q` Controls dragging of traces.
 $q=0$: Normal traces.
 $q=1$: Traces that can be instantly dragged without the normal one second delay. See the **Quickdrag** section below.
 $q=2$: Causes the mouse cursor to change to 4 arrows when over the trace and a reduced search is used.
- `removeCustom= r` Removes per-point trace customizations. See **Customize at Point** on page II-294 for background information. The `removeCustom` keyword was added in Igor Pro 9.00.
The parameter r is required by the `ModifyGraph` syntax, but its value is immaterial. We recommend using 1 for r but any number will work.
These examples show how to use the `removeCustom` keyword given a graph with a trace named `wave0`:

```
// Remove customizations for point 3 of trace wave0
ModifyGraph removeCustom(wave0[3]) = 1

// Remove customizations for all points of trace wave0
ModifyGraph removeCustom(wave0) = 1

// Remove customizations for all points of all traces
ModifyGraph removeCustom = 1
```
- `rgb= $(r,g,b[,a])$` Specifies the color of the trace. r , g , b , and a specify the color and optional opacity as **RGBA Values**.
- `textMarker={<char or wave>,font,style,rot,just,xOffset,yOffset}` or 0
Uses the specified character or text from the specified wave in place of the marker for each point in the trace.
If the first parameter is a quoted string or a string expression of the form `" "+str expr` in a user function, `ModifyGraph` uses the first three bytes of the string as the marker for all points. Three bytes are supported mainly for non-ASCII characters but can be used for 3 separate single-byte characters. Otherwise, it interprets the first parameter as the name of a wave. If the wave is a text wave, it uses the value of each point in the text wave as the marker for the corresponding point in the trace. If the wave is a numeric wave, the value for each point is converted into text and the result is used as the marker for the corresponding point in the trace.
`xOffset` and `yOffset` are offsets in fractional points. Each marker will be drawn offset from the location of the corresponding point in the trace by these amounts.
`style` is a font style code as used with the `ModifyGraph fstyle` keyword.
`rot` is a text rotation between -360 and 360 degrees.
`just` is a justification code as used in the **DrawText** operation except the X and Y codes are combined as `y*4+x`. Use 5 for centered.
The font size is `3*marker size`. Note that marker size and color can be dynamically set via the `zColor` and `zmrkSize` keywords.

toMode= <i>t</i>	<p>Modifies the behavior of the display modes as determined by the mode parameter.</p> <p><i>t</i>=0: Fill to zero.</p> <p><i>t</i>=1: Fill to next trace. Applies to Sticks to zero (mode=1), histogram bars (mode=5), and fill to zero (mode=7).</p> <p><i>t</i>=2: Add the current trace's Y values to the next trace's Y values. Works with all display modes.</p> <p><i>t</i>=3: Stack on next and is the same as <i>t</i>=2 except that the added value is clipped to zero. Works with all display modes.</p> <p><i>t</i>=-1: This mode is used only with category plots and means "keep with next" (i.e., put in the same subcategory as the next trace). It is used for special effects only.</p> <p>For modes 1, 2 and 3, both Y-waves must have the same number of points and must use the same X values. Igor uses the X values from the first wave for both Y-</p>
traceName= <i>name</i>	<p>Sets, changes, or removes a custom trace name.</p> <p>The traceName keyword was added in Igor Pro 9.00.</p> <p>By default Igor assigns trace names based on the name of the displayed wave. You can assign a custom trace name when appending a wave to a graph using the /TN flag with the Display and AppendToGraph operations. See Trace Names on page II-270 for details.</p> <p>The traceName keyword allows you to change the name of a trace after it has been added to a graph. For example:</p> <pre>Make/O wave0; Display wave0 ModifyGraph traceName (wave0)=Custom0</pre> <p>Use "\$" for name to remove the custom name and revert to the default trace name:</p> <pre>ModifyGraph traceName (Custom0)=\$ " "</pre> <p>Renaming a trace can change the names of other traces in the graph from the same wave. For example, if you display two instances of wave0 in one graph, the first trace name is wave0 and the second is wave0#1. If you now rename trace wave0, the name of the second instance of wave0 changes from wave0#1 to wave0. See Instance Notation on page IV-20 for further discussion.</p>
useBarStrokeRGB= <i>u</i>	<p>If <i>u</i>=1 then bar stroked lines use the color specified by the barStrokeRGB keyword. Applies only to Histogram Bars drawing mode (mode=5).</p> <p>The bar fill color continues to be set with the rgb, zColor, usePlusRGB, plusRGB, useNegRGB, and negRGB keywords.</p> <p>If <i>u</i>=0 then the bar stroked line colors are set with the rgb=(<i>r,g,b[,a]</i>) or zColor={...} parameters, just like the bar fill color.</p>
useMrkStrokeRGB= <i>u</i>	<p>If <i>u</i>=1 then marker stroked lines use the color specified by the mrkStrokeRGB keyword. The marker fill color continues to be set with the rgb=(<i>r,g,b[,a]</i>) or zColor={...} parameters.</p> <p>Applies only to the nontext and nonarrow marker modes.</p> <p>If <i>u</i>=0 then the marker stroked line colors are set with the rgb=(<i>r,g,b[,a]</i>) or zColor={...} parameters, just like the marker fill color.</p>
useNegPat= <i>u</i>	<p>If <i>u</i>=1, negative fills use the mode specified by the hBarNegFill keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.</p>
useNegRGB= <i>u</i>	<p>If <i>u</i>=1, negative fills use the color specified by the negRGB keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.</p>

ModifyGraph (traces)

`usePlusRGB=u` If *u* =1, positive fills use the color specified by the `plusRGB` keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.

`userData={udName, doAppend, data}`

Attaches arbitrary data to a trace. You should specify a trace name (`userData(<traceName>)={...}`). Otherwise copies of the data will be attached to every trace, which is most likely not what you intend.

Use the `GetUserData` function to retrieve the data, with the trace name as the object ID.

udName: The name of your user data. Use `$""` for unnamed user data.

doAppend=0: Do not append. Any pre-existing data is replaced.

doAppend=1: Append the data. Data is added to the end of any pre-existing data.

data: A string expression containing the data you wish to attach to the trace.

`zColor={zWave,zMin,zMax,ctName [reverseMode [cWave]]}` or 0

Dynamically sets color based on the values in *zWave* and color table name or mode specified by *ctName*.

zWave may be a subrange expression such as `myZWave [2, 9]` when *zWave* has more points than the trace, in which case `myZWave [2]` provides the Z value for the first point of the trace, and autoscaled *zMin* or *zMax* is determined over only the *zWave* subrange.

If a value in the *zWave* is NaN then a gap or missing marker will be observed. If a value is out of range it will be replaced with the nearest valid value. See also the `zColorMax` and `zColorMin` keywords.

ctName can be the name of a built-in color table such as returned by the **CTabList** function, such as `Grays` or `Rainbow`, for color table mode, `ctableRGB` for color table wave mode, `cindexRGB` for color index wave mode, or `directRGB` for direct color wave mode.

zColor for Built-in Color Table Mode

This mode uses *zWave* to select a color from a built-in color table specified by *ctName*. See **Image Color Tables** on page II-380 for details.

zWave contains values that are used to select a color from the built-in color table specified by *ctName*.

zMin is the *zWave* value that maps to the first entry in the color table. Use `*` for *zMin* to autoscale it to the smallest value in *zWave*.

zMax is the *zWave* value that maps to the last entry in the color table. Use `*` for *zMax* to autoscale it to the largest value in *zWave*.

ctName is the name of a built-in color table such as `Grays` or `Rainbow`. See the **CTabList** function for a list of built-in color tables.

Set *reverseMode* to 1 to reverse the color table lookup or to 0 to use the normal lookup. If you omit *reverseMode* or specify -1, the reverse mode is unchanged.

cWave must be omitted.

Normally the colors from the color table are linearly distributed between *zMin* and *zMax*. Use `logZColor=1` to distribute them logarithmically.

```
// Example zColor command using built-in color table
ModifyGraph zColor(data)={zWave, *, *, Rainbow}
```

zColor for Color Table Wave Mode

This mode is like Built-in Color Table except that the colors are stored in a color table wave that you have created. A color table wave can be a 3 column RGB wave or a 4 column RGBA wave. See **Color Table Waves** on page II-387 for details.

zWave contains values that are used to select a color from the color table wave specified by *cWave*.

zMin is the *zWave* value that maps to the first entry in the color table wave. Use * for *zMin* to autoscale it to the smallest value in *zWave*.

zMax is the *zWave* value that maps to the last entry in the color table wave. Use * for *zMax* to autoscale it to the largest value in *zWave*.

ctName is `ctableRGB`.

Set *reverseMode* to 1 to reverse the color table lookup or to 0 to use the normal lookup. If you omit *reverseMode* or specify -1, the reverse mode is unchanged.

cWave is a reference to your color table wave.

Normally the colors from the color table are linearly distributed between *zMin* and *zMax*. Use `logZColor=1` to distribute them logarithmically.

Example `ctableRGB zColor` command:

```
ColorTab2Wave Rainbow // Creates M_Colors wave
Rename M_Colors, MyColorTableWave
ModifyGraph zColor(data)={zWave,*,*,ctableRGB,0,MyColorTableWave}
```

zColor for Color Index Wave Mode

This mode is like Color Table Wave except that the values in *zWave* represent X indices with respect to *cWave*. You must create the RGB or RGBA color index wave and set its X scaling appropriately. See **Color Index Wave** on page II-360 for details.

zWave contains values that are used to select a color from the color index wave specified by *cWave*.

zMin and *zMax* are not used and should be set to *.

ctName is `cindexRGB`.

Set *reverseMode* to 1 to reverse the color table lookup or to 0 to use the normal lookup. If you omit *reverseMode* or specify -1, the reverse mode is unchanged. Normally the *zWave* values select the color from the row of *cWave* whose X value is closest to the *zWave* value. *reverseMode=1* reverses the colors.

cWave is a reference to your color index wave.

Normally the colors from the color index wave are linearly distributed between the minimum and maximum X values of the color index wave. Use `logZColor=1` to distribute them logarithmically.

```
// Example cindexRGB zColor command
zColor(data)={myZWave,*,*,cindexRGB,0,M_colors}
// M_colors is generated by ColorTab2Wave
```

zColor for Direct Color Wave Mode

In direct color mode, *zWave* is an RGB or RGBA wave that directly specifies the color for each point in the trace. If *zWave* is 8-bit unsigned integer, then color component values range from 0 to 255. For other numeric types, color component values range from 0 to 65535. See **ColorTab2Wave**, which generates RGB waves, and **Direct Color Details** on page II-389.

zWave is an RGB or RGBA wave that directly specifies the color for each point of the trace.

zMin and *zMax* are not used and should be set to * .

ctName is directRGB.

reverseMode is not applicable and should be omitted or set to 0.

cWave must be omitted.

```
// Example directRGB zColor command  
zColor(data)={zWaveRGB, *, *, directRGB}
```

Turning zColor Off

zColor = 0 turns the *zColor* modes off.

zColorMax=(*red, green, blue*)

Sets the color of the trace for *zColor*={*zWave, ...*} values greater than the *zColor*'s *zMax*. Also turns on *zColorMax* mode.

The *red, green, and blue* color values are in the range of 0 to 65535.

zColorMax=1, 0, or NaN

Turns *zColorMax* mode off, on, or transparent. These modes affect the color of *zColor*={*zWave, ...*} values greater than the *zColor*'s *zMax*.

- 1: Turns on *zColorMax* mode. The color of the affected trace pixels is black or the last color set by *zColorMax*=(*red, green, blue*).
- 0: Turns off *zColorMax* mode (default). The color of the affected trace pixels is the last color in the *zColor*'s *ctname* color table.
- NaN: Transparent *zColorMax* mode. Affected trace pixels are not drawn.

zColorMin=(*red, green, blue*)

Sets the color of the trace for *zColor*={*zWave, ...*} values less than the *zColor*'s *zMin*. Also turns *zColorMin* mode on.

The *red, green, and blue* color values are in the range of 0 to 65535.

zColorMin=1, 0, or NaN

Turns *zColorMin* mode off, on, or transparent. These modes affect the color of *zColor*={*zWave, ...*} values less than the *zColor*'s *zMin*.

- 1: Turns on *zColorMin* mode. The color of the affected image pixels is black or the last color set by *zColorMin*=(*red, green, blue*).
- 0: Turns off *zColorMin* mode (default). The color of the affected trace pixels is the first color in the *zColor*'s *ctname* color table.
- NaN: Transparent *zColorMin* mode. Affected trace pixels are not drawn.

zmrkNum={*zWave*} or 0

Dynamically sets the marker number for each point to the corresponding value in *zWave*. The values in *zWave* are the marker numbers (as used with the marker keyword). If a value in the *zWave* is NaN then no marker will be drawn at the corresponding point. If a value is out of range it will be replaced with the nearest valid value.

zmrkNum=0 turns this mode off.

zmrkSize={*zWave*,*zMin*,*zMax*,*mrkMin*,*mrkMax*,[*axis*]} or 0

Dynamically sets marker size based on values in *zWave*. See **Marker Size as f(z)** on page II-287 for background information.

zmrkSize = 0 turns this mode off.

Use * or a missing parameter for *zMin* and *zMax* to autoscale. *mrkMin* and *mrkMax* can be fractional.

mrkMin is the marker size to use when *z* equals *zMin* and *mrkMax* is the marker size to use when *z* equals *zMax*. *mrkMin* and *mrkMax* are not limits; they just control the linear mapping of *z* values to marker size.

If a value in the *zWave* is NaN then the corresponding marker is not drawn.

The marker size is clipped to 400 on the high end and to 1 point on the low end.

axis is an optional parameter specifying an existing axis on the graph. It is supported in Igor Pro 9.00 and later. Passing "" for *axis* is the same as omitting it.

If *axis* is specified, the values in *zWave* are interpreted as in units of the specified axis and specify the half-width of the marker to be drawn. For a circle marker, this is the radius of the marker.

If *axis* is specified, the *zMin*, *zMax*, *mrkMin*, and *mrkMax* parameters have no impact on the marker size unless you remove the specified axis in which case those parameters control the trace's marker sizes.

See **Marker Size as f(z) in Axis Units** on page II-288 for further information.

zpatNum={*zWave*} or 0

Dynamically sets the positive fill type/pattern number for each point to the corresponding value in *zWave*. The values in *zWave* are the pattern numbers (as used with the *hbFill* keyword). If a value in the *zWave* is NaN then the corresponding point will not be drawn. If a value is out of range it will be replaced with the nearest valid value.

zpatNum=0 turns this mode off.

Flags

/W=*winName* Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the Command Line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

/Z Does not generate an error if the indexed trace, named wave, or named axis does not exist in a style macro.

Details

Waves supplied with *zmrkSize*, *zmrkNum*, and *zColor* may use **Subrange Display Syntax** on page II-309.

Live Mode

Bit 0 of *live=lv* controls live mode. Live mode improves graph update performance when one or more of the waves displayed in the graph is frequently modified, for example, if the waves are being acquired from a data acquisition system. Live Mode traces do not autoscale axes.

ModifyGraph (traces)

Fast Line Drawing

Bit 1 of `live=lv` controls fast line drawing. When enabled, Igor draws traces in lines-between-points mode using custom fast code instead of the normal system drawing code. The result is not as esthetically pleasing but can be much faster and may be critical in data acquisition applications. The custom code is used only for drawing to the screen, not for exporting graphics.

Fast line drawing was added in Igor Pro 8.00.

Quickdrag

Quick drag mode (`quickdrag=1`) is a special purpose mode for creating cross hair cursors using a package of Igor procedures. (See the Cross Hair Demo example experiment.) Normally you would have to click and hold on a trace for one second before entering drag mode. When quickdrag is in effect, there is no delay. If a trace is in quickdrag mode it should also be set to live mode. With this combination you can click a trace and immediately drag it to a new XY offset. In addition to quick drag mode, the cross hair package relies on Igor to store information about the drag in a string variable if certain conditions are in effect. The string variable name (that you have to create) is `S_TraceOffsetInfo`, which must reside in a data folder that has the same name as the graph (not title!) which in turn must reside in root:WinGlobals:. If these conditions are met, then after a trace is dragged, information will be stored in the string using the following key-value format: `GRAPH:<name of graph>;XOFFSET:<x offset value>;YOFFSET:<y offset value>;TNAME:<trace name>;`

Customize at Point

You can customize the appearance of individual points on a trace in a graph for bar, marker, dot and lines to zero modes using key (`tracename [pnt])=value` syntax. The point number must be a literal number and the trace name is required.

To remove a customization, use key (`tracename [-pnt -1])=value` where value is not important but must match the syntax for the keyword. The offset of -1 is needed because point numbers start from zero.. You can also remove customizations using the `removeCustom` keyword described above.

Although the syntax is allowed for all trace modifiers, it has meaning only for the following: `rgb`, `marker`, `msize`, `mrkThick`, `opaque`, `mrkFillRGB`, `mrkStrokeRGB`, `barStrokeRGB`, `hbFill`, `patBkgColor` and `lSize`.

Note that `useBarStrokeRGB` and `useMrkStrokeRGB` are not needed. The act of using `barStrokeRGB` or `mrkStrokeRGB` is enough to customize the point. But as a convenience, since these are generated by the modify graph dialog, they are ignored if used with `[pnt]` syntax.

Also note that legend symbols can use `[pnt]` syntax like so:

```
\s(<tracename>[pnt])
```

Automatically generated legends automatically include symbols for customized points.

For example:

```
Make/O/N=10 jack=sin(x); Display jack
ModifyGraph mode=5,hbFill=6,rgb=(0,0,0)
ModifyGraph hbFill(jack[2])=7,rgb(jack[2])=(0,65535,0)
ModifyGraph rgb(jack[3])=(65535,0,0)
Legend/C/N=text1/F=0/A=MC
```

Examples

Arrow markers.

```
Make/N=10 wavel= x; Display wavel
Make/N=(10,2) awave
awave[] [0]= p*5 // length
awave[] [1]= pi*p/9 // angle
ModifyGraph mode=3,arrowMarker(wavel)={awave,1,10,0.3,0}

// Now add an optional column to control headLen
Redimension/N=(-1,3) awave
awave[] [2]= 7+p // will be head length

// Note: nothing changes until the following is executed
SetDimLabel 1,2,headLen,awave
```

Create meteorological wind barb symbols.

```
Make/O/N=50 jack= floor(x/10),jackx= mod(x,10)
Display jack vs jackx
Make/O/N=(50,3) jackbarb
```

```
jackbarb[][0]= 40           // length of stem
jackbarb[][1]= 45*pi/180   // angle (45deg)
jackbarb[][2]= p           // wind speed code
SetDimLabel 1,2,windBarb,jackbarb
ModifyGraph mode=3,arrowMarker(jack)={jackbarb,1,10,0.5,0}
ModifyGraph margin(top)=62,margin(right)=84
```

See also **Wind Barb Plots** on page II-317.

Inline arrows and barb sharpness.

```
Make/O/N=20 wavex=cos(x/3),wavey=sin(x)
Display wavey vs wavex
ModifyGraph mode=3,arrowMarker={_inline_,1,20,.5,0,barbSharp= 0.2}
```

Use direct color mode to individually color each point in a trace:

```
Make jack=sin(x/8)
Make/N=(128,3)/B/U jackrgb
Display jack
ModifyGraph mode=3,marker=19
jackrgb= enoise(128)+128
ModifyGraph zColor(jack)={jackrgb,*,*,directRGB}
```

Use masking.

```
Make/N=100 jack= (p&1) ? sin(x/8) : cos(x/8)
Display jack

Make/N=100 mjack= (p&1) ? 0 : NaN           // just to show NaN can be used
ModifyGraph mask(jack)={mjack,0,NaN}

// now switch which points are shown
mjack= (p&1) ? NaN : 0
```

See Also

Trace Names on page II-270, **Programming With Trace Names** on page IV-87.

ModifyGraph (axes)

```
ModifyGraph [/W=winName/Z] key [(axisName)] = value
[, key [(axisName)] = value]...
```

This section of ModifyGraph relates to modifying the appearance of axes in a graph.

Parameters

Each *key* parameter may take an optional *axisName* enclosed in parentheses.

axisName is “left”, “right”, “top”, “bottom” or the name of a free axis such as “vertCrossing”. For instance, “ModifyGraph axThick(left)=0.5” sets the axis thickness for only the left axis.

If “(*axisName*)” is omitted, all axes in the graph are affected. For instance, “ModifyGraph standoff=0” disables axis standoff for all axes in the graph.

The parameter descriptions below omit the optional “(*axisName*)”.

axisClip= <i>c</i>	Specifies one of three clipping modes for traces.
<i>c</i> =0:	Clips traces to a plot rectangle as defined by the pair of axes used by a given trace (default).
<i>c</i> =1:	Plots traces on an axis with a restricted range (as set by axisEnab) to extend to the full range of the normal plot rectangle.
<i>c</i> =2:	Traces extend outside the normal plot rectangle to the full extent of the graph area.

axisEnab={*lowFrac*,*highFrac*}

Restricts the length of an axis to a subrange of normal. The axis is drawn from *lowFrac* to *highFrac* of graph area height (vertical axis) or width (horizontal axis). For instance, {0.1,0.75} specifies that the axis is drawn from 10% to 75% of the graph area height/width, instead of the normal 0% to 100%. AxisEnab is discussed in **Creating Split Axes** on page II-335 and **Creating Stacked Plots** on page II-312.

ModifyGraph (axes)

axisOnTop= <i>t</i>	Specifies drawing level of axis and associated grid lines. <i>t</i> =0: Draws axis before traces and images (default). <i>t</i> =1: Draws the axis after all traces and images.
axOffset= <i>a</i>	Specifies the distance from default axis position to actual axis position in units of the width of a zero character (0) in a tick mark label. Unlike margin, axOffset adjusts to changes in the size of the graph.
axThick= <i>t</i>	Specifies the axis thickness in points.
barGap= <i>fraction</i>	Sets the fraction of the width available for bars to be used as gap between bars. barGap sets the gap between bars within a single category while catGap sets the gap between categories.
btLen= <i>p</i>	Sets the length of major ("big") tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default length. <i>p</i> may be fractional.
btThick= <i>p</i>	Sets the thickness of major ("big") tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default thickness. <i>p</i> may be fractional.
catGap= <i>fraction</i>	The value for catGap is the fraction of the category width to be used as gap. The gap is divided equally between the start and end of the category width. A value of 0.2 would use 20% of the available space for the gap and leave 80% of the available space for the bars. catGap sets the gap between categories while barGap sets the gap between bars within a single category.
dateFormat={ <i>languageName, yearFormat, monthFormat, dayOfMonthFormat, dayOfWeekFormat, layoutStr, commonFormat</i> }	

Sets the custom date format used in the active graph.

Note: Use a custom date format only if you turn it on via a ModifyGraph dateInfo command. The last parameter to the ModifyGraph dateInfo command must be -1 to turn on the custom date format.

Parameters are the same as for the LoadWave/R flag except for the last one.

commonFormat selects the common date format to use in the Modify Axis dialog. The legal values correspond to the choices in the Common Format pop-up menu of the Modify Axis dialog. They are:

Value	Date Format	Value	Date Format
1	mm/dd/yy	16	mm/yy
2	mm-dd-yy	17	mm.yy
3	mm.dd.yy	18	Abbreviated month and year
4	mmddyy	19	Full month and year
6	dd/mm/yy	21	mm/dd
7	dd-mm-yy	22	dd.mm
8	dd.mm.yy	23	Abbreviated month and day
9	ddmmyy	24	Full month and day
11	yy/mm/dd	26	Abbreviated date without day of week
12	yy-mm-dd	27	Abbreviated date with day of week
13	yy.mm.dd	28	Full date without day of week
14	yymmdd	29	Full date with day of week

If the *commonFormat* parameter is negative, then it will select the Use Custom Format radio button in the Modify Axis dialog rather than Use Common Format and will then use the absolute value of *commonFormat* to determine which item to select in the Common Format pop-up menu.

`dateInfo={sd,tm,dt}` Controls formatting of date/time axes.

sd=0: Show date in the date&time format.

The date is always suppressed if *tm=2* (elapsed time).

The time is always suppressed if there are fewer than one ticks per day and *tm=0* (12-hour time) or *tm=1* (24-hour time).

sd=1: Suppress date.

The date is always suppressed if *tm=2* (elapsed time).

sd=2: Suppress time.

The time is always shown if *tm=2* (elapsed time).

sd=2 requires Igor Pro 9.00 or later.

tm=0: 12 hour (AM/PM) time.

tm=1: 24 hour (military) time.

tm=2: Elapsed time.

dt=-1: Custom date as specified via the *dateFormat* keyword.

dt=0: Short dates (2/22/90).

dt=1: Long dates (Thursday, February 22, 1990).

dt=2: Abbreviated dates (Thurs, Feb 22, 1990).

`font="fontName"` Sets the axis label font, e.g., `font(left) = "Helvetica"`.

`freePos(freeAxName)=p`

Sets the position of the *free* axis relative to the edge of the plot area to which the axis is anchored. *p* is in points. i.e., if the axis was made via `/R=axName` then the axis is placed *p* points from the right edge of the plot area. Positive is away from the central plot area. *freeAxName* may not be any of the standard axes: "left", "bottom", "right" or "top".

`freePos(freeAxName)={crossAxVal,crossAxName}`

Positions the *free* axis so it will cross the perpendicular axis *crossAxName* where it has a value of *crossAxVal*. *freeAxName* may not be any of the standard axis names "left", "bottom", "right", or "top", though *crossAxName* may.

You can position a free axis as a fraction of the distance across the plot area by using `kwFraction` for *crossAxName*. *crossAxVal* must then be between 0 and 1; any values outside this range are clipped to valid values.

`fsize=s`

Autosizes (*s=0*) tick mark labels and axis labels.

If *s* is between 3 and 99 then the labels are fixed at *s* points.

ModifyGraph (axes)

<code>fstyle=f</code>	<p><i>f</i> is a bitwise parameter with each bit controlling one aspect of the font style for the axis and tick mark labels as follows:</p> <ul style="list-style-type: none">Bit 0: BoldBit 1: ItalicBit 2: UnderlineBit 4: Strikethrough <p>See Setting Bit Parameters on page IV-12 for details about bit settings.</p>
<code>ftLen=p</code>	Sets the length of 5th (or emphasized minor) tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default length. <i>p</i> may be fractional.
<code>ftThick=p</code>	Sets the thickness of 5th (or emphasized minor) tick marks to <i>p</i> points (fractional). If <i>p</i> is zero, it uses the default thickness.
<code>grid=g</code>	Controls grid lines. <ul style="list-style-type: none"><i>g</i>=0: Grid off.<i>g</i>=1: Grid on.<i>g</i>=2: Grid on major ticks only.
<code>gridEnab={lowFrac,highFrac}</code>	Restricts the length of axis grid lines to a subrange of normal. The grid is drawn from <i>lowFrac</i> to <i>highFrac</i> of graph area height (if axis is horizontal) or width (if axis is vertical).
<code>gridHair=h</code>	Sets the grid hairline thickness (<i>h</i> = 0 to 3; 0 for thicker lines, 3 for thinner; default is 2). If <i>h</i> =0, the thickness of grid lines on major tick marks is the same as the axis thickness, half for a minor tick and one tenth for a subminor tick (log axis only). As <i>h</i> increases these thicknesses decrease by a factor of 2^h . If you want to see the effect of different values of <code>gridHair</code> , you will need to print a sample graph because you generally can't see the effect of thin lines on the screen. Also see the example experiment "Examples:Graphing Techniques:Graph Grid Demo".
<code>gridStyle=g</code>	Sets the grid style to various combinations of solid and dashed lines. In the following discussion, major, minor and subminor refer to grid lines the corresponding tick marks. Subminor ticks are used only on log axes when there is a small range and sufficient room (they correspond to hundredths of a decade). The different grid styles are solid, dotted, dashed, and blank. The possible grids are as follows: <ul style="list-style-type: none"><i>g</i>=0: Same as mode 1 if graph background is white else uses mode 5.<i>g</i>=1: Major dotted, minor and subminor dashed.<i>g</i>=2: All dotted.<i>g</i>=3: Major solid, minor dotted, subminor blank.<i>g</i>=4: Major and minor solid, subminor dotted.<i>g</i>=5: All solid. <p>Also see the example experiment "Examples:Graphing Techniques:Graph Grid Demo".</p>
<code>highTrip=h</code>	If the extrema of an axis are between its <code>lowTrip</code> and its <code>highTrip</code> then tick mark labels use fixed point notation. Otherwise they use exponential (scientific or engineering) notation.
<code>lblLatPos=p</code>	Sets a lateral offset for the axis label. This is an offset parallel to the corresponding axis. <i>p</i> is in points. Positive is down for vertical axes and to the right for horizontal axes.
<code>lblLineSpacing=linespace</code>	

	Specifies an adjustment to the normal line spacing for multi-line axis labels. <code>linespace</code> is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line.
	<code>lblLineSpacing</code> affects all lines of the axis label. See also the <code>\sa</code> and <code>\sb</code> line spacing escape codes described under General Escape Codes on page III-54. They can be used to affect the spacing between individual lines.
<code>lblMargin=<i>l</i></code>	Specifies the distance from the edge of graph to a label in points.
<code>lblPos=<i>p</i></code>	Sets the distance from an axis to the corresponding axis label in points. If $p=0$, it automatically picks an appropriate distance.
	This setting is used only if the given graph edge has at least one free axis. Otherwise, the <code>lblMargin</code> setting is used to position the axis label.
<code>lblPosMode=<i>m</i></code>	Affects the meaning and usage of <code>lblPos</code> , <code>lblLatPos</code> , and <code>lblMargin</code> parameters. Mainly for use when you have multiple axes on a side and you need axis labels to be properly positioned even as you make graph windows dramatically larger or smaller.
	<i>m</i> =0: Default compatibility mode (Margin or Axis absolute depending on presence of free axis).
	<i>m</i> =1: Margin absolute.
	<i>m</i> =2: Margin scaled.
	<i>m</i> =3: Axis absolute.
	<i>m</i> =4: Axis scaled.
	The absolute modes are measured in points whereas scaled modes have similar values but automatically expand or contract as the axis font height changes. Mode 0 is the default and results in no change relative to previous versions of Igor Pro that used <code>lblMargin</code> unless a given side used a free axis in which case it used <code>lblPos</code> in absolute mode. The margin modes measure relative to an edge of the graph while the axis modes measure relative to the position of the axis. When using stacked axes, use either margin modes. With multiple nonstacked axes, use Axis scaled if the graph edge is not using a fixed margin or use axis absolute if it is.
<code>lblRot=<i>r</i></code>	Rotates the axis label by <i>r</i> degrees. <i>r</i> is a value from -360 to 360. Rotation is counterclockwise and starts from the label's normal orientation.
<code>linTkLabel=<i>tl</i></code>	<i>tl</i> =1 attaches the data units with any exponent or prefix to each tick label on a normal axis. <i>tl</i> =0 removes them.
	In Igor Pro 9.00 and later, <i>tl</i> =2 suppresses the space character normally displayed before units.
<code>log=<i>l</i></code>	Controls axis log mode.
	<i>g</i> =0: Normal axis.
	<i>g</i> =1: Log base 10.
	<i>g</i> =2: Log base 2.
<code>logHTrip=<i>hl</i></code>	Same as <code>highTrip</code> but for log axes.
<code>logLabel=<i>l</i></code>	Sets the maximum number of decades in a log axis before minor tick labels are suppressed.
<code>logLTrip=<i>l</i></code>	Same as <code>lowTrip</code> but for log axes.
<code>loglinear=<i>l</i></code>	Switches to a linear tick method (<i>l</i> =1) on a log axis if the number of decades of ranges is less than 2. It switches to a linear tick exponent method if the number of decades is greater than five.

ModifyGraph (axes)

<code>logmtlOffset=<i>o</i></code>	Offsets the minor tick mark labels on a log axis by <i>o</i> fractional points relative to the default tick mark label position. Positive is away from the axis. Added in Igor Pro 9.00.
<code>logTicks=<i>t</i></code>	Sets the maximum number of decades in log axis before minor ticks are suppressed.
<code>lowTrip=<i>l</i></code>	If the extrema of an axis are between its lowTrip and its highTrip then tick mark labels use fixed point notation. Otherwise they use exponential (scientific or engineering) notation.
<code>manminor={<i>number, emphasizeEvery</i>}</code>	<p>Specifies how to draw minor ticks in manual tick mode. There will be <i>number</i> ticks between each major (labeled) tick. You will usually want to set this to 4 to make 5 divisions, or 9 to make 10 divisions. A medium-sized tick (an emphasized minor tick) will be drawn every <i>emphasizeEvery</i> minor tick.</p>
<code>manTick={<i>cantick, tickinc, exp, digitsrt</i> [, <i>timeUnit</i>]}</code>	<p>Turns on manual tick mode. The tick from which all other ticks are calculated is the cononic tick (<i>cantick</i>). The numerical spacing between ticks is set by <i>tickinc</i>. <i>cantick</i> and <i>tickinc</i> are multiplied by 10^{exp}. The number of digits to the right of the decimal point displayed in the tick labels is set by <i>digitsrt</i>.</p> <p>The optional parameter <i>timeUnit</i> is used with Date/Time axes to specify the units of <i>tickinc</i>. In this case, <i>tickinc</i> must be an integer. The value of <i>timeUnit</i> is one of the following keywords:</p> <p><i>second, minute, hour, day, week, month, year</i></p> <p>On a date/time axis, the <i>exp</i> and <i>digitsrt</i> keywords are ignored, but must be present. You can set them to zero.</p>
<code>manTick=0</code>	Turns off manual tick mode.
<code>margin=<i>m</i></code>	<p>Sets a fixed margin from the edge of the window to the axis in points. Used principally to make axes of multiple graphs on a page line up when “stacked”. You can use the left, right, bottom, and top axis names (even if an axis with that name doesn’t exist) to adjust the graph plot area. See Types of Axes on page II-267.</p> <p><i>m=0</i>: Sets “automatic” margin size (dependent on the length and height of tick marks and labels).</p> <p><i>m=-1</i>: Sets the margin to “none”, or 0. The axis is drawn at the graph window’s edge.</p>
<code>minor=<i>m</i></code>	Disables (<i>m=0</i>) or enables (<i>m=1</i>) minor ticks.
<code>mirror=<i>m</i></code>	<p>Controls axis mirroring.</p> <p><i>m=1</i>: Right axis mirroring left or top mirroring bottom.</p> <p><i>m=2</i>: Mirror axis without tick marks.</p> <p><i>m=3</i>: Mirror axis with tick marks and tick labels.</p> <p><i>m=0</i>: No mirroring.</p>
<code>mirrorPos=<i>pos</i></code>	Specifies the position of the mirror axis relative to the normal position. <i>pos</i> is a value between 0 and 1.
<code>noLabel=<i>n</i></code>	<p>Controls axis labeling.</p> <p><i>n=0</i>: Normal labels.</p> <p><i>n=1</i>: Suppresses tick mark labels.</p> <p><i>n=2</i>: Suppresses tick mark labels and axis labels.</p>

notation= <i>n</i>	<p>Uses engineering (<i>n</i>=0) or scientific (<i>n</i>=1) notation for tick mark labels.</p> <p>Affects tick mark labels displayed exponentially. See highTrip and lowTrip. Does not affect log axes.</p>
nticks= <i>n</i>	Specifies the approximate number of ticks marks (<i>n</i>) on axis.
prescaleExp= <i>exp</i>	Multiplies axis range by 10^{exp} for tick labeling and <i>exp</i> is subtracted from the axis label exponent. In other words, the exponent is moved from the tick labels to the axis label. (This affects the display only, not the source data.)
sep= <i>s</i>	Specifies the minimum number of screen points (<i>s</i>) between minor ticks.
standoff= <i>s</i>	<p>Suppresses (<i>s</i>=0) or enables (<i>s</i>=1) axis standoff.</p> <p>Axis standoff prevents waves or markers from covering the axis.</p>
stLen= <i>p</i>	Sets the length of minor ("small") tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default length. <i>p</i> may be fractional.
stThick= <i>p</i>	Sets the thickness of minor ("small") tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default thickness. <i>p</i> may be fractional.
tick= <i>t</i>	<p>Sets tick position.</p> <p><i>t</i>=0: Outside axis.</p> <p><i>t</i>=1: Crossing axis.</p> <p><i>t</i>=2: Inside axis.</p> <p><i>t</i>=3: None.</p> <p>In a category plot, adding 4 to the usual values for the tick keyword will place the tick marks in the center of each category rather than at the edges.</p> <p>In a normal (non-category) plot specifying <i>t</i>=4 or <i>t</i>=5 replaces tick marks and axis lines with rectangular regions with alternating fills. This feature, which was added in Igor Pro 8.00, is used for cartographic plots.</p> <p><i>t</i>=4 gives even fills and <i>t</i>=5 gives odd fills. The btLen keyword determines the thickness of the fill area.</p> <p>It is recommended that you use mirror axes and axisOnTop=1 as shown in this example:</p> <pre>Make jack=sin(x/8) Display jack ModifyGraph axisOnTop=1 ModifyGraph mirror=1 ModifyGraph standoff=0 ModifyGraph tick=4</pre>
tickEnab={ <i>lowTick</i> , <i>highTick</i> }	Restricts axis ticking to a subrange of normal. Ticks are drawn and labelled only if they fall within this inclusive numerical range.
tickExp= <i>te</i>	<i>te</i> =1 forces tick labels to exponential notation when labels have units with a prefix. <i>te</i> =0 turns this off.
tickUnit= <i>tu</i>	Suppresses (<i>tu</i> =1) or turns on (<i>tu</i> =0) units labels attached to tick marks.
tickZap={{ <i>v1</i> [<i>v2</i> [<i>v3</i>]]}}	Suppresses drawing of the tick mark label for values given in the list. This is useful when you have crossing axes to prevent tick mark labels from overlapping. The list may contain zero, one, two or three values. The values must be exact to suppress the label.

ModifyGraph (axes)

tkLblRot= <i>r</i>	Rotates the tick mark labels by <i>r</i> degrees. <i>r</i> is a value from -360 to 360. Rotation is counterclockwise and starts from the label's normal orientation.
tlOffset= <i>o</i>	Offsets the tick mark labels by <i>o</i> fractional points relative to the default tick mark label position. Positive is away from the axis.
ttLen= <i>p</i>	Sets the length of subminor ("tiny") tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default length. <i>p</i> may be fractional. Subminor ticks are used only in log axes.
ttThick= <i>p</i>	Sets the thickness of subminor ("tiny") tick marks to <i>p</i> points. If <i>p</i> is zero, it uses the default thickness. <i>p</i> may be fractional.
userticks={ <i>tickPosWave</i> , <i>tickLabelWave</i> }	<p>Draws axes with purely user-defined tick mark positions and labels. <i>tickPosWave</i> is a numeric wave containing the desired positions of the tick marks, and <i>tickLabelWave</i> is a text wave containing the labels. See User Ticks from Waves on page II-301 for an example.</p> <p>The tick mark labels can be multiline and use styled text. For more details, see Fancy Tick Mark Labels on page II-346.</p> <p><i>tickPosWave</i> need not be monotonic. Igor will plot a tick if a value is in the range of the axis. Both linear and log axes are supported.</p> <p>Graph margins will adjust to accommodate tick labels. This will not prevent overlap between labels, which you will need fix yourself.</p>
useTsep= <i>t</i>	<i>t</i> =1 displays a thousand's separator character between every group of three digits in the tick mark label (e.g., "1,000" instead of "1000"). The default is <i>t</i> =0.
zapLZ= <i>t</i>	Removes (<i>t</i> =1) leading zeros from tick mark labels. For example 0.5 becomes .5 and -0.5 becomes -.5. Default is <i>t</i> =0.
zapTZ= <i>t</i>	Removes (<i>t</i> =1) trailing zeros from tick mark labels. The the radix point will also be removed if all digits are zero. Default is <i>t</i> =0.
zero= <i>z</i>	Controls the zero line. <i>z</i> =0: A zero line at $x=0$ or $y=0$. The line style is set to <i>z</i> -1. See ModifyGraph (traces) on page V-612, <i>lStyle</i> keyword, for details on line styles. <i>z</i> =1: No zero line.
zeroThick= <i>zt</i>	Sets the thickness of the zero line in points, from 0.0 to 5.0 points. <i>zt</i> =0.0 means the zero line thickness automatically follows the thickness of the axis; this is the default. You can use 0.1 for a thin zero line thickness.
ZisZ= <i>t</i>	<i>t</i> =1 uses the single digit 0 as the zero tick mark label (if any) regardless of the number of digits used for other labels. Default is <i>t</i> =0.

Flags

/W= <i>winName</i>	Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/Z	Does not generate an error if the named axis does not exist in a style macro.

Details

With the *prescaleExp* parameter, you can force tick and axis label scaling to values different from the defaults. For example, if you have data whose X scaling ranges from 9pA to 120pA and you display this on a log axis,

the tick marks will be labelled 10pA and 100pA. But if you really want the tick marks labeled 10 and 100 with pA in the axis label, you can set the `prescaleExp` to 12. To see this, execute the following commands:

```
Make/O jack=x
Display jack
SetScale x, 9e-12, 120e-12, "A", jack
ModifyGraph log(bottom)=1
```

then execute:

```
ModifyGraph prescaleExp(bottom)=12
```

The `tickExp` parameter applies to units that do not traditionally use SI prefix characters. For example, one usually speaks of 10^{-3} Torr and not mTorr. To see how this feature works, execute the following example commands:

```
Make/O jack=x
Display jack
SetScale x, 1E-7, 1E-5, "Torr", jack
ModifyGraph log(bottom)=1
```

then execute:

```
ModifyGraph tickExp(bottom)=1
```

at this point, the tick mark labels have Torr in them. If you want to eliminate the units from the tick marks, execute:

```
ModifyGraph tickUnit(bottom)=1
```

and if you now want Torr in the label string, use the `\U` escape in the label string:

```
Label bottom "\\U"
```

To see the effect of `linTkLabel`, execute these commands:

```
Make/O jack=x
Display jack
SetScale x, 1E-7, 1E-5, "Torr", jack
```

then execute:

```
ModifyGraph linTkLabel(bottom)=1
```

and then try:

```
ModifyGraph tickExp(bottom)=1
```

and finally:

```
ModifyGraph tickUnit(bottom)=1
```

ModifyGraph (colors)

```
ModifyGraph [/W=winName/Z] key [(axisName)]=(r,g,b,[a])
[, key [(axisName)]=(r,g,b[,a])]
```

This section of `ModifyGraph` relates to modifying the use of colors in a graph.

Parameters

Most of the *key* parameters may take an optional *axisName* enclosed in parentheses. *axisName* is "left", "right", "top", "bottom" or the name of a free axis such as "vertCrossing".

Where the parameter descriptions indicate an "(*axisName*)", it may be omitted to change all axes in the graph.

r, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. (0, 0, 0) specifies opaque black and (65535, 65535, 65535) specifies opaque white.

Parameter Specification	Object Colored
<code>alb1RGB(axisName)=(r,g,b[,a])</code>	Axis labels
<code>axRGB(axisName)=(r,g,b[,a])</code>	Axis
<code>cbRGB=(r,g,b[,a])</code>	Control bar background
<code>gbRGB=(r,g,b[,a])</code>	Graph background
<code>gbGradient</code>	See Gradient Fills on page III-500 for details.
<code>gbGradientExtra</code>	See Gradient Fills on page III-500 for details.
<code>gridRGB(axisName)=(r,g,b[,a])</code>	Axis grid lines

ModifyImage

Parameter Specification	Object Colored
<code>tickRGB(axisName) = (r, g, b[, a])</code>	Axis Tick marks
<code>tlblRGB(axisName) = (r, g, b[, a])</code>	Axis Tick labels
<code>wbRGB = (r, g, b[, a])</code>	Window background
<code>wbGradient</code>	See Gradient Fills on page III-500 for details.
<code>wbGradientExtra</code>	See Gradient Fills on page III-500 for details.

Flags

<code>/W=winName</code>	Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
<code>/Z</code>	Does not generate an error if the named axis does not exist in a style macro.

Details

On Windows, use maximum white to set the control bar background color to track the 3D Objects color in the Appearance Tab of the Display Properties control panel:

```
ModifyGraph cbRGB=(65535,65535,65535)
```

See Also

See **Instance Notation** on page IV-20.

ModifyImage

```
ModifyImage [/W=winName] imageInstance, keyword = value  
[, keyword = value]...
```

The ModifyImage operation changes properties of the given image in the top graph (or the specified graph if /W is used). *imageInstance* is the name of the image to be altered. This name is usually simply the name of the matrix wave containing the image data. If the same matrix wave is displayed more than once, you must append #0, #1 etc. to the name to distinguish which is which.

imageInstance can also take the form of a null name with an instance number to affect the instanceth image. That is,

```
ModifyImage ''#1
```

modifies the appearance of the second image that was appended to the top graph, no matter what the image names are. Note: two single quotes are used, not a double quote.

Parameters

Here are the keyword-value pairs. These apply to false color images in which the data in the matrix is used as an index into a color table. They do not apply to direct color images in which the data in the matrix specifies the color directly.

`cindex=matrixWave` Sets the Z value mapping mode such that image colors are determined by doing a lookup in the specified matrix wave.

matrixWave is a 3 column wave that contains red, green, and blue values from 0 to 65535. (The matrix can actually have more than three columns. It ignores any extra columns.)

The color at $Z=z$ is determined by finding the RGB values in the row of *matrixWave* whose scaled X index is z . In other words, the red value is $matrixWave(z)[0]$, the green value is $matrixWave(z)[1]$ and the blue value is $matrixWave(z)[2]$.

If *matrixWave* has default X scaling, where the scaled X index equals the point number, then row 0 contains the color for $Z=0$, row 1 contains the color for $Z=1$, etc.

If you use `cindex`, you should not use `ctab` in the same command.

`ctab={zMin, zMax, ctName, reverse}`

Sets the z mapping mode by which values in the matrix are mapped linearly into the color table specified by *ctName*.

zMin and *zMax* set the range of z values to map. Omit *zMin* or *zMax* to leave as is or use * to autoscale.

The color table name can be missing if you want to leave it as is.

ctName can be any color table name returned by the CTabList function, such as Grays or Rainbow (see **Image Color Tables** on page II-380) or the name of a 3 column or 4 column color table wave (**Color Table Waves** on page II-387).

A color table wave name supplied to `ctab` must not be the name of a built-in color table (see CTabList). A 3 column or 4 column color table wave must have values that range between 0 and 65535. Column 0 is red, 1 is green, and 2 is blue. In column 3 a value of 65535 is opaque, and 0 is fully transparent.

Set *reverse* to 1 to reverse the color table. Setting it to 0 or omitting it leaves the color table unreversed.

`ctabAutoscale=autoBits`

Sets the range of data used for autoscaling `ctab *` values.

Bit 0: Autoscales only the XY subset being displayed.

Bit 1: Autoscales only the current plane being displayed.

If neither bit is set (if *autoBits* = 0, the default), then all of the data in the image wave is used to autoscale the *'d *zMin*, *zMax* values for `ctab`.

`eval={value, red, green, blue, [alpha]}`

If the red, green, and blue values are in the valid range for a color value (0 to 65535) the explicit value-color pair is added (or updated if value already exists). If the color values are out of range (-1 is suggested) then the value is removed from the list if it is present (no error if it is not).

alpha is optional: a value of 65535 is opaque, and 0 is fully transparent.

ModifyImage

- `explicit=1 or 0` Turns explicit (monochrome) mode on (1) or off (0). Meant to be used with unsigned byte data but will do the best it can for other types. If value of data is equal to one of the defined explicit values then its defined color is used otherwise the pixel will be blank. The default predefined values are:
- 255: black
 - 0: white
- You can add, change, or delete explicit values with the `eval` keyword.
- `genericNotRGB=v` Controls the auto-detection of three and four plane images:
- `v=1`: Suppresses the auto-detection of three and four plane images as direct color (RGB or RGBA), like `AppendImage/G=1`.
 - `v=0`: Three and four plane images are treated as direct color (RGB or RGBA). This is the default if `genericNotRGB` is omitted.
- The `genericNotRGB` keyword was added in Igor Pro 9.00.
- `imCmplxMode=m` Sets complex data display mode.
- `m=0`: Magnitude (default).
 - `m=1`: Real only.
 - `m=2`: Imaginary only.
 - `m=3`: Phase in radians.
- `interpolate= mode` `mode = 1` turns on smoothing of the boundaries between pixels. Since this is implemented via system graphics calls and not by Igor actually doing the interpolation, it will not affect EPS or EMF export on Windows and will not affect EPS export on Mac. Although this may create a more esthetically pleasing display, it is not clear that it is appropriate for scientific data.
- `mode = -1` forces pixels to be drawn as individual rectangles. This is sometimes needed when a third-party program improperly interpolates PDF or EPS exported images.
- `log= 1 or 0` 0 sets the default linearly-spaced false-image colors.
- 1 turns on logarithmically-spaced false-image colors. This requires that the image values be greater than 0 to display correctly.
- Affects the image colors for color table and color index images only (see **Color Table Details** on page II-383 and **Indexed Color Details** on page II-388).
- `lookup= waveName` Specifies an optional 1D wave that can be used to modify the mapping of scaled `z` values into the color table specified with the `ctab` parameter. Values should range from 0.0 to 1.0. A linear ramp from 0 to 1 would have no effect while a ramp from 1 to 0 would reverse the image. Used to apply gamma correction to grayscale images or for special effects. Use a NULL wave (`$ " "`) to remove the option.
- `maxRGB=(red, green, blue, [alpha])`
- Sets the color of image values greater than the `ctab zMax` or greater than the `cindex` of the `matrixWave` maximum X scaling value. Also turns max color mode on.
- The `red`, `green`, and `blue` color values are in the range of 0 to 65535.
- `alpha` is optional: a value of 65535 is opaque, and 0 is fully transparent.
- `maxRGB=1 or 0 or NaN`

Turns max color mode off, on, or transparent. These modes affect the display of image values greater than the ctab *zMax* or greater than the cindex of the *matrixWave* maximum X scaling value.

- 1: Turns on max color mode. The color of the affected image pixels is black or the last color set by `maxRGB=(red, green, blue)`.
- 0: Turns off max color mode (default). The color of the affected image pixels is the last color table or color index color.
- NaN: Transparent max color mode. The affected image pixels are not drawn.

`minRGB=(red, green, blue, [alpha])`

Sets the color of image values less than the ctab *zMin* or less than the cindex of the *matrixWave* minimum X scaling value. Also turns min color mode on.

The *red*, *green*, and *blue* color values are in the range of 0 to 65535.

alpha is optional: a value of 65535 is opaque, and 0 is fully transparent.

`minRGB=1 or 0 or NaN`

Turns min color mode off, on, or transparent. These modes affect the display of image values less than the ctab *zMin* or less than the cindex of the *matrixWave* minimum X scaling value.

- 1: Turns on min color mode. The color of the affected image pixels is black or the last color set by `minRGB=(red, green, blue)`.
- 0: Turns off min color mode (default). The color of the affected image pixels is the first color table or color index color.
- NaN: Transparent min color mode. The affected image pixels are not drawn.

`plane=p`

Determines which part of a 3D or 4D image wave to display.

The meaning of *p* depends on the nature of the image wave. If the size of the layer dimension of the image wave is exactly three then the wave is treated as RGB data with R, G, and B data in the three layers. If the size of the layer dimension is exactly four, then the wave is treated as RGBA data, with A in the fourth layer. Otherwise each layer of the wave is treated as a separate grayscale image.

Plane=p With RGB Data

If the wave is 3D, `plane=p` has no effect.

If the wave is 4D, each chunk contains a different set of R, G and B layers and *p* selects which chunk to display.

Plane=p With Grayscale Data

If the wave is 3D, *p* selects which layer to display.

If the wave is 4D, `plane=p` acts as if all of the chunks were combined into a virtual 3D wave and *p* selects which layer of this virtual 3D wave to display.

`rgbMult=m`

If *m* is non-zero, direct color values (3 plane RGB) are multiplied by *m*. This would typically be used for 10, 12 or 14 bit integers in a 16 bit word. For example, if your image data is 14 bits, use `rgbMult=4`.

ModifyLayout

Flags

/W=winName Directs action to a specific window or subwindow rather than the top graph window. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See Also

AppendImage and **RemoveImage**.

ModifyLayout

ModifyLayout [*flags*] **key** [(*objectName*)] =*value* [, **key** [(*objectName*)] =*value*]...

The **ModifyLayout** operation modifies objects in the top layout or in the layout specified by the */W* flag.

Parameters

Each *key* parameter may take an optional *objectName* enclosed in parentheses. If “(*objectName*)” is omitted, all objects in the layout are affected.

Though not shown in the syntax, the optional “(*objectName*)” may be replaced with “[*objectIndex*]”, where *objectIndex* is zero or a positive integer denoting the object to be modified. “[0]” denotes the first object appended to the layout, “[1]” denotes the second object, etc. This syntax is used for style macros, in conjunction with the */Z* flag.

The parameter descriptions below omit the optional “(*objectName*)”.

The “*units*”, “*mag*” and “*bgRGB*” keywords apply to the layout as a whole, not to a specific object and do not accept an *objectName*.

<i>bgRGB=(r,g,b[,a])</i>	Specifies the background color for the layout. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as RGBA Values .
<i>columns=c</i>	Specifies the number of columns for a table object.
<i>fidelity=f</i>	Controls the drawing of layout objects. <i>f</i> =0: Low fidelity. <i>f</i> =1: High fidelity.
<i>frame=f</i>	Specifies the type of frame enclosing the object. <i>f</i> =0: No frame. <i>f</i> =1: Single frame (default). <i>f</i> =2: Double frame. <i>f</i> =3: Triple frame. <i>f</i> =4: Shadow frame.
<i>gradient</i>	See Gradient Fills on page III-500 for details.
<i>gradientExtra</i>	See Gradient Fills on page III-500 for details.
<i>height=h</i>	Sets the height of the object.
<i>left=l</i>	<i>l</i> is the horizontal coordinate of the left edge of the object relative to the left edge of the paper.
<i>mag=m</i>	Sets the on screen layout magnification where <i>m</i> is a value between 0.5 and 10. <i>m</i> =1 corresponds to 100%. Factors of two, such as <i>m</i> =.25, <i>m</i> =.5, <i>m</i> =1, <i>m</i> =2, tend to produce the best on screen graphics.
<i>rows=r</i>	Specifies the number of rows for table object.
<i>top=t</i>	<i>t</i> is the vertical coordinate of the top edge of the object relative to the top edge of the paper.

<code>trans=<i>t</i></code>	Controls the transparency of the layout object: <code>t=0:</code> Opaque (default). <code>t=1:</code> Transparent. For this to be effective, the object itself must also be transparent. Annotations have their own transparent/opaque settings. Graphs are transparent only if their backgrounds are white. PICTs may have been created transparent or opaque, and Igor cannot make an opaque PICT transparent.
<code>units=<i>u</i></code>	Sets dimension units in the layout info panel and in the Modify Objects dialog. <code>u=0:</code> Points. <code>u=1:</code> Inches. <code>u=2:</code> Centimeters.
<code>width=<i>w</i></code>	Sets the object width.

Flags

<code>/I</code>	Dimensions in inches.
<code>/M</code>	Dimensions in centimeters.
<code>/W=<i>winName</i></code>	<i>winName</i> is the name of the page layout window to be modified. If <code>/W</code> is omitted or if <i>winName</i> is \$ " ", the top page layout is modified.
<code>/Z</code>	Does not generate an error if the indexed or named object does not exist in a style macro.

The `/I` and `/M` flags affect the units of the parameters for the left, top, width and height keywords only. If neither `/I` nor `/M` is present then the parameters for the left, top, width and height keywords are points.

Details

Note that the units keyword affects only the units used in the layout info panel and in the Modify Objects dialog. It has nothing to do with the units used for the left, top, width and height keywords. Those units are points unless the `/I` or `/M` flags is present.

`NewLayout`, `AppendLayoutObject`, `RemoveLayoutObjects`, `LayoutPageAction`

ModifyPanel

`ModifyPanel` [`/W=winName`] *keyword* = *value* [, *keyword* = *value* ...]

The `ModifyPanel` operation modifies properties of the top or named control panel window or subwindow.

Parameters

keyword is one of the following:

<code>cbRGB=(<i>r,g,b[,a]</i>)</code>	Specifies the background color of the entire control panel or the graph's control bar area. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as RGBA Values .
<code>drawInOrder=<i>d</i></code>	Determines the drawing order of controls in the control panel. <code>d=0:</code> Draw tab controls before any other controls (default). <code>d=1:</code> Draw all controls in the order in which they appear in the recreation macro, which is also the creation order.

The `drawInOrder` keyword was added in Igor Pro 8.00.

Prior to Igor Pro 8.00 tab controls (see **TabControl**) were always drawn before all other controls. This prevented placing a tab control inside a groupbox with a colored interior. `drawInOrder=1` forces Igor to draw controls in creation order, which is the same as the order in which they appear in a recreation macro.

ModifyPanel

- expand=*e*** Sets the expansion factor of the panel. *e* is a number between 0.25 to 8.0. Values of *e* greater than 1.0 make the panel, its controls, and its subwindows, appear larger than normal.
- Though rarely needed, using the `expand` keyword, you can set the expansion of panel subwindows independent of the main panel window's expansion.
- When you change the expansion of a top-level control panel window, the panel window automatically resizes itself.
- The `expand` keyword was added in Igor Pro 9.00.
- See **Control Panel Expansion** on page III-443 for further discussion.
- fixedSize=*f*** Controls the resizing of the panel window.
- f*=0: Panel can be resized (default).
- f*=1: Panel cannot be resized by adjusting the size box or frame (nor maximized on Windows), but the window can be minimized (on Windows) and the `MoveWindow` operation can still change the size.
- The `fixedSize` keyword overrides any previous size limit set using the `SetWindow sizeLimit` command. If you try to use `SetWindow sizeLimit` on a window with `fixedSize=1`, Igor generates an error.
- frameInset=*i*** Specifies the number of pixels by which to inset the frame of the panel subwindow. Mostly useful for overlaying panels in graphs to give a fake 3D frame a better appearance.
- frameStyle=*f*** Specifies the frame style for a panel subwindow.
- f*=0: None.
- f*=1: Single.
- f*=2: Indented.
- f*=3: Raised.
- f*=4: Text well.
- The last three styles are fake 3D and will look good only if the background color of the enclosing space and the panel itself is a light shade of gray.
- noEdit=*e*** Sets the editability of the panel.
- e*=0: Editable (default).
- e*=1: Not editable. For a panel window, the Panel menu item is not present and the `ShowTools` command is ignored. For a panel subwindow, it can not be activated by clicking.

Flags

- /W=*winName*** Modifies the control panel in the named graph or control panel window or subwindow. When omitted, action will affect the active window or subwindow.
- When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

On Windows, set *r*, *g*, and *b* to 65535 (maximum white) to set the background color of the control panel to track the 3D Objects color in the Appearance Tab of the Display Properties control panel.

The **NewPanel** operation.

Controls in Graphs on page III-441.

ModifyProcedure

```
ModifyProcedure [/A[=all] /W=procWinTitleListStr] /Z[=z]
    [procedure=functionOrMacroNameStr, hide=h, lock=ro, writeProtect=wp,
    userCanOverride=ovr]
```

The ModifyProcedure operation modifies one or more procedure windows, depending on the /A and /W flags and on the procedure keyword.

The ModifyProcedure operation was added in Igor 8.03.

Use /W="Procedure" to modify the built-in procedure window.

Use /W=procWinTitleListStr to modify a procedure window specified by its title, such as /W="MyProc" for packed procedure files or /W="MyProc.ipf" for standalone procedure files.

Use procedure=functionOrMacroNameStr to modify a procedure window containing a particular function.

See **Specifying Which Procedure Windows to Modify** below for other usages.

If the procedure window is associated with a standalone file, as opposed to being packed, the file's read-only setting may be set or cleared, as described below for the lock and writeProtect keywords.

Parameters

procedure=functionOrMacroNameStr

functionOrMacroNameStr is a string containing the name of a function or macro in the procedure window to modify.

functionOrMacroNameStr may be a simple name or may include independent module and/or module name prefixes to designate static functions. For use with independent modules, see **Using ModifyProcedure With Independent Modules** below.

lock=ro

Sets or clears the read-only state of the targeted procedure windows.

ro=-2: Clears the read-only state, like ro=0.

In addition, if the procedure window is associated with a standalone file, as opposed to being packed, the file's read-only setting is set to unlocked, as with **SetFileFolderInfo/RO=0**.

ro=-1: The read-only state is not changed.

ro=0: Clears the read-only state. This allows the user to change the text if the procedure window is also not write-protected.

ro=1: Sets the read-only state. The procedure window shows a lock icon in the lower left corner.

ro=-2: Sets the read-only state, like ro=1.

In addition, if the procedure window is associated with a standalone file, as opposed to being packed, the file's read-only setting is set to locked, as with **SetFileFolderInfo/RO=1**.

hide=h

Hides or shows the targeted procedure windows. Added in Igor 9.00.

h=-1: The procedure window visibility is not changed.

h=0: Shows the procedure window.

h=1: Hides the procedure window.

ModifyProcedure

`writeProtect=wp` Sets or clears the write-protect state of the targeted procedure windows.

`wp=-2`: Clears the write-protect state, like `wp=0`.
In addition, if the procedure window is associated with a standalone file, as opposed to being packed, the file's read-only setting is set to unlocked, as with `SetFileFolderInfo/RO=0`.

`wp=-1`: The write-protect state is not changed.

`wp=0`: Clears the write-protect state. The user can change the text if the procedure window is also not locked.

`wp=1`: Sets the write-protect state. The procedure window shows a write-protect icon (a pencil with a red circle-and-line indicator).

`wp=2`: Sets the write-protect state, like `wp=1`.
In addition, if the procedure window is associated with a standalone file, as opposed to being packed, the file's read-only setting is set to locked, as with `SetFileFolderInfo/RO=1`.

`userCanOverride=ovr`

Controls the ability of the user to change the write-protect state of the targeted procedure windows.

`ovr=0`: Prevents the user from changing the write-protect state by clicking the write-protect icon.

`ovr=1`: Allows the user to change the write-protect state by clicking the write-protect icon.

Flags

`/A[=all]` Specifies all procedure windows as the targets of the `ModifyProcedure` operation.
Use `/A=1` to target all procedure windows in the `ProcGlobal` module. `/A` alone is the same as `/A=1`.
Use `/A=2` to target all procedure windows in independent modules. See **Using `ModifyProcedure` With Independent Modules** for details.

`/W=procWinTitleListStr` Specifies a particular procedure window or a list of procedure windows as the targets of the `ModifyProcedure` operation.
If `procWinTitleListStr` is the title of a single procedure window, this specifies that procedure window as the single target.
If `procWinTitleListStr` contains a semicolon-separated list of procedure window titles, this specifies those procedure windows as targets.
See **Specifying Which Procedure Windows to Modify** below for details.

`/Z[=z]` Prevents procedure execution from aborting if an error occurs. Use `/Z` or `/Z=1` if you want to handle errors from `ModifyProcedure` in your procedures rather than having execution abort.

Details

When changing the lock or write-protect states for a standalone file (`lock=+/-2` or `writeProtect=+/-2`), there are scenarios where the file's locked state can't be changed. This would occur, for example, if the file is open in another program or if you do not have sufficient privileges to modify the file.

Specifying Which Procedure Windows to Modify

The simplest way to modify one procedure window whose title you know is to use `/W`:

```
ModifyProcedure/W="My Procedure.ipf" writeProtect=2 // 2 for standalone file
ModifyProcedure/W="Procedure" writeProtect=1 // Modifies built-in procedure window
```

Use `/A=1` to target all procedure windows in the `ProcGlobal` module:

```
ModifyProcedure/A=1 writeProtect=1
```

Don't specify both /A and /W as this is ambiguous and generates an error.

Use `procedure=functionOrMacroNameStr` to modify all procedure windows in the ProcGlobal module containing a procedure with the specified name:

```
ModifyProcedure procedure=MyFunction, writeProtect=1
```

If you omit `procedure=functionOrMacroNameStr`, /A, and /W then the built-in procedure window is modified.

Use `functionOrMacroNameStr` only when you are not certain which procedure window contains the function or macro. If a procedure window has syntax errors that prevent Igor from determining where functions and macros start and end, then ModifyProcedure may not be able to locate the correct procedure window in which case it returns an error.

You can use /W and `procedure=functionOrMacroNameStr` to search for a function or macro in one or more procedure windows. This is useful when `functionOrMacroNameStr` is the name of a static function in a procedure window that uses `#pragma moduleName`.

Using ModifyProcedure With Independent Modules

To work with independent modules, you must enable independent module development. This is for advanced programmers only. See **Independent Modules** on page IV-236 for details. The material in this section assumes that independent module development is enabled.

`/W=procWinTitleListStr` can be a list of procedure window titles each followed by a space and an independent module name in brackets. Then `procedure=functionOrMacroNameStr` applies to the specified procedure windows and independent modules.

For example, if any procedure file contains these statements:

```
#pragma IndependentModule=myIM
#include <Axis Utilities>
```

then the commands

```
ModifyProcedure/W="Axis Utilities.ipf [myIM]" procedure="HVAxisList"
Print S_windowList, V_isReadOnly, V_writeProtect
```

report the title, read-only state, and write-protect state of the procedure window that contains the HVAxisList function, which is in the "Axis Utilities.ipf" file and the independent module myIM.

Similarly, `procedure=functionOrMacroNameStr` may also specify an independent module prefix followed by the # character. The preceding ModifyProcedure command can be rewritten as:

```
ModifyProcedure/W="Axis Utilities.ipf" procedure="myIM#HVAxisList"
```

or simply:

```
ModifyProcedure procedure="myIM#HVAxisList"
```

You can use the same syntax to modify the procedure window containing a static function in a non-independent module procedure file using a module name instead of, or in addition to, the independent module name.

`procWinTitleListStr` can also be just an independent module name in brackets to target all procedure windows that belong to the named independent module containing the specified function:

```
ModifyProcedure/W="[myIM]" procedure="HVAxisList", writeProtect=0
```

Output Variables

The ModifyProcedure operation returns information in the following variables for the last procedure window targeted by the parameters. The information returned reflects the state of affairs after the ModifyProcedure command performs any requested modifications except for `V_wasHidden`.

<code>V_wasHidden</code>	If the procedure window was previously hidden, <code>V_wasHidden</code> is set to 1, otherwise to 0.
<code>V_isReadOnly</code>	If the procedure's lock icon is showing, <code>V_isReadOnly</code> is set to 1, otherwise to 0.
<code>V_writeProtect</code>	If the pencil with the red line icon is showing, <code>V_writeProtect</code> is set to 1, otherwise to 0.
<code>V_userCanOverride</code>	Set to 1 (the default) if the user can change the write-protect state to writable.

ModifyTable

`S_windowList` Set to a semicolon-separated list of procedure window titles that match the parameters, with an appended independent module name in brackets if necessary.

If `S_windowList` is empty, then no procedure windows matched the parameters, and no modifications were performed.

You can obtain the information provided by the output variables without modifying any procedure windows by omitting the `lock`, `writeProtect`, and `userCanOverride` keywords.

Examples

```
// Completely unlock main Procedure window
ModifyProcedure lock=0, writeProtect=0, userCanOverride=1; Print S_windowList

// Completely unlock the procedure window containing the function named MyFunction
ModifyProcedure procedure="MyFunction", lock=0, writeProtect=0, userCanOverride=1
Print S_windowList           // Print procedure window title

// Lock all procedure windows in the myIM independent module, even those included into it,
// and print the titles of the matching procedure windows
Execute "SetIgorOption IndependentModuleDev=1"
ModifyProcedure/W="[myIM]" lock=1, writeProtect=1, userCanOverride=0; Print S_windowList

// Unlock all procedure windows in the ProcGlobal module
ModifyProcedure/A=1 lock=0, writeProtect=0, userCanOverride=1

// Hide all procedures in ProcGlobal and all independent modules
ModifyProcedure/A=2 hide=1 // Equivalent to HideProcedures
```

ModifyTable

ModifyTable [/W=*winName*/Z] **key** [(*columnSpec*)] =*value* [, **key** [(*columnSpec*)] =*value*]...

The `ModifyTable` operation modifies the appearance the top or named table window or subwindow.

Parameters

Many of the parameter keywords take an optional *columnSpec* enclosed in parentheses. Usually *columnSpec* is simply the name of a wave displayed in the table. All table columns are affected when you omit (*columnSpec*).

More precisely, column specifications are wave names for waves in the current data folder or data folder paths leading to waves in any data folder optionally followed by the suffixes `.i`, `.l`, `.d`, `.id` or `.ld` to specify dimension indices, dimension labels, data values, dimension indices and data values, or dimension labels and data values of the wave. For example, `ModifyTable font (myWave.i) = "Helvetica"`. If the wave is complex, the column specification may be followed by `.real` or `.imag` suffixes.

One additional *columnSpec* is `Point`, which refers to the first column containing the dimension index numbers. If multidimensional waves are displayed in the table, this column may have the title "Row", "Column", "Layer", "Chunk" or "Element", but the *columnSpec* for this column is always `Point`. See **Column Names** on page II-229 for details.

Though not shown in the syntax, the optional (*columnSpec*) may be replaced with [*columnIndex*], where *columnIndex* is zero or a positive integer denoting the column to be modified. [0] denotes the `Point` column, [1] denotes the first column appended to the table, [2] denotes the second appended column, etc. This syntax is used for style macros, in conjunction with the /Z flag.

You can use a range of column numbers instead of just a single column number, for example [0, 3].

The parameter descriptions below omit the optional (*columnSpec*).

alignment=*a* Sets the alignment of table cell text.

- a*=0: Left aligned.
- a*=1: Center aligned.
- a*=2: Right aligned.

autosize={*mode, options, padding, perColumnMaxSeconds, totalMaxSeconds*}

Autosizes the specified column or columns.

- mode*=0: Sets width of each data column from a given multidimensional wave individually.
- mode*=1: Sets width of all data columns from a given multidimensional wave the same.

options is a bitwise parameter. Usually 0 is the best choice.

- Bit 0: Ignores column names.
- Bit 1: Ignores horizontal indices.
- Bit 2: Ignores data cells.

All other bits are reserved and must be set to zero.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

padding specifies extra padding for each column in points. Use -1 to get the default amount of padding (16 points).

perColumnMaxSeconds specifies the maximum amount of time to spend autosizing a single column. Use 0 to get the default amount of time (one second).

totalmaxSeconds specifies the maximum amount of time for autosizing the entire table. Use 0 to get the default amount of time (ten seconds).

digits=*d* Specifies the number of digits after decimal point or, for hexadecimal and octal columns, the number of total digits.

elements=(*row, col, layer, chunk*)

Selects the view of a multidimensional wave in the table. The values given to *row*, *col*, *layer*, and *chunk* specify how to change the view.

- 1: No change from current view.
- 1: Display this dimension vertically.
- 3: Display this dimension horizontally.
- ≥0: For waves with 3 or 4 dimensions, display this element of the other dimensions.

See **ModifyTable Elements Command** on page II-251 for a detailed discussion of

entryMode=*m* Queries or sets the table's entry line mode.

- m*=0: Just queries.
- m*=1: Accepts any entry that was started if possible.
- m*=2: Cancels any entry that was started if possible.

If *m* is 0 then the entry line state is not changed but is returned via *V_flag* as follows:

- 0: No entry is in progress.
- 1: An entry is in progress and is valid.
- Other: An entry is in progress and is invalid.

In Igor Pro 8.03 and later, *S_value* is set to contain the text showing in the entry line.

If m is 1 then the entry is accepted if it is valid and its state is returned via V_flag as follows:

- 0: No entry is in progress.
- 1: The entry was accepted.
- Other: The entry is invalid and was not accepted.

In Igor Pro 8.03 and later, S_value is set to contain the text showing in the entry line whether or not an entry was in progress and whether or not it was accepted.

If m is 2 then the entry is cancelled if possible and its state is returned via V_flag as follows:

- 0: No entry is in progress.
- 1: The entry was cancelled.

In Igor Pro 8.03 and later, S_value is set to contain the text showing in the entry line after the entry was cancelled.

$font="fontName"$

Sets font used in the table, e.g., $font="Helvetica"$.

$format=f$

Sets the data format for the table.

- $f=0$: General.
- $f=1$: Integer.
- $f=2$: Integer with thousands (e.g., "1,234").
- $f=3$: Fixed point (e.g., "1234.56").
- $f=4$: Fixed point with thousands (e.g., "1,234.56").
- $f=5$: Exponential (scientific only).
- $f=6$: Date format.
- $f=7$: Time format (always 24 hour time).
- $f=8$: Date&time format (date followed by time).
- $f=9$: Octal.
- $f=10$: Hexadecimal.

You cannot apply date or date&time formats to a wave that is not double-precision (see **Date, Time, and Date&Time Units** on page II-69). To avoid this error, use **Redimension** to change the wave to double-precision.

$frameInset=i$

Specifies the number of pixels by which to inset the frame of the table subwindow.

$frameStyle=f$

Specifies the frame style for a table subwindow.

- $f=0$: None.
- $f=1$: Single.
- $f=2$: Double.
- $f=3$: Triple.
- $f=4$: Shadow.
- $f=5$: Indented.
- $f=6$: Raised.
- $f=7$: Text well.

The last three styles are fake 3D and will look good only if the background color of the enclosing space and the table itself is a light shade of gray.

`horizontalIndex=h` Controls what is displayed in the horizontal index row when multidimensional waves are displayed.

`h=0:` Displays dimension labels if the multidimensional wave's label column is displayed, otherwise displays numeric indices (default).

`h=1:` Always displays numeric indices for multidimensional waves.

`h=2:` Always displays dimension labels for multidimensional waves.

The horizontal index row appears below the row of column names if the table contains a multidimensional wave. Use `horizontalIndex` to override the default behavior in order to display labels for the horizontal dimension while displaying numeric indices for the vertical dimension or vice versa.

The `horizontalIndex` keyword controls the horizontal index row only. To control what is displayed vertically, use **AppendToTable** to append a numeric index or dimension label column.

`rgb=(r,g,b[,a])` Sets color of text. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. The default is opaque black.

`selection=(firstRow, firstCol, lastRow, lastCol, targetRow, targetCol)`

Sets the selected cells in the table.

If any of the parameters have the value -1 then the corresponding part of the selection is not changed.

Otherwise they set the first and last selected cell and the target cell. Row and column values are 0 or greater. The Point column can not be selected.

The proposed parameters are clipped to avoid invalid combinations, such as the last selected row being before the first selected row.

With one exception, it does not support selecting unused cells. Therefore the proposed selection is clipped to prevent this. The exception is that, if the parameters call for selecting the first cell in the first unused column, then this is permitted.

`showFracSeconds=s` Shows (*s*=1) or hides (*s*=0; default) fractional seconds.

`showParts=parts` Specifies what elements of the table should be visible. Other elements are hidden.

parts is a bitwise parameter specifying what to show.

bit 0: Entry line and other top line controls.

bit 1: Name row.

bit 2: Horizontal index row.

bit 3: Point column.

bit 4: Horizontal scroll bar.

bit 5: Vertical scroll bar.

bit 6: Insertion cells.

bit 7: Insertion cells.

All other bits are reserved and must be set to zero except that you can pass -1 to indicate that you want to show all parts of the table.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

Presentation tables in subwindows in graphs and page layouts do not have an entry line or scroll bars and therefore never show these items.

See **Parts of a Table** on page II-223 and **Showing and Hiding Parts of a Table** on page II-225 for further information.

`sigdigits=d` *d* is the number of significant digits when the numeric format is general.

`size=s` Font size, e.g., `size=14`.

ModifyViolinPlot

<code>style=<i>n</i></code>	<p><i>n</i> is a bitwise parameter with each bit controlling one aspect of the column's font style as follows:</p> <ul style="list-style-type: none">Bit 0: BoldBit 1: ItalicBit 2: UnderlineBit 4: Strikethrough <p>For example, bold underlined is $2^0 + 2^2 = 1 + 4 = 5$. See Setting Bit Parameters on page IV-12 for details about bit settings.</p>
<code>title="title"</code>	Sets the title of a column to <i>title</i> .
<code>topLeftCell=(<i>row</i>, <i>column</i>)</code>	<p>Scrolls the table contents so that the cell identified by (<i>row</i>, <i>column</i>) is the top left visible data cell, or as close as possible.</p> <p>If <i>row</i> is -1 then the table's vertical scrolling is not changed. If <i>column</i> is -1 then the table's horizontal scrolling is not changed.</p> <p>If they are positive, <i>row</i> and <i>column</i> are zero-based numbers which are clipped to valid values before being used. <i>row</i>=0 refers to the first row of data in the table, <i>column</i>=0 refers to the first column of data.</p> <p>The Point column can not be scrolled horizontally.</p>
<code>trailingZeros=<i>t</i></code>	<i>t</i> =1 shows trailing zeros. This affects the general numeric format only.
<code>viewSelection</code>	<p>Scrolls the table contents so that the target cell and selection are maximally in view. The target cell will always be visible. The selection may overflow the visible area.</p> <p>See also the <code>topLeftCell</code> and <code>selection</code> keywords.</p> <p><code>viewSelection</code> was added in Igor Pro 9.00.</p>
<code>width=<i>w</i></code>	<p>Sets column width to <i>w</i> points.</p> <p>You will not always get the exact number of points that you request. This is because a column must have an even number of screen pixels, so that grid lines look good. Igor will modify your requested number of points to meet this requirement.</p>

Flags

<code>/W=<i>winName</i></code>	<p>Modifies the named table window or subwindow. When omitted, action will affect the active window or subwindow.</p> <p>When identifying a subwindow with <i>winName</i>, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.</p>
<code>/Z</code>	No errors generated if the indexed or specified column does not exist in a style macro.

Examples

```
ModifyTable size(myWave)=14      // change font size of myWave column
ModifyTable width(Point)=0      // hide Point column
ModifyTable style(cmplxWave.imag)=32 // condensed= bit 5 = 2^5 = 32
```

See Also

See **Column Names** on page II-229 and **ModifyTable Elements Command** on page II-251.

ModifyViolinPlot

ModifyViolinPlot [/W=*winName*] [keyword=*value*, keyword=*value*, ...]

The `ModifyViolinPlot` operation modifies a violin plot trace in the target or named graph.

`ModifyViolinPlot` was added in Igor Pro 8.00.

For a detailed discussion of violin plots and the parts of a violin plot, see **Violin Plots** on page II-325.

Parameters

ModifyViolinPlot parameters consist of keyword=value pairs. The trace keyword specifies the trace targeted by the subsequent keywords. For example, the command:

```
ModifyViolinPlot trace=trace0, markerSize=5
```

sets the marker size for all datasets of the trace0 trace.

As of Igor Pro 9.00, you can modify a setting for a specific dataset of a specific trace by adding a zero-based dataset index in square brackets after the keyword. For example:

```
ModifyViolinPlot trace=trace0, markerSize[1]=7
```

This sets the marker size for the second dataset (index=1) to 7 leaving the marker size for other datasets unchanged.

General Parameters

trace= <i>traceName</i>	Specifies the name of a violin plot trace to be modified. An error results if the named trace is not a violin plot trace. Without the trace keyword, ModifyViolinPlot uses the first trace in the graph, whether it is a violin plot trace or not but see the instance keyword for an exception.
instance= <i>instanceNum</i>	The combination of trace and instance works the same as (<i>traceName</i> # <i>instanceNum</i>) for a ModifyGraph keyword. The instance keyword without trace keyword accesses the <i>instanceNum</i> 'th trace in the graph, just like [<i>traceNum</i>] used with a ModifyGraph keyword. See Trace Names on page II-270 and Object Indexing on page IV-20.
bandwidth[(<i>ds</i>)]= <i>bw</i>	Sets the bandwidth used in computing the KDE curves. If you include <i>ds</i> , the bandwidth is set to <i>bw</i> for dataset <i>ds</i> . If you omit <i>ds</i> , the bandwidth is set for all datasets. <i>bw</i> must be greater than or equal to 0. 0 uses the bandwidth estimated by the method set by the bandwidthMethod keyword.
bandwidthMethod= <i>m</i>	Sets the method used to estimate the appropriate bandwidth used in computing the KDE curves. The methods are <i>m</i> =0: Silverman <i>m</i> =1: Scott (default) <i>m</i> =2: Bowman and Azzalini See StatsKDE for details. You can override the estimated bandwidth using the bandwidth keyword.
boxWidth= <i>w</i>	For a non-category X axis, boxWidth sets the width of the space reserved for displaying the KDE curves. If <i>w</i> is between zero and one, it is taken to be a fraction of the width of the plot rectangle. If <i>w</i> is greater than one, it is in points. All the KDE curves are normalized such that the maximum density value of the KDEs over all datasets fills the box width so only one of the violin plots will be as wide as <i>w</i> . You can control the normalization using the maxDensity keyword. If the violin plot is displayed using a category X axis, boxWidth is ignored. The space reserved for each dataset is controlled by the category axis and is affected by ModifyGraph barGap and catGap. A new non-category violin plot has box width set as $\text{boxWidth} = 1/(2*n)$ where <i>n</i> is the number of datasets (the number of violin plots) on the trace.
closeOutline[= <i>close</i>]	If <i>close</i> is 1 or omitted, the ends of the KDE curves are connected by a straight line. Closed curves are more visible if side=1 or side=2 in which case the KDE curves are closed by a straight line at the midline between the curves.

ModifyViolinPlot

<code>curveExtension=ext</code>	Sets the range of the KDE curves. The KDE curves are computed for a range of $y=\text{minData}-ext$ to $y=\text{maxData}+ext$, where ext is in units of bandwidth. ext defaults to 1.
<code>dataMarker=marker</code>	Sets the marker number used to display the raw data. If <code>marker</code> is -1, the marker as set by <code>ModifyGraph marker</code> is used. The default is 8 (hollow circle).
<code>jitter=j</code>	In order to separate closely-spaced raw data points, the data points can be displaced horizontally. j controls the maximum offset applied to any data point, expressed as a fraction of the box width. The value of j may be greater than 1, but in general values less than 1 look better. The default value is 0.5.
<code>kernel=k</code>	Sets the kernel function to be used in computing the KDE curves. Supported values are <code>k=1:</code> Epanechnikov <code>k=2:</code> Bi-weight <code>k=3:</code> Tri-weight <code>k=4:</code> Triangular <code>k=5:</code> Gaussian (default) <code>k=6:</code> Rectangular It is unusual for a violin plot to use anything other than Gaussian, which is the default. See <code>StatsKDE</code> for details.
<code>lineStyle=style</code>	Sets the line style used to draw the KDE curves. See Dashed Lines on page III-498 for a description of line styles. A line style of -1 uses the line style set by <code>ModifyGraph lstyle</code> . <code>style</code> defaults to -1.
<code>lineThickness=thick</code>	Sets the thickness of the line used to plot the KDE curves. A thickness less than zero uses the line width set by the <code>ModifyGraph lsize</code> keyword. <code>thick=0</code> hides the KDE curve. The default value is -1.
<code>markerSize=size</code>	Sets the size of the marker used to display the raw data. A marker size of zero uses one-half of the marker size as set by <code>ModifyGraph msize</code> . <code>size</code> defaults to zero.
<code>markerThick=t</code>	Sets the thickness in points of the strokes of markers used to display the raw data. The <code>markerThick</code> keyword was added in Igor Pro 9.00.
<code>maxDensity=d</code>	Sets the normalization for the width of the KDE curves to d . All the KDE curves are normalized such that the maximum density value of all KDEs fills the box width. The width of each curve gives an indication of the relative maximum density. <code>maxDensity</code> allows you to set the same normalization for multiple violin plots so that the width for all is relative to the same value.
<code>plotSide=side</code>	By default, a violin plot is symmetrical with the KDE curve plotted twice in mirror image. You can control which side is plotted: <code>side=0:</code> Both sides in mirror image (default) <code>side=1:</code> The left side <code>side=2:</code> The right side Using 1 or 2 allows you to combine two violin plots in an asymmetric plot.
<code>showData[=sd]</code>	Shows or hides the raw data points. <code>sd</code> is 0 or 1. <code>showData</code> by itself is equivalent to <code>showData=1</code> . The default is 1.

Mean and Median Parameters

You can display markers showing the mean and the median of each dataset using the keywords documented in this section. See **Markers** on page II-279 for a list of available markers. For both mean and median, a marker size of zero uses the marker size set by ModifyGraph msize.

showMean[= <i>show</i>]	Shows or hides the marker representing the mean value. <i>show</i> is 0 or 1. showMean by itself is equivalent to showMean=1. The default is 0.
meanMarker= <i>marker</i>	Sets the marker to use for the mean value. The default for the mean marker is 27 (hollow horizontal diamond with dot).
meanMarkerSize= <i>size</i>	Sets the size of the marker used to display the mean value. A value of zero uses the trace marker size as set by ModifyGraph msize, or the normal trace default marker size. The default is zero.
meanMarkerThick= <i>t</i>	Sets the thickness in points of the stroke of markers used to display the mean value if showMean is enabled. The meanMarkerThick keyword was added in Igor Pro 9.00.
showMedian[= <i>show</i>]	Shows or hides the marker representing the median value. <i>show</i> is 0 or 1. showMedian by itself is equivalent to showMedian=1. The default is 0.
medianMarker= <i>marker</i>	Sets the marker to use for the median value. The default for the median marker is 26 (filled horizontal diamond).
medianMarkerSize= <i>size</i>	Sets the size of the marker used to display the median value. A value of zero uses the trace marker size as set by ModifyGraph msize, or the normal trace default marker size. The default is zero.
medianMarkerThick= <i>t</i>	Sets the thickness in points of the stroke of markers used to display the median value if showMedian is enabled. The medianMarkerThick keyword was added in Igor Pro 9.00.

Color Parameters

All colors are specified as $(r,g,b[,a])$ **RGBA Values**.

fillColor= $(r,g,b[,a])$	Fills the area between the distribution curves with the specified color. Specifying fillColor=(0,0,0,0) removes the fill. If side=1 or side=2, the fill is between the curve and the mid line.
lineColor= $(r,g,b[,a])$	Sets the color of the KDE curves. Specify lineColor=(0,0,0,0) to use the trace color set using ModifyGraph rgb as the line color. The default is black.
markerColor= $(r,g,b[,a])$	Sets the color of markers used to display the raw data. Specify markerColor=(0,0,0,0) to use the trace color set using ModifyGraph rgb as the marker color. This is the default behavior.
markerStrokeColor= $(r,g,b[,a])$	Sets the color of the strokes of markers used to display the raw data. Specify markerStrokeColor=(0,0,0,0) to use the to use the trace color set using ModifyGraph rgb as the marker color. This is the default behavior. The markerStrokeColor keyword was added in Igor Pro 9.00.
markerFilled= <i>f</i>	If <i>f</i> is non-zero, markers are filled with color. Normally, hollow markers have transparent fill. Default fill color is white. Applies only to hollow markers such as marker 8, the hollow circle marker. The markerFilled keyword was added in Igor Pro 9.00.
markerFillColor= $(r,g,b[,a])$	Sets the fill color of markers used to display the raw data. Applies only to hollow markers such as marker 8, the hollow circle marker. The markerFillColor keyword was added in Igor Pro 9.00.

<code>meanMarkerColor=(r,g,b[,a])</code>	<p>Sets the color of markers used to display the mean value.</p> <p>Specify <code>meanMarkerColor=(0,0,0,0)</code> to use the trace color set using <code>ModifyGraph rgb</code> as the mean marker color. This is the default behavior.</p>
<code>meanMarkerStrokeColor=(r,g,b[,a])</code>	<p>Sets the color of the strokes of markers used to display the mean of the data if <code>showMean</code> is enabled.</p> <p>Specify <code>meanMarkerStrokeColor=(0,0,0,0)</code> to use the to use the trace color set using <code>ModifyGraph rgb</code> as the marker color. This is the default behavior.</p> <p>The <code>meanMarkerStrokeColor</code> keyword was added in Igor Pro 9.00.</p>
<code>meanMarkerFilled=f</code>	<p>If <i>f</i> is non-zero, the mean value marker is filled with color. Normally, hollow markers have transparent fill. Default fill color is white. Applies only to hollow markers such as marker 8, the hollow circle marker.</p> <p>The <code>meanMarkerFilled</code> keyword was added in Igor Pro 9.00.</p>
<code>meanMarkerFillColor=(r,g,b[,a])</code>	<p>Sets the fill color of markers used to display the mean value if <code>showMean</code> is enabled. Applies only to hollow markers such as marker 8, the hollow circle marker.</p> <p>The <code>meanMarkerFillColor</code> keyword was added in Igor Pro 9.00.</p>
<code>medianMarkerColor=(r,g,b[,a])</code>	<p>Sets the color of markers used to display the median value.</p> <p>Specify <code>medianMarkerColor=(0,0,0,0)</code> to use the trace color set using <code>ModifyGraph rgb</code> as the median marker color. This is the default behavior.</p>
<code>medianMarkerStrokeColor=(r,g,b[,a])</code>	<p>Sets the color of the strokes of markers used to display the mean of the data if <code>showMedian</code> is enabled.</p> <p>Specify <code>medianMarkerStrokeColor=(0,0,0,0)</code> to use the to use the trace color set using <code>ModifyGraph rgb</code> as the marker color. This is the default behavior.</p> <p>The <code>medianMarkerStrokeColor</code> keyword was added in Igor Pro 9.00.</p>
<code>medianMarkerFilled=f</code>	<p>If <i>f</i> is non-zero, the median value marker is filled with color. Normally, hollow markers have transparent fill. Default fill color is white. Applies only to hollow markers such as marker 8, the hollow circle marker.</p> <p>The <code>medianMarkerFilled</code> keyword was added in Igor Pro 9.00.</p>
<code>medianMarkerFillColor=(r,g,b[,a])</code>	<p>Sets the fill color of markers used to display the median value if <code>showMedian</code> is enabled. Applies only to hollow markers such as marker 8, the hollow circle marker.</p> <p>The <code>medianMarkerFillColor</code> keyword was added in Igor Pro 9.00.</p>

Violin Plot Per-Data-Point Marker Settings

You can override the basic settings for data point marker color, marker style and marker size using marker settings waves containing per-data-point settings.

You can apply per-data-point marker settings to an entire trace (to all datasets comprising a trace) or to a specific dataset of a trace. For example:

```
Function DemoViolinPlotPerPointMarkerSettings ()
  Make/O violin0={1,2,3,4,5}, violin1={2,3,4,5,6}, violin2={3,4,5,6,7}
  String title = "Violin Plot Per Point Marker Settings"
  Display/W=(557,99,948,310)/N=ViolinPlotPerPointPlot as title

  // Create a trace named trace0 with three datasets: violin0, violin1, violin2
  AppendViolinPlot/TN=trace0 violin0,violin1,violin2
```

```

// Set the marker and marker size for all datasets of trace trace0
ModifyViolinPlot trace=trace0, dataMarker=18 // 18=Diamond
ModifyViolinPlot trace=trace0, markerSize=5

// Set the per-data-point marker for all datasets of trace trace0
Make/O violinMarkers = {15,16,17,18,19}
ModifyViolinPlot trace=trace0, dataMarkerWave=violinMarkers

// Set the per-data-point marker for dataset violin1 only
Make/O violinMarkersForViolin1 = {32,33,34,35,36}
ModifyViolinPlot trace=trace0, dataMarkerWave[1]=violinMarkersForViolin1
End

```

Usually a marker settings wave will have the same number of rows as there are data points in a given dataset, but that is not required. If there are fewer rows in the settings wave than in the dataset, the extra data points retain their basic settings. If there are more rows in the settings wave than in the dataset, the extra settings wave points are not used.

See **Making Each Data Point Look Different** on page II-331 for more information and examples.

<code>dataColorWave [=colorWave]</code>	<p>Sets <i>colorWave</i> to override data point marker color on a point-by-point basis. The wave must be a 3 or 4 column wave containing red, green, blue and optionally alpha values.</p> <p>If you omit "<i>=colorWave</i>", any previous marker color wave setting is cleared.</p> <p>The <code>dataColorWave</code> keyword was added in Igor Pro 9.00.</p>
<code>dataMarkerWave [=markerWave]</code>	<p>Sets <i>markerWave</i> to override data point markers on a point-by-point basis. The values in <i>markerWave</i> are standard graph marker numbers. See Markers on page II-279 for a table of the markers and the associated marker numbers. The marker numbers are clipped to a valid range.</p> <p>If you omit "<i>=markerWave</i>", any previous marker wave setting is cleared.</p> <p>The <code>dataMarkerWave</code> keyword was added in Igor Pro 9.00.</p>
<code>dataSizeWave [=markerSizeWave]</code>	<p>Sets <i>markerSizeWave</i> to override data point marker size on a point-by-point basis. The values in <i>markerSizeWave</i> are clipped to the range [0,200].</p> <p>If you omit "<i>=markerSizeWave</i>", any previous marker size wave setting is cleared.</p> <p>The <code>dataSizeWave</code> keyword was added in Igor Pro 9.00.</p>

Examples

A violin plot with transparent marker color used to give a visual indication of the density of data points.

```

// Create a violin plot with transparent marker color used to give a visual
// indication of the density of data points
Make/O/N=(25,3) multicol // A three-column wave with 25 rows
SetRandomSeed(.4) // For reproducible "randomness"
multicol = gnoise(1) // Three normally-distributed datasets
multicol[20][1] = 5 // A "far" outlier
multicol[13][2] = -4 // An outlier
Display; AppendViolinPlot multicol
ModifyViolinPlot lineColor=(0,0,65535)
ModifyViolinPlot fillColor=(0,0,65535,19661)
ModifyViolinPlot jitter=0
ModifyViolinPlot showData=1
ModifyViolinPlot dataMarker=19
ModifyViolinPlot markerSize=6
ModifyViolinPlot markerColor=(0,0,65535,6554)

```

ModifyViolinPlot

```
ModifyViolinPlot fillColor[1]=(0,65535,0,19661) // Second dataset transparent green
```

```
// Add jitter, choose the circle-with-plus marker
ModifyViolinPlot trace=multicol,Jitter=0.7
ModifyViolinPlot trace=multicol,DataMarker=42,MarkerSize=5
// Set marker color to blue with a one-point outline
ModifyViolinPlot trace=multicol,MarkerColor=(16385,16388,65535)
ModifyViolinPlot trace=multicol,MarkerThick=1
// Set the marker to filled with dark green fill color
ModifyViolinPlot trace=multicol,MarkerFilled=1,MarkerFillColor=(3,52428,1)
```

```
// Set a marker size wave for dataset 0 (the first dataset)
Make/N=25/0 sizeWave = enoise(5)+7
ModifyViolinPlot DataSizeWave[0] = sizeWave
```

```
// Create a violin plot with asymmetric curves plotted on a category axis
Make/O/N=(25,3) ds1, ds2
SetRandomSeed(.4) // For reproducible "randomness"
ds1 = gnoise(1)
ds2 = gnoise(2)+q

// We need a text wave to make a category plot
Make/N=3/T/O labels={"treatment 1", "treatment 2", "treatment 3"}
Display
AppendViolinPlot ds1 vs labels
AppendViolinPlot ds2 vs labels

// Keep plots together in a single category space
ModifyGraph toMode(ds1)=-1

// Display ds1 on the left, ds2 on the right
ModifyViolinPlot trace=ds1,plotSide=1
ModifyViolinPlot trace=ds2,plotSide=2

// Extend the KDE curves
ModifyViolinPlot trace=ds1,CurveExtension=2
ModifyViolinPlot trace=ds2,CurveExtension=2

// Close the curves with line at the midline
ModifyViolinPlot trace=ds1,closeOutline=1
ModifyViolinPlot trace=ds2,closeOutline=1

// Use the same normalization for both curves
ModifyViolinPlot trace=ds1,maxDensity=0.36
ModifyViolinPlot trace=ds2,maxDensity=0.36

// Apply jitter to the data points
ModifyViolinPlot trace=ds1,jitter=0.5
ModifyViolinPlot trace=ds2,jitter=0.5

// Set markers and colors
ModifyViolinPlot trace=ds1,showData=1,dataMarker=16,markerColor=(2,39321,1),lineColor=(2,39321,1)
ModifyViolinPlot trace=ds2,showData=1,dataMarker=19,markerColor=(0,0,65535),lineColor=(0,0,65535)
ModifyViolinPlot trace=ds1,fillColor=(2,39321,1,19661)
ModifyViolinPlot trace=ds2,fillColor=(0,0,65535,19661)
```

ModifyWaterfall

See Also

AppendViolinPlot, **AddWavesToViolinPlot**, **ModifyGraph (traces)**

Violin Plots on page II-325

ModifyWaterfall

ModifyWaterfall [*/W=winName*] *keyword = value* [, *keyword = value* ...]

The **ModifyWaterfall** operation modifies the properties of the waterfall plot in the top or named graph.

Parameters

keyword is one of the following:

<i>angle</i> = <i>a</i>	Angle in degrees from horizontal of the angled Y axis (<i>a</i> =10 to 90).
<i>axlen</i> = <i>len</i>	Relative length of angled Y axis. <i>len</i> is a fraction between 0.1 and 0.9.
<i>hidden</i> = <i>h</i>	Controls the hidden line algorithm. <i>h</i> =0: Turns hidden lines off. <i>h</i> =1: Uses painter's algorithm. <i>h</i> =2: True hidden. <i>h</i> =3: Hides lines with bottom removed. <i>h</i> =4: Hides lines using a different color for the bottom. When specified, the top color is the normal color for lines and the bottom color is set using ModifyGraph <i>negRGB</i> = (<i>r</i> , <i>g</i> , <i>b</i> [, <i>a</i>]).

Hidden lines are active only when the mode is lines between points.

Flags

<i>/W=winName</i>	Modifies waterfall plot in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. When identifying a subwindow with <i>winName</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
-------------------	--

Details

Painter's algorithm draws the traces from back to front and erases hidden lines while modes 2, 3 and 4 detect which line segments are hidden and suppresses the drawing of these segments.

See Also

Waterfall Plots on page II-314.

The **NewWaterfall** and **ModifyGraph** operations.

ModuleName

#pragma ModuleName = modName

The ModuleName pragma assigns a name, which must be unique among all procedure files, to a procedure file so that you can use static functions and Proc Pictures in a global context, such as in the action procedure of a control or on the Command Line.

Using the ModuleName pragma involves at least two steps. First, within the procedure file assign it a name using `#pragma ModuleName=modName`, and then access objects in the named file by preceding the object name with the name of the module and the # character, such as or example: `ModName#StatFuncName()`.

See Also

The **Regular Modules** on page IV-234, **Static, Picture**, and **#pragma**.

MoveDataFolder

MoveDataFolder [/O=options /Z] *sourceDataFolderSpec*, *destDataFolderPath*

The MoveDataFolder operation removes the source data folder (and everything it contains) and places it at the specified location with the original name.

Parameters

sourceDataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

Flags

/O=options

Overwrites the destination data folder if it already exists.

The /O flag was added in Igor Pro 8.00.

options=1: Completely overwrites the destination data folder. If the destination data folder exists, MoveDataFolder first deletes it if possible. If it can not be deleted, for example because it contains a wave that is in use, MoveDataFolder generates an error. If the deletion succeeds, MoveDataFolder then copies the source to the destination. Then the source data folder is deleted.

options=2: Merges the source data folder into the destination data folder. If an item in the source data folder exists in the destination data folder, MoveDataFolder overwrites it. Otherwise it copies it. Items in the destination data folder that do not exist in the source data folder remain in the destination data folder. Then the source data folder is deleted.

options=3: Merges the source data folder into the destination data folder and then deletes items that are not in the source data folder if possible. If an item in the source data folder does not exist in the destination data folder, MoveDataFolder attempts to delete it from the destination data folder. If it can not be deleted because it is in use, no error is generated. Then the source data folder is deleted.

/Z

Errors are not fatal - if an error occurs, procedure execution continues. You can check the `V_flag` output variable to see if an error occurred.

Details

MoveDataFolder generates an error if a data folder of the same name already exists at the destination unless the /O flag is used. When the /O flag is non-zero and the destination data folder already exists, MoveDataFolder is equivalent to DuplicateDataFolder followed by a KillDataFolder on the source.

Output Variables

MoveDataFolder sets the following output variable:

`V_flag`

0 if the operation succeeded or a non-zero error code. The `V_flag` output variable was added in Igor Pro 8.00.

MoveFile

Examples

```
MoveDataFolder root:DF0, root:archive // Move DF0 into archive
```

See Also

See the **DuplicateDataFolder** operation. Chapter II-8, **Data Folders**.

MoveFile

MoveFile [*flags*] [*srcFileStr*] [*as destFileOrFolderStr*]

The MoveFile operation moves or renames a file on disk. A file is renamed by “moving” it to the same folder it is already in using a different name.

Parameters

srcFileStr can be a full path to the file to be moved or renamed (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*.

If Igor can not determine the location of the file from *srcFileStr* and *pathName*, it displays an Open File dialog allowing you to specify the source file.

destFileOrFolderStr is interpreted as the name of (or path to) an existing folder when /D is specified, otherwise it is interpreted as the name of (or path to) a possibly existing file.

If *destFileOrFolderStr* is a partial path, it is relative to the folder associated with *pathName*.

If /D is specified, the source file is moved inside the folder using the source file’s name.

If Igor can not determine the location of the destination file from *pathName*, *srcFileStr*, and *destFileOrFolderStr*, it displays a Save File dialog allowing you to specify the destination file (and folder).

If you use a full or partial path for either *srcFileStr* or *destFileOrFolderStr*, see **Path Separators** on page III-453 for details on forming the path.

Folder paths should not end with single Path Separators. See the **Details** section for **MoveFolder**.

Flags

/D	Interprets <i>destFileOrFolderStr</i> as the name of (or path to) an existing folder (or directory). Without /D, <i>destFileOrFolderStr</i> is the name of (or path to) a file. If <i>destFileOrFolderStr</i> is not a full path to a folder, it is relative to the folder associated with <i>pathName</i> .
/I [=i]	Specifies the level of interactivity with the user. /I=0: Interactive only if <i>srcFileStr</i> or <i>destFileOrFolderStr</i> is not specified or if the source file is missing. (Same as if /I was not specified.) /I=1: Interactive even if <i>srcFileStr</i> is specified and the source file exists. /I=2: Interactive even if <i>destFileOrFolderStr</i> is specified. /I=3: Interactive even if <i>srcFileStr</i> is specified and the source file exists. Same as /I only.
/M= <i>messageStr</i>	Specifies the prompt message in the Open File dialog. If /S is not specified, then <i>messageStr</i> will be used for both Open File and for Save File dialogs.
/O	Overwrite existing destination file, if any. Without /O, the user is asked if replacing the existing file is to be allowed.
/P= <i>pathName</i>	Specifies the folder to look in for the source file, and the folder into which the file is copied. <i>pathName</i> is the name of an existing symbolic path. Using /P means that both <i>srcFileStr</i> and <i>destFileOrFolderStr</i> must be either simple file or folder names, or paths relative to the folder specified by <i>pathName</i> .
/S= <i>saveMessageStr</i>	Specifies the prompt message in the Save File dialog.

<code>/Z[=z]</code>	Prevents procedure execution from aborting if it attempts to move a file that does not exist. Use <code>/Z</code> if you want to handle this case in your procedures rather than having execution abort.
<code>/Z=0:</code>	Same as no <code>/Z</code> .
<code>/Z=1:</code>	Moves a file only if it exists. <code>/Z</code> alone is equivalent to <code>/Z=1</code> .
<code>/Z=2:</code>	Moves a file if it exists or displays a dialog if it does not exist.

Variables

The MoveFile operation returns information in the following variables:

<code>V_flag</code>	Set to zero if the file was moved, to -1 if the user cancelled either the Open File or Save File dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.
<code>S_fileName</code>	Stores the full path to where the file was moved from. If an error occurred or if the user cancelled, it is set to an empty string.
<code>S_path</code>	Stores the full path where the file was moved to. If an error occurred or if the user cancelled, it is set to an empty string.

Examples

Rename a file, using full paths:

```
MoveFile "HD:folder:aFile.txt" as "HD:folder:bFile.txt"
```

Rename a file, using a symbolic path:

```
MoveFile/P=myPath "aFile.txt" as "bFile.txt"
```

Move a file into a subfolder (the subfolder must exist):

```
MoveFile/D "Macintosh HD:folder:aFile.txt" as ":subfolder"
```

Move a file into an unrelated folder (the subfolder must exist):

```
MoveFile/D "Macintosh HD:folder:afile.txt" as "Server:archive"
```

Move a file from one folder to another and rename it:

```
MoveFile "Macintosh HD:folder:afile.txt" as "Server:archive:destFile.txt"
```

Move user-selected file into a particular folder:

```
MoveFile/D as "C:My Data:Selected Files Folder"
```

Move user-selected file in any folder as `bFile.txt` in same folder:

```
MoveFile as "bFile.txt"
```

Move user-selected file in any folder as `bFile.txt` in any folder:

```
MoveFile/I=2 as "bFile.txt"
```

The **Open**, **MoveFolder**, **CopyFolder**, **NewPath**, and **CreateAliasShortcut** operations. The **IndexedFile** function. **Symbolic Paths** on page II-22.

MoveFolder

MoveFolder [*flags*] [*srcFolderStr*] [*as destFolderStr*]

The MoveFolder operation moves or renames a folder on disk. A folder is renamed by “moving” it into the same folder it is already in, but with a different name.

Warning: *The MoveFolder command can destroy data by overwriting another folder and its contents!*

If you overwrite an existing folder on disk, MoveFolder will do so only if permission is granted by the user. The default behavior is to display a dialog asking for permission. The user can alter this behavior via the Miscellaneous Settings dialog’s Misc category.

If permission is denied, the folder will not be moved and V_Flag will return 1088 (Command is disabled) or 1275 (You denied permission to overwrite a folder). Command execution will cease unless the /Z flag is specified.

Parameters

srcFolderStr can be a full path to the folder to be moved or renamed (in which case /P is not needed), a partial path relative to the folder associated with *pathName*, or the name of a folder within the folder associated with *pathName*.

If the location of the source folder cannot be determined from *srcFolderStr* and *pathName*, it displays a Select Folder dialog allowing you to specify the source.

If /P=*pathName* is given, but *srcFolderStr* is not, then the folder associated with *pathName* is moved or renamed.

destFolderStr specifies the final location of the folder or, if /D is used, the parent of the final location of the folder.

destFolderStr can be a full path to the output (destination) folder (in which case /P is not needed), or a partial path relative to the folder associated with *pathName*.

If the location of the destination folder cannot be determined from *destFolderStr* and *pathName*, it displays a Save Folder dialog allowing you to specify the destination.

If you use a full or partial path for either file, see **Path Separators** on page III-453 for details on forming the path.

Flags

/D Interprets *destFolderStr* as the name of (or path to) an existing folder (or “directory”) to move the source folder into. Without /D, it interprets *destFolderStr* as the name of (or path to) the moved folder.

If *destFolderStr* is not a full path to a folder, it is relative to the source folder.

/I [=i] Specifies the level of interactivity with the user.

/I=0: Interactive only if *srcFolderStr* or *destFolderStr* is not specified or if the source folder is missing. (Same as if /I was not specified.)

/I=1: Interactive even if *srcFolderStr* is specified and the source folder exists.

/I=2: Interactive even if *destFolderStr* is specified.

/I=3: Interactive even if *srcFolderStr* is specified and the source folder exists. Same as /I only.

/M=*messageStr* Specifies the prompt message in the Open File dialog. If /S is not used, then *messageStr* will be used for both Open File and for Save File dialogs.

/O Overwrite existing destination folder, if any. This deletes the existing destination folder. When /O is specified, the source folder can’t be moved into an existing folder without specifying the name of the moved folder in *destFolderStr*.

/P=*pathName* Specifies the folder for relative paths in *srcFolderStr* and *destFolderStr*. *pathName* is the name of an existing symbolic path.

If *srcFolderStr* is omitted, the folder associated with *pathName* is moved. If *destFolderStr* is omitted, the source folder is moved into the folder associated with *pathName*.

Using /P means that *srcFolderStr* (if specified) and *destFolderStr* must be either simple folder names or paths relative to the folder specified by *pathName*.

<code>/S=<i>saveMessageStr</i></code>	Specifies the prompt message in the Save File dialog.
<code>/Z[=<i>z</i>]</code>	Prevents procedure execution from aborting if it attempts to move a folder that does not exist. Use <code>/Z</code> if you want to handle this case in your procedures rather than having execution abort.
<code>/Z=0:</code>	Same as no <code>/Z</code> .
<code>/Z=1:</code>	Moves a folder only if it exists. <code>/Z</code> alone is equivalent to <code>/Z=1</code> .
<code>/Z=2:</code>	Moves a folder if it exists or displays a dialog if it does not exist.

Variables

The MoveFolder operation returns information in the following variables:

<code>V_flag</code>	Set to zero if the file was moved, to -1 if the user cancelled either the Open File or Save File dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.
<code>S_fileName</code>	Stores the full path to the folder that was moved, with a trailing colon. If an error occurred or if the user cancelled, it is set to an empty string.
<code>S_path</code>	Stores the full path of the moved folder, with a trailing colon. If an error occurred or if the user cancelled, it is set to an empty string.

Details

You can use only `/P=pathName` (omitting `srcFolderStr`) to specify the source folder to be moved.

A folder path should not end with single Path Separators. For example:

```
MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder:"
MoveFolder "Macintosh HD:folder:" as "Macintosh HD:Renamed Folder"
MoveFolder "Macintosh HD:folder:" as "Macintosh HD:Renamed Folder:"
```

will do weird, unexpected things (and probably damaging things when `/O` is also used). Instead, use:

```
MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder"
```

Beware of PathInfo and other command which return paths with an ending path separator. (They can be removed with the **RemoveEnding** function.)

A folder may not be moved into one of its own subfolders.

Conversely, the command:

```
MoveFolder/O/P=myPath "afolder"
```

which attempts to overwrite the folder associated with myPath with a folder that is inside it (namely "afolder") is not allowed. Instead, use:

```
MoveFolder/O/P=myPath "::afolder"
```

On Windows, renaming or moving a folder never updates the value of any Igor Symbolic Paths that point to a moved folder:

```
// Create a folder
NewPath/O/C myPath "C:\\My Data\\My Work"

// Move the folder
MoveFolder/P=myPath as "C:\\My Data\\Moved"

// Display the path's value
PathInfo myPath // (or use the Path Status dialog)
Print S_Path
• C:My Data:My Work
```

You can use PathInfo to determine if a folder referred to by an Igor symbolic path exists and where it is on the disk. Use NewPath/O to reset the path's value.

On the Macintosh, however, renaming or moving a folder on the same volume does alter the value of symbolic path. This is because MoveFolder uses a Mac OS alias to keep track of the folder. A folder renamed or moved on the same volume retains the original "volume refnum" and "directory ID" stored in the alias mechanism, so that the alias (and hence Igor's symbolic path) remains pointing to the moved folder. After moving the folder, using the unchanged volume refnum and directory ID (in PathInfo or when you use `/P=pathName`) returns the updated path.

MoveString

Moving the folder to a different volume actually creates a new folder with new volume refnum and directory IDs, and symbolic paths pointing to or into the moved folder aren't updated. They will be pointing at a deleted folder (they're probably invalid).

Examples

Rename a folder ("move" it to the same folder):

```
MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder"
```

Rename a folder referred to by only a path:

```
NewPath/O myPath "Macintosh HD:folder"  
MoveFolder/P=myPath as "":Renamed Folder"
```

Move a folder from one volume to another. This moves "Macintosh HD:My Folder" inside "Server:My Folder" if "Server:My Folder" already exists:

```
MoveFolder "Macintosh HD:My Folder" as "Server:My Folder"
```

Move a folder from one volume to another. This overwrites "Server:My Folder" (if it existed) with the moved "Macintosh HD:My Folder":

```
MoveFolder/O "Macintosh HD:My Folder" as "Server:My Folder"
```

Move user-selected folder in any folder as "Renamed Folder" into a user-selected folder (possibly the same one):

```
MoveFolder as "Renamed Folder"
```

Move user-selected file in any folder as "Moved Folder" in any folder:

```
MoveFolder/I=3 as "Moved Folder"
```

See Also

MoveFile, **CopyFolder**, **DeleteFolder**, **IndexedDir**, **PathInfo**, and **RemoveEnding**. **Symbolic Paths** on page II-22.

MoveString

MoveString *sourceString*, *destDataFolderPath* [*newname*]

The MoveString operation removes the source string variable and places it in the specified location optionally with a new name.

Parameters

sourceString can be just the name of a string variable in the current data folder, a partial path (relative to the current data folder) and variable name or an absolute path (starting from root) and variable name.

destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

Details

An error is issued if a variable or wave of the same name already exists at the destination.

Examples

```
MoveString :foo:s1,:bar: // Move string s1 into data folder bar  
MoveString :foo:s1,:bar:ss1 // Move string s1 into bar with new name ss1
```

See Also

The **MoveVariable**, **MoveWave**, and **Rename** operations; and Chapter II-8, **Data Folders**.

MoveSubwindow

MoveSubwindow [/W=*winName*] *key* = (*values*) [, *key* = (*values*)]...

The MoveSubwindow operation moves the active or named subwindow to a new location within the host window. This command is primarily for use by recreation macros; users should use layout mode for repositioning subwindows.

Parameters

fguide=(*gLeft*, *gTop*, *gRight*, *gBottom*)

Specifies the frame guide name(s) to which the outer frame of the subwindow is attached inside the host window.

The frame guides are identified by the standard names or user-defined names as defined by the host. Use * to specify a default guide name.

When the host is a graph, additional standard guides are available for the outer graph rectangle and the inner plot rectangle (where traces are plotted).

See **Details** for standard guide names.

fnum=(left, top, right, bottom)

Specifies the new location of the subwindow. The location coordinates of the subwindow sides can have one of two possible meanings:

When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.

When any value is greater than 1, coordinates are taken to be fixed locations measured in points, or **Control Panel Units** for control panel hosts, relative to the top left corner of the host frame.

pguide=(gLeft, gTop, gRight, gBottom)

Specifies the guide name(s) to which the plot rectangle of the graph subwindow is attached inside the host window.

Guides are identified by the standard names or user-defined names as defined by the host. Use * to specify a default guide name.

See **Details** for standard guide names.

Flags

/W= winName

Moves the subwindow in the named window or subwindow. When omitted, action will affect the active subwindow.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

When moving an exterior subwindow, only the *fnum* keyword may be used. The values are the same as the **NewPanel /W** flag for exterior subwindows.

The names for the built-in guides are as defined in the following table:

	Left	Right	Top	Bottom
Subwindow Frame	FL	FR	FT	FB
Outer Graph Rectangle	GL	GR	GT	GB
Inner Plot Rectangle	PL	PR	PT	PB

The frame guides apply to all window and subwindow types. The graph rectangle and plot rectangle guide types apply only to graph windows and subwindows.

See Also

The **MoveWindow** operation. Chapter III-4, **Embedding and Subwindows** for further details and discussion.

MoveVariable

MoveVariable *sourceVar*, *destDataFolderPath* [*newname*]

The MoveVariable operation removes the source numeric variable and places it in the specified location optionally with a new name.

Parameters

sourceVar can be just the name of a numeric variable in the current data folder, a partial path (relative to the current data folder) and variable name or an absolute path (starting from root) and variable name.

destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

Details

An error is issued if a variable or wave of the same name already exists at the destination.

Examples

```
MoveVariable :foo:v1, :bar:           // Move v1 into data folder bar
MoveVariable :foo:v1, :bar:vv1       // Move v1 into bar with new name vv1
```

See Also

The **MoveString**, **MoveWave**, and **Rename** operations; and Chapter II-8, **Data Folders**.

MoveWave

MoveWave *sourceWave*, [*destDataFolderPath:*] [*newName*]

The MoveWave operation removes the source wave and places it in the specified location optionally with a new name.

If you want to rename a wave without moving it, use **Rename** instead.

Parameters

sourceWave can be just the name of a wave in the current data folder, a partial path (relative to the current data folder) and wave name, an absolute path (starting from root) and wave name, or a wave reference variable in a user-defined function.

destDataFolderPath can be a partial path (relative to the current data folder), an absolute path (starting from root), or a data folder reference (DFREF) in a user-defined function.

Details

An error is issued if a variable or wave of the same name already exists at the destination.

MoveWave Destination

Depending on the syntax you use, MoveWave may move sourceWave to another data folder, rename sourceWave, or both. To explain this, we show examples below which call this setup function:

```
Function Setup()
  SetDataFolder root:
  KillDataFolder root:
  NewDataFolder/O root:DF0
  Make/O root:w1
End
```

The Setup function gives you a data hierarchy like this:

```
root (<- current data folder)
  wave0
  DF0
```

```
// 1. Simple dest name: Renames wave0 as wave1
```

```
Function Demo1()
  Setup()
  Wave w = root:wave0
  MoveWave w, wave1
End
```

```
// 2. Dest path with trailing colon: Moves wave0 without renaming
```

```
Function Demo2()
  Setup()
  Wave w = root:wave0
```

```

    MoveWave w, root:DF0:
End
// 3. Dest path with trailing colon and name: Moves wave0 and renames as wave1
Function Demo3()
    Setup()
    Wave w = root:wave0
    MoveWave w, root:DF0:wave1
End
// 4. DFREF dest without trailing colon: Moves wave0 without renaming
Function Demo4()
    Setup()
    Wave w = root:wave0
    DFREF dfr = root:DF0
    MoveWave w, dfr
End
// 5. DFREF dest with trailing colon: Generates error
Function Demo5()
    Setup()
    Wave w = root:wave0
    DFREF dfr = root:DF0
    MoveWave w, dfr:// Error - trailing colon not allowed
End
// 6. Dest path with trailing colon and name: Moves wave0 and renames as wave1
Function Demo6()
    Setup()
    Wave w = root:wave0
    DFREF dfr = root:DF0
    MoveWave w, dfr:wave1
End

```

See Also

The **MoveString**, **MoveVariable**, and **Rename** operations; and Chapter II-8, **Data Folders**.

MoveWindow

MoveWindow [*flags*] *left, top, right, bottom*

The MoveWindow operation moves the target or specified window to the given coordinates.

Flags

<i>/C</i>	Moves Command window instead of the target window.
<i>/F</i>	<i>Windows:</i> Moves the Igor Pro application "frame" and the frame is then adjusted so that no part is offscreen. <i>Macintosh:</i> Moves nothing.
<i>/I</i>	Coordinates are in inches.
<i>/M</i>	Coordinates are in centimeters.
<i>/P=procedureTitleAsName</i>	Moves the specified procedure window instead of the target window.
<i>/W=winName</i>	Moves the named window.

Details

Note that neither *winName* nor *procedureTitleAsName* is a string but is the actual window name or procedure window title. If the procedure window's title (procedure windows don't have names) has a space in it, use \$ and quotes:

```
MoveWindow/P=$"Log Histogram" 0,0,600,400
```

If */W*, */F*, */C*, and */P* are omitted, MoveWindow moves the target window.

The coordinates are in points if neither */I* nor */M* is used.

In Igor Pro 7.00 or later, to move the window without changing its size, pass -1 for both *right* and *bottom*.

MPFXEMGPeak

You can use the `MoveWindow` operation to minimize, restore, or maximize a window by specifying 0, 1, or 2 for all of the coordinates, respectively, as follows:

```
MoveWindow 0, 0, 0, 0 // Minimize target window.  
MoveWindow 1, 1, 1, 1 // Restore target window.  
MoveWindow 2, 2, 2, 2 // Maximize target window.
```

On Macintosh, “maximize” means to move and resize the window so that it fills the screen. “Minimize” means to minimize to the dock.

If the window size has been constrained by `SetWindow sizeLimit`, those limits are silently applied to the size set by `MoveWindow`.

See Also

The **MoveSubwindow** and **DoWindow** operations.

MPFXEMGPeak

MPFXEMGPeak(*cw*, *yw*, *xw*)

The `MPFXEMGPeak` function implements a single exponentially modified Gaussian peak with no Y offset in the format of an all-at-once fitting function. The exponentially modified Gaussian peak shape is a convolution of an exponential and a Gaussian peak.

Parameters

- cw* Coefficient wave. The Gaussian peak shape is defined by the coefficients as follows:
- `cw[0]`: Peak location. This is actually the location of the underlying Gaussian peak. There is no analytic expression for the actual peak location.
 - `cw[1]`: Standard deviation of the Gaussian portion.
 - `cw[2]`: Amplitude-related parameter.
 - `cw[3]`: Decay constant of the exponential portion.
- yw* Y wave into which values are stored.
- xw* X wave containing the X values at which the peak function is to be evaluated.

Details

There is no analytic expression for peak parameters of common interest like the amplitude, location and width. The `Multipeak Fitting` package uses numerical techniques to get approximations.

This function is primarily intended to support the `Multipeak Fitting` package. For other purposes we recommend the **VoigtPeak** function which has more convenient parameters.

To use `MPFXEMGPeak` as a fitting function, wrap it in an all-at-once user-defined fitting function:

```
Function FitVoigtPeak(Wave cw, Wave yw, Wave xw) : FitFunc  
  Variable dummy = MPFXEMGPeak(cw, yw, xw)  
End
```

The assignment to “dummy” is required because you must explicitly do something with the return value of a built-in function.

See Also

All-At-Once Fitting Functions on page III-256

MPFXExpConvExpPeak

MPFXExpConvExpPeak(*cw*, *yw*, *xw*)

The `MPFXExpConvExpPeak` function implements a single peak with no Y offset in the format of an all-at-once fitting function. The peak shape is that of an exponential convolved with another exponential.

`MPFXExpConvExpPeak` is similar to the `MPFXEMGPeak`, but it has a sharp onset. It fills the wave *yw* with peak values as if a simple wave assignment was executed.

Parameters

- cw* Coefficient wave. The Gaussian peak shape is defined by the coefficients as follows:
- cw*[0]: Peak location.
 - cw*[1]: Peak height.
 - cw*[2]: Inverse of the decay constant of one exponential.
 - cw*[3]: Inverse of the decay constant of the other exponential.
- yw* Y wave into which values are stored.
- xw* X wave containing the X values at which the peak function is to be evaluated.

Details

The following equations and discussion use these definitions:

$$c0 = cw[0], \quad c1 = cw[1], \quad c2 = cw[2], \quad c3 = cw[3]$$

The peak location given by *c0* is not the actual peak location; it is simply a parameter that offsets the peak in the X direction. The actual location is given by

$$loc = \frac{\ln\left(\frac{c2}{c3}\right)}{c2 - c3} + c0$$

The actual peak height is given by

$$h = \frac{c1 \cdot c2 \left\{ \left(\frac{c2}{c3}\right)^{-\frac{c2}{c2-c3}} - \left(\frac{c2}{c3}\right)^{-\frac{c3}{c2-c3}} \right\}}{c3 - c2}$$

The peak area is given by *c1/c3*.

We are not aware of an analytic expression for the full width at half maximum (FWHM).

This function is primarily intended to support the Multi-peak Fitting package.

To use MPFXExpConvExpPeak as a fitting function, wrap it in an all-at-once user-defined fitting function:

```
Function FitVoigtPeak(Wave cw, Wave yw, Wave xw) : FitFunc
  Variable dummy = MPFXExpConvExpPeak(cw, yw, xw)
End
```

The assignment to "dummy" is required because you must explicitly do something with the return value of a built-in function.

See Also

All-At-Once Fitting Functions on page III-256

MPFXGaussPeak**MPFXGaussPeak(cw, yw, xw)**

The MPFXGaussPeak function implements a single Gaussian peak with no Y offset in the format of an all-at-once fitting function. It fills the wave *yw* with values defined by a Gaussian peak as if this wave assignment statement was executed:

```
yw = cw[2] * exp( -((xw - cw[0])/cw[1])^2 )
```

MPFXLorentzianPeak

Parameters

- cw* Coefficient wave. The Gaussian peak shape is defined by the coefficients as follows:
- cw*[0]: Peak location.
 - cw*[1]: Peak width as variance (standard deviation squared).
 - cw*[2]: Amplitude.
- yw* Y wave into which values are stored.
- xw* X wave containing the X values at which the peak function is to be evaluated.

Details

This function is primarily intended to support the Multipeak Fitting package. To use MPFXGaussPeak as a fitting function, wrap it in an all-at-once user-defined fitting function:

```
Function FitGaussPeak(Wave cw, Wave yw, Wave xw) : FitFunc
    Variable dummy = MPFXGaussPeak(cw, yw, xw)
End
```

The assignment to "dummy" is required because you must explicitly do something with the return value of a built-in function.

See Also

All-At-Once Fitting Functions on page III-256

MPFXLorentzianPeak

MPFXLorentzianPeak(*cw*, *yw*, *xw*)

The MPFXLorentzianPeak function implements a single Lorentzian peak with no Y offset in the format of an all-at-once fitting function. It fills the wave *yw* with values defined by a Lorentzian peak as if this wave assignment statement was executed:

$$yw = 2 * cw[2] / \pi * cw[1] / (4 * (xw - cw[0])^2 + cw[1]^2)$$

Parameters

- cw* Coefficient wave. The Lorentzian peak shape is defined by the coefficients as follows:
- cw*[0]: Peak location.
 - cw*[1]: Peak width as full width at half maximum.
 - cw*[2]: Peak area.
- yw* Y wave into which values are stored.
- xw* X wave containing the X values at which the peak function is to be evaluated.

Details

This function is primarily intended to support the Multipeak Fitting package. To use MPFXLorentzianPeak as a fitting function, wrap it in an all-at-once user-defined fitting function:

```
Function FitLorentzianPeak(Wave cw, Wave yw, Wave xw) : FitFunc
    Variable dummy = MPFXLorentzianPeak(cw, yw, xw)
End
```

The assignment to "dummy" is required because you must explicitly do something with the return value of a built-in function.

See Also

All-At-Once Fitting Functions on page III-256

MPFXVoigtPeak

MPFXVoigtPeak(*cw*, *yw*, *xw*)

The MPFXVoigtPeak function implements a single Voigt peak with no Y offset in the format of an all-at-once fitting function. It fills the wave *yw* with values defined by a Voigt peak as if this wave assignment statement was executed:

```
yw = cw[2]*VoigtFunc(cw[1]*(xw-cw[0]), cw[3])
```

The **VoigtFunc** function here is a basic Voigt peak shape, a convolution of a Gaussian and Lorentzian peak shapes. The first parameter of VoigtFunc controls the shape. A value of zero results in a peak shape that is 100% Gaussian. As the first parameter approaches infinity the shape transitions to 100% Lorentzian. At a value of $\sqrt{\ln(2)} \approx 0.832555$ the mix is 50/50.

Parameters

- cw* Coefficient wave. The Gaussian peak shape is defined by the coefficients as follows:
- cw*[0]: Peak location.
 - cw*[1]: Affects the width; the actual width is a complicated function of *cw*[1], *cw*[2], and *cw*[3]
 - cw*[2]: Amplitude factor; the actual amplitude is affected by the other parameters.
 - cw*[3]: Shape factor. Zero results in pure Gaussian, infinity results in pure Lorentzian, one is 50% Gaussian and 50% Lorentzian.
- yw* Y wave into which values are stored.
- xw* X wave containing the X values at which the peak function is to be evaluated.

Details

This function is primarily intended to support the Multipeak Fitting package. For other purposes we recommend the **VoigtPeak** function which has more convenient parameters.

To use MPFXVoigtPeak as a fitting function, wrap it in an all-at-once user-defined fitting function:

```
Function FitVoigtPeak(Wave cw, Wave yw, Wave xw) : FitFunc
    Variable dummy = MPFXVoigtPeak(cw, yw, xw)
End
```

The assignment to "dummy" is required because you must explicitly do something with the return value of a built-in function.

References

The code used to compute VoigtPeak was written by Steven G. Johnson of MIT. You can learn more about it at <http://ab-initio.mit.edu/Faddeeva>.

All-At-Once Fitting Functions on page III-256, **VoigtPeak**, **VoigtFunc**

MultiTaperPSD

MultiTaperPSD [*flags*] *srcWave*

The MultiTaperPSD operation estimates the power spectral density of *srcWave* using Slepian (DPSS) tapers. The MultiTaperPSD operation was added in Igor Pro 7.00.

Flags

- /A Uses Thomson's adaptive algorithm. In this case the operation also creates the wave *W_MultiTaperDF* that contains the effective degrees of freedom. For each frequency of the PSD the algorithm is expected to converge within few iterations. When it fails to converge, the operation prints in the history the total number of frequencies where it did not converge while the actual output contains the last iteration estimate.
- /DB Scale the PSD results as $10 * \log_{10}(\text{spectralEst}(f))$.

MultiTaperPSD

<code>/DBF=f0</code>	Scale the PSD results as $10 * \log_{10}(\text{spectralEst}(f) / \text{spectralEst}(f0))$ where $f0$ must be in the range $[0, 0.5 / \text{DimDelta}(\text{srcWave}, 0)]$.
<code>/DEST=destWave</code>	<p>Saves the PSD estimate in a wave specified by <code>destWave</code>. The destination wave is created or overwritten if it already exists.</p> <p>Creates a wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-71 for details.</p> <p>If you omit <code>/DEST</code> the operation saves the resulting spectral estimate in the wave <code>W_MultiTaperPSD</code> in the current data folder.</p>
<code>/F</code>	<p>Computes F-test statistic for each output frequency. The results are stored in the wave <code>W_MultiTaperF</code>.</p> <p>If <code>/DEST</code> is also used then the F-test results are stored in the same data folder as <code>destWave</code>. Otherwise <code>W_MultiTaperF</code> is created in the current data folder.</p> <p>The statistic is a variance ratio, of the background and the power at the specific frequency. Since the PSDs of the background and the line are assumed to be distributed as Chi-squared with 2 and $2 * n\text{Tapers} - 2$ degrees of freedom respectively, the relevant critical value for computing confidence intervals can be obtained from:</p> <p><code>StatsInvFCdf(percentSignificance/100, 2, 2 * nTapers - 2)</code></p>
<code>/NOR=N</code>	Sets the normalization factor that is used to multiply each element of the output. For example, if you want to normalize the output such that the sum of the PSD estimate matches the variance of the input use <code>/NOR=2/(np*np)</code> where <code>np</code> is the number of points in <code>srcWave</code> .
<code>/NTPR=nTapers</code>	Specifies the number of Slepian tapers to be used. If you do not specify a number of tapers, the operation uses $2 * nw$ (twice the time-bandwidth product).
<code>/NW=nw</code>	Specifies the time-bandwidth product. This value should typically be in the range $[2, 6]$. Given a time-bandwidth product <code>nw</code> it is recommended to use no more than $2 * nw$ tapers in order to maximize variance efficiency.
<code>/Q</code>	Quiet mode; suppresses printing in the history area.
<code>/R=[startPoint,endPoint]</code>	<p>Calculates the PSD estimate for a specified input range. <code>startPoint</code> and <code>endPoint</code> are expressed in terms of point numbers of the source wave.</p>
<code>/R=(startX,endX)</code>	Calculates the PSD estimate for a specified input range. <code>startX</code> and <code>endX</code> are expressed in terms of X values. Note that this option converts your X specifications to point numbers and some roundoff may occur.
<code>/Z</code>	Do not report errors.

Details

The MultiTaperPSD operation estimates the PSD of `srcWave` by computing a set of discrete prolate spheroidal functions (Slepian DPSS) and using them as optimal window functions. The window functions/tapers are applied to the input signal and squares of the resulting Fourier transforms are weighted together to produce the PSD estimate.

`srcWave` must be a real-valued numeric wave of single or double precision and must not contain any INFs or NaNs.

The mean value of the input is subtracted prior to multiplication by the tapers. Like DSPPeriodogram, the MultiTaperPSD operation leaves the normalization to the user.

The default PSD estimate is calculated by combining the Fourier transforms of the tapered signal with weights from the DPSS calculation. You can use the `/A` flag to improve the PSD estimate for increasing tapers. Thomson's adaptive algorithm is reasonably efficient and also provides an estimate of the effective degrees of freedom as a function of frequency.

The operation sets the variable `V_Flag` to zero if successful or to a -1 if it encounters an error. If you are using Thomson's adaptive algorithm (/A) `V_Flag` is set to the number of frequencies at which the algorithm failed to converge.

MultiThread

MultiThread [/N=*numThreads*] *wave = expression*

In user-defined functions, the **MultiThread** keyword can be inserted in front of wave assignment statements to speed up execution on multiprocessor computer systems.

Warning: Misuse of this keyword can result in a performance penalty or even a crash. Be sure to read **Automatic Parallel Processing with MultiThread** on page IV-321 before using **MultiThread**.

The expression must be thread-safe. This means that if it calls a function, the function must be thread-safe. This goes for both built-in and user-defined functions.

Not all built-in functions are thread-safe. Use the Command Help tab in the Igor Help Browser to see which functions are thread-safe.

User-defined functions are thread-safe if they are defined using the **ThreadSafe** keyword. See **ThreadSafe Functions** on page IV-105 for details.

You can specify the number of threads using the /NT flag. The default value, which takes effect if you omit /NT or specify /NT=0, uses the number returned by **ThreadProcessorCount**. /NT=1 specifies a single thread and is equivalent to omitting the **MultiThread** keyword; you might want to turn off threading to avoid its overhead when the wave has few points. *numThreads* values greater than one specify the desired number of threads to be used. Igor may use fewer threads depending on how it is able to partition the task. The /NT flag was added in Igor Pro 8.00.

The "MultiThread Mandelbrot Demo" experiment.

MultiThreadingControl

MultiThreadingControl *keyword* [=value]

The **MultiThreadingControl** operation allows you to control how automatic multithreading works with those IGOR operations that support it. Automatic multithreading is described below under Details.

For most purposes you will not need to use this operation.

The **MultiThreadingControl** operation was added in Igor Pro 7.00.

Keywords

`getMode` Writes the current mode value into the variable `V_autoMultiThread`.

MultiThreadingControl

getThresholds	Creates the wave <code>W_MultiThreadingArraySizes</code> in the current data folder. See Automatic Multithreading Thresholds below for details.
setMode= <i>m</i>	Sets the mode for automatic multithreading. The mode controls the circumstances in which automatic multithreading is enabled. <i>m</i> =0: Disables automatic multithreading unconditionally. <i>m</i> =1: Enables automatic multithreading based on operation-specific thresholds for operations called from the main thread only. This is the default setting. <i>m</i> =4: Enables automatic multithreading based on operation-specific thresholds for operations called from the main thread and from user-created explicit threads. <i>m</i> =8: Enables automatic multithreading unconditionally - regardless of thresholds or the type of the calling thread. You can not combine modes by ORing. The only valid values for <i>m</i> are those shown above.
setThresholds= <i>tWave</i>	Sets the thresholds for automatic multithreading. See Automatic Multithreading Thresholds below for details.

Details

Some IGOR operations and functions have internal code that can execute calculations in parallel using multiple threads. These operations are marked as "Automatically Multithreaded" in the Command Help pane of the Igor Help Browser.

Running on multiple threads reduces the time required for number-crunching tasks on multi-processor machines when the benefit of using multiple processors exceeds the overhead of running in multiple threads. This is usually the case only for large-scale jobs.

By default Igor uses automatic multithreading in operations that support it when the number of calculations exceeds a threshold value. This is called "automatic multithreading" to distinguish it from the explicit multithreading that you can instruct Igor to do. Explicit multithreading is described under **ThreadSafe Functions and Multitasking** on page IV-327. You don't need to do anything to benefit from automatic multithreading.

By default automatic multithreading is enabled for operations called from the main thread and disabled for operations called from explicit threads that you create (mode=1). You can change this using the `setMode` keyword described above.

The state of automatic multithreading is not saved with the experiment. It is initialized to mode=1 with default thresholds every time you start IGOR.

Automatic Multithreading Thresholds

Executing these commands

```
MultiThreadingControl getThresholds  
Edit W_MultiThreadingArraySizes.ld
```

creates a wave named `W_MultiThreadingArraySizes` and displays it in a table. This shows you the current threshold for each operation that supports automatic multithreading. The wave includes dimension labels so you can see which row represents which operation's threshold.

The meaning of a given threshold value depends on the operation. For most operations the threshold is in terms of the number of points in the input wave. For some operations the threshold depends on the complexity of the calculation. For example, the threshold for the CurveFit operation takes the complexity of the fitting function into account.

You can change the threshold for a given operation by setting the data for the appropriate row of `W_MultiThreadingArraySizes` and passing it back to the `MultiThreadingControl` operation using the `setThresholds` keyword. For example:

```
W_MultiThreadingArraySizes[%ICA]=5000 // Set the ICA threshold  
MultiThreadingControl setThresholds=W_MultiThreadingArraySizes // Apply
```

You should not change any aspect of the wave other than the threshold values.

Multithreading and Roundoff Error

Every floating point operation can potentially lead to roundoff error. Normally, if you run the exact same code on the the exact same data, you get the exact same roundoff error and the exact same result.

This is not necessarily the case with multithreaded calculations. Because the partitioning of work among threads depends on circumstances, such as how many threads are free, different calculation runs on the same data may partition work differently. This can lead to differences in roundoff error and therefore differences in results.

You can obtain reproducibility at the expense of performance by turning off automatic multithreading:

```
MultiThreadingControl setMode=0
```

Although this provides reproducibility, it does not necessarily reduce the size of roundoff error.

Examples

```
MultiThreadingControl setMode=0           // Disable automatic multithreading
MultiThreadingControl setMode=8           // Always multithread regardless of wave size
```

NameOfWave

NameOfWave (*wave*)

The NameOfWave function returns a string containing the name of the specified wave.

In a user-defined function that has a parameter or local variable of type WAVE, NameOfWave returns the actual name of the wave identified by the WAVE reference. It can also be used with wave reference functions such as **WaveRefIndexedDFR**.

NameOfWave does not return the full data folder path to the wave. Use **GetWavesDataFolder** for this information.

A null wave reference returns a zero-length string. This might be encountered, for instance, when using WaveRefIndexedDFR in a loop to act on all waves in a data folder, and the loop has incremented beyond the highest valid index.

Examples

```
Function ZeroWave(w)
    Wave w
    w = 0
    Print "Zeroed the contents of", NameOfWave(w)
End
```

See Also

See **WAVE**; the **GetWavesDataFolder** and **WaveRefIndexed** functions; and **Wave Reference Functions** on page IV-197.

NaN

NaN

The NaN function returns the “Not a Number” value according to the IEEE standards.

Comparison operators do not work with NaN parameters because, by definition, NaN compared to anything, even another NaN, is false. Use **numtype** to test if a value is NaN.

NeuralNetworkRun

NeuralNetworkRun [/Q/Z] **Input=testWave, WeightsWave1=w1, WeightsWave2=w2**

The NeuralNetworkRun operation uses the interconnection weights generated by NeuralNetworkTrain, and saved in the waves M_Weights1 and M_Weights2, to execute the network for a given input. The input can contain a single run represented by a 1D wave or M runs represented by M columns of a 2D wave. The

NeuralNetworkTrain

output of the calculation is saved in the wave *W_NNResults* or *M_NNResults* depending on the dimensionality of the input wave. The structure of the network is completely specified by the two weights waves and must match the number of rows in the input wave.

Flags

<i>/Q</i>	Suppresses printing information in the History area.
<i>/Z</i>	No error reporting.

Parameters

<i>Input=testWave</i>	Specifies the input to the neural network. <i>testWave</i> must be a single or double precision wave containing entries in the range [0,1] and have the correct number of rows to match the weights. Execute the network for multiple runs by using a 2D input wave where each column corresponds to a single run. For a 2D input, the result will be stored in <i>M_NNResults</i> with a corresponding column structure.
<i>WeightsWave1=w1</i>	Specifies the interconnection weights between the input and the hidden layer.
<i>WeightsWave2=w2</i>	Specifies the interconnection weights between the hidden layer and the output.

See Also

The **NeuralNetworkTrain** operation.

NeuralNetworkTrain

NeuralNetworkTrain [*/Q/Z*] [*keyword = value*]...

The **NeuralNetworkTrain** operation trains a three-layer neural network. The training produces two 2D waves that store the interconnection weights between the network neurodes. Once you obtain the weights, you can use them with **NeuralNetworkRun**.

Flags

<i>/Q</i>	Suppresses printing information in the History area.
<i>/Z</i>	No error reporting.

Parameters

keyword is one of the following:

<i>Input=inWave</i>	Specifies the input patterns for training. <i>inWave</i> is a 2D wave where each row corresponds to a single training event and each column corresponds to the input values. The number of rows in <i>inWave</i> (the number of training sets) and in the output wave must be equal. <i>inWave</i> must be single or double precision and all entries must be in the range [0,1].
<i>Iterations=num</i>	Specifies the number of iterations. Default is 10000.
<i>MinError=val</i>	Terminates training when the total error drops below <i>val</i> (default is 1e-8). The total error is normalized, and is defined as the sum of the squared errors divided by the number of training sets times outputs.
<i>Momentum=val</i>	Specifies a coefficient for the back-propagation algorithm. This coefficient adds to the change in a particular weight a contribution proportional to the error in a previous iteration. Default momentum is 0.075.
<i>NHidden=num</i>	Specifies the number of hidden neurodes. You do not need to use the Structure keyword with NHidden because the network is completely specified by the training waves and NHidden .
<i>NReport=num</i>	Specifies over how many iterations (default is 1000) to print the global RMS error to the history area. Ignored with <i>/Q</i> .

Output= <i>outWave</i>	Specifies the expected outputs corresponding to the entries in the input wave. The number of rows in <i>outWave</i> (the number of training sets) and in the input wave must be equal. <i>outWave</i> must be single or double precision and all entries must be in the range [0,1].
LearningRate= <i>val</i>	Sets the network learning rate, which is used in the backpropagation calculation. Default is 0.15.
Restart	Allows specification of your own set of weights as the starting values. Use this to run the training and feed the output weights of one training session as the input for the next.
Structure={ <i>Ni, Nh, No</i> }	Specifies the structure of the network. <i>Ni</i> is the number of neurodes at the input, <i>Nh</i> is the number of hidden neurodes, and <i>No</i> is the number of output neurodes. Structure is unnecessary when using NHidden is because the remaining numbers are determined by the sizes of the input and output waves.
WeightsWave1= <i>w1</i>	Specifies the weights for propagation from the first layer to the second. The 2D wave must be double precision and the dimensions must match the specified neurodes with the same numbers of rows and inputs and with matching numbers of columns and hidden neurodes.
WeightsWave2= <i>w2</i>	Specifies the weights for propagation from the second to the third layer. The 2D wave must be double precision and the dimensions must match the specified neurodes with the same numbers of rows and hidden neurodes and with matching numbers of columns and outputs.

Details

NeuralNetworkTrain is the first half of the implementation of a three-layer neural network in which both in inputs and outputs are taken as normalized quantities in the range [0,1]. Network training is based on back-propagation to iteratively minimize the error between the output and the expected output for any given training set. Training creates in two 2D waves that contain the interconnection weights between the neurodes. M_Weights1 contains the weights between the input layer and the hidden layer and M_Weights2 contains the weights between the hidden layer and the output layer. During the iteration stage, global error information can be printed in the history area.

The algorithm computes the output of the *k*th neurode by

$$V_k = \left[1 + \exp \left(- \sum_{i=1}^n w_i s_i \right) \right]^{-1},$$

where w_i is the weight corresponding to input i , s_i is the signal corresponding to that input, and n is the number of inputs connected to the neurode.

The total error is defined as the sum (over all training sets and all outputs) of the squared differences between the network outputs and the expected values. The sum is normalized by the product of the number of training sets and the number of outputs. The history reports (see NReport parameter) the square root of the total error (RMS error). The square root of the error computed at the end of the last iteration is stored in the variable V_rms.

See Also

The **NeuralNetworkRun** operation.

NewCamera

NewCamera [*flags*] [*keywords*]

The NewCamera operation creates a new camera window.

Documentation for the NewCamera operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "NewCamera"
```

NewDataFolder

NewDataFolder [/O/S] *dataFolderSpec*

The NewDataFolder operation creates a new data folder of the given name.

Parameters

dataFolderSpec can be just a data folder name, a partial path (relative to the current data folder) with name or a full path (starting from root) with name. If just a data folder name is used then the new data folder is created in the current data folder. If a full or partial path is used, all data folders except for the last in the path must already exist.

Flags

- /O No error if a data folder of the same name already exists.
- /S Sets the current data folder to *dataFolderSpec* after creating the data folder.

Examples

```
NewDataFolder foo // Creates foo in the current data folder
NewDataFolder :bar:foo // Creates foo in bar in current data folder
NewDataFolder root:foo // Creates foo in the root data folder
```

See Also

Chapter II-8, **Data Folders**.

NewFIFO

NewFIFO *FIFOName*

The NewFIFO operation creates a new FIFO.

Details

Useless until channel info is added with **NewFIFOChan**.

An error is generated if a FIFO of same name already exists. *FIFOName* needs to be unique only among FIFOs. You can not overwrite a FIFO.

See Also

FIFOs are used for data acquisition. See **FIFOs and Charts** on page IV-310 and the **NewFIFOChan** operation for more information.

NewFIFOChan

NewFIFOChan [*flags*] *FIFOName*, *channelName*, *offset*, *gain*, *minusFS*, *plusFS*, *unitsStr* [, *vectPnts*]

The NewFIFOChan operation creates a new channel for the named FIFO.

Parameters

channelName must be unique for the specified FIFO.

The *offset*, *gain*, *plusFS*, *minusFS* and *unitsStr* parameters are used when the channel's data is displayed in a chart or transferred to a wave. If given, *vectPnts* must be between 1 and 65535.

Flags

The flags define the type of data to be stored in the FIFO channel:

- /B 8-bit signed integer. Unsigned if /U is present.
- /C Complex.
- /D Double precision IEEE floating point.
- /I 32-bit signed integer. Unsigned if /U is present.
- /S Single precision IEEE floating point (default).
- /U Unsigned integer data.

/W 16-bit signed integer. Unsigned if */U* is present.
/Y=type Specifies wave data type. See details below.

Wave Data Types

As a replacement for the above number type flags you can use */Y=numType* to set the number type as an integer code. See the **WaveType** function for code values. Do not use */Y* in combination with other type flags.

Details

You can not invoke **NewFIFOChan** while the named FIFO is running.

If you provide a value for *vectPnts*, you will create a channel capable of holding a vector of data rather than just a single data value. When such a channel is used in a Chart, it is displayed as an image using one of the built-in color tables.

Igor scales values in the FIFO channel before displaying them in a chart or transferring them to a wave as follows:

$$\text{scaled_value} = (\text{FIFO_value} - \text{offset}) * \text{gain}$$

Igor uses the *plusFS* and *minusFS* parameters (plus and minus full scale) to set the default display scaling for charts.

The *unitsStr* parameter is limited to a maximum of three bytes.

When you transfer a channel's data to a wave, using the **FIFO2Wave** operation, Igor stores the *plusFS* and *minusFS* values and the *unitsStr* in the wave's Y scaling.

See Also

FIFOs are used for data acquisition. See **FIFOs and Charts** on page IV-310 and the **NewFIFO** and **FIFO2Wave** operations for more information.

The **Chart** operation for displaying FIFO data.

NewFreeAxis

NewFreeAxis [*flags*] *axisName*

The **NewFreeAxis** operation creates a new free axis that has no controlling wave.

Parameters

axisName is the name for the new free axis.

Flags

/L/R/B/T Specifies whether to attach the free axis to the Left, Right, Bottom, or Top plot edge, respectively. The Left edge is used by default.
/O Replaces *axisName* if it already exists, which means any existing axis is marked as truly free.
/W=winName Draws in the named graph window. *winName* may also be the name of a subwindow. *winName* must not conflict with other axis names except when using the */O* flag. If */W* is omitted, it creates a new axis in the active graph window or subwindow.

Details

A truly free axis does not use any scaling or units information from any associated waves (which need not exist.) You can set the properties of a free axis using **SetAxis** or **ModifyFreeAxis**.

Example

Copy this function to your Procedure window and compile:

```
Function axhook(s)
  STRUCT WMAxisHookStruct &s
  Variable t= s.max
  s.max= s.min
  s.min= t
  return 0
End
```

NewFreeDataFolder

Now execute this code on the Command line:

```
Make jack=x
Display jack
NewFreeAxis fred
ModifyFreeAxis fred, master=left, hook=axhook
```

See Also

The **SetAxis**, **KillFreeAxis**, and **ModifyFreeAxis** operations.

NewFreeDataFolder

NewFreeDataFolder ()

The **NewFreeDataFolder** function creates a free data folder and then returns its data folder reference.

Recommended for advanced programmers only.

Details

Free data folders are those that are not a part of the normal data folder hierarchy and can not be located by name.

See Also

Chapter II-8, **Data Folders**, **Free Data Folders** on page IV-95 and **Data Folder References** on page IV-78.

NewFreeWave

NewFreeWave (*type*, *numPoints* [, *nameStr*])

The **NewFreeWave** function creates a free 1D wave of the given type and number of points and then returns its wave reference.

Recommended for advanced programmers only.

Details

By default, **NewFreeWave** creates a free wave named '_free_'. You can specify another name via the optional *nameStr* input. The ability to specify the name of a free wave was added in Igor Pro 9.00 as a debugging aid - see **Free Wave Names** on page IV-94 and **Wave Tracking** on page IV-207 for details.

You can also create free waves using **Make/FREE** and **Duplicate/FREE**. These are preferable for creating multidimensional free waves and also fine for general use.

The *type* parameter can be either a code as documented for **WaveType** or can be 0x100 to create a data folder reference wave or 0x200 to create a wave reference wave.

You can redimension free waves as desired but, for maximum efficiency, you should create the wave with the desired type and total number of points and then use the /E=1 flag with **Redimension** to simply reshape without moving data.

A free wave is automatically discarded when the last reference to it disappears.

See Also

Free Waves on page IV-90, **Make**, **Duplicate**.

NewGizmo

NewGizmo [*flags*]

The **NewGizmo** operation creates a new Gizmo display window.

Documentation for the **NewGizmo** operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "NewGizmo"
```

NewImage

NewImage [*flags*] *matrix*

The NewImage operation creates a new image graph much like “Display;AppendImage *matrix*” except the graph is prepared using a style more appropriate for images. Rather than using preferences, NewImage provides several discrete styles to choose from.

Parameters

matrix is usually an MxN matrix containing image data. See **AppendImage** for details.

Flags

/F	By default, the image is flipped vertically to correspond to normal image orientation. if /F is present then the image is not flipped.
/G= <i>g</i>	Controls treatment of three-plane images as direct (RGB) color. <i>g</i> =1: Suppresses the autodetection of three-plane images as direct (RGB) color. <i>g</i> =0: Same as no /G flag (default).
/HIDE= <i>h</i>	Hides (<i>h</i> = 1) or shows (<i>h</i> = 0, default) the window.
/HOST= <i>hcSpec</i>	Embeds the new image plot in the host window or subwindow specified by <i>hcSpec</i> . When identifying a subwindow with <i>hcSpec</i> , see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/K= <i>k</i>	Specifies window behavior when the user attempts to close it. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing. <i>k</i> =3: Hides the window. If you use /K=2 or /K=3, you can still kill the window using the KillWindow operation.
/N= <i>name</i>	Requests that the created graph have this name, if it is not in use. If it is in use, then <i>name0</i> , <i>name1</i> , etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen graph name.
/S= <i>s</i>	Specifies one of several window styles. <i>s</i> =0: Fills entire window with image. No axes. However, this can result in the lower-right corner not being visible due to the target icon or grow icon (<i>Macintosh</i>). <i>s</i> =1: Like <i>s</i> =0 but insets image to avoid corner icon. <i>s</i> =2: Provides minimalist axes (default).

Details

The graph is sized to make the image pixels a multiple of the screen pixels with the graph size constrained to be not too small and not too large.

If *matrix* appears to fit Igor’s standard monochrome category, then explicit mode is set (See **ModifyImage** explicit). To be considered monochrome the wave must be unsigned byte and contain only values of 0, 64 or 255.

Once the graph is created it is a normal graph and has no special properties other than the settings it was created with. Specifically, it will not autosize itself if the dimensions of *matrix* are changed. NewImage is just a shortcut for creating a graph window with a style appropriate for images.

This operation is limited in scope by design. If you need to specify the position, size or title, then use the operations **Display** and **AppendImage**.

If the styles provided are not what you desire, touch up an image graph to meet your needs and then use **Capture Graph Prefs** from the **Graphs** menu. Then use “Display;AppendImage” rather than NewImage.

NewLayout

See Also

The **Display**, **DoWindow**, **AppendImage**, and **ModifyImage** operations.

NewLayout

NewLayout [*flags*] [*as titleStr*]

The NewLayout operation creates a page layout.

Unlike the Layout operation, NewLayout can be used in user-defined functions. Therefore, NewLayout should be used in new programming instead of Layout.

NewLayout just creates the layout window. Use **AppendLayoutObject** to add objects to the window.

Parameters

The optional *titleStr* parameter is a string expression containing the layout's title. If not specified, Igor will provide one which identifies the objects displayed in the graph.

Flags

<i>/B=(r,g,b[,a])</i>	Specifies the background color for the layout. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as RGBA Values . The default is opaque white.
<i>/C=colorOnScreen</i>	Obsolete. In ancient times, this flag switched the screen display of the layout between black and white and color. It is still accepted but has no effect.
<i>/HIDE=h</i>	Hides (<i>h</i> = 1) or shows (<i>h</i> = 0, default) the window.
<i>/K=k</i>	Specifies window behavior when the user attempts to close it. <i>k</i> =0: Normal with dialog (default). <i>k</i> =1: Kills with no dialog. <i>k</i> =2: Disables killing. <i>k</i> =3: Hides the window. If you use <i>/K</i> =2 or <i>/K</i> =3, you can still kill the window using the KillWindow operation.
<i>/N=name</i>	Requests that the layout have this name, if it is not in use. If it is in use, then <i>name0</i> , <i>name1</i> , etc. are tried until an unused window name is found. In a function or macro, <i>S_name</i> is set to the chosen layout name. If <i>/N</i> is not used, a name of the form "Layout <i>n</i> ", where <i>n</i> is some integer, is assigned. In a function or macro, the assigned name is stored in the <i>S_name</i> string. This is the name you can use to refer to the page layout window from a procedure. Use the RenameWindow operation to rename the window.
<i>/P=orientation</i>	Sets the orientation of the page in the layout to either Portrait or Landscape (e.g., <i>Layout/P=Landscape</i>). See Details .
<i>/W=(left,top,right,bottom)</i>	Gives the layout window a specific location and size on the screen. Coordinates for <i>/W</i> are in points.

Details

When you create a new page layout window, if preferences are enabled, the page size is determined by the preferred page size as set via the Capture Layout Prefs dialog. If preferences are disabled, as is usually the case when executing a procedure, the page is set to the factory default size.

See Also

AppendLayoutObject, **DoWindow**, **RemoveLayoutObjects**, and **ModifyLayout**.

NewMovie

NewMovie [*flags*] [*as fileNameStr*]

The NewMovie operation opens a movie file in preparation for adding frames.

By default, NewMovie creates MP4 movies on both Macintosh and Windows. Prior to Igor Pro 8, it created QuickTime movies on Macintosh and AVI movies on Windows. That older technology is still available using the /A flag on Windows, but it is deprecated and may not be available in future operating systems. QuickTime is no longer available as of Mac OS 10.15 (Catalina) and the /A flag results in an error in Igor Pro 9 on all Mac operating system versions.

Parameters

The file to be opened is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If NewMovie can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

Flags

/A	Windows: NewMovie/A creates movie files using the deprecated AVI technology. Macintosh: NewMovie/A returns an error.
/CF= <i>factor</i>	Specifies a compression factor relative to the theoretical uncompressed value. The default compression factor of 200 is used if you omit /CF. /CF was added in Igor Pro 8.00. It is ignored if you use the /A flag.
/CTYPE= <i>typeStr</i>	Specifies the compression codec to use. Windows: <i>typeStr</i> can be "WMV3" to create .wmv files or "mp4v" to create MP4 files (default). Macintosh: /CTYP is ignored and an MP4 file is created.
/F= <i>frameRate</i>	Frames per second between 1 and 60. <i>frameRate</i> defaults to 30.
/I	Obsolete.
/L[= <i>flatten</i>]	Obsolete.
/O	Overwrite existing file, if any.
/P= <i>pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
/PICT= <i>pictName</i>	Uses the specified picture (see Pictures on page III-509) rather than the top graph.
/S= <i>soundWave</i>	Adding a sound track is not currently supported. If you would like this feature, let us know.
/Z	No error reporting; an error is indicated by nonzero value of the output variable V_flag. If the user clicks the cancel button in the Save File dialog, V_flag is set to -1.

Details

If either the path or the file name is omitted then NewMovie displays a Save File dialog to let you create a movie file. If both are present, NewMovie creates the file automatically.

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-22 for details.

There can be only one open movie at a time.

The target window at the time you invoke NewMovie must be a graph, page layout or Gizmo plot unless the /PICT flag is present. The window size should remain constant while adding frames to the movie. The window and optional sound wave are used to determine the size and sound properties only; they do not specify the first frame.

NewNotebook

In Igor7 or later, the target window at the time you call `NewMovie` is remembered and is used by `AddMovieFrame` even if it is not the target window when you call `AddMovieFrame`.

The `/PICT` flag allows you to create a movie from a page layout in conjunction with the `SavePICT/P=_PictGallery_` method. See **SavePICT** on page V-824. This allows creation of a movie from a source other than a graph, page layout or Gizmo window, but is rarely needed.

See Also

Movies on page IV-243.

The **AddMovieFrame**, **AddMovieAudio**, **CloseMovie**, **PlayMovie**, **PlayMovieAction** and **SavePICT** operations.

NewNotebook

NewNotebook [*flags*] [*as titleStr*]

The `NewNotebook` operation creates a new notebook document.

Parameters

The optional *titleStr* is a string containing the title of the notebook window.

Flags

`/FG=(gLeft, gTop, gRight, gBottom)`

Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window.

The standard frame guide names are `FL`, `FR`, `FT`, and `FB`, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use `*` to specify a default guide name.

Guides may override the numeric positioning set by `/W`.

`/HOST=hcSpec`

Embeds the new notebook in the host window or subwindow specified by *hcSpec*. The host window or subwindow must be a control panel. Graphs and page layouts are not supported as hosts for notebook subwindows.

When identifying a subwindow with *hcSpec*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

See **Notebooks as Subwindows in Control Panels** on page III-91 for more information.

`/ENCG=textEncoding`

textEncoding specifies the text encoding for the new notebook. This determines the text encoding used for later saving the notebook to a file.

See **Text Encoding Names and Codes** on page III-492 for a list of accepted values for *textEncoding*.

This flag was added in Igor Pro 7.00.

This flag is relevant for plain text notebooks only and has no effect for formatted notebooks because formatted text notebooks can contain multiple text encodings. See **Plain Text File Text Encodings** on page III-468 and **Formatted Text Notebook File Text Encodings** on page III-474 for details.

If you omit */ENCG* or pass 0 (unknown) for *textEncoding*, the notebook's text encoding is determined by the default text encoding - see **The Default Text Encoding** on page III-467 for details.

For most purposes, UTF-8 (*textEncoding=1*) is recommended. Other values are available for compatibility with software that requires a specific text encoding. This includes Igor Pro 6 which uses MacRoman (*textEncoding=2*), Windows-1252 (*textEncoding=3*) or Shift-JIS (*textEncoding=4*) depending on the operating system and localization.

This flag has an optional form that allows you to control whether the byte order mark is written when the notebook is later saved to disk. It applies to Unicode text encodings also. The form is:

```
/ENCG = {textEncoding, writeBOM }
```

If you use the simpler form or omit */ENCG* entirely, the notebook's *writeBOM* property defaults to 1.

See **Byte Order Marks** on page III-473 for background information.

/F=format

Specifies the format of the notebook:

format=0: Plain text.

format=1: Formatted text.

format=-1: Displays a dialog in which the user can choose plain text or formatted text (default).

/K=k

Specifies window behavior when the user attempts to close it.

k=0: Normal with dialog (default).

k=1: Kills with no dialog.

k=2: Disables killing.

k=3: Hides the window.

If you use */K=2* or */K=3*, you can still kill the window using the **KillWindow** operation.

/N=winName

Sets the notebook's window name to *winName*.

/OPTS=options

Sets special options. *options* is a bitwise parameter interpreted as follows:

Bit 0: Hide the vertical scroll bar.

Bit 1: Hide the horizontal scroll bar.

Bit 2: Set the write-protect icon initially to on.

Bit 3: Sets the *changeableByCommandOnly* bit. When set, the user can not make any modifications.

All other bits are reserved and must be set to zero.

If */OPTS* is omitted, all bits default to zero.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

NewPanel

/N=visible Specifies whether the notebook window is visible (*visible=1*; default) or invisible (*visible=0*).

/W=(left,top,right,bottom)

Sets window location. Coordinates are in points for normal notebook windows.

When used with the */HOST* flag, the specified location coordinates can have one of two possible meanings:

When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.

When any value is greater than 1, coordinates are taken to be fixed locations measured in points, or **Control Panel Units** for control panel hosts, relative to the top left corner of the host frame.

Details

A notebook has a file name, a window name, *and* a window title. In the simplest case these will all be the same.

The file name is the name by which the operating system identifies the notebook once it is saved to disk. When you initially create a notebook, it is not associated with any file. However it still has a file name. This is the name that will be used when the file is saved to disk.

The window name is the name by which Igor identifies the window and therefore the name you specify in operations that act on the notebook.

The window title is what appears in the window's title bar. If you omit the title, NewNotebook uses a default title that is the same as the window name.

If you specify the window name and the notebook format and omit the window title, this is the simplest case. NewNotebook creates the document with no user interaction. The file name, window name and window title will all be the same. For example:

```
NewNotebook/N=Notebook1/F=0
```

If you omit the window name, NewNotebook chooses a default name (e.g., "Notebook0") and presents the standard New Notebook dialog.

If you omit the format or specify a format of -1 (either plain or formatted text), NewNotebook presents the standard New Notebook dialog. For example:

```
NewNotebook/N=Notebook1 // no format specified
```

See Also

The **Notebook** and **OpenNotebook** operations, and Chapter III-1, **Notebooks**.

Notebooks as Subwindows in Control Panels on page III-91.

NewPanel

NewPanel [*flags*] [*as titleStr*]

The NewPanel operation creates a control panel window or subwindow, which may contain Igor controls and drawing objects.

Flags

/EXP=e Sets the expansion of the panel. *e* is a number between 0.25 to 8.0. Values of *e* greater than 1.0 make the panel, its controls, and its subwindows, appear larger than normal.

The expansion factor affects the size of the window specified by */W*.

If you omit */EXP* or specify */EXP=0*, the expansion defaults to the value set in the Panel section of the Miscellaneous Settings dialog.

To change the expansion after the panel is created, use ModifyPanel expand=*e* or the Expansion submenu of the Panel menu.

The */EXP* flag was added in Igor Pro 9.00.

See **Control Panel Expansion** on page III-443 for further discussion.

<code>/EXT=<i>e</i></code>	<p>Creates an exterior subwindow in combination with <code>/HOST</code>. <i>e</i> specifies the host window side location:</p> <p><i>e</i>=0: Right. <i>e</i>=1: Left. <i>e</i>=2: Bottom. <i>e</i>=3: Top.</p>
<code>/FG=(<i>gLeft, gTop, gRight, gBottom</i>)</code>	<p>Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window.</p> <p>The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name.</p> <p>Guides may override the numeric positioning set by <code>/W</code>.</p>
<code>/FLT[=<i>f</i>]</code>	<p><code>/FLT</code> or <code>/FLT=1</code> makes the panel a floating panel. <code>/FLT=2</code> makes it a floating panel with no close box. <code>/FLT=0</code> is the same as omitting <code>/FLT</code> and creates a regular (non-floating) control panel.</p> <p>You must execute the following after the NewPanel command:</p> <pre>SetActiveSubwindow _endfloat_</pre> <p>See Floating Panels below for further information.</p>
<code>/FLTH=<i>h</i></code>	<p>Selects whether a floating panel is automatically hidden when Igor is deactivated.</p> <p><i>h</i>=0: The panel is not automatically hidden. <i>h</i>=1: The panel is automatically hidden.</p> <p>The default is platform specific and matches the behavior prior to Igor Pro 9. On Macintosh floating panels are hidden when Igor is deactivated. On Windows they are not hidden when Igor is deactivated.</p>
<code>/HIDE=<i>h</i></code>	<p>Hides (<i>h</i> = 1) or shows (<i>h</i> = 0, default) the window.</p>
<code>/HOST=<i>hcSpec</i></code>	<p>Embeds the new control panel in the host window or subwindow specified by <i>hcSpec</i>.</p> <p>When identifying a subwindow with <i>hcSpec</i>, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.</p>
<code>/I</code>	<p>Sets coordinates to inches.</p>
<code>/K=<i>k</i></code>	<p>Specifies window behavior when the user attempts to close it.</p> <p><i>k</i>=0: Normal with dialog (default). <i>k</i>=1: Kills with no dialog. <i>k</i>=2: Disables killing. <i>k</i>=3: Hides the window.</p> <p>If you use <code>/K=2</code> or <code>/K=3</code>, you can still kill the window using the KillWindow operation.</p> <p>Exterior subwindows never display a dialog when killed.</p>
<code>/M</code>	<p>Sets coordinates to centimeters.</p>
<code>/N=<i>name</i></code>	<p>Requests that the created panel have this name, if it is not in use. If it is in use, then <i>name0</i>, <i>name1</i>, etc. are tried until an unused window name is found. In a function or macro, <code>S_name</code> is set to the chosen panel name.</p> <p>Note that a function or macro with the same name will cause a name conflict.</p>

NewPanel

`/NA= n` Sets panel no-activate mode.
`n=0:` Normal (default).
`n=1:` Button click doesn't activate window but click outside of any control does.
`n=2:` No activation even if click is outside controls. Title bar clicks still activate.

`/W=(left,top,right,bottom)`

Sets the initial coordinates of the panel window. See **Interpretation of NewPanel Coordinates** on page III-445 for a discussion of the *left*, *top*, *right*, and *bottom* parameters.

When used with the `/HOST` flag, the specified location coordinates of the sides can have one of two possible meanings:

When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size. This applies to interior panels only, not to exterior panels.

When any value is greater than 1, coordinates are taken to be fixed locations measured in points, or **Control Panel Units** for control panel hosts, relative to the top left corner of the host frame.

When the subwindow position is fully specified using guides (using the `/HOST` or `/FG` flags), the `/W` flag may still be used although it is not needed.

Details

If `/N` is not used, `NewPanel` automatically assigns to the panel a window name of the form "Panel n ", where n is some integer. In a function or macro, the assigned name is stored in the `S_name` string. This is the name you can use to refer to the panel from a procedure. Use the **RenameWindow** operation to rename the panel.

On Windows there are special considerations relating to screen resolution and control panels. See **Control Panel Resolution on Windows** on page III-458 for details.

Floating Panels

Floating control panels float above all other windows except dialogs. Because floating panels cover up other windows, you should use them sparingly and you should take care to make them small and unobtrusive.

Floating panels are not resizable by default. To allow panel resizing use

```
ModifyPanel fixedSize=0
```

Because floating panels always act as if they are on top, the standard rules for target windows and keyboard focus do not apply.

Normally, a floating panel is never the target window and control procedures will need to explicitly designate the target. But a newly-created floating panel is the default target and will remain so until you execute

```
SetActiveSubwindow _endfloat_
```

It also becomes the default target when the tools are showing and in any non-Operate mode. Similarly, a floating panel with tools not in Operate mode has keyboard focus. To avoid confusion, do not attempt to work on other windows when a floating panel is the default target.

When working with a floating panel, you can show or hide tools or create a recreation macro by Control-clicking (*Macintosh*) or right-clicking (*Windows*) in the panel.

A floating panel does not have keyboard focus. However, a floating panel gains keyboard focus when a control that needs focus is clicked. Focus remains until you press Enter or Escape for a text entry in a setvariable, press Tab until no control has the focus, or until you click outside a focusable control.

On Macintosh, if a floating panel has focus and you activate another window, focus will leave the panel. However on Windows, if a floating panel has focus and you activate another window, the activate sequence will be fouled up leaving the windows in an indeterminate state. Consequently, it is important that you always finish any keyboard interaction started in a floating panel before moving on to other windows. If this can cause confusion, you should not use controls such as `SetVariable` and `ListBox` in a floating panel.

On Macintosh, floating panels are hidden when dialogs are up or when Igor Pro is not the front application.

Exterior Subwindows

Exterior subwindows are automatically positioned along the designated side of a host window. The host window can be a graph, table, panel or Gizmo plot. You can designate fixed sizes or automatic size with minima. Subwindows are stacked beside the designated side in their creation order with the first one closest.

Subwindow dimensions have various meanings depending on their location. Interior values are taken to be additional grout, exterior values are taken to be sizes. For left or right panels, top is taken to be the minimum height and bottom, if not zero, is height. For top and bottom, left is taken to be the minimum width and right, if not zero, is width. Zero values default to 50 for width and height or size of host.

Exterior subwindows are nonresizable by default. Use `ModifyPanel fixedSize=0` to allow manual resizing. If you resize a panel, the original window dimensions are lost. You can also use **MoveSubwindow** to resize the subwindow.

Unlike normal subwindows, exterior subwindows have a tools palette. Click in the window and then choose the Show Tools or Hide Tools menu item.

Exterior subwindows have hook functions independent of the host window.

Examples

In a new experiment, execute these commands on the command line to create two exterior subwindows:

```
Display
// Create panel on right with min height of 200 points, width of 100.
NewPanel/HOST=Graph0/EXT=0/W=(0,200,100,0)
// Create another panel on right with grout of 10 and height= width= 100.
NewPanel/HOST=Graph0/EXT=0/W=(10,0,100,100)
```

Now try resizing and moving the graph.

For a demonstration of how the various exterior panels work, copy the following code to the procedure window in a new experiment:

```
Function bpNewExSw(ba) : ButtonControl
    STRUCT WMBUTTONACTION &ba

    switch( ba.eventCode )
        case 2: // mouse up
            ControlInfo/W=$ba.win ckUseRect
            Variable useR= V_Value
            ControlInfo/W=$ba.win popSide
            Variable side= V_Value-1
            ControlInfo/W=$ba.win ckResizable
            Variable resizable= V_Value
            WAVE w=root:epsizes
            if( useR )
                NewPanel/HOST=$ba.win/EXT=(side)/W=(w[0],w[1],w[2],w[3])
            else
                NewPanel/HOST=$ba.win/EXT=(side)
            endif
            if( resizable )
                ModifyPanel fixedSize=0 // default is 1 for floating and exterior sw
            endif
            break
        endswitch

    return 0
End

Window ExSwTest() : Graph
    PauseUpdate; Silent 1 // building window...
    Display /W=(803,377,1158,591)
    Button bNewSW,pos={35,21},size={181,30},proc=bpNewExSw,title="Exterior Subwindow"
    SetVariable svLeft,pos={118,82},size={96,15},title="left"
    SetVariable svLeft,limits={0,100,1},value= epsizes[0],bodyWidth= 76
    SetVariable svTop,pos={120,97},size={94,15},title="top"
    SetVariable svTop,limits={0,100,1},value= epsizes[1],bodyWidth= 76
    SetVariable svRight,pos={112,113},size={102,15},title="right"
    SetVariable svRight,limits={0,100,1},value= epsizes[2],bodyWidth= 76
    SetVariable svBottom,pos={103,129},size={111,15},title="bottom"
    SetVariable svBottom,limits={0,100,1},value= epsizes[3],bodyWidth= 76
    CheckBox ckUseRect,pos={70,62},size={61,14},title="Use Rect:",value= 0
    PopupMenu popSide,pos={73,149},size={78,20},title="Side"
```

NewPath

```
PopupMenu popSide,mode=1,popvalue="Right",value= #"\Right;Left;Bottom;Top\""  
CheckBox ckResizable,pos={76,176},size={65,14},title="Resizable",value= 0  
EndMacro  
  
Function test()  
  Make/O/N=4 epsizes=0  
  Execute "ExSwTest()"  
End
```

After compiling the procedures, execute `test()` on the command line. You can now experiment with different sides and size values.

See Also

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

Interpretation of NewPanel Coordinates on page III-445 for a discussion of the units used with `NewPanel /W`.

The **ModifyPanel** operation.

NewPath

NewPath [*flags*] *pathName* [, *pathToFolderStr*]

The `NewPath` operation creates a new symbolic path name that can be used as a shortcut to refer to a folder on disk.

Parameters

pathToFolderStr is a string containing the path to the folder for which you want to make a symbolic path. *pathToFolderStr* can also point to an alias (*Macintosh*) or shortcut (*Windows*) for a folder.

If you use a full path for *pathToFolderStr*, see **Path Separators** on page III-453 for details on forming the path. If you use a partial path or just a simple name for *pathToFolderStr*, and you use the `/C` flag, a new folder is created relative to the Igor Pro folder. No dialog is presented.

If you omit *pathToFolderStr*, you get a chance to select a folder or create a new folder from a dialog.

Flags

<code>/C</code>	Create the folder specified by <i>pathToFolderStr</i> if it does not already exist.
<code>/M=messageStr</code>	Specifies the prompt message in the dialog.
<code>/O</code>	Overwrites the symbolic path if it exists.
<code>/Q</code>	Suppresses printing path information in the history.
<code>/Z</code>	Doesn't generate an error if the folder does not exist.

Details

Symbolic paths help to isolate your experiments from specific file system paths that contain files created or used by Igor. By using a symbolic path, if the actual location or name of the folder changes, you won't need to change all of your commands. Instead, you need only to change the symbolic path so that it points to the changed folder location.

`NewPath` sets the variable `V_flag` to zero if the operation succeeded or to nonzero if it failed. The main use for this is to determine if the user clicked Cancel when you use `NewPath` to display a choose-folder dialog.

On the Macintosh, pressing Command-Option as the Choose Folder dialog comes up will allow you to choose package folders and folders inside packages.

Examples

```
NewPath Path1, "hd:IgorStuff:Test 1"           // Macintosh  
NewPath Path1, "C:IgorStuff:Test 1"           // Windows
```

creates the symbolic path named Path1 which refers to the specified folder (the path's "value"). You can then refer to this folder in many Igor operations and dialogs by using the symbolic path name Path1.

Windows Note:

You can use either the colon or the backslash character to separate folders. However, the backslash character is Igor's escape character in strings. This means that you have to double each backslash to get one backslash like so:

```
NewPath stuff, "C:\\IgorStuff\\Test 1"
```

Because of this complication, it is recommended that you use Macintosh path syntax even on Windows. See **Path Separators** on page III-453 for details.

See Also

The **PathInfo** operation; especially if you need to preset a starting path for the dialog.

KillPath

NewWaterfall

NewWaterfall [*flags*] *matrixWave* [*vs* {*xWave*,*yWave*}]

The NewWaterfall operation creates a new waterfall plot window or subwindow using each column in the 2D matrix wave as a waterfall trace.

You can manually set x and z scaling by specifying *xWave* and *yWave* to override the default scalings. Either *xWave* or *yWave* may be omitted by using a "*" .

Flags

/FG=(gLeft, gTop, gRight, gBottom)

Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window.

The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name.

Guides may override the numeric positioning set by */W*.

/HIDE=h

Hides (*h* = 1) or shows (*h* = 0, default) the window.

/HOST=hcSpec

Embeds the new waterfall plot in the host window or subwindow specified by *hcSpec*.

When identifying a subwindow with *hcSpec*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

/I

Sets window coordinates to inches.

/K=k

Specifies window behavior when the user attempts to close it.

k=0: Normal with dialog (default).

k=1: Kills with no dialog.

k=2: Disables killing.

k=3: Hides the window.

If you use */K=2* or */K=3*, you can still kill the window using the **KillWindow** operation.

/M

Sets window coordinates to centimeters.

/N=name

Requests that the created waterfall plot window have this name, if it is not in use. If it is in use, then *name0*, *name1*, etc. are tried until an unused window name is found. In a function or macro, *S_name* is set to the chosen name.

/PG=(gLeft, gTop, gRight, gBottom)

Specifies the inner plot rectangle of the waterfall plot subwindow inside its host window.

The standard plot rectangle guide names are PL, PR, PT, and PB, for the left, right, top, and bottom plot rectangle guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name.

Guides may override the numeric positioning set by /W.

/W=(left,top,right,bottom)

Specifies window size. Coordinates are in points unless /I or /M is specified before /W.

When used with the /HOST flag, the specified location coordinates of the sides can have one of two possible meanings:

When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.

When any value is greater than 1, coordinates are taken to be fixed locations measured in points, or **Control Panel Units** for control panel hosts, relative to the top left corner of the host frame.

When the subwindow position is fully specified using guides (using the /HOST, /FG, or /PG flags), the /W flag may still be used although it is not needed.

Details

The X and Z axes are always at the bottom and left, whereas the Y axis runs at a default 45 degrees along the right-hand side. The angle and length of the Y axis can be changed using the ModifyWaterfall operation. Other features of the graph can be changed using normal graph operations.

Each column from *matrixWave* is plotted in, and clipped by, a rectangle defined by the X and Z axes with the rectangle displaced along the angled Y axis as a function of the Y value.

Except when hidden lines are active, the traces are drawn from back to front.

To modify certain properties of a waterfall plot, you need to use the ModifyWaterfall operation. For other properties, use the usual axis and trace dialogs.

See Also

Waterfall Plots on page II-314.

The **ModifyWaterfall** and **ModifyGraph** operations.

norm

norm(*srcWave*)

The norm function evaluate the norm of *srcWave*. It returns:

$$\sqrt{\sum abs(w[i])^2}$$

This function does not support text waves.

See Also

MatrixOp

NormalizeUnicode

NormalizeUnicode(*sourceTextStr*, *normalizationForm*[, *options*])

The NormalizeUnicode function normalizes the UTF-8-encoded text in *sourceTextStr* using the specified normalization form. The output text encoding is UTF-8.

NormalizeUnicode was added in Igor Pro 7.00. Most users will have no need for this function and can ignore it.

As explained under Details, in Unicode there are sometimes multiple ways to spell what appears visually to be the same word. This can cause problems when comparing text. Two strings that appear to represent

the same word and which you consider equivalent may be spelled differently, causing a comparison operation to indicate that they are unequal. The NormalizeUnicode function converts *sourceTextStr* to a normalized form, which aides comparison.

Parameters

sourceTextStr is the text that you want to normalize. It must be encoded as UTF-8.

normalizationForm specifies the normalization form to use. These forms are described at http://unicode.org/reports/tr15/#Norm_Forms. The allowed values are:

- 0: NFD (Canonical Decomposition)
- 1: NFC (Canonical Decomposition, followed by Canonical Composition)
- 2: NFKD (Compatibility Decomposition)
- 3: NFKC (Compatibility Decomposition, followed by Canonical Composition)

options is a bitwise parameter, with the bits defined as follows:

Bit 0: If cleared, in the event of an error, a null string is returned and an error is generated. Use this if you want to abort procedure execution if an error occurs.

If set, in the event of an error, a null string is returned but no error is generated. Use this if you want to detect and handle an error yourself. You can test for null using `strlen` as shown in **String Variable Text Encoding Error Example** on page III-481.

All other bits are reserved and must be cleared.

Details

The Unicode standard specifies that some sequences of code points represent essentially the same character. There are two types of equivalence: canonical equivalence and compatibility.

Sequences of code points defined as canonically equivalent are assumed to have the same appearance and meaning when printed or displayed. For example, the code point U+006E (LATIN SMALL LETTER N) followed by U+0303 (COMBINING TILDE) is defined by Unicode to be canonically equivalent to the single code point U+00F1 (LATIN SMALL LETTER N WITH TILDE). The former is called "decomposed" while the later is called "precomposed".

Sequences that are defined as compatible are assumed to have possibly distinct appearances, but the same meaning in some contexts. Thus, for example, the code point U+FB00 (LATIN SMALL LIGATURE FF) is defined to be compatible, but not canonically equivalent, to the sequence U+0066 U+0066 (two Latin "f" letters). Sequences that are canonically equivalent are also compatible, but the opposite is not necessarily true.

Text searching and sorting routines in Igor do not do any form of Unicode normalization. As a consequence, searching for the precomposed form of small letter n with tilde (U+00F1) in a string that contains the decomposed form (U+006E U+0303) will not result in a match. To get the desired result, you would need to first pass both the target string and the string to be searched through NormalizeUnicode using the same value for the *normalizationForm* parameter.

Example

```
Function TestNormalizeUnicode()
    String precomposed = "Ni" + "\u00F1" + "o"
    String decomposed = "Ni" + "\u006E\u0303" + "o"
    String precomposedTarget = "\u00F1"
    String decomposedTarget = "\u006E\u0303"
    Variable foundPos

    // SUCCESSFUL TESTS
    // Searching the precomposed string for the precomposed target is successful.
    foundPos = strstrsearch(precomposed, precomposedTarget, 0)
    Print foundPos // Prints 2

    // Likewise, searching the decomposed string for the decomposed target is successful.
    foundPos = strstrsearch(decomposed, decomposedTarget, 0)
    Print foundPos // Prints 2
```

note

```
// UNSUCCESSFUL TESTS
// Searching the precomposed string for the decomposed target fails.
foundPos = strsearch(precomposed, decomposedTarget, 0)
Print foundPos // Prints -1

// Likewise, searching the decomposed string for the precomposed target fails.
foundPos = strsearch(decomposed, precomposedTarget, 0)
Print foundPos // Prints -1

// USING NormalizeUnicode() FUNCTION
Variable normForm = 2 // Could use 0-3 and the results would be the same.

String precomposedNorm = NormalizeUnicode(precomposed, normForm)
String decomposedNorm = NormalizeUnicode(decomposed, normForm)
String precomposedTargetNorm = NormalizeUnicode(precomposedTarget, normForm)
String decomposedTargetNorm = NormalizeUnicode(decomposedTarget, normForm)

// Now, searching either precomposedNorm or decomposedNorm for either
// precomposedTargetNorm or decomposedTargetNorm will give a match.
Print strsearch(precomposedNorm, precomposedTargetNorm, 0) // Prints 2
Print strsearch(decomposedNorm, precomposedTargetNorm, 0) // Prints 2
Print strsearch(precomposedNorm, decomposedTargetNorm, 0) // Prints 2
Print strsearch(decomposedNorm, decomposedTargetNorm, 0) // Prints 2
End
```

http://en.wikipedia.org/wiki/Unicode_equivalence

http://unicode.org/reports/tr15/#Norm_Forms

note

note (*waveName*)

The note function returns a string containing the note associated with the specified wave.

See Also

To create a wave note, use the **Note operation**.

Note

Note [/K/NOCR] *waveName* [, *str*]

The Note operation appends *str* to the wave note for the named wave.

Parameters

str is a string expression.

Flags

/K	Kills existing note for specified wave.
/NOCR	Appends note without a preceding carriage return (\r character). No effect when used with /K.

Examples

```
Note/K wave0 // remove existing note
Note wave0, "This is the first line of the note"
Note wave0, "This is the second line of the note"
Note/K wave0, "This is now the only line of the note"
```

See Also

To get the contents of a wave note, use the **note function**.

Notebook

Notebook *winName*, *keyword=value* [, *keyword=value*]...

The Notebook operation sets various properties of the named notebook window. Notebook also inserts text and graphics. See Chapter III-1, **Notebooks**, for general information on notebooks.

Notebook returns an error if the notebook is open for read-only. Keywords that don't materially change the notebook, including `findText`, `findPicture`, `selection`, `visible`, `magnification`, `userKillMode`, `showRuler` and `rulerUnits`, are still permitted. See **Notebook Read/Write Properties** on page III-10 for further information.

Parameters

winName is either `kwTopWin` for the top notebook window, the name of a notebook window or a host-child specification (an `hcSpec`) such as `Panel0#nb0`. See **Subwindow Syntax** on page III-92 for details on host-child specifications.

If *winName* is an `hcSpec`, the host window or subwindow must be a control panel. Graphs and page layouts are not supported as hosts for notebook subwindows.

The parameters to the Notebook operation are of the form *keyword=value* where *keyword* says what to do and *value* is a parameter or list of parameters. Igor limits the parameters that you specify to legal values before applying them to the notebook.

The parameters are classified into related groups of *keywords*.

See Also

To create or modify a notebook action special character, see **NotebookAction**.

To create a notebook subwindow in a control panel, see **Notebooks as Subwindows in Control Panels** on page III-91.

Notebook (Document Properties)

Notebook document property parameters

This section of Notebook relates to setting the document properties of the notebook.

- `adopt=a` Adopts a notebook if it is a file saved to disk. Adopting a notebook makes it part of the packed experiment file, which becomes more self-contained; if you send the experiment to a colleague you will not need to send a notebook file.
- `a=0:` Checks only whether the notebook is adoptable. Sets `V_flag` to 0 if the notebook is already adopted or to 1 if it is adoptable.
 - `a=1:` Checks only whether the notebook is adoptable. Sets `V_flag` to 0 if the notebook is already adopted or to 1 if it is adoptable.
- `backRGB=(r,g,b[,a])` Sets background color. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. Alpha (*a*) is accepted but ignored.

`changeableByCommandOnly=c`

This `changeableByCommandOnly` property is used to prevent manual modifications to the notebook but allow modifications using commands.

- `c=0:` Turn `changeableByCommandOnly` off.
- `c=1:` Turn `changeableByCommandOnly` on.

See **Notebook Read/Write Properties** on page III-10 for details.

`defaultTab=dtwp` *dtwp* is the default tab width in points.

The `defaultTab` keyword sets the default tab mode to 1 meaning that the default tab width for all paragraphs is specified in units of points. See the `defaultTab2` keyword for further discussion.

`defaultTab2={mode,dtwp,dtws}`

Controls the width of default tab stops.

The `defaultTab2` keyword was added in Igor Pro 9.00.

`mode` is defined as follows:

- `mode=1:` Points mode: The default tab width for all paragraphs is specified in units of points by *dtwp*.
- `mode=2:` Spaces mode: The default tab width for all paragraphs is specified in units of spaces by *dtws*.
- `mode=3:` Mixed mode: The default tab width for paragraphs controlled by proportional fonts is specified in units of points by *dtwp*. The default tab width for paragraphs controlled by monospace fonts is specified in units of spaces by *dtws*.

Specify -1 for `mode` to leave the mode unchanged.

The space character unit used in mode 2 and in mode 3 for monospace fonts is the width of a space character in the ruler font for a given paragraph. Plain text notebooks have only one ruler so the space character width is the same for all paragraphs. Formatted text notebooks can have many rulers and each has an associated space character width.

dtwp is the default tab width in points. It is used in mode 1 and in mode 3 for proportional fonts. Specify -1 for *dtwp* to leave the default tab width in points unchanged.

dtws is the default tab width in spaces. It is used in mode 2 and in mode 3 for monospace fonts. Specify -1 for *dtws* to leave the default tab width in spaces unchanged.

See **Notebook Default Tabs** on page III-6 for further discussion.

magnification= <i>m</i>	<p>Specifies the desired magnification in percent (between 25 and 500). Otherwise, <i>m</i> can be one of these special values:</p> <p><i>m</i>=1: Default magnification.</p> <p><i>m</i>=2: Default magnification.</p> <p style="padding-left: 40px;">In Igor Pro 6 this specified the no-longer-supported Fit Width mode.</p> <p><i>m</i>=3: Default magnification.</p> <p style="padding-left: 40px;">In Igor Pro 6 this specified the no-longer-supported Fit Page mode.</p>
pageMargins={ <i>left, top, right, bottom</i> }	<p>Sets page margins in points. <i>left, top, right, and bottom</i> are distances from the respective edges of the physical page.</p> <p>This setting overrides the margins set via the the page setup dialog and the PrintSettings operation margins keyword.</p>
rulerUnits= <i>r</i>	<p>Sets the units for the ruler:</p> <p><i>r</i>=0: Points.</p> <p><i>r</i>=1: Inches.</p> <p><i>r</i>=2: Centimeters.</p>
showRuler= <i>s</i>	Hides (<i>s</i> =0) or shows (<i>s</i> =1) the ruler.
startPage= <i>sp</i>	Sets the starting page number for printing.
statusWidth= <i>sw</i>	<p>As of Igor7, because of changes to the layout of notebook windows, this keyword does nothing.</p> <p>In Igor6 it set the width in points of the status area on the left of the horizontal scroll bar.</p>
userKillMode= <i>k</i>	<p>Specifies window behavior when the user attempts to close it.</p> <p><i>k</i>=0: Normal with dialog (default).</p> <p><i>k</i>=1: Clicking the close button kills the notebook with no dialog.</p> <p><i>k</i>=2: Clicking the close button does nothing.</p> <p><i>k</i>=3: Clicking the close button hides the notebook with no dialog.</p>
writeBOM= <i>w</i>	<p>Sets the document's writeBOM property which determines if Igor writes a byte order mark when saving the notebook. This applies to plain text notebooks only and is ignored for formatted text notebooks.</p> <p><i>w</i>=-1: Does not change writeBOM flag.</p> <p><i>w</i>=0: Sets writeBOM to false.</p> <p><i>w</i>=1: Sets writeBOM to true.</p> <p>See Byte Order Marks on page III-473 for details.</p> <p>This keyword was added in Igor Pro 7.00.</p>
writeProtect= <i>wp</i>	<p>The write-protect property is used to prevent inadvertent manual changes to the notebook.</p> <p><i>wp</i>=0: Turn write-protect off.</p> <p><i>wp</i>=1: Turn write-protect on.</p> <p>See Notebook Read/Write Properties on page III-10 for details.</p>

Notebook (Headers and Footers)

Notebook (Headers and Footers)

Notebook headers and footers

You can turn headers and footers on and off and position headers and footers using the keywords in this section.

There is currently no way to set the content of headers and footers except manually through the Document Settings dialog. You may be able to use stationery files to create files with specific headers and footers.

`footerControl={defaultFooter, firstFooter, evenOddFooter}`

defaultFooter is 1 to turn the default footer on, 0 to turn it off.

firstFooter is 1 to turn the first page footer on, 0 to turn it off.

evenOddFooter is 1 to turn different footers for even and odd pages on, 0 to use the same footer for even and odd pages.

`footerPos=pos` *pos* is the position of the footer relative to the bottom of the page in points.

`headerControl={defaultHeader, firstHeader, evenOddHeader}`

defaultHeader is 1 to turn the default header on, 0 to turn it off.

firstHeader is 1 to turn the first page header on, 0 to turn it off.

evenOddHeader is 1 to turn different headers for even and odd pages on, 0 to use the same header for even and odd pages.

`headerPos=pos` *pos* is the position of the header relative to the top of the page in points.

Notebook (Miscellaneous)

Notebook miscellaneous parameters

This section of Notebook relates to setting miscellaneous properties of the notebook.

`autoSave=v` Controls auto-save mode.

v=0: Notebook subwindow contents will not be saved in recreation macros.

v=1: Notebook subwindow contents will be saved in recreation macros (default).

This affects notebook subwindows in control panels only. Use `autoSave=0` if you do not want the notebook's contents to be saved and restored when the control panel is recreated. Otherwise the notebook subwindow's contents will be restored when recreated.

`frameInset= i` Specifies the number of pixels by which to inset the frame of a notebook subwindow. Does not affect a normal notebook window.

This keyword was added in Igor Pro 7.00.

`frameStyle=f` Specifies the frame style for a notebook subwindow. Does not affect a normal notebook window.

- `f=0:` None.
- `f=1:` Single.
- `f=2:` Double.
- `f=3:` Triple.
- `f=4:` Shadow.
- `f=5:` Indented.
- `f=6:` Raised.
- `f=7:` Text well.

The last three styles are fake 3D and will look best if the background color behind the subwindow is a light shade of gray.

This keyword was added in Igor Pro 7.00.

`status={messageStr, flags}`

Sets the message in the status area at the bottom left of the notebook window.

`flags` is interpreted bitwise. Message is erased when:

- Bit 0: Selection changes.
- Bit 1: Window is activated.
- Bit 2: Window is deactivated.
- Bit 3: Document is modified.

If all bits are zero, the message stays until a new message comes along. All other bits are reserved for future use and should be zero. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

`updating={flags, r}` Sets parameters related to the updating of special characters.

`flags` is interpreted bitwise:

- Bit 0: Suppress automatic periodic updating of date and time special characters. By default this bit is set so date and time special characters are updated only when the user explicitly requests it or during printing when they appear in headers and footers.
- Bit 1: Allow manual updating of special characters via the `specialUpdate` keyword or via the Special menu. By default this is cleared so manual updating is not allowed.

All other bits are reserved for future use and should be zero. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

`r` is the update rate in seconds for updating date and time special characters.

These settings have no effect on the updating of special characters in headers or footers. These characters are always automatically updated when the document is printed.

We recommend that you leave automatic updating off (set bit 0 of the `flags` parameter to 1) so that updating occurs only via the `specialUpdate` keyword or via the Special menu.

`visible=v` Sets notebook visibility.

- `v=0:` Hides notebook.
- `v=1:` Shows notebook but does not make it top window.
- `v=2:` Shows notebook and makes it top window.

Notebook (Paragraph Properties)

Notebook paragraph property parameters

This section of Notebook relates to setting the paragraph properties of the current selection in the notebook.

The margins, spacing, justification, tabs and rulerDefaults keywords provide control over paragraph properties which are governed by rulers. These keywords, in conjunction with the ruler and newRuler keywords, allow you to set paragraph properties. They are allowed for formatted text notebooks only, not for plain text notebooks.

The ruler keywords are described in detail below. Before we get to the detail, you should understand the different things you can do with rulers.

There are four things you can do with a ruler:

- modify it (analogous to manually adjusting a ruler).
- redefine it (analogous to the Redefine Ruler dialog).
- create it (analogous to the Define New Ruler dialog).
- apply it (analogous to selecting a ruler name from Ruler pop-up menu).

Igor's behavior in response to ruler keywords depends on the order in which the keywords appear.

To modify the ruler(s) for the selected paragraph(s), use the margins, spacing, justification, tabs and rulerDefaults keywords *without* using the newRuler or ruler keywords. For example:

```
Notebook Notebook0 tabs={36,144,288},justification=1
```

To redefine an existing ruler, invoke the ruler=*rulerName* keyword *before* any other keywords. For example:

```
Notebook Notebook0 ruler=Ruler1,tabs={36,144,288},justification=1
```

Unlike redefining the ruler manually, when you redefine an existing ruler using ruler=*rulerName*, it does not apply the ruler to the selected text. However, it does update any text governed by the redefined ruler.

To create a new ruler, invoke the newRuler=*rulerName* keyword *before* any other keywords. For example:

```
Notebook Notebook0 newRuler=Ruler1,tabs={36,144,288},justification=1
```

Unlike creating it manually, when you create a new ruler using newRuler=*rulerName*, it does not apply the new ruler to the selected text. If you do not set a particular ruler property when creating a new ruler, the property will be the same as for the Normal ruler. If the specified ruler already exists, newRuler=*rulerName* overwrites the existing ruler.

To apply an existing ruler to the selected text, invoke the ruler=*rulerName* keyword without any other keywords. For example:

```
Notebook Notebook0 ruler=ruler1
```

You and Igor will get confused if you mix ruler keywords with other types of keywords in the same command. It is alright, however to put a selection keyword at the start of the command. Mixing will not cause a crash or any drastic problem but it will likely produce results that you don't understand.

To keep things clear, follow these rules:

- If you use ruler=*rulerName* or newRuler=*rulerName*, put them before any other ruler keywords.
- Do not mix ruler keywords with other kinds, except that it is alright to use the selection keyword at the start of the command.

justification=*j* Sets text justification:
j=0: Left aligned.
j=1: Center aligned.
j=2: Right aligned.
j=3: Fully justified.

margins={*indent*,*left*,*right*}

indent sets the indentation of first line from left page margin.

left sets the paragraph's left margin in points measured from the left page margin.

right sets the paragraph's right margin in points measured from the left page margin.

`newRuler=rulerName`

Creates a new ruler with the specified name. If a ruler with this name already exists, it is overwritten.

`ruler=rulerName` Applies the named ruler to the selected text or to redefine the named ruler, as explained above.

`rulerDefaults={"fontName", fSize, fStyle, (r,g,b[,a])}`
}

fontName sets the ruler's text font, e.g., "Helvetica".

fSize sets the ruler's text size.

fStyle sets the ruler's text style.

(r,g,b[,a]) sets the ruler's text color. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. The default is opaque white.

You can use `rulerDefaults` only if you are redefining an existing ruler using `ruler=rulerName` or you are creating a new ruler using `newRuler=rulerName`.

`spacing={spaceBefore,spaceAfter,lineSpace}`

spaceBefore sets the extra space before paragraph in points.

spaceAfter sets the extra space after paragraph in points.

lineSpace sets the extra space between lines of a paragraph in points.

`tabs={tabSpec}` *tabSpec* is list of tab stops in points added to special values that change the tab stop type.

Tab stops have two parts: the tab stop position and the tab type. Each integer in the list of tabs encodes both of these parts as follows:

The low 11 bits contains the tab stop position in points.

The next two bits are reserved for future use and must be zero.

The high three bits are used to contain the tab type as follows:

left tab	0	
center tab	1	add 1*8192 to tab stop position.
right tab	2	add 2*8192 to tab stop position.
decimal tab	3	add 3*8192 to tab stop position.
comma tab	4	add 4*8192 to tab stop position.

Tabs Example

The following puts a left tab at 1 inch, a center tab at 3 inches and a decimal tab at 5 inches:

```
Notebook Notebook1 tabs={1*72, 3*72 + 8192, 5*72 + 3*8192}
```

Notebook (Selection)

Notebook selection parameters

This section of Notebook relates to selecting a range of the content of the notebook.

`findPicture={graphicNameStr, flags}`

Searches for the picture containing the named graphic (*Macintosh only*) or the next picture if you pass "". Sets `V_flag` to 1 if the picture was found or to 0 if not found.

`flags` is a bitwise parameter interpreted as follows:

Bit 0: Show selection after the find.

All other bits are reserved for future use. Set bit 0 by setting `flags = 1`.

The search is always forward from the end of the current selection to the end of the document.

`findSpecialCharacter={specialCharacterNameStr, flags}`

Searches for the special character with the specified name or the next special character if you pass "". Selects the special character if it is found.

Sets `V_flag` to 1 if the special character was found or to 0 if not. Sets `S_name` to the name of the found special character or to "" if it was not found.

`flags` is a bitwise parameter interpreted as follows:

Bit 0: Show selection after the find.

All other bits are reserved for future use. Set bit 0 by setting `flags = 1`.

If `specialCharacterNameStr` is empty (""), the search proceeds from the end of the current selection to the end of the document. Otherwise the search always covers the entire document.

`findText={textToFindStr, flags}`

Searches for the specified text. Sets `V_flag` to 1 if the text was found or to 0 if not found.

`textToFindStr` is a string expression for the text you want to find. If the text contains a carriage return, Igor considers only the part of the text before the carriage return.

`flags` is a bitwise parameter interpreted as follows:

Bit 0: Show selection after the find.

Bit 1: Do case-sensitive search.

Bit 2: Search for whole words.

Bit 3: Wrap around.

Bit 4: Search backward.

All other bits are reserved and must be set to zero.

To set bit 0 and bit 3, use $2^0 + 2^3 = 9$ for `flags`. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

If you are searching forward, the search starts from the end of the current selection. If you are searching backward, the search starts from the start of the current selection.

If you specify "" as the text to search for, it "finds" the current selection. This displays the current selection using `findText={"", 1}`.

`selection={selStart, selEnd}`

selStart and *selEnd* are locations within the document. You can specify these document locations by using the following expressions:

<i>(paragraph, pos)</i>	<i>paragraph</i> and <i>pos</i> are numeric expressions. <i>paragraph</i> is a paragraph number from 0 to <i>n</i> -1 where <i>n</i> is the number of paragraphs in the document. <i>pos</i> is a byte position from 0 to <i>n</i> where <i>n</i> is the number of bytes in the paragraph. Position 0 is to the left of the first character in the paragraph. Position <i>n</i> is to the right of the last character in the paragraph.
startOfFile	Start of the document.
endOfFile	End of the document.
startOfParagraph	Start of current <i>selStart</i> paragraph.
endOfParagraph	End of current <i>selStart</i> paragraph.
startOfNextParagraph	Start of paragraph after current <i>selStart</i> paragraph.
endOfNextParagraph	End of paragraph after current <i>selStart</i> paragraph.
startOfPrevParagraph	Start of paragraph before current <i>selStart</i> paragraph.
endOfPrevParagraph	End of paragraph before current <i>selStart</i> paragraph.
endOfChars	Just before the carriage return of current <i>selStart</i> paragraph.
startOfPrevChar	Start of the character before the character at the current selection start or selection end. This moves the selection start or selection end like pressing the left arrow key. Added in Igor Pro 7.00.
startOfNextChar	Start of the character after the character at the current selection start or selection end. This moves the selection like pressing the right arrow key. Added in Igor Pro 7.00.

Igor clips the specified locations to legal values. It also sets the *V_flag* variable to 0 if the *selStart* location that you specified was valid, to 1 if the start paragraph was out of bounds and to 2 if the start position was out of bounds. You can use the *startOfNextParagraph* keyword to step through the document one paragraph at a time. When *V_flag* is nonzero, you are at the end of the document.

The terms *next* and *prev* are relative to the paragraph containing the start of the selected text before the selection keyword was invoked.

The selection keyword just sets the selection. If you also want to scroll the selected text into view you must also use the *findText* keyword as shown in the examples.

Selection Examples

Following are some examples of setting the selection:

```
// select all text in notebook
Notebook Notebook1 selection={startOfFile, endOfFile}

// move selection to the start of the notebook and display the selection
Notebook Notebook1 selection={startOfFile,startOfFile}, findText={"",1}

// move selection to the end of the notebook and display the selection
Notebook Notebook1 selection={endOfFile,endOfFile}, findText={"",1}

// select all of paragraph 3
Notebook Notebook1 selection={(3,0), (4,0)}

// select all of paragraph 3 and display the selection
Notebook Notebook1 selection={(3,0), (4,0)}, findText={"",1}

// select all of current paragraph except for trailing CR, if any
Notebook Notebook1 selection={startOfParagraph, endOfChars}
```

Notebook (Selection)

```
// select the first occurrence of "Hello" in the document and display the selection
Notebook Notebook1 selection={startOfFile,startOfFile}, findText={"Hello",1}

// select the first picture in the document
Notebook Notebook1 selection={startOfFile,startOfFile}, findPicture={"",1}
```

See Also

The **GetSelection** operation to “copy” the selection.

Notebook (Text Properties)

Notebook text property parameters

This section of Notebook relates to setting the text properties of the current selection in the notebook.

<code>font="fontName"</code>	<p><i>fontName</i> is the name of the font. Use "default" to specify the paragraph's ruler font.</p> <p>If you specify an unavailable font, it does nothing. This is so that, when you share procedures with a colleague, using a font that the colleague does not have will not cause your procedures to fail. The downside of this behavior is that if you misspell a font name you will get no error message.</p>								
<code>fSize=fontSize</code>	<p>Text size from 3 to 32000 points.</p> <p>Use -1 to specify the paragraph's ruler size.</p>								
<code>fStyle=fontStyle</code>	<p>A binary coded integer with each bit controlling one aspect of the text style as follows:</p> <table> <tr> <td>Bit 0:</td> <td>Bold</td> </tr> <tr> <td>Bit 1:</td> <td>Italic</td> </tr> <tr> <td>Bit 2:</td> <td>Underline</td> </tr> <tr> <td>Bit 4:</td> <td>Strikethrough</td> </tr> </table> <p>Use -1 to specify the paragraph's ruler style. To set bit 0 and bit 1 (bold italic), use $2^0+2^1 = 3$ for <i>fontStyle</i>. See Setting Bit Parameters on page IV-12 for details about bit settings.</p>	Bit 0:	Bold	Bit 1:	Italic	Bit 2:	Underline	Bit 4:	Strikethrough
Bit 0:	Bold								
Bit 1:	Italic								
Bit 2:	Underline								
Bit 4:	Strikethrough								
<code>syntaxColorSelection=n</code>	<p>Use $n=1$ to syntax-color the selected text in the notebook. This is the equivalent of selecting Notebook→Syntax Color Selection. Other values of n are reserved for future use.</p> <p>To remove syntax coloring, use the <code>textRGB</code> keyword to set the selected text to a specified color.</p> <p>The <code>syntaxColorSelection</code> keyword was added in Igor Pro 9.00.</p>								
<code>textRGB=(r,g,b[,a])</code>	<p>Specifies text color. r, g, b, and a specify the color and optional opacity as RGBA Values. The default is opaque black.</p>								
<code>vOffset=v</code>	<p>Sets the vertical offset in points (positive offset is down, negative is up). Use this to create subscripts and superscripts. <code>vOffset</code> is allowed for formatted text files only, not for plain text files.</p>								

Notebook (Writing Graphics)

Writing notebook graphics parameters

This section of Notebook relates to inserting graphics at the current selection in the notebook.

These graphics keywords are allowed for formatted text files only, not for plain text files.

<code>convertToPNG=x</code>	<p>Converts all pictures in the current selection to cross-platform PNG format. If the picture is already PNG, it does nothing.</p> <p>x is the resolution expansion factor, an integer from 1 to 16 times screen resolution. x is clipped to legal limits.</p>
-----------------------------	---

`frame=f` Sets the frame used for the picture and `insertPicture` keywords.

`f=0`: No frame (default).

`f=1`: Single frame.

`f=2`: Double frame.

`f=3`: Triple frame.

`f=4`: Shadow frame.

`insertPicture={pictureName, pathName, filePath, options}`

Inserts a picture from a file specified by `pathName` and `filePath`. The supported graphics file formats are listed under **Inserting Pictures** on page III-13.

`pictureName` is the special character name (see **Special Character Names** on page III-14) to use for the inserted notebook picture or `$""` to automatically assign a name.

`pathName` is the name of an Igor symbolic path created via **NewPath** or `$""` to use no path.

`filePath` is a full path to the file to be loaded or a partial path or simple file name relative to the specified symbolic path.

If `pathName` and `filePath` do not fully specify a file, an Open File dialog is displayed from which the user can choose the file to be inserted.

`options` is a bitwise parameter interpreted as follows:

Bit 0: If set, an Open File dialog is displayed even if the file is fully specified by `pathName` and `filePath`.

Bit 1: Determines what to do in the event of a name conflict. If set, the existing special character with the conflicting name is overwritten. If cleared, a unique name is created and used as the special character name for the inserted picture.

All other bits are reserved and must be set to zero.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

The variable `V_flag` is set to 1 if the picture was inserted or to 0 otherwise, for example, if the user canceled from the Open File dialog.

The string variable `S_name` is set to the special character name of the picture that was inserted or to `""` if no picture was inserted.

The string variable `S_fileName` is set to the full path of the file that was inserted or to `""` if no picture was inserted.

`picture={objectSpec, mode, flags [, expansion]}`

Inserts a picture based on the specified object.

`objectSpec` is usually just an object name, which is the name of a graph, table, page layout, Gizmo plot, or picture from Igor's picture gallery (Misc→Pictures). See further discussion below.

`mode` controls what happens when you insert a picture of a graph, table or page layout window. It does not affect insertions of pictures from the picture gallery.

mode specifies the format of the picture as follows:

<i>mode</i>	Macintosh	Windows
-9	SVG	SVG
-8	Igor PDF	Igor PDF
-7	TIFF	TIFF
-6	JPEG	JPEG
-5	PNG	PNG
-4	4X PNG	Device-independent bitmap
-2	8X PDF	8X Enhanced metafile
-1	8X PDF	8X Enhanced metafile
0	8X PDF	8X Enhanced metafile
1	1X PDF	8X Enhanced metafile
2	2X PDF	8X Enhanced metafile
4	4X PDF	8X Enhanced metafile
8	8X PDF	8X Enhanced metafile

Modes -6, -7, -8, and -9 require Igor Pro 7.00 or later.

In Igor 7 and 8, *mode*=-8 produced PDF on Macintosh and EMF on Windows. As of Igor Pro 9.00, it produces PDF on both Macintosh and Windows. If you were using -8 for EMF on Windows, change your code to use -2.

Mode -2 (PDF on Macintosh, EMF on Windows) is recommended for platform-specific graphics. Mode -5 (PNG) is recommended for platform-independent bitmap graphics. Mode -8 (PDF) is recommended for platform-independent vector graphics but see the note above about -8 on Windows.

If *objectSpec* names a Gizmo window, only modes -5, -6, or -7 are allowed.

Modes -2 through 8 are supported for backward compatibility. In previous versions of Igor, they selected other formats that are now obsolete.

See Chapter III-5, **Exporting Graphics (Macintosh)**, Chapter III-6, **Exporting Graphics (Windows)**, and **Metafile Formats** on page III-102 for further discussion of these formats.

flags is a bitwise parameter interpreted as follows:

Bit 0: 0 for black and white, 1 for color.

All other bits are reserved and must be set to zero.

For color, set *flags* = $2^0 = 1$.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

expansion is optional and requires Igor Pro 7.00 or later. It affects only modes -5, -6, and -7.

expansion sets the expansion factor over screen resolution. *expansion* must be an integer between 1 and 8 and is usually 1, 2, 4 or 8. The default value is 1.

scaling={*h*, *v*}

Sets the horizontal(*h*) and vertical(*v*) scaling for the selected picture or the picture and insertPicture keywords. *h* and *v* are in percent.

When using the picture keyword, you may include a coordinate specification after the object name in *objectSpec*. For example:

```
Notebook Notebook1 picture={Layout0(100, 50, 500, 700), 1, 1}
```

The coordinates are in points. A coordinate specification of (0, 0, 0, 0) behaves the same as no coordinate specification at all.

Notebook (Writing Graphics)

If the object is a graph, the coordinate specification determines the width and height of the graph. If you omit the coordinate specification, Igor takes the width and height from the graph window.

If the object is a layout, the coordinate specification identifies a section of the layout. If you omit the coordinate specification, Igor selects a section of the layout that includes all objects in the layout plus a small margin.

For any other kind of object, Igor ignores the coordinate specification if it is present.

The scaling and frame keywords affect the selected picture, if any. If no picture is selected, they affect the insertion of a picture using the picture or insertPicture keywords. For example, this command inserts a picture of Graph0 with 50% scaling and a double frame:

```
Notebook Test1 scaling={50, 50}, frame=2, picture={Graph0, 1, 1}
```

If no picture is selected and no picture is inserted, scaling and frame have no effect.

InsertPicture Example

```
Function InsertPictureFromFile(nb)
    String nb          // Notebook name or "" for top notebook

    if (strlen(nb) == 0)
        nb = WinName(0, 16, 1)
    endif

    if (strlen(nb) == 0)
        Abort "There are no notebooks"
    endif

    // Display Open File dialog to get the file to be inserted
    Variable refNum    // Required for Open but not really used
    String fileFilter = "Graphics Files:.eps,.jpg,.png;All Files:.*;"
    Open /D /R /F=fileFilter refNum
    String filePath = S_fileName
    if (strlen(filePath) == 0)
        Print "You cancelled"
        return -1
    endif

    Notebook $nb, insertPicture={$"", $"", filePath, 0}
    if (V_flag)
        Print "Picture inserted"
    else
        Print "No picture inserted"
    endif

    return 0
End
```

Save notebook pictures to files

The savePicture keyword is allowed for formatted text files only, not for plain text files.

```
savePicture={pictureName, pathName, filePath, options}
```

Saves a picture from a formatted text notebook to a file specified by *pathName* and *filePath*.

pictureName is the special character name (see **Special Character Names** on page III-14) of the picture to be saved or "\$"" to save the selected picture in which case one picture and one picture only must be selected in the notebook.

pathName is the name of an Igor symbolic path created via **NewPath** or "\$"" to use no path.

filePath is a full path to the file to be written or a partial path or simple file name relative to the specified symbolic path.

If *pathName* and *filePath* do not fully specify a file, a Save File dialog is displayed in which the user can specify the file to be written.

options is a bitwise parameter interpreted as follows:

- Bit 0: If set, a Save File dialog is displayed even if the file is fully specified by *pathName* and *filePath*.
- Bit 1: If set, a file with the same name is overwritten if it exists. If cleared, a Save File dialog is displayed if the specified file already exists.
- Bit 2: If set then the leaf name specified by *filePath* is ignored and a name is automatically generated based on the picture name.

All other bits are reserved and must be set to zero.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

The variable *V_flag* is set to 1 if the picture was written or to 0 otherwise, for example, if the user canceled from the Save File dialog.

The string variable *S_name* is set to the special character name of the picture that was saved or to "" if no picture was saved.

The string variable *S_fileName* is set to the full path of the file that was written or to "" if no picture was written.

Notebook (Writing Special Characters)

Writing special character parameters

This section of Notebook relates to inserting special characters at the current selection in the notebook. To insert a notebook action, see **NotebookAction**.

The special characters are page break, short date, long date, abbreviated date and time. They act in some respects like a single character but have special properties. You can insert the special characters using the *specialChar* keyword.

The *specialChar* keyword is allowed for formatted text files only, not for plain text files.

Other special characters are allowed in headers and footers only and you can not insert them in a document using the *specialChar* keyword. These are window title, page number and total pages.

The special characters other than page break character are dynamic and update periodically.

specialChar={*type*, *flags*, *optionsStr*}

type is the special character type as follows:

- 1: Page break.
- 2: Short date.
- 3: Long date.
- 4: Abbreviated date.
- 5: Time.

flags is reserved for future use. You should pass 0 for *flags*.

optionsStr is reserved for future use. You should pass "" for *optionsStr*.

specialUpdate=*flags*

Updates special characters in the notebook.

flags is interpreted bitwise:

- Bit 0: 0 to update all special characters.
- Bit 1: 1 to update special characters in the selected text.

If 1, updates regardless of whether updating is enabled or not.

All other bits are reserved and must be set to zero.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

Notebook (Accessing Contents)

The specialUpdate keyword can update pictures of graphs, tables, and page layouts that were created from windows in the current experiment.

See Also

Chapter III-1, **Notebooks**. The **NewNotebook**, **NotebookAction**, and **OpenNotebook** operations; the **SpecialCharacterInfo** and **SpecialCharacterList** functions.

Notebook (Accessing Contents)

Accessing Notebook Contents

`getData=mode` Causes Igor to return the contents of the notebook in the `S_value` variable. The contents are binary data in a private Igor format encoded as text. The only use for this keyword is to transfer data from one notebook to another by calling `getData` followed by `setData`.

Causes Igor to return the contents of the notebook in the `S_value` variable. The contents are binary data in a private Igor format encoded as text. The only use for this keyword is to transfer data from one notebook to another by calling `getData` followed by `setData`.

- `mode=1:` Stores in `S_value` plain text or formatted text data, depending on the type of the notebook, from the entire notebook.
- `mode=2:` Stores in `S_value` plain text data, regardless of the type of the notebook, from the entire notebook.
- `mode=3:` Stores in `S_value` plain text or formatted text data, depending on the type of the notebook, from the notebook selection only.
- `mode=4:` Stores in `S_value` plain text data, regardless of the type of the notebook, from the notebook selection only.

See the Notebook In Panel example experiment for examples using `getData` and `setData`.

Notebook (Writing Text)

Writing notebook text parameters

This section of Notebook relates to inserting text at the current selection in the notebook.

<code>text=<i>textStr</i></code>	<p>Inserts the text at the current selection.</p> <p>Before the text is inserted, Igor converts escape sequences in <i>textStr</i> as described in Escape Sequences in Strings on page IV-14.</p> <p>Then, it checks for illegal characters. The only character code that is illegal is zero (ASCII NUL character). If it finds an illegal character, Igor generates an error and does not insert the text.</p>
<code>setData=<i>dataStr</i></code>	<p>Inserts the data at the current selection.</p> <p><i>dataStr</i> is either a regular string expression or the result returned by Notebook <code>getData</code>.</p>
<code>zData=<i>dataStr</i></code>	<p>This keyword is used by Igor during the recreation of a notebook subwindow in a control panel. <i>dataStr</i> is encoded binary data created by Igor when the recreation macro was generated. It represents the contents of the notebook subwindow in a format private to Igor.</p>
<code>zDataEnd=1</code>	<p>This keyword is used by Igor during the recreation of a notebook subwindow in a control panel. It marks the end of encoded binary data created by Igor when the recreation macro was generated.</p>

NotebookAction

NotebookAction [/W=*winName*] **keyword** = **value** [, **keyword** = **value** ...]

The NotebookAction operation creates or modifies an “action” in a notebook. A notebook action is an object that executes commands when clicked.

See Chapter III-1, **Notebooks**, for general information about notebooks.

NotebookAction returns an error if the notebook is open for read-only. See **Notebook Read/Write Properties** on page III-10 for further information.

Parameters

The parameters are in *keyword=value* format. Parameters are automatically limited to legal values before being applied to the notebook.

<code>bgRGB=(<i>r</i>, <i>g</i>, <i>b</i>)</code>	<p>Specifies the action background color. <i>r</i>, <i>g</i>, and <i>b</i> specify the amount of red, green, and blue as integers from 0 to 65535.</p>
<code>commands=<i>str</i></code>	<p>Specifies the command string to be executed when clicking the action. For multiline commands, add a carriage return (<code>\r</code>) between lines.</p>
<code>enableBGRGB=<i>enable</i></code>	<p>Uses the background color specified by <code>bgRGB</code> (<i>enable</i>=1). Background color is ignored for <i>enable</i>=0.</p>
<code>frame=<i>f</i></code>	<p>Specifies the frame enclosing the action.</p> <ul style="list-style-type: none"> <code>f=0</code>: No frame. <code>f=1</code>: Single frame (default). <code>f=2</code>: Double frame. <code>f=3</code>: Triple frame. <code>f=4</code>: Shadow frame.
<code>helpText=<i>helpTextStr</i></code>	

NotebookAction

Specifies the help string for the action. The text is limited to 255 bytes. On Macintosh, help appears when the cursor is over the action after choosing Help→Show Igor Tips. On Windows, help appears in the status line when the cursor is over the action.

`ignoreErrors=ignore`

Controls whether an error dialog will appear (*ignore*=0) or not (*ignore* is nonzero) if an error occurs while executing the action commands.

`linkStyle=linkStyle`

Controls the action title text style. If *linkStyle*=1, the style is the same as a help link (blue underlined). If *linkStyle*=0, the style properties are the same as the preceding text.

`name=name`

Specifies the name of the new or modified notebook action. This is a standard Igor name. See **Standard Object Names** on page III-503 for details.

`padding={leftPadding, rightPadding, topPadding, bottomPadding, internalPadding}`

Sets the padding in points. *internalPadding* sets the padding between the title and the picture when both elements are present.

`picture=name`

Specifies a picture for the action icon. *name* is the name of a picture in the picture gallery (see **Pictures** on page III-509).

If *name* is null (`$ " "`), it clears the picture parameter.

`procPictName=name`

Specifies a Proc Picture for the action icon (see **Proc Pictures** on page IV-56). *name* is the name of a Proc Picture or null (`$ " "`) to clear it. This will be a name like `ProcGlobal#myPictName` or `MyModuleName#myPictName`. If you use a module name, the Proc Picture must be declared static.

If you specify both *picture* and *procPictName*, *picture* will be used.

`quiet=quiet`

Displays action commands in the history area (*quiet*=0), otherwise (*quiet*=1) no commands will be recorded.

`scaling={h, v}`

Scales the picture in percent horizontally, *h*, and vertically, *v*.

`showMode=mode`

Determines if the title or picture are displayed.

mode=1: Title only.

mode=2: Picture only.

mode=3: Picture below title.

mode=4: Picture above title.

mode=5: Picture to left of title.

mode=6: Picture to right of title.

Without a picture specification, the action will use title mode regardless of what you specify.

`title=titleStr`

Sets the action title to *titleStr*, which is limited to 255 bytes.

Flags

`/W=winName`

Specifies the notebook window of interest.

winName is either `kwTopWin` for the top notebook window, the name of a notebook window or a host-child specification (an `hcSpec`) such as `Panel0#nb0`. See **Subwindow Syntax** on page III-92 for details on host-child specifications.

If `/W` is omitted, `NotebookAction` acts on the top notebook window.

Examples

```
String nb = WinName(0, 16, 1)           // Top visible notebook
NotebookAction name=Action0, title="Beep", commands="Beep" // Create action
NotebookAction name=Action0, enableBGRGB=1, padding={4,4,4,4,4}
```

```
Notebook $nb, findSpecialCharacter={"Action0",1} // Select action
Notebook $nb, frame=1 // Set frame
```

See Also

Chapter III-1, **Notebooks**.

The **Notebook**, **NewNotebook**, and **OpenNotebook** operations; the **SpecialCharacterInfo** and **SpecialCharacterList** functions.

num2char

num2char(*num* [, *options*])

The num2char function returns a string containing a character.

The *options* parameter was added in Igor Pro 7.00 and defaults to 0.

As of Igor7, Igor represents text internally as UTF-8, a form of Unicode. Previously it represented text as system text encoding. Because of this change, the behavior of num2char is complicated.

Recommended use of num2char in Igor7 or later

If *num* is a Unicode code point, pass 0 for *options* and num2char will return a UTF-8 string containing the character for the Unicode code point represented by *num*.

If you want a string containing a single byte, even though it may not be a valid UTF-8 string, pass 1 for *options* and num2char will return a string containing the single byte whose value is *num*, provided that *num* is between 0 and 255.

Detailed description of num2char in Igor7 or later

If *num* is between 0 and 127, num2char returns a string containing a single byte whose value is *num*. This represents an ASCII character.

If *num* is between 128 and 255 and *options* is 1, num2char returns a string containing a single byte whose value is *num*. This is not valid UTF-8 text, but it is consistent with the behavior of num2char in Igor6.

If *num* is between 128 and 255 and *options* is 0 or omitted, num2char returns the UTF-8 representation of the character for the Unicode code point represented by *num*.

If *num* is greater than 255, num2char returns the UTF-8 representation of the character for the Unicode code point represented by *num* regardless of the value of *options*.

If you provide the *options* parameter, it must be either 0 or 1. Other values may be used for other purposes in the future.

Examples

```
Print num2char(65) // Prints A
Print num2char(97) // Prints a
Print num2char(0xF7) // Prints division sign
Print num2char(0xF7,0) // Prints division sign
Print num2char(0xF7,1) // Prints missing character symbol
Print num2char(0x0127) // Prints small letter h with stroke (h-bar)
Print num2char(0x0127,0) // Prints small letter h with stroke (h-bar)
Print num2char(0x0127,1) // Prints small letter h with stroke (h-bar)

// In the case of num2char(0xF7,1), num2char returns a string containing
// a single byte whose value is 0xF7. This is not a valid UTF-8 string.
```

See Also

The **char2num**, **str2num** and **num2str** functions.

Text Encodings on page III-461.

num2istr

num2istr(*num*)

The num2istr function returns a string representing *num* after rounding to the nearest integer.

num2str

num2str(*num* [, *formatStr*])

The num2str function returns a string representing the number *num*.

The optional *formatStr* parameter was added in Igor Pro 9.00.

If you omit *formatStr*, the precision of the output string is limited to only five decimal places. This can cause unexpected and confusing results. For this reason, we recommend that you specify a larger precision with *formatStr* or use **num2istr** or **sprintf** for more control of the format and precision of the number conversion.

Parameters

<i>num</i>	The value to be converted to string representation.
<i>formatStr</i>	Controls the format of the output string. See printf for details on format strings. <i>formatStr</i> is optional and requires Igor Pro 9.00 or later. If you omit <i>formatStr</i> , the format used is "%.5g". For more precision use something like "%.15g".

See Also

printf, **sprintf**, **str2num**, **char2num**, **num2char**

NumberByKey

NumberByKey(*keyStr*, *kwListStr* [, *keySepStr* [, *listSepStr* [, *matchCase*]])

The NumberByKey function returns a numeric value extracted from *kwListStr* based on the specified key contained in *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1, KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use NumberByKey to extract a numeric value from a strings containing "key1=value1;key2=value2;" style lists such as those returned by functions like **AxisInfo** or **TraceInfo**.

If the key is not found or if any of the arguments is "" or if the conversion to a number fails then it returns NaN.

keySepStr, *listSepStr*, and *matchCase* are optional; their defaults are ":", ";", and 0 respectively.

Details

kwListStr is searched for an instance of the key string bound by *listSepStr* on the left and a *keySepStr* on the right. The text up to the next *listSepStr* is converted to the returned number.

kwListStr is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are usually case-insensitive. Setting the optional *matchCase* parameter to 1 makes the comparisons case sensitive.

In Igor6, only the first byte of *keySepStr* and *listSepStr* was used. In Igor7 and later, all bytes are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *matchCase* is specified, *keySepStr* and *listSepStr* must be specified.

Examples

```
Print NumberByKey("AKEY", "AKEY:123;") // prints 123
Print NumberByKey("BKEY", "AKEY=123;Bkey=456;", "=") // prints 456
Print NumberByKey("KEY2", "KEY1=123,KEY2=999;", "=", ",") // prints 999
Print NumberByKey("ckey", "CKEY=123;ckey=456;", "=") // prints 123
Print NumberByKey("ckey", "CKEY=123;ckey=456;", "=", ";", 1) // prints 456
```

See Also

The **StringByKey**, **RemoveByKey**, **ReplaceNumberByKey**, **ReplaceStringByKey**, **ItemsInList**, **AxisInfo**, **IgorInfo**, **SetWindow**, and **TraceInfo** functions.

numpnts

numpnts(*waveName*)

The numpnts function returns the total number of data points in the named wave. To find the number of elements in a dimension of a multidimensional wave, use the **DimSize** function.

Do not use `numpts` to test if a wave reference is null as this causes a runtime error. Use `WaveExists`.

numtype

numtype (*num*)

The `numtype` function returns a number which indicates what kind of value *num* contains.

Details

If *num* is a real number, `numtype` returns a real number whose value is:

- 0: If *num* contains a normal number.
- 1: If *num* contains +/-INF.
- 2: If *num* contains NaN.

If *num* is a complex number, `numtype` returns a complex number in which the real part is the number type of the real part of *num* and the imaginary part is the number type of the imaginary part of *num*.

NumVarOrDefault

NumVarOrDefault (*pathStr*, *defVal*)

The `NumVarOrDefault` function checks to see if the *pathStr* points to a numeric variable. If the numeric variable exists, `NumVarOrDefault` returns its value. If the numeric variable does not exist, it returns *defVal* instead.

Details

`NumVarOrDefault` initializes input values of macros so they can remember their state without needing global variables to be defined first. String variables use the corresponding numeric function, **StrVarOrDefault**.

Examples

```
Function DemoNumVarOrDefault()
  Variable nVal = NumVarOrDefault("root:Packages:MyPackage:gNVal", 2)
  String sVal = StrVarOrDefault("root:Packages:MyPackage:gSVal", "Hello")

  Print nVal, sVal

  // Store values in package data folder for next time

  // Create package data folder if it does not yet exist
  NewDataFolder/O root:Packages
  NewDataFolder/O root:Packages:MyPackage

  DFREF dfr = root:Packages:MyPackage // Get reference to package data folder

  // Create or overwrite globals in package data folder
  Variable/G dfr:gNVal = nVal
  String/G dfr:gSVal = sVal

  NVAR gNVal = dfr:gNVal
  gNVal += 1

  SVAR gSVal = dfr:gSVal
  gSVal += "!"
End
```

NVAR

NVAR [/C] [/Z] [/SDFR=*dfr*] *localName* [= *pathToVar*] [, *localName1* [= *pathToVar1*]]...

`NVAR` is a declaration that creates a local reference to a global numeric variable accessed in a user-defined function.

The `NVAR` declaration is required when you access a global numeric variable in a function. At compile time, the `NVAR` statement specifies the local name referencing a global numeric variable. At runtime, it makes the connection between the local name and the actual global variable. For this connection to be made, the global numeric variable must exist when the `NVAR` statement is executed.

NVAR_Exists

When *localName* is the same as the global numeric variable name and you want to reference a global variable in the current data folder, you can omit *pathToVar*.

pathToVar can be a full literal path (e.g., root:FolderA:var0), a partial literal path (e.g., :FolderA:var0) or \$ followed by string variable containing a computed path (see **Converting a String into a Reference Using \$** on page IV-61).

You can also use a data folder reference or the /SDFR flag to specify the location of the numeric variable if it is not in the current data folder. See **Data Folder References** on page IV-78 and **The /SDFR Flag** on page IV-79 for details.

If the global variable may not exist at runtime, use the /Z flag and call **NVAR_Exists** before accessing the variable. The /Z flag prevents Igor from flagging a missing global variable as an error and dropping into the Igor debugger. For example:

```
NVAR/Z nv=<pathToPossiblyMissingNumericVariable>
if( NVAR_Exists(nv) )
    <do something with nv>
endif
```

Note that to create a global numeric variable, you use the **Variable/G** operation.

Flags

/C	Variable is complex.
/SDFR= <i>dfr</i>	Specifies the source data folder. See The /SDFR Flag on page IV-79 for details.
/Z	Ignores variable reference checking failures.

See Also

NVAR_Exists function.

Accessing Global Variables and Waves on page IV-64.

Converting a String into a Reference Using \$ on page IV-61.

NVAR_Exists

NVAR_Exists (*name*)

The **NVAR_Exists** function returns one if specified NVAR reference is valid or zero if not. It can be used only in user-defined functions.

For example, in a user function you can test if a global numeric variable exists like this:

```
NVAR /Z var1 = gVar1           // /Z prevents debugger from flagging bad NVAR
if (!NVAR_Exists(var1))      // No such global numeric variable?
    Variable/G gVar1 = 0      // Create and initialize it
endif
```

See Also

WaveExists, **SVAR_Exists**, and **Accessing Global Variables and Waves** on page IV-64.

Open

Open [*flags*] *refNum* [*as fileNameStr*]

The **Open** operation can, depending on the flags passed to it:

- Open an existing file to read data from (/R flag without /D).
- Open a to append results to (/A flag without /D).
- Create a new file or overwrite an existing file to write results to (no /D, /R or /A flags).
- Display an Open File dialog (/D/R or /D/A flags with or without /MULT).
- Display a Save File dialog (/D flag without /R or /A).

Parameters

refNum is the name of a numeric variable to receive the file reference number. *refNum* is set by **Open** if **Open** actually opens a file for reading or writing (cases 1, 2 and 3). You use *refNum* with the **FReadLine**, **FStatus**, **FGetPos**, **FSetPos**, **FBinWrite**, **FBinRead**, **fprintf**, and **wfprintf** operations to read from or write to the file. When you're finished, use pass *refNum* to the **Close** operation to close the file.

Open does not set the file reference number when the /D flag is used (cases 4 and 5) but you must still supply a *refNum* parameter.

The following discussion of the *pathName* and *fileNameStr* parameters applies when you are attempting to open a file for reading or writing (cases 2, 3, and 5 above).

The targeted file is specified by a combination of the *pathName* parameter and the *fileNameStr* parameter. There are three ways to specify the targeted file:

Method	How To Use It
Symbolic path and simple file name	Use /P= <i>pathName</i> and <i>fileNameStr</i> , where <i>pathName</i> is the name of an Igor symbolic path (see Symbolic Paths on page II-22) that points to the folder containing the file and <i>fileNameStr</i> is the name of the file.
Symbolic path and partial path	Use /P= <i>pathName</i> and <i>fileNameStr</i> , where <i>pathName</i> is the name of an Igor symbolic path that points to the folder containing the file and <i>fileNameStr</i> is a partial path starting from the folder and leading to the file.
Full path	Use just <i>fileNameStr</i> , where <i>fileNameStr</i> is a full path to the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

The targeted file is fully specified if *fileNameStr* is a full path or if both *pathName* and *fileNameStr* are present and not empty strings.

The targeted file is not fully specified in any of these cases:

- as *fileNameStr* is omitted
- *fileNameStr* is an empty string
- *fileNameStr* is not a full path and no symbolic path is specified

Opening an Existing File For Reading Only

This covers cases 1 (/R without /D).

If the file is fully-specified but does not exist, an error is generated. If you want to detect and handle the error yourself, use the /Z flag.

If the file is not fully-specified, Open displays an Open File dialog.

If a file is opened, *refNum* is set to the file reference number.

Opening an Existing File For Appending

This covers cases 1 (/R without /D) and 2 (/A without /D).

If the file is fully-specified and exists, it is opened for read/write and the current file position is moved to the end of the file.

If the file is fully-specified but does not exist, the file is created and opened for read/write.

If the file is not fully-specified, Open displays an Open File dialog.

If a file is opened, *refNum* is set to the file reference number.

Opening a File For Write

This covers case 3 (no /R, /A or /D).

If the targeted file exists, it is overwritten.

If the targeted file does not exist and it is fully-specified and targets a valid path, a new file is created.

If the file is fully-specified and targets an invalid path, an error is generated. If you want to detect and handle the error yourself, use the /Z flag.

If the file is not fully-specified, Open displays a Save File dialog.

If a file is opened, *refNum* is set to the file reference number.

Displaying an Open File Dialog To Select a Single File

This covers cases 4 (/D with /R or /A).

Open does not actually open the file but just displays the Open File dialog.

If the user chooses a file in the Open File dialog, the `S_fileName` output string variable is set to a full path to the file. You can use this in subsequent commands. If the user cancels, `S_fileName` is set to "".

See the documentation for the `/D`, `/F` and `/M` flags and then read **Displaying an Open File Dialog** on page IV-148 for details.

`refNum` is left unchanged.

Displaying an Open File Dialog To Select Multiple Files

This covers cases 4 (`/D` with `/R` or `/A`) with the `/MULT=1` flag.

Open does not actually open the file but just displays the Open File dialog.

If the user chooses one or more files in the Open File dialog, the `S_fileName` output string variable is set to a carriage-return-delimited list of full paths to one or more files. You can use this in subsequent commands. If the user cancels, `S_fileName` is set to "".

See the documentation for the `/D`, `/F`, `/M` and `/MULT` flags and then read **Displaying a Multi-Selection Open File Dialog** on page IV-149 for details.

`refNum` is left unchanged.

Displaying a Save File Dialog

This covers cases 5 (`/D` without `/R` or `/A`).

Open does not actually open the file but just displays the Save File dialog.

If the user chooses a file in the Save File dialog, the `S_fileName` output string variable is set to a full path to the file. You can use this in subsequent commands. If the user cancels, `S_fileName` is set to "".

See the documentation for the `/D`, `/F` and `/M` flags and then read **Displaying a Save File Dialog** on page IV-150 for details.

`refNum` is left unchanged.

Flags

<code>/A</code>	Opens an existing file for appending or, if the file does not exist, creates a new file and opens it for appending.
<code>/C=creatorStr</code>	Specifies the file creator code. This is meaningful on Macintosh only and is ignored on Windows. For opening an existing file, creator defaults to "?????" which means "any creator". For creating a new file, <code>creatorStr</code> defaults to "IGR0" which is Igor's creator code.
<code>/D[=mode]</code>	Specifies dialog-only mode. <code>/D:</code> A dialog is always displayed. <code>/D=1:</code> Same as <code>/D</code> . <code>/D=2:</code> A dialog is displayed only if <code>pathName</code> and <code>fileNameStr</code> do not specify a valid file.

Use this mode to allow the user to choose a file to be opened by a subsequent operation, such as **LoadWave**.

With `/D` or `/D=1`, open presents a dialog from which the user can select a file but does not actually open the file. Instead, Open puts the full path to the file into the string variable `S_fileName`.

`/D=2` does the same thing except that it skips the dialog if `pathName` and `fileNameStr` specify a valid file. In this case, if `pathName` and `fileNameStr` refer to an alias (Macintosh) or shortcut (Windows), the target of the alias or shortcut is returned.

If the user clicks the Cancel button, `S_fileName` is set to an empty string.

	Use Open/D/R to bring up an Open File dialog. See Displaying an Open File Dialog on page IV-148 for details.
	Use Open/D/R/MULT=1 to bring up an Open File dialog to select multiple files. See Displaying a Multi-Selection Open File Dialog on page IV-149 for details.
	Use Open/D to bring up a Save File dialog. See Displaying a Save File Dialog on page IV-150 for details.
	See Using Open in a Utility Routine on page IV-151 for an example using /D=2.
	Do not use /Z with /D.
<i>/F=fileFilterStr</i>	/F provides control over the file filter menu in the Open File dialog. See Open File Dialog File Filters on page IV-149 and Save File Dialog File Filters on page IV-151 for details.
<i>/M=messageStr</i>	Prompt message text in the dialog used to select the file, if any.
<i>/MULT=m</i>	Use /D/R/MULT=1 to display a multi-selection Open File dialog. /D/R/MULT=0 or just /D/R displays a single-selection Open File dialog. /MULT=1 is allowed only if /D or /D=1 and /R are specified. See Displaying a Multi-Selection Open File Dialog on page IV-149 for details.
<i>/P=pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
<i>/R</i>	The file is opened read only.
<i>/T=typeStr</i>	When creating a new file on Macintosh (/A and /R flag omitted), /T sets the Macintosh file type property for the file if it does not already exist. For example, /T="BINA" sets the Macintosh file type to 'BINA'. If /T is omitted the Macintosh file type will be 'TEXT'. Apple has deemphasized Macintosh file types in favor of file name extensions. For new code, /F is recommended instead of /T. When opening an existing file (/A or /R flag used), /T provides control over the file filter menu in the Open File dialog. See Open File Dialog File Filters on page IV-149 for details. When creating a new file (/A and /R flag omitted), /T provides control over the file filter menu in the Save File dialog. See Save File Dialog File Filters on page IV-151 for details.
<i>/Z[=z]</i>	Prevents aborting of procedure execution if an error occurs, for example if the procedure tries to open a file that does not exist for reading. Use /Z if you want to handle this case in your procedures rather than having execution abort. When using /Z, /Z=1, or /Z=2, V_flag is set to 0 if no error occurred or to a nonzero value if an error did occur. Do not use /Z with /D. /Z=0: Same as no /Z. /Z=1: Suppresses normal error reporting. When used with /R, it opens the file if it exists. /Z alone has the same effect as /Z=1. /Z=2: Suppresses normal error reporting. When used with /R, it opens the file if it exists or displays a dialog if it does not exist.

Details

When Open returns, if a file was actually opened, the *refNum* parameter will contain a file reference number that you can pass to other operations to read or write data. If the file was not opened because of an error or because the user canceled or because /D was used, *refNum* will be unchanged.

If you use /R (open for read), Open opens an existing file for reading only.

Open

If you use /A, Open opens an existing file for appending. If the file does not exist, it is created and then opened for appending.

If both /R and /A are omitted then Open creates and opens a file. If the specified file does not already exist, Open creates it and opens it for writing. If the file does already exist then Open opens it and sets the current file position to the start of the file. The current file position determines where in the file data will be written. Thus, you will be overwriting existing data in the file.

Warning: If you open an existing file for writing (you do not use /R) then you will overwrite or truncate existing data in the file. To avoid this, open for read (use /R) or open for append (use /A).

Output Variables

The Open operation returns information in the following variables:

V_flag	Set only when the /Z flag is used. V_flag is set to zero if the file was opened, to -1 if Open displayed a dialog (because the file was not fully-specified) and the user canceled, and to some nonzero value if an error occurred.
S_fileName	Stores the full path to the file that was opened. If /MULT=1 is used, S_fileName is a carriage-return-separated list of full paths to one or more files. If an error occurred or if the user canceled, S_fileName is set to an empty string.

When using /D, the value of V_flag is undefined. Do not use /Z with /D. Use S_fileName to determine if the user selected a file or canceled.

Examples

This example function illustrates using Open to open a text file from which data will be read. The function takes two parameters: an Igor symbolic path name and a file name. If either of these parameters is an empty string, the Open operation will display a dialog allowing the user to choose the file. Otherwise, the Open operation will open the file without displaying a dialog.

```
Function DemoOpen(pathName, fileName)
  String pathName      // Name of symbolic path or "" for dialog.
  String fileName      // File name, partial path, full path or "" for dialog.
  Variable refNum
  String str

  // Open file for read.
  Open/R/Z=2/P=$pathName refNum as fileName

  // Store results from Open in a safe place.
  Variable err = V_flag
  String fullPath = S_fileName

  if (err == -1)
    Print "DemoOpen canceled by user."
    return -1
  endif

  if (err != 0)
    DoAlert 0, "Error in DemoOpen"
    return err
  endif

  Printf "Reading from file \"%s\". First line is:\r", fullPath
  FReadLine refNum, str      // Read first line into string variable
  Print str
  Close refNum
  return 0
End
```

OpenHelp

OpenHelp [*flags*] *fileNameStr*

The OpenHelp operation opens the specified help file.

The OpenHelp operation was added in Igor Pro 7.00.

Parameters

The help file to be opened is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If OpenHelp can not determine the location of the file from *fileNameStr* and *pathName*, it returns an error.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

Flags

- /INT[=interactive]* Controls whether opening the help file is interactive or not.
- /INT=1*: If the help file being opened needs to be compiled, OpenHelp presents a dialog asking the user whether the file should be compiled. During the compile, a progress dialog is displayed. Any errors are presented to the user in an error dialog. This is the default behavior if */INT* is omitted.
 - /INT=0*: If the help file being opened needs to be compiled, OpenHelp compiles it without presenting a dialog. Compilation errors are not presented to the user but are reflected in the *V_Flag* output variable.
- /P=pathName* Specifies the folder to look in for the file. *pathName* is the name of an existing Igor symbolic path.
- /PICT* Scans the compiled help file for pictures and stores information about all pictures in a semicolon separated list into the *S_pictureInfo* output string. If the help file needs to be compiled but compilation fails, *S_pictureInfo* is set to "".
- /V=visible* Controls help window visibility.
- visible=0*: The help window will be initially hidden.
 - visible=1*: The help window will be initially visible. This is the default if */V* is omitted.
