- /W=(left,top,right,bottom)* Specifies window size and position. Coordinates are in points.

OpenNotebook

`/Z[=z]` Controls error reporting.

`/Z=0:` Report errors normally. `/Z=0` is the same as omitting `/Z` altogether. This is the default behavior if `/Z` is omitted.

`/Z=1:` Suppresses normal error reporting.
`/Z` alone has the same effect as `/Z=1`.

`/Z=1` prevents aborting procedure execution if an error occurs, for example if the file does not exist or if there is a compilation error. Use `/Z=1` if you want to handle errors in your procedures rather than having execution abort.

When using `/Z` or `/Z=1`, check `V_Flag` to see if an error occurred.

Details

If you use `/P=pathName`, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-22 for details.

If the specified file is already open but not as a help window (for example as a notebook), **OpenHelp** returns an error.

If the `/W` or `/V` flag is used, or both, the window size and position and visibility are set as specified even if the file itself is already open, so long as the file is already opened as a help window.

Output Variables

The **OpenHelp** operation returns information in the following variables:

<code>V_Flag</code>	Set to a non-zero value if an error occurred and to zero if no error occurred.
<code>V_alreadyOpen</code>	Set to 1 if the specified help file was already open as a help file or to zero otherwise.
<code>S_pictureInfo</code>	Scans the compiled help file for pictures and stores information about all pictures in a semicolon separated list into the <code>S_pictureInfo</code> output string. If the help file needs to be compiled but compilation fails, <code>S_pictureInfo</code> is set to "".

CloseHelp

OpenNotebook

OpenNotebook [*flags*] [*fileNameStr*]

The **OpenNotebook** operation opens a file for reading or writing as an Igor notebook.

Unlike the **Open** operation, **OpenNotebook** will not create a file if the specified file does not exist. To create a new notebook, use the **NewNotebook** operation.

Parameters

The file to be opened is specified by *fileNameStr* and `/P=pathName` where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case `/P` is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

Flags

<code>/A</code>	Moves the notebook's selection to the end of the notebook.
<code>/ENCG=<i>textEncoding</i></code>	<p>Specifies the text encoding of the plain text file to be opened as a notebook.</p> <p>This flag was added in Igor Pro 7.00.</p> <p>This is relevant for plain text notebooks only and is ignored for formatted notebooks because they can contain multiple text encodings. See Plain Text File Text Encodings on page III-468 and Formatted Text Notebook File Text Encodings on page III-474 for details.</p> <p>OpenNotebook uses the text encoding specified by <code>/ENCG</code> and the rules described under Determining the Text Encoding for a Plain Text File on page III-469 to determine the source text encoding for conversion to UTF-8.</p> <p>Passing 0 for <i>textEncoding</i> acts as if <code>/ENCG</code> were omitted.</p> <p>See Text Encoding Names and Codes on page III-492 for a list of accepted values for <i>textEncoding</i>.</p>
<code>/K=<i>k</i></code>	<p>Specifies window behavior when the user attempts to close it.</p> <p><i>k</i>=0: Normal with dialog (default). <i>k</i>=1: Kills with no dialog. <i>k</i>=2: Disables killing. <i>k</i>=3: Hides the window.</p> <p>If you use <code>/K=2</code> or <code>/K=3</code>, you can still kill the window using the KillWindow operation.</p>
<code>/M=<i>messageStr</i></code>	Prompt message text in the dialog used to find the file, if any.
<code>/N=<i>winName</i></code>	Specifies the window name to be assigned to the new notebook. If omitted, it assigns a name like "Notebook0".
<code>/P=<i>pathName</i></code>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
<code>/R</code>	Opens the file as read only.
<code>/T=<i>typeStr</i></code>	Specifies the type or types of files that can be opened.
<code>/V=<i>visible</i></code>	Hides (<i>visible</i> = 0) or shows (<i>visible</i> = 1; default) the notebook.
<code>/W=(<i>left,top,right,bottom</i>)</code>	Specifies window size and position. Coordinates are in points.
<code>/Z</code>	Suppresses error generation. Use this to check if a file exists. If you use <code>/Z</code> , OpenNotebook sets the variable <code>V_flag</code> to 0 if the notebook was opened or to nonzero if there was an error, usually because the specified file does not exist.

Details

The `/A` (append) flag has no effect other than to move the selection to the end of the notebook after it is opened.

If you use `/P=pathName`, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-22 for details.

The `/T=typeStr` flag affects only the dialog that OpenNotebook presents if you do not specify a path and filename. The dialog presents only those files whose type is specified by `/T=typeStr`. There are two file types that are allowed for notebooks: 'TEXT' which is a plain text file and 'WMT0' which is a WaveMetrics formatted text file. Therefore, the file type, if you use it, should be either "TEXT" or "WMT0". If `/T=typeStr` is missing, it defaults to "TEXTWMT0". This opens either type of notebook file. On Windows, Igor considers files with ".txt" extensions to be of type TEXT and considers files with ".ifn" to be of type WMT0. See **File Types and Extensions** on page III-457 for details.

OpenProc

See Also

The **Notebook** and **NewNotebook** operations, and Chapter III-1, **Notebooks**.

OpenProc

OpenProc [*flags*] [*fileNameStr*]

The OpenProc operation opens a file as an Igor procedure file.

Note: This operation is used automatically to open procedure files when you open an Igor experiment. You can invoke OpenProc only from the command line. Do not invoke it from a procedure. To open procedure files from a procedure or from a menu definition, use the Execute/P operation.

Parameters

The file to be opened is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

Flags

<i>/A</i>	Moves the procedure window's selection to the end of the window.
<i>/ENCG=textEncoding</i>	<p>Specifies the text encoding of the plain text file to be opened as a procedure file.</p> <p>This flag was added in Igor Pro 7.00.</p> <p>OpenProc uses the text encoding specified by <i>/ENCG</i> and the rules described under Determining the Text Encoding for a Plain Text File on page III-469 to determine the source text encoding for conversion to UTF-8.</p> <p>Passing 0 for <i>textEncoding</i> acts as if <i>/ENCG</i> were omitted.</p> <p>See Text Encoding Names and Codes on page III-492 for a list of accepted values for <i>textEncoding</i>.</p>
<i>/M=messageStr</i>	Prompt message text in the dialog used to find the file, if any.
<i>/P=pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
<i>/R</i>	The file is opened read only.
<i>/T=typeStr</i>	Specifies the type or types of files that can be opened.
<i>/V=visible</i>	Hides (<i>visible=0</i>) or shows (<i>visible=1</i> ; default) the procedure window.
<i>/Z</i>	Suppresses error generation if the specified file does not exist.

Details

The */A* (append) flag has no effect other than to move the selection to the end of the procedure file after it is opened.

If you use */P=pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-22 for details.

OpenProc automatically opens procedure files when you open an Igor experiment. Normally, you will have no use for it. You can not open a procedure file while procedures are executing. Thus, you can't invoke OpenProc from within a procedure. You can only invoke it from the command line or from a user menu definition (actually, you may get away with it in a macro, but it's not recommend).

The **Execute** operation.

OperationList

OperationList(*matchStr*, *separatorStr*, *optionsStr*)

The OperationList function returns a string containing a list of internal (built-in) or external operation names corresponding to *matchstr*.

Parameters

Only operation names that match *matchStr* string are listed. Use "*" to match all names. See **WaveList** for examples.

separatorStr is appended to each operation name as the output string is generated. *separatorStr* is usually ";" for list processing (See **Processing Lists of Waves** on page IV-198 for details).

Use *optionsStr* to further qualify the list of operations. *optionsStr* is a (case-insensitive) string containing one of these values:

- "internal" Restricts the list to built-in operations.
- "external" Restricts the list to external operations (see **Igor Extensions** on page III-511).

Any other value for *optionsStr* ("all" is recommended) will return both internal and external operations.

The **DisplayProcedure** operation and the **FunctionList**, **MacroList**, **StringFromList**, and **WinList** functions.

Optimize

Optimize [*flags*] *funcSpec*, *pWave*

The Optimize operation determines extrema (minima or maxima) of a specified nonlinear function. The function must be defined in the form of an Igor user function.

Use the first form for univariate functions (one dimensional functions; functions taking just one variable). Use the second form with multivariate functions (functions in more than one dimension; functions of more than one variable).

Optimize uses Brent's method for univariate functions. For multivariate functions you can choose several variations of quasi-Newton methods or simulated annealing.

Flags

- /A* [= *findMax*] Finds a maximum (*/A*=1 or */A*) or minimum (*/A*=0 or no flag).
- /D*=*nDigits* Specifies the number of good digits returned (default is 15) by the function being optimized. If you use */X=xWave* with a single-precision wave, the default is seven. Ignored with simulated annealing (*/M*={3,0}).
- /DSA*=*destWave* Sets a wave to track the current best model only found with simulated annealing (*/M*={3,0}). *destWave* must have the same number of points as the X vector.
- /F*=*trustRegion* Sets the initial trust region when */M*={1 or 2, ...} with multivariate functions. The value is a scaled step size (see **Multivariate Details**). After the first iteration the trust region is adjusted according to conditions. Ignored with simulated annealing (*/M*={3,0}).
- /H*= *highBracket* Find the extrema of a univariate function. *lowBracket* and *highBracket* are X values on either side of the extreme point. An extreme point is found between the bracketing values.
- /L*= *lowBracket* If *lowBracket* and *highBracket* are equal, Optimize adds 1.0 to *highBracket* before looking for an extreme point. Default values for *lowBracket* and *highBracket* are zero. Thus, if neither *lowBracket* nor *highBracket* is present, this is the same as */L*=0/*H*=1. Ignored with simulated annealing (*/M*={3,0}).

Optimize

/I=maxIters Sets the maximum number of iterations in searching for an extreme point to *maxIters*. Default is 100 for *stepMethod* (/M flag) 0-2, 10000 for *stepMethod* = 3 (simulated annealing).
If you use this form of the /I flag with simulated annealing, *maxItersAtT* is set to *maxIters/2* and *maxAcceptances* is set to *maxIters/10*.

/I={maxIters, maxItersAtT, maxAcceptances}

Specifies the number of iterations for simulated annealing. The maximum number of iterations is set by *maxIters*, *maxItersAtT* sets the maximum number of iterations at a given temperature in the cooling schedule, and *maxAcceptances* sets the total number of accepted changes in the X vector (whether they increase or decrease the function) at a given temperature.

If you use this form of the flag with any *stepMethod* (/M flag) other than 3, *maxItersAtT* and *maxAcceptances* are ignored.

Defaults for *stepMethod* = 3 are {10000, 5000, 500}.

/M={stepMethod, hessMethod}

Specifies the method used for selecting the next step (*stepMethod*) and the method for calculating the Hessian (matrix of second derivatives) with multivariate functions.

<i>stepMethod</i>	Method	<i>hessMethod</i>	Method
0	Line Search	0	secant (BFGS)
1	Dogleg	1	finite differences
2	More-Hebdon		
3	Simulated Annealing		

Default values are {0,0}. The *hessMethod* variable is ignored if you select *stepMethod* = 3.

/Q Suppresses printout of results in the history area. Ordinarily, the results of root searches are printed in the history.

/R={typX1, typX2, ...}

/R=typXWave Specifies the expected size of X values with multivariate functions. These values are used to scale X values. If the X values you expect are very different from one, you will get more accurate results if you can give a reasonable estimate. Optimize will use *typXi* to scale X_i to reduce floating-point truncation error.

You must provide the same number of values in either a wave or a list of values as you provide to the /X flag.

Ignored with simulated annealing (/M={3,0}).

/S=stepMax Limits the largest scaled step size allowed with multivariate functions. Optimize will stop if five consecutive steps exceed *stepMax*.

Ignored with simulated annealing (/M={3,0}).

/SSA=stepWave Name of a 3-column wave having number of rows equal to the length of the X vector only when used with simulated annealing (/M={3,0}). *stepWave* sets information about the step size used to generate new X vectors. The step sizes are in terms of normalized X values. The normalization is such that the X_i ranges from -1 to 1 based on the ranges set by the /XSA flag.

Column zero sets the step size used when creating new trial X vectors. Default is 1.0.

Column one sets the minimum step size. Default is 0.001.

Column two sets the maximum step size. Default is 1.0.

<i>/T=tol</i>	<p>Sets the stopping criterion with univariate functions. Optimize will attempt to find a minimum within $\pm tol$.</p> <p>When this form is used with a multivariate function, <i>gradTol</i> is set to <i>tol</i> and <i>stepTol</i> is set to <i>gradTol</i>².</p> <p>Ignored with simulated annealing (<i>/M={3,0}</i>).</p>
<i>/T={gradtol, stepTol}</i>	<p>Sets the stopping criteria for multivariate functions. Iterations stop if a point is found with estimated scaled gradient less than <i>gradTol</i>, or if an iteration takes a scaled step shorter than <i>stepTol</i>. Default values are {8.53618x10⁻⁶, 7.28664x10⁻¹¹}. These values are (6.022x10⁻¹⁶)^{1/3} and (6.022x10⁻¹⁶)^{2/3} as suggested by Dennis and Schnabel. 6.022x10⁻¹⁶ is the smallest double precision floating point number that, when added to 1, is different from 1.</p> <p>Ignored with simulated annealing (<i>/M={3,0}</i>).</p>
<i>/TSA={InitialTemp, CoolingRate}</i>	<p>Used only with simulated annealing (<i>/M={3,0}</i>).</p> <p><i>InitialTemp</i> sets the initial temperature. If <i>InitialTemp</i> is set to zero, Optimize calls your function 100 times to estimate the best initial temperature. This is the recommended setting unless your function is very expensive to evaluate (in which case, you may not want to use simulated annealing at all).</p> <p><i>CoolingRate</i> sets the factor by which the temperature is decreased.</p>
<i>/X=xWave</i> <i>/X={x1, x2, ...}</i>	<p>Sets the starting point for searching for an extreme point with multivariate functions or with simulated annealing (<i>/M={3,0}</i>). The starting point can be specified with a wave having as many points as the number of independent variables, or you can write out a list of <i>X</i> values in braces. If you are finding extreme points of a univariate function, use <i>/L</i> and <i>/H</i> instead unless you are using the simulated annealing method. If you specify a wave, this wave is also used to receive the result of the extreme point search.</p>
<i>/XSA=XLimitWave</i>	<p>Name of a 2-column wave having number of rows equal to the length of the <i>X</i> vector only when used with simulated annealing (<i>/M={3,0}</i>).</p> <p>Column zero sets the minimum value allowed for each element of the <i>X</i> vector.</p> <p>Column one sets the maximum value allowed for each element of the <i>X</i> vector.</p> <p>Default is $\pm X_i * 10$ if X_i is nonzero, or ± 1 if X_i is zero. While a default is provided, it is highly recommended that you provide an <i>XLimitWave</i>.</p>
<i>/Y=funcSize</i>	<p>Specifies expected sizes of function values with multivariate functions. If you expect your function will return values very different from one, you should set <i>funcSize</i> to the expected size. Optimize will use this value to scale the function results to reduce floating-point truncation error.</p>

Parameters

func specifies the name of your user-defined function that will be optimized.

pwave gives the name of a parameter wave that will be passed to your function as the first parameter. It is not modified by Igor. It is intended for your private use to pass adjustable constants to your function.

Function Format

Finding extreme points of a nonlinear function requires that you realize the function as a Igor user function of a certain form. See **Finding Minima and Maxima of Functions** on page III-343 for detailed examples.

Your function must look like this:

```
Function myFunc(w,x1, x2, ...)
  Wave w
  Variable x1, x2
```

```
    return f(x1, x2, ...)          // an expression ...  
End
```

A univariate function would have only one X variable.

A multivariate function can use a wave to pass in the X values:

```
Function myFunc(w, xw)  
    Wave w  
    Wave xw  
  
    return f(xw)                  // an expression ...  
End
```

Replace “f(…)” with an appropriate numerical expression.

Univariate Details

The method used by Optimize to find extreme points of univariate functions requires that the point be bracketed before starting. If you don’t use /L and /H to specify the bracketing X values, the defaults are zero and one. Optimize first attempts to find the requested extreme point using the bracketing values (or the default). If that is unsuccessful, it attempts to bracket an extreme point by expanding the bracketing interval. If a suitable interval is found (the search is by no means perfectly reliable), then the search for an extreme point is made again.

Optimize uses Brent’s method for univariate functions, which requires no derivatives. This combines a quadratic extrapolation with checking for wild results. In the case of wild results (points beyond the best current bracketing values) the method reverts to a golden section bisection algorithm. For well-behaved functions, the quadratic extrapolation converges superlinearly. The golden section bisection algorithm converges more slowly but features global convergence, that is, if an extremum is there, it will be found.

The stopping criterion is

$$\left| x + \frac{a+b}{2} \right| + \frac{a-b}{2} \leq \frac{2}{3} tol.$$

In this expression, a and b are the current bracketing values, and x is the best estimate of the extreme point within the bracketing interval.

The left side of this expression works out to being simply the distance from the current solution to the boundary of the bracketing interval.

Note: Optimizing a univariate function with the simulated annealing method (/M={3,0}) works like a multivariate function, and this section does not apply. See the sections devoted to simulated annealing.

Multivariate Details

With multivariate functions, Optimize scales certain quantities to reduce floating point truncation error. You enter scaling factors using the /R and /Y flags. The /R flag specifies the expected magnitude of X values; Optimize then uses $X_i/typX_i$ in all calculations. Likewise, /Y specifies the expected magnitude of function values.

This scaling can be important for maintaining accuracy if your X’s or Y’s are very different from one, and especially if your X’s have values spanning orders of magnitude.

The Optimize operation uses a quasi-Newton method with derivatives estimated numerically. The function gradient is calculated using finite differences. For estimation of the Hessian (second derivative matrix) you can use either a secant method (*hessMethod* = 0) or finite differences (*hessMethod* = 1). The finite difference method gives a more accurate estimate and may succeed with difficult functions but requires more function evaluations per iteration. The finite difference method’s greater accuracy may reduce the total number of iterations required, so the overall number of function evaluations depends on details of the problem being solved. Usually the secant method requires fewer function evaluations and is preferred for functions that are expensive to evaluate.

Once a Newton step is calculated, there are three choices for the method used to find the best next value-line search along the Newton direction (*stepMethod* = 0), double dogleg (*stepMethod* = 1), or More-Hebdon (*stepMethod* = 2). The best method can be found only by experimentation. See Dennis and Schnabel (cited in **References**) for details.

The /F=*trustRegion*, /S=*stepMax* and /T={*...*, *stepTol*} all refer to scaled step sizes. That is,

$$stepX_i = \frac{|\Delta x_i|}{\max(|x_i|, typX_i)}.$$

The Optimize operation presumes that an extreme point has been found when either the gradient at the latest point is less than *gradTol* or when the last step taken was smaller than *stepTol*. These criteria both refer to scaled quantities:

$$\max_{1 \leq i \leq n} \left\{ |g_i| \frac{\max(|x_i|, typX_i)}{\max(|f|, funcSize)} \right\} \leq gradTol,$$

or

$$\max_{1 \leq i \leq n} \left\{ |g_i| \frac{|\Delta x_i|}{\max(|x_i|, typX_i)} \right\} \leq stepTol.$$

Simulated Annealing Introduction

The simulated annealing or Metropolis algorithm optimizes a function using a random search of the X vector space. It does not use derivatives to guide the search, making it a good choice if the function to be optimized is in some way poorly behaved. For instance, it is a good method for functions with discontinuities in the function value or in the derivatives.

Simulated annealing also has a good chance of finding a global minimum or maximum of a function having multiple local minima or maxima.

Because simulated annealing uses a random search method, it may require a large number of function evaluations to find a minimum, and it is not guaranteed that it will stop at an actual minimum. For these reasons, it is best to use one of the other methods unless those methods have failed.

The simulated annealing method generates new trial solutions by adding a random vector to the current X vector. The elements of the random vector are set to $stepsize_i * R_i$, where R_i is a random number in the interval (-1, 1). As the solution progresses, the *stepsize* is gradually decreased.

Bad trials, that is, those that change the function value in the wrong direction are accepted with a probability that depends on the simulated temperature. It is this aspect that allows simulated annealing to find a global minimum.

Function values are generated and accepted or rejected for some number of iterations at a given temperature, then the temperature is reduced. The probability of a bad iteration being accepted decreases with decreasing temperature. A too-fast cooling rate can freeze in a bad solution.

Simulated Annealing Details

It is highly recommended that you use the XSA flag to specify *XLimitWave*. This wave sets bounds on the values of the elements of the X vector during the random search. The defaults may be adequate but are totally *ad hoc*. You are better off to specify bounds that make sense to the problem you are solving.

The values of *XLimitWave* in addition to bounding the search space also scale the X vector during computations of probabilities, temperatures, etc. Consequently, the X limits can affect the performance of the algorithm.

A large number of iterations is required to have a good probability of finding a reasonable solution.

It is recommended that you set the initial temperature to zero so that Optimize can estimate a good initial temperature. If you can't afford the 100 function evaluations required, you probably shouldn't be using simulated annealing.

Optimize uses an exponential cooling schedule in which $T_{i+1} = CoolingRate * T_i$ (see the /TSA flag). *CoolingRate* must be in the range 0 to 1. A fast cooling rate (small value of *CoolingRate*) can cause simulated quenching; that is, a bad solution can be frozen in. Very slow cooling will result in slow convergence.

When simulated annealing is selected, the optimization is treated as multivariate even if your function has only a single X input. That is, the output variables and waves are the ones listed under multivariate functions.

Optimize

Variables and Waves for Output

The Optimize operation reports success or failure via the V_flag variable. A nonzero value is an error code.

Variables for a univariate function:

V_flag	0:	Search for an extreme point was successful.
	57:	User abort.
	785:	Function returned NaN.
	786:	Unable to find bracketing values for an extreme point.

If you searched for a minimum:

V_minloc	X value at the minimum.
V_min	Function value (Y) at the minimum.

If you searched for a maximum:

V_maxloc	X value at the maximum.
V_max	Function value (Y) at the maximum.

For simulated annealing only:

V_SANumIncreases	Number of "bad" iterations accepted.
V_SANumReductions	Number of iterations resulting in a better solution.

Variables for a multivariate function:

V_flag	0:	Search for an extreme point was successful.
	57:	User abort.
	788:	Iteration limit was exceeded.
	789:	Maximum step size was exceeded in five consecutive iterations.
	790:	The number of points in the typical X size wave specified by /R does not match the number of X values specified by the /X flag
	791:	Gradient nearly zero and no iterations taken. This means the starting point is very nearly a critical point. It could be a solution, or it could be so close to a saddle point or a maximum (when searching for a minimum) that the gradient has no useful information. Try a slightly different starting point.

V_OptTermCode	Indicates why Optimize stopped. This may be useful information even if V_flag is zero. Values are:
	1: Gradient tolerance was satisfied.
	2: Step size tolerance was satisfied.
	3: No step was found that was better than the last iteration. This could be because the current step is a solution, or your function may be too nonlinear for Optimize to solve, or your tolerances may be too large (or too small), or finite difference gradients are not sufficiently accurate for this problem.
	4: Iteration limit was exceeded.

- 5: Maximum step size was exceeded in five consecutive iterations. This may mean that the maximum step size is too small, or that the function is unbounded in the search direction (that is, goes to -inf if you are searching for a minimum), or that the function approaches the solution asymptotically (function is bounded but doesn't have a well-defined extreme point).
- 6: Same as V_flag = 791.

If you searched for a minimum:

V_min Function value (Y) at the minimum.

If you searched for a maximum:

V_max Function value (Y) at the maximum.

Variables for all functions:

V_OptNumIters Number of iterations taken before Optimize terminated.

V_OptNumFunctionCalls Number of times your function was called before Optimize terminated.

Waves for a multivariate function:

W_extremum Solution if you didn't use /X=<xWave>. Otherwise the solution is returned in your X wave.

W_OptGradient Estimated gradient of your function at the solution.

Finding Minima and Maxima of Functions on page III-343 for further details and examples.

References

The Optimize operation uses Brent's method for univariate functions. *Numerical Recipes* has an excellent discussion (see section 10.2) of this method (but we didn't use their code):

Press, William H., Saul A. Teukolsky, William T. Vetterling, and Brian P. Flannery, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992.

For multivariate functions Optimize uses code based on Dennis and Schnabel. To truly understand what Optimize does, read their book:

Dennis, J. E., Jr., and Robert B. Schnabel, *Numerical Methods for Unconstrained Optimization and Nonlinear Methods*, 378 pp., Society for Industrial and Applied Mathematics, Philadelphia, 1996.

Override

Override constant *objectName* = *newVal*

Override strconstant *objectName* = *newVal*

Override Function *funcName* ()

The Override keyword redefines a constant, strconstant, or user function. The *objectName* or *funcName* must be the same as the name of the original object or function that is being redefined. The override must be defined before the target object appears in the compile sequence.

See Also

Function Overrides on page IV-106 and **Constants** on page IV-50 for further details.

p

p

The p function returns the row number of the current row of the destination wave when used in a wave assignment statement. The row number is the same as the point number for a 1D wave.

p2rect

Details

Outside of a wave assignment statement `p` acts like a normal variable. That is, you can assign a value to it and use it in an expression.

See Also

Waveform Arithmetic and Assignments on page II-74.

For other dimensions, the `q`, `r`, and `s` functions.

For scaled dimension indices, the `x`, `y`, `z`, and `t` functions.

p2rect

`p2rect(z)`

The `p2rect` function returns a complex value in rectangular coordinates derived from the complex value `z` which is assumed to be in polar coordinates (magnitude is stored in the real part and the angle, in radians, in the imaginary part of `z`).

Examples

Assume `waveIn` and `waveOut` are complex, then:

```
waveOut = p2rect(waveIn)
```

sets each point of `waveOut` to the rectangular coordinates based on the magnitude in the real part and the angle (in radians) in the imaginary part of the points in `waveIn`.

You may get unexpected results if the number of points in `waveIn` differs from the number of points in `waveOut`.

See Also

The functions `cmplx`, `conj`, `imag`, `r2polar`, and `real`.

PadString

`PadString(str, finalLength, padValue)`

The `PadString` function returns a string identical to `str` except that it has been extended to a total length of `finalLength` using bytes of `padValue`. Use zero to create a C-language style string or use `0x20` to pad with spaces (FORTRAN style). This is useful when reading or writing binary files using `FBinRead` and `FBinWrite`.

See Also

`UnPadString`, `ReplaceString`, `ReplicateString`

Panel

Panel

`Panel` is a procedure subtype keyword that identifies a macro as being a control panel recreation macro. It is automatically used when Igor creates a window recreation macro for a control panel. See **Procedure Subtypes** on page IV-204 and **Saving a Window as a Recreation Macro** on page II-47 for details.

PanelResolution

`PanelResolution(wName)`

The `PanelResolution` function returns the current resolution of the specified window in pixels per inch.

If `wName` is empty, it returns the current global setting for panel resolution in pixels per inch which is controlled by **SetIgorOption PanelResolution** (see page III-458).

If `wName` is the name of a graph window, it returns the resolution for the **ControlBar** area in pixels per inch.

`wName` can be a subwindow specification.

The `PanelResolution` function was added in Igor Pro 7.00.

In general, `PanelResolution` and **ScreenResolution** return the same thing. However, on Windows when the screen resolution is 96 DPI, which is typical for normal-resolution screens, panels can use 72 DPI for compatibility with Igor Pro 6 and earlier.

See Also

Control Panel Resolution on Windows on page III-458, **ScreenResolution**, **Control Panel Expansion** on page III-443

ParamIsDefault**ParamIsDefault** (*pName*)

The ParamIsDefault function determines if an optional user function parameter *pName* was specified during the function call. It returns 1 when *pName* is default (not specified) or it returns 0 when it was specified.

Details

ParamIsDefault works only in the body of a user function and only with optional parameters. The variable *pName* must be valid at compile time; you can not defer lookup to runtime with \$.

See Also

Optional Parameters on page IV-33 and **Using Optional Parameters** on page IV-60.

ParseFilePath**ParseFilePath**(*mode*, *pathInStr*, *separatorStr*, *whichEnd*, *whichElement*)

The ParseFilePath function provides the ability to manipulate file paths and to extract sections of file paths.

Parameters

The meaning of the parameters depends on *mode*.

<i>mode</i>	Information Returned
0	Returns the element specified by <i>whichEnd</i> and <i>whichElement</i> . <i>whichEnd</i> is 0 to select an element relative to the beginning of <i>pathInStr</i> , 1 to select an element relative to the end. <i>whichElement</i> is zero-based. Pass ":" if <i>pathInStr</i> is a Macintosh HFS path, "\\ \" if it is a Windows path. See Path Separators on page III-453 for details about Macintosh versus Windows paths.
1	Returns the entire <i>pathInStr</i> , up to but not including the element specified by <i>whichEnd</i> and <i>whichElement</i> . <i>whichEnd</i> is 0 to select an element relative to the beginning of <i>pathInStr</i> , 1 to select an element relative to the end. <i>whichElement</i> is zero-based. Pass ":" if <i>pathInStr</i> is a Macintosh HFS path, "\\ \" if it is a Windows path. See Path Separators on page III-453 for details about Macintosh versus Windows paths.
2	Returns the entire <i>pathInStr</i> with a trailing separator added if it is not already there. This is useful when you have a path to a folder and want to tack on a file name. Pass ":" if <i>pathInStr</i> is a Macintosh HFS path, "\\ \" if it is a Windows path. See Path Separators on page III-453 for details about Macintosh versus Windows paths. <i>whichEnd</i> and <i>whichElement</i> are ignored. Pass 0 for them.
3	Returns the last element of <i>pathInStr</i> with the extension, if any, removed. The extension is anything after the last dot in <i>pathInStr</i> . <i>whichEnd</i> and <i>whichElement</i> are ignored. Pass 0 for them.
4	Returns the extension in <i>pathInStr</i> or "" if there is no extension. The extension is anything after the last dot in <i>pathInStr</i> . Pass ":" if <i>pathInStr</i> is a Macintosh HFS path, "\\ \" if it is a Windows path. See Path Separators on page III-453 for details about Macintosh versus Windows paths. <i>whichEnd</i> and <i>whichElement</i> are ignored. Pass 0 for them.
5	Returns the entire <i>pathInStr</i> but converts it to a format determined by <i>separatorStr</i> .

ParseFilePath

<i>mode</i>	Information Returned
	<p><i>separatorStr</i> = ":"</p> <p>Converts the path to Macintosh HFS style if it is Windows style. Does nothing to a Macintosh HFS path.</p> <p><i>separatorStr</i> = "\\ \"</p> <p>Converts the path to Windows style if it is Macintosh style. Does nothing to a Windows path.</p> <p><i>separatorStr</i> = "*"</p> <p>Converts the path to the native style of the operating system Igor is running on. Does nothing to a native path.</p> <p>For historical reasons, on Macintosh "native" means colon-separated HFS path, not UNIX path.</p> <p><i>separatorStr</i> = "/"</p> <p>Macintosh-only: Converts the Macintosh-style <i>pathInStr</i> input to a Posix (UNIX) path. Unlike the other conversions, the directory or file to which <i>pathInStr</i> refers must exist, otherwise "" is returned.</p> <p>To generate a Posix path for a non-existent file, generate the path for the existing folder and append the file name.</p> <p>This always returns "" on Windows.</p> <p><i>whichEnd</i> and <i>whichElement</i> are ignored. Pass 0 for them.</p>
6	<p>UNC volume name (" \\Server\Share") if <i>pathIn</i> starts with a UNC volume name or "" if not. Pass "*" for <i>separatorStr</i>.</p> <p><i>whichEnd</i> and <i>whichElement</i> are ignored. Pass 0 for them.</p>
7	<p>UNC server name ("Server" from " \\Server\Share") if <i>pathIn</i> starts with a UNC volume name or "" if not. Pass "*" for <i>separatorStr</i>.</p> <p><i>whichEnd</i> and <i>whichElement</i> are ignored. Pass 0 for them.</p>

<i>mode</i>	Information Returned
8	<p>UNC share name ("Share" from "\\Server\Share") if <i>pathInStr</i> starts with a UNC volume name or "" if not. Pass "*" for <i>separatorStr</i>.</p> <p><i>whichEnd</i> and <i>whichElement</i> are ignored. Pass 0 for them.</p>
9	<p>Macintosh only. On Windows this mode returns an error.</p> <p>Returns a Posix version of <i>pathInStr</i> which must be a full HFS path pointing to an existing volume, directory or file.</p> <p>This is the same as mode 5 except that <i>separatorStr</i> must be "*".</p> <p><i>whichEnd</i> and <i>whichElement</i> are ignored. Pass 0 for them.</p> <p>You would typically use this mode when you are about to execute a Unix command, which requires Posix paths, via <code>ExecuteScriptText</code>.</p> <p>This mode was created in Igor Pro 7.00 to provide an alternative to the obsolete <code>HFSToPosix</code> function provided by the <code>HSFAndPosix XOP</code>. With <code>HFSToPosix</code>, if the input path referred to a directory, the output always ended with a slash. With <code>ParseFilePath(9)</code>, the output will end with a slash only if the input path ends with a colon.</p>
10	<p>Macintosh only. On Windows this mode returns an error.</p> <p>Returns the HFS path corresponding to the Posix path in <i>pathInStr</i>.</p> <p><i>pathInStr</i> must be a full Posix path starting with a slash character. It does not need to point to an existing directory or file.</p> <p>The returned path may or may not refer to an existing volume, folder or file, depending on <i>pathInStr</i>.</p> <p>Pass "*" for <i>separatorStr</i>.</p> <p><i>whichEnd</i> and <i>whichElement</i> are ignored. Pass 0 for them.</p> <p>You would typically use this mode when you receive a Posix path from a Unix command executed via <code>ExecuteScriptText</code> and you want to use that path in Igor.</p> <p>This mode was created in Igor Pro 7.00 to provide an alternative to the obsolete <code>PosixToHFS</code> function provided by the <code>HSFAndPosix XOP</code>.</p>

Details

When dealing with Windows paths, you need to be aware that Igor treats the backslash character as an escape character. When you want to put a backslash in a literal string, you need to use two backslashes. See **Escape Sequences in Strings** on page IV-14 and **Path Separators** on page III-453 for details.

On Windows two types of file paths are used: drive-letter paths and UNC ("Universal Naming Convention") paths. For example:

```
// This is a drive-letter path.
C:\Program Files\WaveMetrics\Igor Pro Folder\WaveMetrics Procedures

// This is a UNC path.
\\BigServer\SharedApps\WaveMetrics\Igor Pro Folder\WaveMetrics Procedures
```

In this example, `ParseFilePath` considers the volume name to be `C:` in the first case and `\\BigServer\SharedApps` in the second. The volume name is treated as one element by `ParseFilePath`, except for modes 7 and 8 which permit you to extract the components of the UNC volume name.

Except for the leading backslashes in a UNC path, `ParseFilePath` modes 0 and 1 internally strip any leading or trailing separator (as defined by the *separatorStr* parameter) from *pathInStr* before it starts parsing. So if you pass `":Igor Pro Folder:WaveMetrics Procedures:"`, it is the same as if you had passed `"Igor Pro Folder:WaveMetrics Procedures"`.

If there is no element corresponding to *whichElement* and *mode* is 0, `ParseFilePath` returns `" "`.

If there is no element corresponding to *whichElement* and *mode* is 1, `ParseFilePath` returns the entire *pathInStr*.

ParseOperationTemplate

Examples

```
String pathIn, pathOut
// Full path
pathIn= "hd:Igor Pro Folder:WaveMetrics Procedures:Waves:Wave Lists.ipf"
// Extract first element.
Print ParseFilePath(0, pathIn, ":", 0, 0)      // Prints "hd"
// Extract second element.
Print ParseFilePath(0, pathIn, ":", 0, 1)      // Prints "Igor Pro Folder"
// Extract last element.
Print ParseFilePath(0, pathIn, ":", 1, 0)      // Prints "Wave Lists.ipf"
// Extract next to last element.
Print ParseFilePath(0, pathIn, ":", 1, 1)      // Prints "Waves"
// Get path to folder containing the file.
// Prints "hd:Igor Pro Folder:WaveMetrics Procedures:Waves:"
Print ParseFilePath(1, pathIn, ":", 1, 0)
// Extract the file name without extension.
Print ParseFilePath(3, pathIn, ":", 0, 0)      // Prints "Wave Lists"
// Extract the extension.
Print ParseFilePath(4, pathIn, ":", 0, 0)      // Prints ".ipf"
// Make sure the given path ends with a colon and concatenate file name.
String path = <routine that returns a Macintosh-style path to a folder>
path = ParseFilePath(2, path, ":", 0, 0)
path += "AFile.txt"
```

See Also

Escape Sequences in Strings on page IV-14, **UNC Paths** on page III-453, and **Path Separators** on page III-453 for details. The **RemoveEnding** function.

ParseOperationTemplate

ParseOperationTemplate [*flags*] *cmdTemplate*

The ParseOperationTemplate operation helps XOP programmers and WaveMetrics programmers write code to implement Igor operations. If you are not an XOP programmer nor a WaveMetrics programmer, it will be of no interest.

ParseOperationTemplate generates starter code for programmers who are creating Igor operations. The starter code is copied to the clipboard, overwriting any previous clipboard contents.

Flags

/C=c If *c* is nonzero, ParseOperationTemplate stores code for your ExecuteOperation and RegisterOperation functions in the clipboard.

- c*=0: Do not generate code
- c*=1: Generate simplified C code - not recommended
- c*=2: Generate C code
- c*=6: Generate C++ code

The only difference between */C=6* and */C=2* is that the ExecuteOperation function is declared as extern "C" instead of static. C++ files that use static work fine although extern "C" is correct.

- `/S=s` Stores a definition of your runtime parameter structure in the clipboard if `s` is nonzero.
- `s=0:` Do not generate the runtime parameter structure
 - `s=1:` Use your mnemonic names - recommended
 - `s=2:` Automatically generate mnemonic names - not recommended
- We recommend that you use `/S=1` and provide unique mnemonic parameter names in your template. `ParseOperationTemplate` then uses your parameter names as structure field names.
- If you use `/S=2`, `ParseOperationTemplate` creates unique field names by concatenating flag or keyword text and your mnemonic names. This is left over from the early days of Operation Handler and is not recommended.
- `/T` Stores a comment listing your command template in the clipboard.
- `/TS` Identifies a ThreadSafe operation by adding an extra field to the runtime parameter structure. This is only of use to WaveMetrics programmers.

Parameters

`cmdTemplate` is the template that describes the syntax for your operation. See the *Igor XOP Toolkit Reference Manual* for details.

Details

`ParseOperationTemplate` parses your command template, generating structures that embody the syntax of your operation. It then uses these structures to generate code that can serve as a starting point for implementing your operation. The starter code is stored in the clipboard.

For most uses, the recommended flags are:

```
/T/S=1/C=2      // For non-threadsafe operations
/T/S=1/C=2/TS   // For threadsafe operations
```

`ParseOperationTemplate` sets the following output variable, but only when called from a function or macro:

<code>V_flag</code>	0:	<code>cmdTemplate</code> was successfully parsed.
	-1:	<code>cmdTemplate</code> was not successfully parsed.

If `V_flag` is nonzero, this indicates that your `cmdTemplate` syntax is incorrect. See the *Igor XOP Toolkit Reference Manual* for details.

Examples

```
Function Test()
  String cmdTemplate
  cmdTemplate = "MyTest"
  cmdTemplate += " /A={number:aNum1,string:aStrH}"
  cmdTemplate += " /B=wave:bWaveH"
  cmdTemplate += " key1={name:k1N1[,wave:k1WaveH,name:k1N2,string[2]:k1StrHArray]}"

  // If your XOP is C instead of C++, use /C=2 instead of /C=6
  TestOperationParser/T/S=1/C=6 cmdTemplate
  Print V_flag, S_value
End
```

See Also

Igor Extensions on page III-511.

PathInfo

PathInfo [`/S` `/SHOW`] *pathName*

The `PathInfo` operation stores information about the named symbolic path in the following variables:

<code>V_flag:</code>	0 if the symbolic path does not exist, 1 if it does exist.
<code>S_path:</code>	The full path (e.g., "hd:This:That:").

PathList

The path returned is a colon-separated path which can be used on Macintosh or Windows. See **Path Separators** on page III-453 for details.

Flags

- `/S` Presets the next otherwise undirected open or save file dialog to the given disk folder. This flag is ignored when `PathInfo` is called from a preemptive thread.
- `/SHOW` Shows the folder, if it exists, in the Finder (Mac OS X) or Windows Explorer (Windows). This flag is ignored when `PathInfo` is called from a preemptive thread.

Details

The use of `PathInfo` in a preemptive thread requires Igor Pro 8.00 or later.

Examples

```
// The following lines perform equivalent actions:
PathInfo/S myPath;Open refNum
Open/P=myPath refNum

// Show Igor's Preferences folder in the Finder/Windows Explorer.
String fullpath= SpecialDirPath("Preferences",0,0,0)
NewPath/O/Q tempPathName, fullpath
PathInfo/SHOW tempPathName
```

See Also

Symbolic Paths on page II-22.

The **NewPath**, **GetFileFolderInfo**, **ParseFilePath** and **SpecialDirPath** operations.

PathList

PathList(*matchStr*, *separatorStr*, *optionsStr*)

The `PathList` function returns a string containing a list of symbolic paths selected based on the *matchStr* parameter.

Details

For a path name to appear in the output string, it must match *matchStr*. *separatorStr* is appended to each path name as the output string is generated.

`PathList` works like the `WaveList` function, except that the *optionsStr* parameter is reserved for future use. Pass "" for it.

Examples

When a new experiment is created there is only one path:

```
Print PathList("*",";","")
```

Prints the following in the history area:

```
Igor;
```

See Also

The **WaveList** function for an explanation of the *matchStr* and *separatorStr* parameters and for examples. See also **Symbolic Paths** on page II-22 for an explanation of symbolic paths.

PauseForUser

PauseForUser [/C] *mainWindowName* [, *targetWindowName*]

The `PauseForUser` operation pauses function execution to allow the user to manually interact with a window. For example, you can call `PauseForUser` from a loop to allow the user to move the cursors on a graph. In this scenario, *targetWindowName* would be the name of the graph and *mainWindowName* would be the name of a control panel containing a message telling the user to adjust the cursors and then click, for example, the Continue button.

If *targetWindowName* is omitted then *mainWindowName* plays the role of target window.

`PauseForUser` works with graph, table, and panel windows only.

Flags

/C Tells PauseForUser to return immediately after handling any pending events. See Details.

Details

During execution of PauseForUser, only mouse and keyboard activity directed toward either *mainWindowName* or *targetWindowName* is allowed.

While waiting for user action, PauseForUser disables double-clicks and any contextual menus that can lead to dialogs in order to prevent changes on the command line. It also disables killing windows by clicking the close icon in the title bar unless the window was originally created with the **/K=1** flag (kill with no dialog).

If **/C** is omitted, PauseForUser returns only when the main window has been killed.

If **/C** is present, PauseForUser handles any pending events, sets **V_Flag** to the truth the target window still exists, and then returns control to the calling user-defined function. Use PauseForUser/C in a loop if you need to do something while waiting for the user to finish interacting with the target window, such as updating a progress indicator.

As of Igor Pro 8.00, the PauseForUser operation is allowed only in user-defined functions. It returns an error if called from a macro or from the command line.

See Also

Pause For User on page IV-152 for examples and further discussion.

PauseUpdate

PauseUpdate

The PauseUpdate operation delays the updating of graphs and tables until you invoke a corresponding ResumeUpdate command.

Details

PauseUpdate is useful in a macro that changes a number of things relating to the appearance of a graph. It prevents the graph from being updated after each change. Its effect ends when the macro in which it occurs ends. It also affects updating of tables.

This operation is not allowed from the command line. It is allowed but has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the DoUpdate operation.

See Also

The **DelayUpdate**, **DoUpdate**, **ResumeUpdate**, and **Silent** operations.

PCA

PCA [*flags*] [*wave0*, *wave1*,... *wave99*]

The PCA operation performs principal component analysis. Input data can be in the form of a list of 1D waves, a single 2D wave, or a string containing a list of 1D waves. The operation can produce multiple output waves depending on the specified flags.

Flags

/ALL	Shortcut for the combination of commonly used flags: /CVAR , /SL , /NF , /IND , /IE , and /RMS .
/COV	Calculates the input wave(s) covariance matrix, which as the input for the remainder of the analysis. The covariance matrix is computed by first creating a matrix copying each input 1D wave into sequential columns and then multiplying that matrix by its transpose.
/CVAR	Computes the cumulative percent variance defined as $100 * \text{sum of first } m \text{ eigenvalues} / \text{sum of all eigenvalues}$. The results are stored in the wave W_CumulativeVAR in the current data folder. See also /VAR .

/IE	Computes the imbedded error. Returns errors in the wave W_IE in the current data folder. The wave is scaled using <code>SetScale/P x 1,1,"", W_IE</code> . The imbedded error is a function of the number of factors, the number of rows and columns and the sum of the eigenvectors not included in the significant factors. The behavior of IE determines the number of significant factors.
/IND	Computes the factor indicator function. Note that if you specify /IND the residual standard deviation will also be calculated. Returns results in the wave W_IND in the current data folder. The wave is scaled using <code>SetScale/P x 1,1,"", W_IND</code> .
/LEIV	Limits eigenvalues so that the SVD calculation does not require too much memory. The limit is set to the minimum of the number of rows or columns of the input.
/NF	Finds the number of significant factors and stores it in the variable V_npnts. You must use /IND in order to compute the significant factors.
/O	Overwrites input waves.
/Q	Suppresses printing of factors in the history area.
/RSD[= <i>rsdMode</i>]	Computes the Residual Standard Deviation (RSD) and returns the RSD in the wave W_RSD in the current data folder. The first element in W_RSD is NaN and all remaining wave elements correspond to the number of significant factors. <i>rsdMode</i> =0: Covariance about the origin. <i>rsdMode</i> =1: Correlation about the origin.
/RMS	Computes the RMS error. Returns results in the wave W_RMS in the current data folder. The wave is scaled using <code>SetScale/P x 1,1,"", W_RMS</code> .
/SCMT	Saves C matrix after the singular value decomposition (SVD) in the wave M_C in the current data folder.
/SCR	Converts the individual wave input into standard scores. Does not work when the input is a single 2D wave. It is an error to convert to standard scores when one or more entries in the waves are NaN or INF. If you use this feature make sure to use the appropriate form of the RSD calculation.
/SDM	Saves a copy of the data matrix at the end of the calculation. This is useful if your input consists of individual waves or if you want to save the computed standard scores. If the input is a 2D matrix, you will get a copy of the input matrix in the wave M_D.
/SEVC	Saves the eigenvalue vector in the wave W_Eigen, which are the raw eigenvalues generated by the SVD, in the current data folder. Normally, if the SVD was applied to a raw data matrix, i.e., not covariance or correlation matrix, you must square each element of the wave to obtain the PCA eigenvalues. Note that this wave has default wave scaling.
/SL	Computes percent significance level and stores it in the wave W_PSL in the current data folder.
/SQEV	Does not square SVD eigenvalues. If you specify /COV there is no need to use this flag. Use only if your input is already a covariance matrix. In this case the results of the SVD are the eigenvalues not their square roots.
/SRMT	Saves R matrix after the SVD in the wave M_R in the current data folder.
/U	Leaves the input waves unchanged only when the input is a 2D wave. Note that covariance calculations will not be made even if the appropriate flag is used.
/VAR	Computes the variance associated with each eigenvalue. The variance is defined as the ratio of the eigenvalue to the sum of all eigenvalues. The results are stored in the wave W_VAR in the current data folder. See also /CVAR above.
/WSTR= <i>waveListStr</i>	

Semicolon-separated string list of the names of all input waves.

/Z No error reporting.

Details

The input is either via /WSTR=*waveListStr* or a list of up to 100 1D waves or a single 2D wave following the last flag.

waveListStr is string containing a semicolon-separated list of 1D waves to be used for the data matrix. *waveListStr* can include any legal path to a wave. Liberal names can be quoted or not quoted. It is assumed that all waves are of the same numerical type (either single or double precision) and that all waves have the same number of points.

Regardless of the inputs, the operation expects that the number of rows in the resulting matrix is greater than or equal to the number of columns.

The operation starts by creating the data matrix from the input wave(s). If you provide a list of 1D waves they become the columns of the data matrix. You can choose to use the covariance matrix (/COV) as the data matrix and you can also choose to normalize each column of the data matrix to convert it into standard scores. This involves computing the average and standard deviation of each column and then setting the new values to be:

$$newValue = \frac{oldValue - colAverage}{colStdv}.$$

You can pre-process the input data using **MatrixOp** with the SubtractMean, NormalizeRows, and NormalizeCols functions.

After creating the data matrix the operation computes the singular value decomposition (SVD) of the data matrix. Results of the SVD can be saved or processed further. Save the C and R matrices using /SCMT and /SRMT. These are related to the input data matrix through: $D = R \cdot C$.

The remainder of the operation lets you compute various statistical quantities defined by Malinowski (see References). Use the flags to determine which ones are computed.

The operation generates a number of output waves. All waves are stored in the current data folder.

You can save the input matrix D in the wave M_D, the optional SVD results are stored in the waves M_C that contains the column matrix C, M_R that contains the row matrix R, and W_Eigen that contains the eigenvalues of the data matrix. Note that these can be the eigenvalues or the square of the eigenvalues depending on the input matrix being a covariance matrix or not (see /SQEV).

The optional 1D output waves (W_RSD, W_RMS, W_IE, W_IND, W_PSL) are saved with wave scaling to make it easier to display the wave as a function of the number of factors.

ICA

pcsr

pcsr(*cursorName* [, *graphNameStr*])

The pcsr function returns the point number of the point which the specified cursor (A through J) is on in the top (or named) graph. When used with cursors on images or waterfall plots, pcsr returns the row number, and when used with a free cursor, it returns the relative X coordinate.

Parameters

cursorName identifies the cursor, which can be cursor A through J.

graphNameStr specifies the graph window or subwindow.

Pi

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

Details

The *pcsr* result is not affected by any X axis.

See Also

The *hcsr*, *qcsr*, *vcsr*, *xcsr*, and *zcsr* functions.

Programming With Cursors on page II-309.

Pi

Pi

The Pi function returns π (3.141592...).

PICTInfo

PICTInfo(*pictNameStr*)

The PICTInfo function returns a string containing a semicolon-separated list of information about the named picture. If the named picture does not exist, then "" is returned. Valid picture names can be found in the Pictures dialog.

Details

The string contains six pieces of information, each prefaced by a keyword and colon and terminated with a semicolon.

Keyword	Information Following Keyword
TYPE	One of: "PICT", "PNG", "JPEG", "Enhanced metafile", "Windows metafile", "DIB", "Windows bitmap", or "Unknown type".
BYTES	Amount of memory used by the picture.
WIDTH	Width of the picture in pixels.
HEIGHT	Height of the picture in pixels.
PHYSWIDTH	Physical width of the picture in points.
PHYSHEIGHT	Physical height of the picture in points.

Examples

```
Print PICTInfo("PICT_0")
```

will print the following in the history area:

```
TYPE:PICT;BYTES:55734;WIDTH:468;HEIGHT:340;PHYSWIDTH:468;PHYSHEIGHT:340;
```

See Also

The **ImageLoad** operation for loading PICT and other image file types into waves, and the **PICTList** function. The **StringFromList** operation for parsing the information string.

See **Pictures** on page III-509 and **Pictures Dialog** on page III-511 for general information on picture handling.

PICTList

PICTList(*matchStr*, *separatorStr*, *optionsStr*)

The PICTList function returns a string containing a list of pictures based on *matchStr* and *optionsStr* parameters. See **Details** for information on listing pictures in graphs, panels, layouts, and the picture gallery.

Details

For a picture name to appear in the output string, it must match *matchStr* and also must fit the requirements of *optionsStr*. *separatorStr* is appended to each picture name as the output string is generated.

The name of each picture is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

"*"	Matches all picture names.
"xyz"	Matches picture name xyz only.
"*xyz"	Matches picture names which end with xyz.
"xyz*"	Matches picture names which begin with xyz.
"*xyz*"	Matches picture names which contain xyz.
"abc*xyz"	Matches picture names which begin with abc and end with xyz.

matchStr may begin with the ! character to return items that do not match the rest of *matchStr*. For example:

"!*xyz"	Matches picture names which do not end with xyz.
---------	--

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

optionsStr is used to further qualify the picture.

Use "*" accept all pictures in the Pictures Dialog that are permitted by *matchStr*.

Use the WIN: keyword to limit the pictures to the named or target window:

"WIN:"	Match all pictures displayed in the top graph, panel, or layout.
"WIN:windowName"	Match all pictures displayed in the named graph, panel, or layout window.

Examples

PICTList ("*", ";", "")	Returns a list of all pictures in the Pictures Dialog.
PICTList ("*", ";", "WIN:")	Returns a list of all pictures displayed in the top panel, graph, or layout.
PICTList ("*_bkg", ";", "WIN:Layout0")	Returns a list of pictures whose names end in "_bkg" and which are displayed in Layout0.

See Also

The **ImageLoad** operation for loading PICT and other image file types into waves, and the **PICTInfo** function. Also the **StringFromList** function for retrieving items from lists.

See **Pictures** on page III-509 and **Pictures Dialog** on page III-511 for general information on picture handling.

Picture

Picture *pictureName*

The Picture keyword introduces an ASCII code picture definition of binary image data.

See Also

Proc Pictures on page IV-56 for further information.

PixelFromAxisVal

PixelFromAxisVal(*graphNameStr*, *axNameStr*, *val*)

The PixelFromAxisVal function returns the local graph pixel coordinate corresponding to the axis value in the graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

PlayMovie

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

If the specified axis is not found and if the name is “left” or “bottom” then the first vertical or horizontal axis will be used.

If *graphNameStr* references a subwindow, the returned pixel value is relative to top left corner of base window, not the subwindow.

Axis ranges and other graph properties are computed when the graph is redrawn. Since automatic screen updates are suppressed while a user-defined function is running, if the graph was recently created or modified, you must call DoUpdate to redraw the graph so you get accurate axis information.

See Also

The **AxisValFromPixel** and **TraceFromPixel** functions.

PlayMovie

PlayMovie [*flags*] [*as fileNameStr*]

The PlayMovie operation opens a movie file in a window and plays it.

Parameters

The file to be opened is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

The file is passed to the operating system to be opened with the default program for the given filename extension and the */W* flag is ignored.

On Macintosh, prior to Mac OS 10.15 (Catalina,) QuickTime could be used to play a movie in an Igor window and could be controlled using **PlayMovieAction**. Since QuickTime is no longer available, movies no longer open in Igor windows on any operating system and PlayMovieAction after PlayMovie is no longer of use.

Flags

<i>/I</i>	This flag is obsolete and is ignored.
<i>/M</i>	This flag is obsolete and is ignored.
<i>/P=pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
<i>/W=(left,top,right,bottom)</i>	This flag is obsolete and is ignored.
<i>/Z</i>	No error reporting; an error is indicated by nonzero value of the variable <i>V_flag</i> . If the user clicks the cancel button in the Open File dialog, <i>V_flag</i> is set to -1.

Details

If the movie file to be played is not fully specified by */P* and *fileNameStr*, PlayMovie displays an Open File dialog to let you choose a movie file. See **Symbolic Paths** on page II-22 and **Path Separators** on page III-453 for details.

Movies on page IV-243.

The **PlayMovieAction** operation.

PlayMovieAction

PlayMovieAction [/A/Z] *keyword* [=value] [, *keyword* [=value]]

The PlayMovieAction operation is used to extract frames from a movie file.

Flags

/A	Macintosh: /A is ignored. Windows: Uses alternate deprecated technology, AVI instead of MMF.
/Z	Errors do not stop procedure execution. Use V_Flag to see if an error occurred.

Keywords

extract	Extracts current frame into an 8-bit RGB image wave named M_MovieFrame. (Can be combined with frame=f.)
extract=e	Extracts <i>e</i> frames into a single multiframe wave, M_MovieChunk. This wave will have 3 planes for RGB and will have <i>e</i> chunks. <i>e</i> =1 is the same as plain extract. For <i>e</i> >1, the current time is automatically updated.
frame=f	Moves to specified movie frame.
getID	Returns top movie ID number in V_Value. Do not use in same call with getTime.
getTime	Reads current movie time into variable V_value (in seconds).
gotoBeginning	Goes to beginning of movie.
gotoEnd	Closes the movie opened using the open keyword movie file.
kill	Closes open movie.
loop=mode	On Macintosh only, <i>mode</i> chooses between two extraction methods. The default, equivalent to loop=0, is fast but can not back up; an attempt to extract a frame previous to the last one extracted results in an error. The alternate method, loop=1, provides random access but can be very slow when reading sequential frames. The loop keyword was added in Igor Pro 8.00. It is ignored on Windows.
open=fullPath	Opens the specified movie file to enable frame extraction. V_Flag is set to zero if no error occurred and V_Value is set to the file reference number.
ref=refNum	The ref keyword is used with all PlayMovieAction commands after using the open keyword to access a movie file. <i>refNum</i> must be the file reference number returned in V_Value in the open step. The ref keyword is needed only if multiple files or windows are open. You can also use setFrontMovie to set the active movie.
setFrontMovie=id	Sets the movie with given <i>id</i> as the active movie file. Do not use setFrontMovie and getID in same call to PlayMovieAction.
start	Obsolete. Movie windows are no longer supported in Igor itself.
step=s	Moves by <i>s</i> frames into movie (0 is same as 1, negative values move backwards).
stop	Obsolete. Movie windows are no longer supported in Igor itself.

Details

Operations are performed in the following order: kill, gotoBeginning, gotoEnd, frame, step, getTime, extract. kill overrides all other parameters.

If you want to extract a grayscale image, you can convert the RGB image into grayscale using the ImageTransform command as follows:

PlaySnd

```
PlayMovieAction extract
ImageTransform rgb2gray M_MovieFrame
NewImage M_RGB2Gray
```

When you are finished extracting frames, use the kill keyword to close the file.

To get a full path for use with the open keyword, use the **PathInfo** or **Open /D/R** commands.

Examples

These commands show to determine the number of frames in a simple movie:

```
PlayMovieAction open = <full path to movie file>
PlayMovieAction gotoEnd,getTime
Variable tend= V_value
PlayMovieAction step=-1,getTime
Print "frames= ",tend/(tend-V_value)
PlayMovieAction kill
```

See Also

Movies on page IV-243.

The **PlayMovie** operation.

PlaySnd

PlaySnd [*flags*] *fileNameStr*

Note: PlaySnd is obsolete. Use **PlaySound** instead.

Available only on the Macintosh.

The PlaySnd operation plays a sound from the file's data fork, or from an 'snd ' resource.

Parameters

The file containing the sound is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

Flags

<i>/I=resourceIndex</i>	Specifies the 'snd ' resource to load by resource index, starting from 1.
<i>/M=promptStr</i>	Specifies a prompt if PlaySnd needs to put up a dialog to find the file.
<i>/N=resNameStr</i>	Specifies the resource to load by resource name.
<i>/P=pathName</i>	Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.
<i>/Q</i>	Quiet: suppresses the insertion of 'snd ' info into the history area.
<i>/R=resourceID</i>	Specifies the 'snd ' resource to load by resource ID.
<i>/Z</i>	Does not play the sound, just checks for its existence.

Details

If none of */I*, */N* or */R* are specified, PlaySnd tries to play a sound stored in the data fork of the file. If the file dialog is used, only files of type 'sfil' are shown.

If any of */I*, */N* or */R* are specified, PlaySnd tries to play a sound from an 'snd ' resource. Most programs store sounds in 'snd ' resources. If the file dialog is used, files of all types are shown.

If */P=pathName* is omitted, then *fileNameStr* can take on three special values:

"Clipboard"	Loads data from Clipboard.
"System"	Loads data from System file.

“Igor” Loads data from Igor Pro application.

If you specify */P=pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like “hd:Folder1:” or “C:\\Folder1\\”. See **Symbolic Paths** on page II-22 for details.

There are no sounds in the Igor Pro application file.

If the file is not fully specified and *fileNameStr* is not one of these special values, then PlaySnd presents a dialog from which you can select a file. “Fully specified” means that Igor can determine the name of the file (from the *fileNameStr* parameter) and the folder containing the file (from the */P=pathName* flag or from the *fileNameStr* parameter).

PlaySnd sets the variable *V_flag* to 1 if the sound exists and fits in available memory or to 0 otherwise.

If the sound exists, PlaySnd also sets the string variable *S_Info* to:

```
"SOURCE: sourceName; RESOURCENAME: resourceName; RESOURCEID: resourceID"
```

If the sound is not a resource then *resourceName* is "" and *resourceID* is 0. *sourceName* will be the name of the file that was loaded or “Clipboard”, “System” or “Igor”.

Examples

```
PlaySnd/I=1/P=mySnds/Z "Wild Eep"
If (V_flag) // Any 'snd ' in the "Wild Eep" file?
    Print S_info // Yes, print resource number, etc.
Endif
```

This prints the following into the history area:

```
SOURCE:resource fork;RESOURCENAME:Wild Eep;RESOURCEID:8;
```

PlaySound

```
PlaySound [/A [=a] /BITS=bits /C] soundWave
```

```
PlaySound /A [=a] /BITS=bits {soundWave1, soundWave2 [, soundWaveN...]}
```

The PlaySound operation plays the audio samples in the named wave. The various sound output parameters — number of samples, sample rate, number of channels, and number of bits of resolution — are determined by the corresponding parameters of the wave.

Flags

/A [=a] Plays sounds asynchronously so that sounds will continue to play after the command itself has executed.

/A=0: Same as no */A* flag.

/A=1: Plays sounds asynchronously; same as */A*.

/A=2: Stop playing any current sound before starting this one.

/A=3: Return with user abort error if output buffers are full (rather than waiting.)
Use `GetRTErr` (1) to detect and clear the error condition.

/BITS=bits Controls the number of bits used for each sound sample sent to the sound output hardware.

Use */BITS=24* with a 32-bit integer wave for 24-bit sound data capable of representing values from -8,388,608 to +8,388,607.

If you omit */BITS* or use */BITS=0*, PlaySound uses the wave's data type and size to determine how many bits are used for each sound sample.

The */BITS* flag was added in Igor Pro 9.00.

/C Obsolete - do not use.

On Windows */C* causes sound wave data greater than 16-bits to be converted to 16-bit integer. Such data should range from -32768 to +32767.

On Macintosh */C* is ignored.

Details

The wave's time per point, as determined by its X scaling, must be a valid sampling rate. A value of 1/44100 (CD standard) is typical.

Sound waves can be 8, 16, or 32-bit signed integer waves, or single-precision floating point waves:

- 8-bit integer waves support a sample range of -128 to +127.
- 16-bit integer waves support a sample range of -32768 to +32767.
- 32-bit integer waves are used to hold both 24-bit and 32-bit audio. Use /BITS=24 to tell PlaySound that the wave contains 24-bit instead of 32-bit values.
- 32-bit floating point waves support a range of -1 to +1.

Do not use complex waves with PlaySound.

To play a stereo sound, provide a 2 column wave with the left channel in column 0. Actually, the software will attempt to play as many channels as there are columns in the wave. You can also use multiple 1D waves with the /A flag. To use this method, enclose the list of 1D waves in braces

With the /A flag, the sound plays asynchronously (i.e., the command returns before the sound is finished). If another command is issued before the sound is finished then the new command will wait until the last sound finishes. A PlaySound without the /A flag can play on top of the current sound. The transition between sounds should be seamless on Macintosh but may be slightly delayed on Windows.

It is OK to kill the sound wave immediately after PlaySound returns even if the /A flag is used.

Examples

Under Windows, support for sound is somewhat idiosyncratic so these sound examples may not work correctly with your particular hardware configuration.

```
Make/B/O/N=1000 sineSound           // 8 bit samples
SetScale/P x,0,1e-4,sineSound       // Set sample rate to 10Khz
sineSound= 100*sin(2*Pi*1000*x)     // Create 1Khz sinewave tone
PlaySound sineSound
```

The following example will create a rising pitch in the left channel and a falling pitch in the right channel:

```
Make/W/O/N=(20000,2) stereoSineSound // 16 bit data
SetScale/P x,0,1e-4, stereoSineSound // Set sample rate to 10Khz
stereoSineSound= 20000*sin(2*Pi*(1000 + (1-2*q)*150*x)*x)
PlaySound/A stereoSineSound         // 16 bit, asynchronous
```

Multichannel sounds as in the previous example but from multiple 1D waves:

```
Make/W/O/N=20000 stereoSineSoundL, stereoSineSoundR // 16 bit data
SetScale/P x,0,1e-4, stereoSineSoundL, stereoSineSoundR // Set sample rate to 10Khz
stereoSineSoundL= 20000*sin(2*Pi*(1000 + 150*x)*x) // rising pitch in left
stereoSineSoundR= 20000*sin(2*Pi*(1000 - 150*x)*x) // falling in right
PlaySound/A {stereoSineSoundL, stereoSineSoundR} // two 1D waves
```

See Also

SoundLoadWave, SoundSaveWave

pnt2x

pnt2x(waveName, pointNum)

The pnt2x function returns the X value of the named wave at the point *pointNum*. The point number is truncated to an integer before use.

For higher dimensions, use **IndexToScale**.

Details

The result is derived from the wave's X scaling, not any X axis of a graph it may be displayed in.

If you would like to convert a fractional point number to an X value you can use:

```
leftx(waveName) + deltax(waveName) * pointNum.
```

See Also

DimDelta, DimOffset, x2pnt, IndexToScale

Waveform Model of Data on page II-62 and **Changing Dimension and Data Scaling** on page II-68 for an explanation of waves and dimension scaling.

Point

The Point structure is used as a substructure usually to store the location of the mouse on the screen.

```
Structure Point
  Int16 v
  Int16 h
EndStructure
```

PointF

The PointF structure is the same as Point but with floating point fields.

```
Structure Point
  float v
  float h
EndStructure
```

poissonNoise

poissonNoise (*num*)

The poissonNoise function returns a pseudo-random value from the Poisson distribution whose probability distribution function is

$$f(x; \lambda) = \frac{e^{-\lambda} \lambda^x}{x!}, \quad \begin{array}{l} \lambda > 0 \\ x = 0, 1, 2, \dots \end{array}$$

with mean and variance equal to *num* (= λ).

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

See Also

The **SetRandomSeed** operation.

Noise Functions on page III-390.

Chapter III-12, **Statistics** for a function and operation overview.

poly

poly (*coefsWaveName*, *x1*)

The poly function returns the value of a polynomial function at $x = x1$.

coefsWaveName is a wave that contains the polynomial coefficients. The number of points in the wave determines the number of terms in the polynomial.

If you use poly in a real expression, *x1* must be real and poly returns a real value. The wave containing the coefficients can be real or complex. Complex coefficients are interpreted as real(coef).

If you use poly in a complex expression, *x1* must be complex and poly returns a complex value. The wave containing the coefficients can be real or complex. Real coefficients are interpreted as cmplx(coef,0). Support for complex expressions was added in Igor Pro 9.00.

Examples

```
// Fill wave0 with 100 points containing the polynomial 1 + 2*x + 3*x^2 + 4*x^3
// evaluated over the range from x = -1 to x= 1
Make coefs = {1, 2, 3, 4} // f(x) = 1 + 2*x + 3*x^2 + 4*x^3
Make/N=100/O wave0; SetScale/I x, -1, 1, wave0
wave0 = poly(coefs, x)
Display wave0
```

poly2D

poly2D (*coefsWaveName*, *x1*, *y1*)

The poly2D function returns the value of a 2D polynomial function at $x = x1$, $y = y1$.

PolygonArea

coefsWaveName is a wave that contains the polynomial coefficients. The number of points in the wave determines the number of terms in the polynomial and therefore the polynomial degree.

In a complex expression, `poly2D` requires *x1* and *y1* to be complex numbers, and returns a complex value. The wave containing the coefficients may be real or complex. Real coefficients are interpreted as `cmplx(coef, 0)`. Passing complex coefficients in a real expression will use only the real part of the coefficients.

Details

The coefficients wave contains polynomial coefficients for low degree terms first. All coefficients for terms of a given degree must be present, even if they are zero. Among coefficients for a given degree, those for terms having higher powers of *X* are first. Thus, `poly2D` returns, for a coefficient wave *cw*:

$$f(x,y) = cw[0] + cw[1]*x + cw[2]*y + cw[3]*x^2 + cw[4]*x*y + cw[5]*y^2 + \dots$$

A 2D polynomial of degree *N* has $(N+1)(N+2)/2$ terms.

Poly2D Example 1

Fill *mat1* with the polynomial $1 + 2*x + 2.5*y + 3*x^2 + 3.5*xy + 4*y^2$ evaluated over the range $x = (-1, 1)$ and $y = (-1, 1)$:

```
Function Poly2DExample1()
  Make/O coefs1 = {1, 2, 2.5, 3, 3.5, 4}
  Make/N=(20,20)/O mat1
  SetScale/I x, -1, 1, mat1
  SetScale/I y, -1, 1, mat1
  mat1 = poly2D(coefs1, x, y)
  Display; AppendMatrixContour mat1
End
```

The polynomial is second degree, so the first command above made the wave *coefs* with six elements because $(2+1)(2+2)/2 = 6$.

Poly2D Example 2

Fill *mat2* with the polynomial $1 + 2*x + 3*y + 4*x^2 + 4*y^2 + 5*x^3 + 6*y^3$ evaluated over the range $x = (-1, 1)$ and $y = (-1, 1)$. The first zero eliminates the second-order cross term $x*y$ and the second and third zeros eliminate the third-order cross terms x^2*y and $x*y^2$:

```
Function Poly2DExample2()
  Make/O coefs2 = {1, 2, 3, 4, 0, 4, 5, 0, 0, 6}
  Make/N=(20,20)/O mat2
  SetScale/I x, -1, 1, mat2
  SetScale/I y, -1, 1, mat2
  mat2 = poly2D(coefs2, x, y)
  Display; AppendMatrixContour mat2
End
```

Poly2D Example 3

This example illustrates using `poly2D` in a complex expression:

```
Function Poly2DExample3()
  Make/N=(200,200)/C/O cMat3 // Complex-valued matrix
  SetScale/I x -pi,pi,cMat3
  SetScale/I y -pi,pi,cMat3
  Make/D/O coefs3={1,1.5,2,2.5,3,3.5}
  cMat3 = poly2d(coefs3, cmplx(sin(x),cos(y)), cmplx(cos(x),sin(y)))
  Display; Appendimage cMat3
  ModifyImage cMat3 ctab= {*,*,Rainbow256,0}
  ModifyImage cMat3 imCmplxMode=3 // Display the complex phase
End
```

PolygonArea

PolygonArea(*xWave*, *yWave*)

The `PolygonArea` function returns the area of a simple, closed, convex or nonconvex planar polygon described by consecutive vertices in *xWave* and *yWave*.

A simple polygon has no internal “holes” and its boundary curve does not intersect itself. Both *xWave* and *yWave* must be 1D, real, numerical waves of the same dimensions. The minimum number of vertices is 3. The function uses the shoelace algorithm to compute the area (see theorem 1.3.3 in the reference below). If there is any error in the input, the function returns NaN.

Example

```
Function estimatePi(num)
  Variable num

  Make/O/N=(num+1) xxx,yyy
  xxx=sin(2*pi*x/num)
  yyy=cos(2*pi*x/num)

  Printf "Relative Error=%g\r", (pi-PolygonArea(xxx,yyy))/pi
End
```

References

O'Rourke, Joseph, *Computational Geometry in C*, 2nd ed., Cambridge University Press, New York, 1998.

PolygonOp

PolygonOp [*flags*] [*keyword=value*]

The PolygonOp operation performs operations on planar polygons. Polygons and polygon paths are represented by XY pairs of waves with NaNs separating closed polygons.

The operation performed is specified using the operation keyword. The resulting polygon is returned as an XY pair of waves as specified by the /DSTX and /DSTY flags.

PolygonOp uses the clipper library by Angus Johnson. It was added in Igor Pro 9.00.

Flags

/ADDR=addingRule

addingRule determines how the primary and secondary polygons are added to the primary and secondary paths. The interior of the polygon is defined as the region that would be "filled" using one of the standard fill rules. The even-odd rule applies to scan lines while the other rules are based on winding counts.

addingRule is one of the following:

- 0: Even-odd (default). All odd numbered sub-regions are filled, while even numbered sub-regions are not filled.
- 1: Non-zero. All non-zero winding subregions are filled.
- 2: Positive. All sub-regions with winding counts>0 are filled.
- 3: Negative. All sub-regions with winding counts<0 are filled.

/NCFP

Disables closing the resulting polygons by connecting the last vertex to the first vertex of each output path.

/DIST=dist

Specifies the distance in scaled units (see the /SM flag) below which vertices are stripped. The default value is approximately sqrt(2).

/DSTX=destX

Specifies the X destination wave. The output is corrected for any scaling (see /SM below).

In a user-defined function, if *destX* is a simple wave name, PolygonOp automatically creates a real wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-71 for details.

If you omit /DSTX, the X destination wave defaults to polyOpWaveX in the current data folder.

If *destX* is a simple name and you include /FREE, the X destination is created as a free wave.

PolygonOp

<i>/DSTY=destY</i>	<p>Specifies the Y destination wave. The output is corrected for any scaling (see <i>/SM</i> below).</p> <p>In a user-defined function, if <i>destY</i> is a simple wave name, PolygonOp automatically creates a real wave reference for the destination wave. See Automatic Creation of WAVE References on page IV-71 for details.</p> <p>If you omit <i>/DSTY</i>, the Y destination wave defaults to polyOpWaveX in the current data folder.</p> <p>If <i>destY</i> is a simple name and you include <i>/FREE</i>, the Y destination is created as a free wave.</p>
<i>/FA</i>	<p>Computes the final area of the resulting polygon and stores it in V_area. This is an algebraic (signed) area in contrast to the area returned by PolygonArea which is always non-negative.</p>
<i>/FREE</i>	<p>Creates the output waves specified by <i>/DSTX</i> and <i>/DSTY</i> as free waves.</p>
<i>/JTYP=jointType</i>	<p>Specifies the joint type used when offsetting a polygon. The following joint types are supported:</p> <ul style="list-style-type: none">0: Square joint1: Round joint2: Miter joint <p>Square and round joints may give rise to additional vertices along the path.</p>
<i>/MLMT=miterLimit</i>	<p>When the path consists of two edges connected at an acute angle, the offset could give rise to very long spikes. The miter limit sets the maximum distance in multiples of the offset that vertices can be offset from their original positions before a square joint (see <i>/JTYP</i>) is used. The default value for <i>miterLimit</i> is 2. The <i>miterLimit</i> parameter is scaled by <i>/SM scaleFactor</i>.</p>
<i>/OFST=offset</i>	<p>Applies an offset to the final polygon. For example, if the polygon represents a rectangle, a positive offset creates an inscribing rectangle while a negative offset creates an inscribed rectangle. If the command includes a binary operation between primary and secondary polygon paths then the offset applies to the result of the binary operation. The <i>offset</i> parameter is scaled by <i>/SM scaleFactor</i>.</p>
<i>/Q</i>	<p>Quiet mode. Do not print any information in the history area of the command window.</p>
<i>/RPRC=rPrecision</i>	<p>The rounding precision <i>rPrecision</i> specifies the maximum distance in scaled units that a line segment can deviate from the exact arc. This applies only when <i>/JTYP=1</i> and when offsetting a polygon. The <i>rPrecision</i> parameter is scaled by <i>/SM scaleFactor</i>.</p>
<i>/SM={scaleMethod [,scaleFactor]}</i>	

Specifies a scaling method and a scaling factor used when converting the input data into the internal integer representation employed by the algorithm.

scaleMethod is one of the following:

- 0: No scaling. Floating point vertex locations are converted to integers by simple truncation:

$$V_c = \text{trunc}(V_{in})$$
- 1: Multiplication by *scaleFactor* followed by truncation to integer:

$$V_c = \text{trunc}(V_{in} * \text{scaleFactor})$$
- 2: Scaling followed by rounding to integer:

$$V_c = \text{round}(V_{in} * \text{scaleFactor})$$

scaleFactor must be a finite positive number and defaults to 1.0. All scaling is reversed on output using multiplication by the reciprocal of *scaleFactor*. Depending on the range of your data you may be able to use a scale factor which improves the resolution of the calculation. For example, if your data are $O(1)$ and you use a scale factor of 10 or 100 the resulting conversion into integers will be more accurate. On the other hand, if your data are $O(2^{30})$ a scale factor greater than 1 is not ideal.

/SPT={testPointX, testPointY}

Specifies a single point for testing if the point is inside the primary path polygon. The coordinates of point are scaled using the same scaling as the primary waves. The result of the test is stored in *V_value* with non-zero indicating a point that is inside the polygon.

/Z

Suppresses error reporting. If you use */Z*, check the *V_Flag* output variable to see if the operation succeeded.

PolygonOp

Keywords

`operation=op` You can omit the `operation=op` pair when you are applying an offset to the primary polygon or when testing for `pointsInPoly`. Otherwise, *op* is one of the following:

opN is one of the following:

Intersection	Computes the intersection of the region defined by the primary path or paths and the region defined by the secondary path or paths.
Union	Computes the union between the region defined by the primary path or paths and the region defined by the secondary path or paths.
Difference	Computes the difference between the region defined by the primary path or paths and the region defined by the secondary path or paths.
XOR	Computes the exclusive OR between the regions defined by the primary path or paths and the regions defined by the secondary path or paths. This includes all regions where either the primary or secondary polygons are filled but not where both are filled.
PointInPoly	Tests if the points specified by <i>pointsWaves</i> are inside the target polygon. The results, 0 for a point outside and 1 for inside, are stored in the unsigned byte wave <code>W_inPoly</code> in the current data folder. The target polygon is defined by <i>primaryWaves</i> . The tested points are internally scaled with the same scaling method (<i>/SM</i>) that applies to primary waves. You can perform this test on a target polygon that is a result of any binary polygon operation if you only specify the <i>pointsWaves</i> , for example: <pre>PolygonOp operation=union, primaryWaves={wx,wy}, secondarywaves={sx,sy}, pointsWaves={px,py}</pre>
Area	Computes the polygon area and stores it in <code>V_area</code> when
CleanPolygon	Removes vertices from the primary paths that satisfy one of the following conditions: <ol style="list-style-type: none">1. The vertices lie on a co-linear edge. For every three vertices the middle vertex is removed if it lies close enough (see <i>/DIST</i> above) to the edge connecting the vertices on both of its sides.2. The vertices are situated below a critical distance from an adjacent vertex (see <i>/DIST</i> above). See also the <code>Simplify</code> operation.
MinkowskiDiff	If the primary and secondary paths represent sets of vectors, the Minkowski difference of the two sets is defined as the set formed by subtracting each vector in the primary set from each vector in the secondary set.
MinkowskiSum	If the primary and secondary paths represent sets of vectors, the Minkowski sum of the two sets is defined as the set formed by adding each vector in the primary set to each vector in the secondary set.
Simplify	Removes self-intersections from the input polygons. In case of touching vertices the resulting polygon is split into two polygons.
Reverse	Reverses the polygon paths.

`pointsWaves={pointsXWave, pointsYWave}`

Specifies a pair of 1D waves that define points for testing `pointInPoly`. The waves must have the same number type and the same number of points. The polygon that is used in the test is either the primary polygon, when the operation is `PointInPoly`, or the polygon resulting from the combination of the primary and secondary polygons together with the operation specified by the operation keyword. The waves must contain at least one point.

`primaryWaves={srcXWave, srcYWave}`

Specifies the primary path or paths. In case of more than one path, the paths are separated by a NaN in both waves. Both waves must have the same number type and the same number of points. The waves must contain at least 3 points.

`secondaryWaves={secondaryXWave, secondaryYWave}`

Specifies a the secondary or clipping path or paths. In case of more than one path, the paths are separated by a NaN in both waves. Both waves must have the same number type and the same number of points. The waves must contain at least 3 points.

Details

`PolygonOp` performs various operations on polygon paths that are defined by pairs of 1D real numeric waves. A path is defined by an XY pair of waves that may describe one or more closed polygons. Consecutive polygons are separated by a single NaN value in both path waves.

You must always specify the primary path waves. You must specify the secondary waves if you need to perform a binary polygon operation.

To simplify the computation the input waves are internally mapped into 32-bit signed integer arrays so that vertices correspond to discrete integer pairs (pixels).

To support a broad range of inputs, the operation allows you to specify how the input waves are scaled into integers. Scaling is isotropic; there is currently no support for anamorphic scaling. The scaling factor determines the number of significant figures that remain after conversion to integers. In extreme cases it is advisable to preprocess the polygon waves, e.g., by removing a mean offset and/or applying anamorphic scaling. On output, an inverse scaling is applied with no compensation for the initial truncation or rounding. The inverse scaling is also applied to area calculations.

Output Variables

`PolygonOp` sets the following output variables:

<code>V_flag</code>	Zero if the operation succeeds or to a non-zero error code.
<code>V_value</code>	The <code>pointInPolyResult</code> result for a single point specified using <code>/SPT</code> .
<code>V_area</code>	The area of the resulting polygon corrected for scaling.
<code>S_waveNames</code>	Semicolon separated list of the names of the waves created by the operation.

popup

`popup menuList`

The `popup` keyword is used with `Prompt` statements in Functions and Macros. It indicates that you want a pop-up menu instead of the normal text entry item in a `DoPrompt` simple input dialog (or a Macro's missing parameter dialog (archaic)). `menuList` is a string expression containing a list of items, separated by semicolons, that are to appear in the pop-up menu.

Pop-up menus accept both numeric and string parameters. For numeric parameters, the number of the item selected is placed in the variable. Numbering starts from one. For string parameters, the selected item's text is placed in the string variable.

PopupContextualMenu

Pop-up items support all of the special characters available for user-defined menu definitions (see **Special Characters in Menu Item Strings** on page IV-133) with the exception that items in pop-up menus are limited to 50 bytes, keyboard shortcuts are not supported, and special characters must be enabled.

See Also

Prompt, **DoPrompt**, and **Pop-Up Menus in Simple Dialogs** on page IV-145.

See **WaveList**, **TraceNameList**, **ContourNameList**, **ImageNameList**, **FontList**, **MacroList**, **FunctionList**, **StringList**, and **VariableList** for functions useful in generating lists of Igor objects.

Chapter III-14, **Controls and Control Panels** for details about control panels and controls.

PopupContextualMenu

PopupContextualMenu [/C=(*xpix*, *ypix*) /N /ASYN[=*func*]] *popupStr*

The **PopupContextualMenu** operation displays a pop-up menu.

The menu appears at the current mouse position or at the location specified by the /C flag.

The content of the menu is specified by *popupStr* as a semicolon-separated list of items or, if you include the /N flag, by a user-defined menu definition referred to by the name contained in *popupStr*.

If you omit the /ASYN flag, the menu is tracked and the operation does not return until the user makes a selection or cancels the menu by clicking outside of its window.

If you include /ASYN, the menu is displayed and the operation returns immediately. When the user makes a selection, then the result is sent to the specified function or to the user-defined menu's execution text. You can use /ASYN to allow a background task to continue while a contextual menu is popped up. /ASYN requires Igor Pro 7.00 or later.

Parameters

If *popupStr* specifies the pop-up menu's items (/N is not specified), then *popupStr* is a semicolon-separated list of items such as "yes;no;maybe;", or a string expression that returns such a list, such as **TraceNameList**.

The menu items can be formatted and checked, like user-defined menus can. See **Special Characters in Menu Item Strings** on page IV-133.

If /N is specified, *popupStr* must be the name of a user-defined menu that also has the **popupcontextualmenu** keyword. See Example 3.

Flags

- /ASYN* When used with */N*: The user-defined menu is displayed and operation returns immediately. The result of menu selection is handled by the user-defined menu's execution text. See **User-Defined Menus** on page IV-125.
- /ASYN=func* When used without */N*: The user-defined menu is displayed and operation returns immediately. The result of menu selection or cancellation is handled by calling the named function, which must have the following format:
- ```
Function func (popupStr, selectedText, menuItemNum)
 String popupStr
 String selectedText
 Variable menuItemNum
```
- In Igor Pro 8.05 and later, if the user cancels the menu selection, *selectedText* will be "" and *menuItemNum* will be 0.
- /C=(xpix, ypix)* Sets the coordinates of the menu's top left corner.
- Units are in pixels relative to the top-most window or the window specified by */W*, like the *MOUSEX* and *MOUSEY* values passed to a window hook. See the window hook example, below and **SetWindow**.
- If */C* is not specified, the menu's top left corner appears at the current mouse position.
- /N* Indicates that *popupStr* contains the name of a menu definition instead of containing a list of menu items.
- /W=winName* The */C* coordinates are relative to the top/left corner of the named window or subwindow. If you omit */W*, */C* uses the top-most window having focus.
- When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.
- /W* was added in Igor Pro 7.00.

**Details**

If you omit */N* and */ASYN*, *PopupContextualMenu* sets the following variables:

- V\_flag=0* User cancelled the menu without selecting an item, or there was an error such as an empty *popupStr*.
- V\_flag>=1* 1 if the first menu item was selected, 2 for the second, etc.
- S\_selection* "" if the user cancelled or error, else the text of the selected menu item.

## PopupContextualMenu

---

If you include /N and omit /ASYN, PopupContextualMenu sets the following variables in a manner similar to `GetLastUserMenuInfo`:

V\_kind                    The kind of menu that was selected:

| V_kind | Menu Kind                                                                                                                       |
|--------|---------------------------------------------------------------------------------------------------------------------------------|
| 0      | Normal text menu item, including <b>Optional Menu Items</b> (see page IV-130) and <b>Multiple Menu Items</b> (see page IV-131). |
| 3      | "*FONT*"                                                                                                                        |
| 6      | "*LINESTYLEPOP*"                                                                                                                |
| 7      | "*PATTERNPOP*"                                                                                                                  |
| 8      | "*MARKERPOP*"                                                                                                                   |
| 9      | "*CHARACTER*"                                                                                                                   |
| 10     | "*COLORPOP*"                                                                                                                    |
| 13     | "*COLORTABLEPOP*"                                                                                                               |

See **Specialized Menu Item Definitions** on page IV-132 for details about these special user-defined menus.

V\_flag                    -1 if the user didn't select any item, otherwise V\_flag returns a value which depends on the kind of menu the item was selected from:

| V_kind | V_flag Meaning                                                             |
|--------|----------------------------------------------------------------------------|
| 0      | Text menu item number (the first menu item is number 1).                   |
| 3      | Font menu item number (use S_selection, instead).                          |
| 6      | Line style number (0 is solid line)                                        |
| 7      | Pattern number (1 is the first selection, a SW-NE light diagonal).         |
| 8      | Marker number (1 is the first selection, the X marker).                    |
| 9      | Character as an integer, = char2num(S_selection). Use S_selection instead. |
| 10     | Color menu item (use V_Red, V_Green, V_Blue, and V_Alpha instead).         |
| 13     | Color table list menu item (use S_selection instead).                      |

S\_selection                The menu item text, depending on the kind of menu it was selected from:

| V_kind | S_selection Meaning                     |
|--------|-----------------------------------------|
| 0      | Text menu item text.                    |
| 3      | Font name or "default".                 |
| 6      | Name of the line style menu or submenu. |
| 7      | Name of the pattern menu or submenu.    |
| 8      | Name of the marker menu or submenu.     |
| 9      | Character as string.                    |
| 10     | Name of the color menu or submenu.      |
| 13     | Color table name.                       |

In the case of **Specialized Menu Item Definitions** (see page IV-132), `S_selection` will be the title of the menu or submenu, etc.

`V_Red`, `V_Green`, `V_Blue`, `V_Alpha`

If a user-defined color menu ("\*COLORPOP\*" menu item) was selected then these values hold the red, green, and blue values of the chosen color. The values range from 0 to 65535 - see **RGBA Values**.

Will be 0 if the last user-defined menu selection was not a color menu selection.

If you include `/N` and `/ASYN`, `PopupContextualMenu` sets the following variables:

```
V_flag=0 There was an error such as an empty popupStr or popupStr did not name a compiled
 user-defined menu.

V_flag=-1 No error. The named user menu was valid and no item was selected yet.

S_selection ""
```

If you include `/N` and omit `/ASYN`, `PopupContextualMenu` sets the following variables:

```
V_flag=0 There was an error such as an empty popupStr.

V_flag=-1 No error. popupStr was valid and no item was selected yet.

S_selection ""
```

### Examples

#### Example 1 - *popupStr* contains a list of menu items

```
// Menu formatting example
String checked= "\\M0:!" + num2char(18) + ":" // checkmark code
String items= "first;\M1-;" + checked + "third;" // 2nd is divider, 3rd is checked
PopupContextualMenu items
switch(V_Flag)
 case 1:
 // do something because first item was chosen
 break;
 case 3:
 // do something because first item was chosen
 break;
endswitch
```

#### Example 2 - *popupStr* contains a list of menu items

```
// Window hook example
SetWindow kwTopWin hook=TableHook, hookevents=1 // mouse down events
Function TableHook(infoStr)
 String infoStr

 Variable handledEvent=0
 String event= StringByKey("EVENT",infoStr)
 strswitch(event)
 case "mousedown":
 Variable isContextualMenu= NumberByKey("MODIFIERS",infoStr) & 0x10
 if(isContextualMenu)
 Variable xpix= NumberByKey("MOUSEX",infoStr)
 Variable ypix= NumberByKey("MOUSEY",infoStr)
 PopupContextualMenu/C=(xpix,ypix) "yes;no;maybe;"
 strswitch(S_selection)
 case "yes":
 // do something because "yes" was chosen
 break
 case "no":
 break
 case "maybe":
 // do something because "maybe" was chosen
 break
```

## PopupContextualMenu

---

```
 endswitch
 handledEvent=1
 endif
endswitch
return handledEvent
End
```

### Example 3 - popupStr contains the name of a user-defined menu

```
// User-defined contextual menu example
// dynamic menu (to keep WaveList items updated), otherwise not required.
// contextualmenu keyword is required, and implies /Q for all menu items.
//
// NOTE: Actions here are accomplished by the menu definition's
// execution text, such as DoSomethingWithColor.
// See Example 4 for another approach.
//
Menu "ForContext", contextualmenu, dynamic
 "Hello", Beep
 Submenu "Color"
 "*COLORPOP*", DoSomethingWithColor()
 End
 Submenu "Waves"
 WaveList("*",",",""), /Q, DoSomethingWithWave()
 End
End

Function DoSomethingWithColor()
 GetLastUserMenuInfo
 Print V_Red, V_Green, V_Blue, V_Alpha
End

Function DoSomethingWithWave()
 GetLastUserMenuInfo
 WAVE w = $$_value
 Print "User selected "+GetWavesDataFolder(w,2)
End

// Use this code in a function or macro:
PopupContextualMenu/N "ForContext"
if(V_flag < 0)
 Print "User did not select anything"
endif
```

### Example 4 - popupStr contains the name of a user-defined menu

```
// User-defined contextual menu example
Menu "JustColorPop", contextualmenu
 "*COLORPOP*(65535,0,0)", ;// initially red, empty execution text
End

// Use this code in a function or macro
PopupContextualMenu/C=(xpix, ypix)/N "JustColorPop"
if(V_flag < 0)
 Print "User did not select anything"
else
 Print V_Red, V_Green, V_Blue, V_Alpha
endif
```

### Example 5 - popupStr contains a list of menu items, asynchronous popup result

```
Function YourFunction()
 // Use this code in a function or macro:
 PopupContextualMenu/ASYN=Callback "first;second;third;"
 (YourFunction continues...)
End

// Routine called when/if popup menu item is selected. selectedItem=1 is the first item.
Function Callback(String list, String selectedText, Variable selectedItem)
```

```
Print "Callback: ", list, selectedText, selectedItem
End
```

**Example 6 - popupStr contains the name of a user-defined menu, asynchronous popup result**

```
Function YourFunction()
 PopupContextualMenu/ASYN/N "ForContext"
 (YourFunction continues...)
End
// Selection result is handled in "ForContext" menu's execution texts, as in Example 4
```

**Special Characters in Menu Item Strings** on page IV-133.

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

The **SetWindow** and **PopupMenu** operations.

## PopupMenu

**PopupMenu** [/Z] *ctrlName* [**keyword** = **value** [, **keyword** = **value** ...]]

The PopupMenu operation creates or modifies a pop-up menu control in the target or named window.

For information about the state or status of the control, use the **ControlInfo** operation.

**Parameters**

*ctrlName* is the name of the PopupMenu control to be created or changed.

The following keyword=value parameters are supported:

- align=*alignment*      Sets the alignment mode of the control. The alignment mode controls the interpretation of the *leftOrRight* parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.  
                           If *alignment*=0 (default), *leftOrRight* specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.  
                           If *alignment*=1, *leftOrRight* specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.
- appearance={*kind* [, *platform*]}  
                           Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.  
                           *kind* can be one of default, native, or os9.  
                           *platform* can be one of Mac, Win, or All.  
                           See **Button** and **DefaultGUIControls** for more appearance details.
- bodyWidth=*width*      Specifies an explicit size for the body (nontitle) portion of a PopupMenu control. By default (bodyWidth=0), the body portion autosizes depending on the current text. If you supply a bodyWidth>0, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.
- disable=*d*             Sets user editability of the control.  
                           *d*=0:       Normal.  
                           *d*=1:       Hide.  
                           *d*=2:       Draw in gray state; disable control action.

## PopupMenu

---

|                                    |                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fColor=(r,g,b[,a])</code>    | Sets the initial color of the title. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> . The default is opaque black.<br>To further change the color of the title text, use escape sequences as described for <code>title=titleStr</code> .                                                           |
| <code>focusRing=fr</code>          | Enables or disables the drawing of a rectangle indicating keyboard focus:<br><i>fr</i> =0: Focus rectangle will not be drawn.<br><i>fr</i> =1: Focus rectangle will be drawn (default).<br>On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences. |
| <code>font="fontName"</code>       | Sets the font used for the pop-up title, e.g., <code>font="Helvetica"</code> .                                                                                                                                                                                                                                                                                 |
| <code>fontSize=s</code>            | Sets the font size for the pop-up title.                                                                                                                                                                                                                                                                                                                       |
| <code>fstyle=fs</code>             | <i>fs</i> is a bitwise parameter with each bit controlling one aspect of the font style as follows:<br>Bit 0: Bold<br>Bit 1: Italic<br>Bit 2: Underline<br>Bit 4: Strikethrough<br>See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings.                                                                                             |
| <code>help={helpStr}</code>        | Sets the help for the control.<br><i>helpStr</i> is limited to 1970 bytes (255 in Igor Pro 8 and before).<br>You can insert a line break by putting “\r” in a quoted string.                                                                                                                                                                                   |
| <code>mode=m</code>                | Specifies the pop-up title location.<br><i>m</i> =0: Title is in pop-up menu.<br><i>m</i> =1: Title is to the left of pop-up menu, the chosen menu item appears in the pop-up menu, and menu item number <i>m</i> is initially selected.                                                                                                                       |
| <code>noproc</code>                | Specifies that no procedure is to execute when choosing in the pop-up menu.                                                                                                                                                                                                                                                                                    |
| <code>popColor=(r,g,b[,a])</code>  | Specifies the color initially chosen in the color pop-up palette. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> . See the <b>Colors, Color Tables, Line Styles, Markers, and Patterns</b> section.                                                                                                |
| <code>popmatch=matchStr</code>     | Sets mode to the enabled menu item that matches <i>matchStr</i> . <i>matchStr</i> may be a "wildcard" expression. See <b>StringMatch</b> . If no item is matched, mode is unchanged.                                                                                                                                                                           |
| <code>popvalue=valueStr</code>     | Sets the string displayed by the menu when first created, if mode is not zero. See <b>Popvalue Keyword</b> section.                                                                                                                                                                                                                                            |
| <code>pos={leftOrRight,top}</code> | Sets the position in <b>Control Panel Units</b> of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.                                                                                                                                   |
| <code>pos+={dx,dy}</code>          | Offsets the position of the pop-up in <b>Control Panel Units</b> .                                                                                                                                                                                                                                                                                             |
| <code>proc=procName</code>         | Specifies the procedure to execute when the pop-up menu is clicked. See <b>Pop-up Menu Action Procedure</b> below.                                                                                                                                                                                                                                             |
| <code>rename=newName</code>        | Gives pop-up menu a new name.                                                                                                                                                                                                                                                                                                                                  |
| <code>size={width,height}</code>   | Sets pop-up menu size in <b>Control Panel Units</b> .                                                                                                                                                                                                                                                                                                          |

- `title=titleStr` Sets title of pop-up menu to the specified string expression. Defaults to "" (no title). Using escape codes you can change the font, size, style, and color of the title. See **Annotation Escape Codes** on page III-53 or details.
- `userdata(UDName)=UDStr` Sets the unnamed user data to *UDStr*. Use the optional (*UDName*) to specify a named user data to create. You can retrieve the data using **GetUserData**.
- `userdata(UDName)+=UDStr` Appends *UDStr* to the current unnamed user data. Use the optional (*UDName*) to append to the named *UDStr*.
- `value=itemListSpec` Specifies the pop-up menu's items. *itemListSpec* can take several forms as described below under **Setting The Popup Menu Items**.
- `win=winName` Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Flags

- `/Z` No error reporting.

### Details

The target window, or the window named with the `win=winName` keyword, must be a graph or panel.

### Pop-up Menu Action Procedure

The action procedure for a pop-up menu control takes a predefined `WMPopupAction` structure as a parameter to the function:

```
Function PopupMenuAction(PU_Struct) : PopupMenuControl
 STRUCT WMPopupAction &PU_Struct
 ...
 return 0
End
```

The ": PopupMenuControl" designation tells Igor to include this procedure in the list of available popup menu action procedures in the `PopupMenu` Control dialog used to create a popup menu.

See **WMPopupAction** for details on the `WMPopupAction` structure.

Although the return value is not currently used, action procedures should always return zero.

You may see an old format pop-up menu action procedure in old code:

```
Function PopupMenuAction (ctrlName, popNum, popStr) : PopupMenuControl
 String ctrlName
 Variable popNum // which item is currently selected (1-based)
 String popStr // contents of current popup item as string
 ...
 return 0
End
```

This old format should not be used in new code.

### Setting The Popup Menu Items

This section discusses popup menus containing lists of text items. The next section discusses popup menus for choosing colors, line styles, markers and patterns.

The items in the popup menu are determined by the *itemListSpec* parameter used with the `value` keyword. *itemListSpec* can take several different forms from simple to complex.

No matter what the form, Igor winds up storing an expression that returns a string in the popup menu's internal structure. This expression may be a literal string ("Red;Green;Blue;"), a call to a built-in or user-defined function that returns a string, or the path to a global string variable. Igor evaluates this expression

## PopupMenu

---

when the popup menu is first created and again each time the user clicks on the menu. You can see the string expression for a given popup menu using the PopupMenu Control dialog.

The right form for *itemListSpec* depends on your application. Here is a guide to choosing the right form with the simpler forms first.

### A literal string expression

Use this if you know the items you want in your popup menu when you write the PopupMenu call. For example:

```
Function PopupDemo1() // Literal string
 NewPanel
 PopupMenu popup0, value="Red;Green;Blue;"
End
```

This method is limited to 2500 bytes of menu item text.

### A function call

Use this if you need to compute the popup menu item list when the user clicks the popup menu. The function must return a string containing a semicolon-separated list of menu items. This example creates a popup menu which displays the name of each wave in the current data folder at the time the menu is clicked:

```
Function PopupDemo2() // Built-in function
 NewPanel
 PopupMenu popup0, value=WaveList("*", ";", "")
End
```

You can also use a user-defined function. This example shows how to list waves from other than the current data folder:

```
Function/S MyPopupMenuWaveList()
 DFREF saveDF

 // Create some waves for demo purposes
 saveDF = GetDataFolderDFR()
 NewDataFolder/O/S root:Packages
 NewDataFolder/O/S PopupMenuDemo
 Make/O demo0, demo1, demo2
 SetDataFolder saveDF

 saveDF = GetDataFolderDFR()
 SetDataFolder root:Packages:PopupMenuDemo
 String list = WaveList("*", ";", "")
 SetDataFolder saveDF

 return list
End

Function PopupDemo3() // User-defined function
 NewPanel
 PopupMenu popup0, value=MyPopupMenuWaveList()
End
```

### # followed by a local string variable specifying items

Use this when the popup menu item list is not known when you write the code but you can compute it at runtime. For example:

```
Function PopupDemo4() // Local string variable specifying items
 NewPanel
 String quote = "\""
 String list
 if (CmpStr(IgorInfo(2), "Windows") == 0)
 list = quote + "Windows XP; Windows VISTA;" + quote
 else
 list = quote + "Mac OS X 10.4;Mac OS X 10.5;" + quote
 endif
 PopupMenu popup0, value=#list
End
```

The strange-looking use of the quote string variable is necessary because the parameter passed to the value=# keyword is evaluated once when the PopupMenu command executes and the result of that

evaluation is evaluated again when the PopupMenu is created or clicked. The result of the first evaluation must be a legal string expression.

This method is limited to 2500 bytes of menu item text.

**# followed by a local string variable specifying a function**

Use this when you need to compute the popup menu item list at click time and you need to select the function which computes the list when the popup menu is created. For example:

```
Function/S WindowsItemList()
 String list
 list = "Windows XP; Windows VISTA;"
 return list
End

Function/S MacItemList()
 String list
 list = "Mac OS X 10.4;Mac OS X 10.5;"
 return list
End

Function PopupDemo5() // Local string variable specifying function
 String listFunc
 if (CmpStr(IgorInfo(2),"Windows") == 0)
 listFunc = "WindowsItemList()"
 else
 listFunc = "MacItemList()"
 endif
 NewPanel
 PopupMenu popup0, value=#listFunc
End
```

This form is useful when you create a control panel in an independent module. Since the control panel runs in the global name space, you must specify the independent module name in the invocation of the function that provides the popup menu items. For example:

```
// Calling a non-static function in an independent module from #included code
#pragma IndependentModuleName=IM
.
.
String listFunc= GetIndependentModuleName()+"#PublicFunctionInIndepMod()"
PopupMenu popup0, value=#listFunc

// Calling a static function in an independent module from #included code
#pragma IndependentModuleName=IM
#pragma ModuleName=ModName
.
.
String listFunc= GetIndependentModuleName()+"#ModName#StaticFunctionInIndepMod()"
PopupMenu popup0, value=#listFunc
```

We use `GetIndependentModuleName` rather than hard-coding the name of the independent module so that the code will continue to work if the name of the independent module is changed. Also, because this code does not depend on the specific name of the independent module, it can be added to an independent module via a `#included` procedure file.

Also see **GetIndependentModuleName** and **Independent Modules and Popup Menus** on page IV-239.

**# followed by a quoted literal path to a global string variable**

Use this if you want to compute the popup menu item list before it is clicked, not each time it is clicked. This would be advantageous if it takes a long time to compute the item list, and the list changes only at well-defined times when you can set the global string variable.

The global string variable must exist when the `PopupMenu` command executes and when the menu is clicked. In this example, the `gPopupMenuItems` global string variable is created and initialized when the popup menu is created but can be changed to a different value later before the menu is clicked:

```
Function PopupDemo6() // Global string variable containing list
 NewDataFolder/O root:Packages
 NewDataFolder/O root:Packages:PopupMenuDemo
 String/G root:Packages:PopupMenuDemo:gPopupMenuItems = "Red;Green;Blue;"

 NewPanel
 PopupMenu popup0 ,value=#"root:Packages:PopupMenuDemo:gPopupMenuItems"
End
```

## PopupMenu

---

### # followed by a local string variable containing a path to a global string variable

Use this when the popup menu item list contents will be stored in a global string variable whose location is not known until the popup menu is created. For example:

```
Function PopupDemo7() // Local string containing path to global string
 String graphName = WinName(0, 1, 1) // Name of top graph
 if (strlen(graphName) == 0)
 Print "There are no graphs."
 return -1
 endif

 NewDataFolder/O root:Packages
 NewDataFolder/O root:Packages:PopupMenuDemo

 // Create data folder for graph
 NewDataFolder/O root:Packages:PopupMenuDemo:(graphName)

 String list = "Red;Green;Blue;"
 String/G root:Packages:PopupMenuDemo:(graphName):gPopupMenuItems = list

 NewPanel

 String path // Local string containing path to global string
 path = "root:Packages:PopupMenuDemo:" + graphName + ":gPopupMenuItems"
 PopupMenu popup0, value=#path

 return 0
End
```

### Colors, Color Tables, Line Styles, Markers, and Patterns

You can create PopupMenu controls for color, color tables, line style (dash modes), markers, and patterns. To do so, simply specify the *itemListSpec* parameter to the value keyword as one of `"*COLORPOP*`", `"*COLORTABLEPOP*`", `"*COLORTABLEPOPNONAMES*`", `"*LINESTYLEPOP*`", `"*MARKERPOP*`", or `"*PATTERNPOP*`". In these modes the body of the control will contain a color box, a color table (gradient), a line style sample, a marker, or a pattern sample.

For these special pop-up menus, `mode=0` ("Title in Box" checked) is not used.

For a line style pop-up menu, the mode value is the line style number plus one. Thus line style 0 (a solid line) is `mode=1`.

For a marker pop-up, the mode value is the marker number plus one, and marker 0 (the + marker) is `mode=1`.

For a pattern pop-up, the mode value is the `SetDrawEnv` fillPat number minus 4, so `mode=1` corresponds to `fillpat=5`, the SW-NE lines fill pattern shown above.

For a color table pop-up, the mode value is the `CTabList()` index plus 1, so `mode=1` corresponds to the first item in the list returned by `CTabList`, which is "Grays":

```
ControlInfo $ctrlName // Sets V_Value
Print StringFromList(V_Value-1,CTabList()) // Prints "Grays"
```

`ControlInfo` also returns the color table name in `S_Value`.

To set the pop-up to a given color table name, you can use code like this:

```
Variable m = 1 + WhichListItem(ctabName, CTabList())
PopupMenu $ctrlName mode=m
```

For color pop-up menus, you set the current value using the `popColor=(r,g,b[,a])` keyword. On output (via the `popStr` parameter of your action procedure or via the `S_value` output from `ControlInfo`) the color is encoded as `"(r,g,b)"` or `"(r,g,b,a)"`. To get these numerical values, you can extract them from the string using the `MyRGBStrToRGB` function below or use `ControlInfo` which sets `V_Red`, `V_Green`, `V_Blue` and `V_Alpha`.

The following example demonstrates the line style and color pop-up menus. To run the example, copy the following code to the procedure window of a new experiment and then run the panel macro.

```
Window Panel0() : Panel
 PauseUpdate; Silent 1 // building window ...
 NewPanel /W=(150,50,400,182)
 PopupMenu popup0,pos={74,31},size={96,20},proc=ColorPopupMenuProc,title="colors"
 PopupMenu popup0,mode=1,popColor=(0,65535,65535),value="*COLORPOP*"
 PopupMenu popup1,pos={9,68},size={221,20},proc=LStylePopupMenuProc
```

```

 PopupMenu popup1,title="line styles",mode=1,value= "*LINESTYLEPOP*"
EndMacro

Function ColorPopupMenuProc(ctrlName,popNum,popStr) : PopupMenuControl
 String ctrlName
 Variable popNum
 String popStr

 Variable r,g,b,a
 MyRGBStrToRGB(popStr,r,g,b,a) // One way to get r, g, b
 print popStr," gives: ",r,g,b,a

 ControlInfo $ctrlName // Another way: Sets V_Red,V_Green,V_Blue,V_Alpha
 Printf "ControlInfo returned (%d,%d,%d,%d)\r", V_Red, V_Green, V_Blue, V_Alpha

 return 0
End

// Take (r,g,b, and possibly a) as a string and extract numeric r,g,b,a values
Function MyRGBStrToRGB(rgbStr,r,g,b,a)
 String rgbStr
 Variable &r, &g, &b, &a

 if (CmpStr(rgbStr[0], "(") == 0)
 rgbStr = rgbStr[1,inf]
 endif
 r = str2num(StringFromList(0, rgbStr, ","))
 g = str2num(StringFromList(1, rgbStr, ","))
 b = str2num(StringFromList(2, rgbStr, ","))
 a = 65535
 if (itemsinList(rgbStr) > 3)
 a = str2num(StringFromList(3, rgbStr, ","))
 endif
End

Function LStylePopupMenuProc(ctrlName,popNum,popStr) : PopupMenuControl
 String ctrlName
 Variable popNum
 String popStr

 Print "style:",popNum-1

 return 0
End

```

### Popvalue Keyword

There are times when the displayed value cannot be determined and saved such that it can be displayed when the pop-up menu is recreated. For instance, because window recreation macros are evaluated in the root folder, a pop-up menu of waves may not contain the correct list when a panel is recreated. That is, the intention may be to have the menu show a particular wave from a data folder other than root. When the panel recreation macro runs, the function that lists waves will list waves in the root data folder. The desired selection may be wrong or nonexistent.

Similarly, a pop-up menu of fonts may need to display a particular font upon recreation on a different computer having a different list of fonts. The mode=*m* keyword probably won't pick the correct font from the new list.

The solution to these problems is to save the correct selection with the popvalue=*valueStr* keyword. The list function will not be executed when the menu is first created. If the menu is popped, the list function will be evaluated, and the correct list will be displayed then.

It is a good idea to set the mode=*m* keyword to the correct number, if it is known. That way, when the menu is popped the correct item is chosen.

Normally you can let Igor redraw the pop-up menu when it redraws the graph or control panel containing it. However, there are situations in which you may want to force the pop-up menu to be redrawn. This can be done using the **ControlUpdate** operation.

Chapter III-14, **Controls and Control Panels**, for details about control panels and controls.

**Control Panel Units** on page III-444 for a discussion of the units used for controls.

The **GetUserData** function for retrieving named user data.

The **ControlInfo** operation for information about the control.

## PopupMenuControl

---

The `ControlUpdate`, `WaveList`, and `TraceNameList` operations.  
**Special Characters in Menu Item Strings** on page IV-133.

## PopupMenuControl

### PopupMenuControl

PopupMenuControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined pop-up menu control. See **Procedure Subtypes** on page IV-204 for details. See **PopupMenu** for details on creating a popup menu control.

## PossiblyQuoteName

### PossiblyQuoteName (*nameStr*)

The PossiblyQuoteName function returns the input name string if it conforms to the rules of standard wave or Data Folder names. If it does not, then the name is returned in single quotes. This is used when generating a command string that you will pass to the Execute command. You might get the input name string from a function such as `NameOfWave` or `CsrXWave`.

### Examples

```
Print PossiblyQuoteName("wave0") // prints wave0
Print PossiblyQuoteName("wave 0") // prints 'wave 0'
```

### Details

See **Programming with Liberal Names** on page IV-168 for an example.

## Preferences

### Preferences [/Q] [*newPrefsState*]

The Preferences operation sets or displays the state of user preferences.

User preferences affect the creation of *new* graphs, panels, tables, layouts, notebooks, procedure windows, and the command window. They also affect the appearance of waves appended to graphs and tables, and objects appended to layouts.

### Parameters

If *newPrefsState* is present, it sets the state of user preferences as follows:

*newPrefsState*=0: Preferences off (use factory defaults).  
*newPrefsState*=1: Preferences on.

If *newPrefsState* is omitted, the state of user preferences is printed in the history area.

### Flags

/Q Disables printing to the history.

### Details

The Preferences operation sets the variable `V_flag` to the state of user preferences that were in effect *before* the Preferences command executed: 1 for on, 0 for off.

You can also set the state of Preferences with the Misc menu.

Under most circumstances we want procedures to be independent of preferences so that a particular procedure will do the same thing regardless of the state of preferences. To achieve this, preferences are automatically off when you initiate procedure execution. When execution is complete, the state of preferences is restored to what it was before.

If you want preferences to be in effect during procedure execution, you must turn it on with the Preferences operation.

If the preferences setting is changed by a procedure, the effect of the call is propagated down the calling chain. If a macro changes the preferences setting, that change is undone when the macro returns. If a function changes the preferences setting, the change persists after the function returns. However, even with a function, the changed preferences state does not persist when Igor regains control.

**Examples**

```
Function Test()
 Variable oldPrefState
 Preferences 1; oldPrefState=V_flag // remember prefs setting
 Make wave0=x
 Display wave0 // Display uses preferences
 Preferences oldPrefState // put prefs back, like a macro would
End
```

**See Also**

Chapter III-18, **Preferences**.

**PrimeFactors**

**PrimeFactors** [/Q] *inNumber*

PrimeFactors calculates the prime factors of *inNumber*. By default factors are printed in the history and are also stored in the wave *W\_PrimeFactors* in the current data folder.

**Flags**

/Q                    Suppresses printing of factors in the history area.

**Details**

The largest number that this operation can handle is  $2^{32}-1$ .

**Print**

**Print** [*flags*] *expression* [, *expression*]...

The Print operation prints the evaluated expressions in the history area.

**Parameters**

An expression can be a wave, a numeric expression (e.g.,  $3*\pi/4$ ), a string expression (e.g., "Today is " + date()), or a individual structure element or an entire structure variable.

**Flags**

/C                    Evaluates all numeric expressions as complex.

/D                    Prints a greater number of digits.

/F                    Prints numeric wave data (1D and 2D waves only) using "nice," easily readable formatting.

/LEN=*len*           Sets the string break length to *len* number of bytes. The default is 200 and *len* is clipped to between 200 and 2500.

/S                    Obsolete. Numeric results are printed with a moderate number of digits whether you use /S or not. To print more digits, use /D.

/SR                   Prints a wave subrange for expressions that start as "*waveName* [". Without /SR, such an expression is taken as the start of a numeric expression such as *wave* [3] - *wave* [2]. (You can still use *wave*[*pnt*] but only if it does not start the numeric expression.)

Wave subrange printing is not done with /F.

You can specify a single row or column using [*r*] syntax. For example, to print column 4 of a matrix, use:

```
Print mymat [] [4]
```

**Details**

Numeric expressions are always evaluated in double precision. The /D flag just controls the number of digits displayed.

Print determines if an expression is real, complex, or string from the first symbol in the expression. Usually this works fine, but occasionally Print guesses wrong and you may have to rearrange your expression. For example:

```
Print 1+cmplx(1,2)
```

## printf

---

will give an error because the first symbol, "1", is real but the expression should be complex. Changing this to

```
Print cmplx(1,2)+1
```

will work.

Printing numeric or string expressions involving structure elements must not start with the structure element. Instead an appropriate numeric or string literal must appear first so that Igor can determine what kind of expression to compile. For example rather than

```
Print astruct.astring + "hello"
```

use

```
Print "" + astruct.astring + "hello"
```

Print breaks long strings into multiple lines. If there are no natural breaks (carriage returns or semicolons) within a default length, then it breaks the string arbitrarily.

The default line length is 200 bytes. You can override this using the /LEN flag. The maximum number of bytes that can be printed on a line in the history area is 2500.

When printing waves, you can use either formatted (specified by /F) or unformatted (default) methods. Unformatted output is in an executable syntax for each printed line: `wave={ }`.

**Note:** Executing lines printed from floating point waves will not exactly reproduce the source data due to roundoff or insufficient digits in the printed output.

Printing formatted wave data gives easily (human) readable output, and works best for small 1D and 2D waves. If the data are too large or in an unsupported format (3D or greater, or the wave is text), then the output will be unformatted. Formatting is done using spaces, so the output will look best in a fixed-width font.

Printed wave data, both formatted and unformatted, are limited to no more than 100 lines of output. When the line limit is exceeded a warning message will be printed at the end of the truncated output. For text waves, output is limited to 50 bytes of each string element, and there is no warning when a string is truncated.

## printf

```
printf formatStr [, parameter [, parameter]...]
```

The `printf` operation prints formatted output to the history area.

### Parameters

*formatStr* is a string which specifies the formatting of the output.

The type of the parameter, string or numeric, must agree with the corresponding conversion specification in *formatStr*, or else the results will be indeterminate.

The `printf` parameters can be numeric or string expressions. Numeric and string structure fields are allowed except that complex structure fields and non-numeric (e.g., `WAVE`, `FUNCREF`) structure fields are not allowed.

### Details

The *formatStr* contains literal text and conversion specifications.

A conversion specification starts with the % character and ends with a conversion character (for example, `g`, `e`, `f`, `d`, or `s` as illustrated below). In between the % and the conversion character you may include one or more flag characters, a field width specifier, and a precision specifier. The first % corresponds to the first parameter, the second % corresponds to the second parameter, etc. If *formatStr* contains no % characters, no parameters are expected.

Here are some simple examples. `numVar` is a numeric variable and `strVar` is a string variable.

```
printf "The answer is: %g\r", numVar
printf "Created wave %s\r", strVar
printf "Created wave %s, %d points\r", strVar, numVar
```

`%g` is a general-purpose format (floating point or scientific notation) that represents the value of `numVar`. `%d` is an integer format that represents the value of `numVar`. `%s` specifies that the corresponding parameter (`strVar`) is a string.

The `"\r"` in these examples appends a carriage return to the end of the printed text.

Here is a complex example using all of these elements of a conversion specification:

```
printf "%+015.4f\r", 1e6*PI
```

This prints:

```
The answer is: +003141592.6536
```

`"+"` is a flag character that tells `printf` to put a `+` or `-` sign in front of the number.

`"015"` is a field width specifier that tells `printf` to print the number in a field of at least 15 bytes, padded with leading zeros. Using `"15"` instead of `"015"` would cause `printf` to pad with spaces before the `+` sign instead of zeros after it.

`".4"` is a precision specifier that tells `printf` to print four digits after the decimal point.

`"f"` tells `printf` to use a floating point format.

The most common conversions characters are `"f"` for floating point, `"g"` for general, `"d"` for decimal, and `"s"` for string. They are interpreted as for the `printf()` function in the C programming language.

The escape codes `\t` and `\r` represent the tab and return characters respectively. See **Escape Sequences in Strings** on page IV-14 for more information.

### Printf Flag Characters

The supported flag characters and their meanings are as follows:

- Left align the result in the field.
- + Put a plus or minus sign before the number.
- <space> Put a space before a positive number.
- # Specifies alternate form for e, f, g, and x formats.

The meaning of the precision specifier depends on the numeric format (`%g`, `%e`, `%f`, `%d`, etc.) being used:

- e, E, f Precision specifies number of digits after decimal point.
- g, G Precision specifies maximum number of significant digits.
- d, o, u, x, X Precision specifies minimum number of digits.

You can replace both the field width and precision specifiers with an asterisk. This gets the field width or precision specifier from a parameter. For example:

```
printf "%*.*f\r" 4, 3, 1e6*PI
```

means that the field width is 4 and the precision is 3. You could use numeric expressions instead of the literal numbers to control the field width and precision algorithmically.

### Printf Conversion Characters

Here is a complete list of the conversion characters supported by `printf`:

To include a literal percent character, use two consecutive `%` characters, like this:

```
Variable percentage = 37.3
```

```
Printf "%.1f%% of participants had prior medical conditions", percentage
```

Igor also supports a non-C, WaveMetrics extension to the conversion characters recognized by `printf`. This conversion specification starts with `"%W"`. It is followed by a flag digit and a format character. For example,

```
printf "%W0Ps", 12.345E-6
```

prints `12.345000μs`. In this example, the `"%W0"` introduces the WaveMetrics conversion specification. The `"0"` (zero) following the `"W"` is the flag digit. The `"P"` that follows is the format specifier character, which prints the number using a prefix, in this case, `"μ"`.

There is only one WaveMetrics format specifier character, `"P"`, which prints using a prefix such as `μ`, `m`, `k`, or `M`. It recognizes two flag-digits, `"0"` or `"1"`. Option `"0"` prints with no space between the numeric part

- f** Converts a numeric parameter as [-]ddd.ddd, where the number of digits after the decimal point is determined by the precision specifier and defaults to 6. If the # flag is present, a decimal point will be used even if there are no digits to the right of it.
- This conversion character uses the “round-to-half-even” rule, also known as “banker’s rounding”. When the truncated digits are exactly 0.5000..., the quantity is rounded to an even number. For example:
- ```
Printf "%.0f\r", 15.5 // Prints 16 (rounded up to even)
Printf "%.0f\r", 16.5 // Prints 16 (rounded down to even)
```
- e, E** Converts a numeric parameter as [-]d.ddde+/-dd, where the number of digits after the decimal point is determined by the precision specifier and defaults to 6. If you use “E” instead of “e” then printf uses a capital “E” in the number. If the # flag is present, a decimal point will be used even if there are no digits to the right of it.
- g, G** Converts a numeric parameter using “f” or “e” style conversion depending on the magnitude of the number. “e” is used if the exponent is less than -4 or greater than the precision. “G” uses “f” or “E” style conversion. If the # flag is present, a decimal point will be used even if there are no digits to the right of it and trailing zeros will not be removed.
- d, o, u** Converts a numeric parameter as a signed decimal integer, unsigned octal integer or unsigned decimal integer. The precision defaults to one and specifies the minimum number of digits to print.
- These conversion characters use the “round-away-from-zero” rule, like Igor’s **round** function. For example:
- ```
Printf "%d\r", 15.5 // Prints 16 (rounded away from zero)
Printf "%d\r", 16.5 // Prints 17 (rounded away from zero)
```
- x, X** Converts a numeric parameter as an unsigned hexadecimal integer, rounding floating point values. Also supports integer data up to 64 bits.
- The “x” style uses lower case for the hexadecimal numerals “abcdef” where the “X” style uses upper case.
- The precision defaults to one and specifies the minimum number of digits to print.
- If the # flag is present, the string “0x” or “0X” is prepended to the number if it is not zero.
- s** Converts a string parameter. If a precision is specified, it sets the maximum number of bytes from the string parameter to be printed.
- As of Igor Pro 9.00, there is no limit to the length of the string parameter. It was limited to 2400 bytes in Igor Pro 8 and to 1000 bytes before that.
- b** WaveMetrics extension. Converts a numeric parameter to binary.
- c** Converts a numeric parameter to a single ASCII character.
- %** Prints a % sign. No parameter is used.
- %W** WaveMetrics extension. See description below.

and the prefix character while flag “1” prints with 1 space. Numbers greater than tera or less than femto print using a power of ten notation. Here are a few examples:

```
printf "%.2W0PHz", 12.342E6 // prints 12.34MHz
printf "%.2W1PHz", 12.342E6 // prints 12.34 MHz
printf "%.0W0Ps", 12.342E-6 // prints 12µs
printf "%.0W1Ps", 12.342E-9 // prints 12 ns
```

## PrintGraphs

**PrintGraphs** [*flags*] *graphSpec* [, *graphSpec*]...

The PrintGraphs operation prints one or more graphs.

PrintGraphs prints one or more graphs on a single page from the command line or from a procedure. The graphs can be overlaid or positioned any way you want.

### Parameters

The *graphSpec* specifies the name of a graph to print, the position of the graph on the page and some other options.

### Flags

|                 |                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/C=num</i>   | Renders graphs in black and white ( <i>num=0</i> ) or in color ( <i>num=1</i> ; default).                                                                                                                                                                                                                                                                                                        |
| <i>/D</i>       | Disables high resolution printing. This flag is of use only on Macintosh. It has no effect on Windows.                                                                                                                                                                                                                                                                                           |
| <i>/G=grout</i> | Specifies grout, the spacing between objects, for tiling in prevailing units.                                                                                                                                                                                                                                                                                                                    |
| <i>/I</i>       | Coordinates are in inches.                                                                                                                                                                                                                                                                                                                                                                       |
| <i>/M</i>       | Coordinates are in centimeters.                                                                                                                                                                                                                                                                                                                                                                  |
| <i>/R</i>       | Coordinates are in percent of page size (see <b>Examples</b> ).                                                                                                                                                                                                                                                                                                                                  |
| <i>/PD[=d]</i>  | Displays print dialog. This allows the user to use Print Preview or to print to a file.<br>If present the <i>/PD</i> flag must be the first flag.<br><i>d=0</i> : Default. Prints without displaying the Print dialog.<br><i>d=1</i> : Displays the Print dialog. <i>/PD</i> is equivalent to <i>/PD=1</i> .<br><i>d=2</i> : Displays the Print Preview dialog. Requires Igor Pro 7.00 or later. |
| <i>/S</i>       | Stacks graphs.                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>/T</i>       | Tiles graphs.                                                                                                                                                                                                                                                                                                                                                                                    |

### Details

Graph coordinates are in inches (*/I*) or centimeters (*/M*) relative to the top left corner of the physical page. If none of these options is present, coordinates are assumed to be in points.

The form of a *graphSpec* is:

**graphName** [(*left, top, right, bottom*)] [*/F=f*] [*/T*]

Here are some examples:

```
// Take size and position from window size and position.
PrintGraphs Graph0, Graph1

// Specify size and position explicitly.
PrintGraphs/I Graph0(1, 1, 6, 5)/F=1, Graph1(1, 6, 6, 10)/F=1
```

If the coordinates are missing and the */T* or */S* flags are present before *graphSpec* then the graphs are tiled or stacked. If the coordinates are missing but no */T* or */S* flags are present then the graph is sized and positioned based on its position on the desktop.

Finally there are these *graphSpec* options, which appear after the graph name:

|              |                                     |
|--------------|-------------------------------------|
| <i>/F=f</i>  | Specifies a frame around the graph. |
| <i>f=0</i> : | No frame (default).                 |
| <i>f=1</i> : | Single frame.                       |
| <i>f=2</i> : | Double frame.                       |
| <i>f=3</i> : | Triple frame.                       |
| <i>f=4</i> : | Shadow frame.                       |

## PrintLayout

---

`/T` Graph is transparent. This allows special effects when graphs are overlaid. For this to be effective, the graph and its contents must also be transparent. Graphs are transparent only if their backgrounds are white. Annotations have their own transparent/opaque settings. PICTs may have been created transparent or opaque; an opaque PICT cannot be made transparent.

### Examples

You can put an entire *graphSpec* into a string variable and use the string variable in its place. In this case the name of the string variable must be preceded by the \$ character. This is handy for printing from a procedure and also keeps the PrintGraphs command down to a reasonable number of characters. For example:

```
String spec0, spec1, spec2
spec0 = "Graph0(1, 1, 6, 5)/F=1"
spec1 = "Graph1(1, 6, 6, 10)/F=1"
spec2 = "" // PrintGraphs will ignore spec2.
PrintGraphs/I $spec0, $spec1, $spec2
```

If you use a string for a *graphSpec* and that string contains no characters then PrintGraphs will ignore that *graphSpec*.

### See Also

The **PrintSettings**, **PrintTable**, **PrintLayout** and **PrintNotebook** operations.

## PrintLayout

**PrintLayout** [`/C=num /D`] *winName*

The PrintLayout operation prints the named page layout window.

### Parameters

*winName* is the window name of the page layout to print.

### Flags

`/C=num` Renders graphs, tables, and annotations in black-and-white (*num*=0) or in color (*num*=1; default). It has no effect on pictures, which are colored independently.

`/D` Prints the layout at the default resolution of the output device. Otherwise it is printed at the highest resolution. This flag is of use only on Macintosh. It has no effect on Windows.

### Details

Normally page layouts are printed at the highest available resolution of the output device (printer, plotter, or whatever). On Macintosh, it may not work properly at high resolution with some unusual output devices. If this happens, you can try using the `/D` flag to see if it works properly at the default resolution.

### See Also

The **PrintSettings**, **PrintGraphs**, **PrintTable** and **PrintNotebook** operations.

## PrintNotebook

**PrintNotebook** [*flags*] *notebookName*

The PrintNotebook operation prints the named notebook window.

### Parameters

*notebookName* is either `kwTopWin` for the top notebook window, the name of a notebook window or a host-child specification (an `hcSpec`) such as `Panel0#nb0`. See **Subwindow Syntax** on page III-92 for details on host-child specifications.

**Flags**

|                               |                                                                                                               |
|-------------------------------|---------------------------------------------------------------------------------------------------------------|
| <i>/B=hiResMethod</i>         | <i>Macintosh only</i> ; this flag has no effect on Windows.                                                   |
| <i>hiResMethod=1:</i>         | Print HiRes PICTs using high resolution bitmaps.                                                              |
| <i>hiResMethod=0:</i>         | Don't print HiRes PICTs using high resolution bitmaps.                                                        |
| <i>hiResMethod=-1:</i>        | Print using the default method. Prints HiRes PICTs using high resolution bitmaps and is the same as method 1. |
| <i>/P=(startPage,endPage)</i> | Specifies a page range to print. 1 is the first page.                                                         |
| <i>/S=selection</i>           | Controls what is printed.                                                                                     |
| <i>selection=0:</i>           | Print entire notebook (default).                                                                              |
| <i>selection=1:</i>           | Print selection only.                                                                                         |

**Details**

If no */B* flag is given, the default method of handling HiRes PICTs is used (*/B=1*). Printing of HiRes PICTs is not well supported on the Macintosh, so by default it prints them using temporary high resolution bitmaps. If a future version of the Mac OS improves in this respect, we will change the default method to print directly.

**See Also**

Chapter III-1, **Notebooks**.

The **PrintSettings**, **PrintGraphs**, **PrintTable** and **PrintLayout** operations.

**PrintSettings**

```
PrintSettings [/I /M /W=winName] [copySource=source, orientation=o,
 margins={left,top,right,bottom}, scale=s, colorMode=m, getPrinterList,
 getPrinter, setPrinter=printerNameStr, getPageSettings, getPageDimensions]
```

The **PrintSettings** operation gets or sets parameters associated with printing, such as a list of available printers or page setup information for a particular window.

An exception is the *graphMode* and *graphSize* keyword pair which affect printing of all graphs. This pair was added in Igor Pro 7.00.

Prior to Igor Pro 7.00, **PrintSettings** applied to a page layout affected the size and orientation of the layout page. In Igor Pro 7.00 and later, the size and orientation of the layout page are independent of print settings. See **Page Layout Page Sizes** on page II-466 for details.

When getting or setting page setup information, **PrintSettings** acts on a particular window called the destination window. The destination window is the top graph, table, page layout, or notebook window or the window specified by the */W* flag.

**PrintSettings** can not act on page setup records associated with the command window, procedure windows, help windows, control panel, XOP windows, or any type of window other than graphs, tables, page layouts, and notebooks.

The **PrintSettings** operation services the keywords in the order shown above, not in the order in which they appear in the command. Thus, for example, the *getPageSettings* and *getPageDimensions* keywords report the settings after all other keywords are executed.

## PrintSettings

### Flags

|                    |                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /I                 | Measurements are in inches. If both /I and /M are omitted, measurements are in points.                                                                                                                                      |
| /M                 | Measurements are in centimeters. If both /I and /M are omitted, measurements are in points.                                                                                                                                 |
| /W= <i>winName</i> | Acts on the page setup record of the graph, table, page layout, or notebook window identified by <i>winName</i> . If <i>winName</i> is omitted or if <i>winName</i> is " ", then it used the page setup for the top window. |

### Keywords

|                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| colorMode= <i>m</i>                           | Sets the color mode for the page setup to monochrome ( <i>m</i> =0) or to color ( <i>m</i> =1).<br>This keyword does nothing on Macintosh because it is not supported by Mac OS X.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| copySource= <i>source</i>                     | Copies page setup settings from the specified source to the destination window. <i>source</i> can be the name of a graph, table, page layout, or notebook window or it can be one of the following special keywords:<br>Default_Settings: Sets the page setup record to the default for the associated printer as specified by the printer driver.<br>Factory_Settings: Sets the page setup record to the WaveMetrics factory default. This is the page setup you get when creating a new window with user preferences turned off.<br>Preferred_Settings: Sets the page setup record to the user preferred page setup. This is the page setup you get when creating a new window with user preferences turned on. Because there is only one page setup for all graphs and one page setup for all tables, this has no effect when the destination window is a graph or table. It does work for layouts and notebooks. |
| getPageDimensions                             | Returns page dimensions via the string variable <i>S_value</i> , which contains keyword-value pairs that can be extracted using <b>NumberByKey</b> and <b>StringByKey</b> . See <b>Details</b> for keyword-value pair descriptions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| getPageSettings                               | Returns page setup settings in the string variable <i>S_value</i> , which contains keyword-value pairs that can be extracted using <b>NumberByKey</b> and <b>StringByKey</b> . See <b>Details</b> for keyword-value pair descriptions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| getPrinter                                    | Returns the name of the selected printer for the destination window in the string variable <i>S_value</i> . On Macintosh the returned value will be " " if the setPrinter keyword was never used on the destination window. This means that the window will use the operating system's "current printer".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| getPrinterList                                | Returns a semicolon-separated list of printer names in the string variable <i>S_value</i> .<br>Mac OS X: Returns a list of printers added through Print Center.<br>Windows: Returns the names of any local printers and names of network printers to which the user has made previous connections.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| graphMode= <i>g</i>                           | Sets the printing mode for graphs:<br>1: Fill page<br>2: Same size<br>3: Same aspect ratio<br>4: Custom size as set by graphSize keyword<br>5: Same size or shrink to fit page (default)<br><br>The graphMode keyword was added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| graphSize={ <i>left, top, width, height</i> } |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Sets the custom graph size used when graphMode is 4. Parameters are in points unless /I or /M is used.

Invoking the graphSize keyword automatically sets the graphMode to 4.

*left* and *top* are clipped so that they are no smaller than the minimum allowed by the printer driver. *width* and *height* are not clipped.

This setting is not saved and is set to a default value when Igor starts.

The graphSize keyword was added in Igor Pro 7.00.

margins={*left, top, right, bottom*}

Sets the page margins. Dimensions are in points unless /I or /M is used.

This setting is ignored for notebook windows. Use the Notebook operation pageMargins keyword instead.

The margins are clipped so that they are no smaller than the minimum allowed by the printer driver and no larger than one-half the size of the paper.

The terms *left*, *top*, *right*, and *bottom* refer to the sides of the page after possible rotation for landscape orientation.

Passing zero for all four margins sets the margins to the minimum margin allowed by the printer.

On Macintosh only, passing -1 for all four margins sets the margins to whatever minimum margin is allowed by the printer, even if the printer is changed later. This is how Igor Pro behaved on Macintosh prior to the creation of the PrintSettings operation, when the minimum printer margins were always used.

orientation=*o*

Sets the paper orientation to portrait (*o*=0) or to landscape (*o*=nonzero).

scale=*s*

In Igor Pro 7 and later, the scale keyword returns an “unimplemented” error, unless *s*=100, because it is currently not supported. Let us know if this feature is important to you. Though *s*=100 does not generate an error, it does nothing. You can still set the scaling manually using the Page Setup dialog.

setPrinter=*printerNameStr*

Sets the selected printer for the destination window.

SetPrinter attempts to preserve orientation, margins, scale, and color mode but other settings may revert to the default state.

*printerNameStr* is a name as returned by the getPrinterList keyword and may not be identical to the name displayed in various dialogs. For example, on Mac OS X, the printer name “DESKJET 840C” is returned by getPrinterList as “DESKJET\_840C”. The latter is the “Queue Name” displayed by the Mac OS X Print Center or Printer Setup Utility programs.

If *printerNameStr* is “”, the printer for the destination window is set to the default state. This means different things depending on the operating system:

Mac OS X:           The destination window will use the operating system’s “current printer”, as if the setPrinter keyword had never been used.

Windows:            The destination window will use the system default printer.

If you receive an error when using setPrinter, use the getPrinterList keyword to verify that the printer name you are using is correct. Verify that the printer is connected and turned on.

Windows printer names are sometimes UNC names of the form “\\Server\Printer”. You must double-up backslashes when using a UNC name in a literal string. See **UNC Paths** on page III-453 for details.

## PrintSettings

---

### Details

All graphs in the current experiment share a single page setup record so if you change the page setup for one graph, you change it for all graphs.

All tables in the current experiment share a single page setup record.

Each page layout window has its own page setup record.

Each notebook window has its own page setup record.

The keyword-value pairs for the `getPageSettings` keyword are as follows:

| Keyword      | Information Following Keyword                                                                                                                                                                    |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORIENTATION: | 0 if the page is in portrait orientation, 1 if it is in landscape orientation.                                                                                                                   |
| MARGINS:     | The left, top, right, and bottom margins in points, separated by commas.<br>These margins are ignored for notebook windows. Use the Notebook operation <code>pageMargins</code> keyword instead. |
| SCALE:       | The page scaling expressed in percent. 50 means that the graphics are drawn at 50% of their normal size.                                                                                         |
| COLORMODE:   | 0 for black&white, 1 for color. This is not supported on Macintosh and always returns 1.                                                                                                         |

---

The keyword-value pairs for the `getPageDimensions` keyword are as follows:

| Keyword    | Information Following Keyword                                                                                                                                                                                                                                                                                                             |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PAPER:     | The left, top, right, and bottom coordinates of the paper in points, separated by commas. The top and left are negative numbers so that the page can start at (0,0).                                                                                                                                                                      |
| PAGE:      | The left, top, right, and bottom coordinates of the page in points, separated by commas. The term page refers to the part of the paper inside the margins. The top/left corner of the page is always at (0, 0).                                                                                                                           |
| PRINTAREA: | The left, top, right, and bottom coordinates of the page in points, separated by commas. The print area is the part of the paper on which printing can occur, as determined by the printer. This is equal to the paper inset by the minimum supported margins. The top and left are negative numbers so that the page can start at (0,0). |

---

### Examples

For an example using the `PrintSettings` operation, see the `PrintSettings Tests` example experiment file in the "Igor Pro Folder:Examples:Testing" folder.

Here are some simple examples showing how you can use the `PrintSettings` operation.

```
Function GetOrientation(name) // Returns 0 (portrait) or 1 (landscape)
 String name // Name of graph, table, layout or notebook

 PrintSettings/W=$name getPageSettings
 Variable orientation = NumberByKey("ORIENTATION", S_value)
 return orientation
End

Function SetOrientationToLandscape(name)
 String name // Name of graph, table, layout or notebook

 PrintSettings/W=$name orientation=1
End

Function/S GetPrinterList()
 PrintSettings getPrinterList
 return S_value
End

Function SetPrinter(destWinName, printerName)
 String destWinName, printerName

 PrintSettings/W=$destWinName setPrinter=printerName
 return 0
End
```

**See Also**

The **PrintGraphs**, **PrintTable**, **PrintLayout** and **PrintNotebook** operations.

**PrintTable**

**PrintTable** [/P=(*startPage*,*endPage*) /S=*selection*] *winName*

The PrintTable operation prints the named table window.

**Parameters**

*winName* is the window name of the table to print.

**Flags**

*/P*=(*startPage*,*endPage*) Specifies a page range to print. 1 is the first page.  
If */P* is omitted all pages are printed unless */S* is used.

*/S*=*selection* Controls what is printed.

*selection*=0: Print entire table (default).  
*selection*=1: Print selection only.

**See Also**

Chapter II-12, **Tables**.

The **PrintSettings**, **PrintGraphs**, **PrintLayout** and **PrintNotebook** operations.

**Proc**

**Proc** *macroName*( [*parameters*] ) [:*macro type*]

The Proc keyword introduces a macro that does not appear in any menu. Otherwise, it works the same as **Macro**. See **Macro Syntax** on page IV-118 for further information.

**ProcedureText**

**ProcedureText**(*macroOrFunctionNameStr* [, *linesOfContext* [, *procedureWinTitleStr*] ] )

The ProcedureText function returns a string containing the text of the named macro or function as it exists in some procedure file, optionally with additional lines that are before and after to provide context or to collect documenting comments.

Alternatively, all of the text in the specified procedure window can be returned.

**Parameters**

*macroOrFunctionNameStr* identifies the macro or function. It may be just the name of a global (nonstatic) procedure, or it may include a module name, such as "myModule#myFunction" to specify the static function myFunction in a procedure window that contains a #pragma ModuleName=myModule statement.

If *macroOrFunctionNameStr* is set to "", and *procedureWinTitleStr* specifies the title of a single procedure window, then all of the text in the procedure window is returned.

*linesOfContext* optionally specifies the number of lines around the function to include in the returned string. The default is 0 (no additional contextual lines of text are returned). This parameter is ignored if *macroOrFunctionNameStr* is "" and *procedureWinTitleStr* specifies the title of a single procedure window.

Setting *linesOfContext* to a positive number returns that many lines before the procedure and after the procedure. Blank lines are not omitted.

Setting *linesOfContext* to -1 returns lines before the procedure that are not part of the preceding macro or function. Usually these lines are comment lines describing the named procedure. Blank lines are omitted.

Setting *linesOfContext* to -n, where n>1, returns at most n lines before the procedure that are not part of the preceding macro or function. Blank lines are not omitted in this case. n can be -inf, which acts the same as -1 but includes blank lines.

The optional *procedureWinTitleStr* can be the title of a procedure window (such as "Procedure" or "File Name Utilities.ipf"). The text of the named macro or function in the specified procedure window is returned.

## ProcGlobal

---

You can use *procedureWinTitleStr* to select one of several static functions with identical names among different procedure windows, even if they do not use a `#pragma moduleName=myModule` statement.

### Advanced Parameters

If `SetIgorOption IndependentModuleDev=1`, *procedureWinTitleStr* can also be a title followed by a space and, in brackets, an independent module name. In such cases `ProcedureText` retrieves function text from the specified procedure window and independent module. (See **Independent Modules** on page IV-236 for independent module details.)

For example, in a procedure file containing:

```
#pragma IndependentModule=myIM
#include <Axis Utilities>
```

A call to `ProcedureText` like this:

```
String text=ProcedureText("HVAxisList",0,"Axis Utilities.ipf [myIM]")
```

will return the text of the `HVAxisList` function located in the `Axis Utilities.ipf` procedure window, which is normally a hidden part of the `myIM` independent module.

You can see procedure window titles in this format in the `Windows→Procedure Windows` menu when `SetIgorOption IndependentModuleDev=1` and when an experiment contains procedure windows that comprise an independent module, as does `#include <New Polar Graphs>`.

*procedureWinTitleStr* can also be just an independent module name in brackets to retrieve function text from any procedure window that belongs to the named independent module:

```
String text=ProcedureText("HVAxisList",0,"[myIM]")
```

### See Also

**Regular Modules** on page IV-234 and **Independent Modules** on page IV-236.

The **WinRecreation** and **FunctionList** functions.

## ProcGlobal

### ProcGlobal#procPictureName

The `ProcGlobal` keyword is used with `Proc Pictures` to avoid possible naming conflicts with any other global pictures in the experiment. When you add a picture to an experiment using the `Pictures` dialog, such a picture is global in scope and may potentially have the same name as a `Proc Picture`. When a `Proc Picture` is global (and only then), you should use the `ProcGlobal` keyword to make sure that the `Proc Picture` is used with your code and to avoid confusion with pictures in the `Pictures` dialog.

### See Also

See **Proc Pictures** on page IV-56 for details. **Pictures Dialog** on page III-511.

## Project

```
Project [/C={long,lat}/M=method /P={p1,p2,...}] longitudeWave, latitudeWave
```

The `Project` operation calculates projections of `XY` data, which most often are longitude and latitude waves of geographic coordinates. The output waves are `W_XProjection` and `W_YProjection`. Longitude and Latitude are in degrees.

### Parameters

*longitudeWave* is the name of the wave supplying the longitude or equivalent coordinates. *latitudeWave* is the name of the wave supplying the latitude or equivalent coordinates.

### Flags

`/C={long,lat}` Specifies longitude and latitude center of projection. By default `long=0` and `lat=90`.

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/M=method</i>      | Indicates the type of projection. <i>method</i> can be one of the following: <ol style="list-style-type: none"> <li>0: Orthographic (default).</li> <li>1: Stereographic.</li> <li>2: Gnomonic.</li> <li>3: General perspective.</li> <li>4: Lambert equal area.</li> <li>5: Equidistant.</li> <li>6: Mercator.</li> <li>7: Transverse Mercator.</li> <li>8: Albers Equal Area conic.</li> <li>9: Eckert IV (Igor Pro 9.00 or later)</li> <li>10: Winkel III (Igor Pro 9.00 or later)</li> </ol> |
| <i>/P={p1,p2,...}</i> | One or more parameters required by a particular projection. See the following sections for parameters required by the various projections.                                                                                                                                                                                                                                                                                                                                                       |

### Gnomonic

Here there is one extra parameter that defines the boundaries based on the angle. The specific expression for the limit is that  $\cos(c)$  in Eq. (5-3) of Snyder is greater than the specified parameter:

$/P=\{\cos(c)\}$

The actual transformation uses Eqs. (22-4) and (22-5) of Snyder with  $k'$  given by (22-3).

### General Perspective

Here there is one extra parameter that defines the boundaries based on the angle. The specific expression for the limit is that  $\cos(c)$  in Eq. (5-3) of Snyder is greater than the specified parameter.

The actual transformation uses Eqs. (22-4) and (22-5) with  $k'$  given by (22-3). Here we specify the height  $H$  is units of sphere radius. The tilt of the plane is specified by  $\omega$  and  $\gamma$  following the notation of Snyder page 175.

The parameters actually specified by the command are:

$/P=\{H, \omega, \gamma, \text{deltax}, \text{deltay}\}$

$H$  is the height (in radii) above the surface of the earth,  $\gamma$  is the azimuth east of north of the Y axis, and  $\omega$  is the tilt angle or the angle between the projection plane and the tangent plane. The x output will be limited to  $\pm \text{deltax}$  and the y output will be limited to the range  $\pm \text{deltay}$ .

### Mercator

This projection requires the following parameters:

$/P=\{\text{minLong}, \text{maxLong}, \text{minLat}, \text{maxLat}\}$

If  $/P$  is not specified, the default is  $\{0,360,-90,90\}$

Note that this projection flips the sign of  $y$  when  $\cos(\text{longitude}-\text{long}_0)$  changes sign. If you are plotting a continuous path in which consecutive points exhibit the sign change, you should add a NaN entry in the wave so that the path does not wrap.

### Albers Equal Area Conic

This projection requires:

$/P=\{\text{minLong}, \text{maxLong}, \text{minLat}, \text{maxLat}, \text{Phi1}, \text{Phi2}\}$

$\text{Phi1}$  and  $\text{Phi2}$  are the specification of the two standard parallels, the other four parameters determine the boundary of the map area for display.

## Prompt

---

### Prompt

**Prompt** *variableName*, *titleStr* [, *popup*, *menuListStr*]

The Prompt command is used in functions for the simple input dialog and in macros for the missing parameter dialog. Prompt supplies text to describe *variableName* to the user, and optionally provides a pop-up menu of choices for the value of *variableName*.

#### Parameters

*variableName* is the name of a macro input parameter or function variable.

*titleStr* is a string or string expression containing the text to present in the dialog to describe what *variableName* is. *titleStr* is limited to 255 bytes.

The optional keyword *popup* is used to provide a pop-up list of choices for the values of *variableName*. If *popup* is used, then *menuListStr* is required.

*menuListStr* is a string or string expression that contains a semicolon-separated list of choices for the value of *variableName*. If *variableName* is a string, choosing from this list will set the string to the selection. If it is a numeric variable, then it is set to the item number of the selection (if the first item is selected, the numeric variable is set to 1, etc.).

#### Details

In macros, there must be a blank line after the set of input parameter declarations and prompt statements and there must not be any blank lines within the set.

In user-defined functions, Prompt may be used anywhere within the body of the function, but must precede any DoPrompt that uses the Prompt variable.

*menuListStr* may be continued on succeeding lines only in macros, as long as no comment is appended to the Prompt line. The additional lines should start with a semicolon, and are appended to the *menuListStrs* on preceding lines.

For use in user-defined functions, see **The Simple Input Dialog** on page IV-144.

For use in macros, see **The Missing Parameter Dialog** on page IV-122.

For use in functions and macros, see the **DoPrompt** and **popup** keywords.

## PulseStats

**PulseStats** [*flags*] *waveName*

The PulseStats operation produces simple statistics on a region of the named wave that is expected to contain three edges as shown below. If more than three edges exist, PulseStats works on the first three edges it finds.

PulseStats handles other cases in which there are only one or two edges.

**Case 2:** 2 edges.  
There is no point 3

**Case 3:** 1 edge.  
There is no point 2 or 3

## Flags

- /A=*n*** Determines *startLevel* and *endLevel* automatically by averaging *n* points centered at *startX* and *endX*. This does not work in case 2, which requires that you use the **/L** flag. Default is **/A=1**.
- /B=*box*** Sets box size for sliding average. This should be an odd number. If **/B=*box*** is omitted or *box* equals 1, no averaging is done.
- /F=*f*** Specifies levels 1, 2, and 3 as a fraction of (*endLevel*-*startLevel*):  

$$\text{level1} = \text{level2} = \text{level3} = f * (\text{endLevel} - \text{startLevel}) + \text{startLevel}$$
*f* must be between 0 and 1. The default value is 0.5 which sets the levels to midway between the base levels.
- /L=(*startLevel*, *endLevel*)**  
 Sets *startLevel* and *endLevel* explicitly.
- /M=*dx*** Sets minimum edge width. Once an edge is found, the search for the next edge starts *dx* units beyond the found edge. Default *dx* is 0.
- /P** Output edge locations (see **Details**) are set in terms of point number. If **/P** is omitted, edge locations are set in terms of X values.
- /Q** Prevents results from being printed in history and prevents error if edge is not found.
- /R=(*startX*, *endX*)** Specifies an X range of the wave to search. You may exchange *startX* and *endX* to reverse the search direction.
- /R=[*startP*, *endP*]** Specifies a point range of the wave to search. You may exchange *startP* and *endP* to reverse the search direction.  
 If you specify the range as **/R=[*startP*]** then the end of the range is taken as the end of the wave. If **/R** is omitted, the entire wave is searched.
- /T=*dx*** Forces search in two directions for a possibly more accurate result. *dx* controls where the second search starts.

## Details

The **/B=*box***, **/T=*dx***, **/P** and **/Q** flags behave the same as for the **FindLevel** operation.

PulseStats considers a region of the input wave between two X locations, called *startX* and *endX*. *startX* and *endX* are set by the **/R=(*startX*, *endX*)** flag. If this flag is missing, *startX* and *endX* default to the start and end of the entire wave.

The *startLevel* and *endLevel* values define the base levels of the pulse. You can explicitly set these levels with the **/L=(*startLevel*, *endLevel*)** flag or you can let PulseStats find the base levels for you by using the **/A=*n*** flag. With this flag, PulseStats determines *startLevel* and *endLevel* by averaging *n* points centered at *startX* and at *endX*. In case 2, you must use **/L=(*startLevel*, *endLevel*)** since *startLevel* is not at point 0.

## PutScrapText

---

Given *startLevel* and *endLevel* and an *f* value (which you can set with the */F=f* flag), PulseStats computes level1, level2 and level3 which are always equal. With the default *f* value of 0.5, level1 is midway between *startLevel* and *endLevel*.

With these levels defined, PulseStats searches the wave from *startX* to *endX* looking for one, two or three level crossings. PulseStats sets the following variables:

|                 |                                                                                                                            |
|-----------------|----------------------------------------------------------------------------------------------------------------------------|
| V_flag          | 0: All three level crossings were found.<br>1: One or two level crossings were found.<br>2: No level crossings were found. |
| V_PulseLoc1     | X location where level1 was found.                                                                                         |
| V_PulseLoc2     | X location where level2 was found.                                                                                         |
| V_PulseLoc3     | X location where level3 was found.                                                                                         |
| V_PulseLvl0     | <i>startLevel</i> value.                                                                                                   |
| V_PulseLvl123   | Level1 value that is the same as level2 and level3.                                                                        |
| V_PulseLvl4     | <i>endLevel</i> value.                                                                                                     |
| V_PulseAmp4_0   | Pulse amplitude ( <i>endLevel</i> - <i>startLevel</i> ).                                                                   |
| V_PulseWidth2_1 | Left pulse width (x distance between point 2 and point 1).                                                                 |
| V_PulseWidth3_2 | Right pulse width (x distance between point 3 and point 2).                                                                |
| V_PulseWidth3_1 | Pulse period (x distance between point 3 and point 1).                                                                     |
| V_PulsePolarity | Trend of the edge at point 1 (-1 if decreasing, +1 if increasing).                                                         |

X locations and distances are in terms of the X scaling of the source wave, unless you use the */P* flag in which case they are in terms of point number.

If any level crossings are missing then PulseStats sets the associated variables to NaN (Not a Number). If one crossing is missing, variables depending on point 3 are set to NaN. If two crossings are missing, variables depending on points 2 and 3 are set to NaN. If all crossings are missing, variables depending on points 1, 2, and 3 are set to NaN. You can use the numtype function to test a variable to see if it is NaN.

The PulseStats operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details.

### See Also

The **FindLevel** operation about the */B=box*, */T=dx*, */P* and */Q* flags, **EdgeStats** and the **numtype** function.

## PutScrapText

**PutScrapText** *textStr*

The PutScrapText operation places *textStr* on the Clipboard (aka "scrap"). This text will be used when the user subsequently chooses Paste from the Edit menu.

### Details

All contents of the Clipboard (including pictures) are cleared before the text is placed there.

### Examples

Put two lines of text into the Clipboard:

```
String text = "This is the first line.\r\nAnd this is the second."
PutScrapText text
```

Empty the Clipboard:

```
PutScrapText ""
```

### See Also

The **GetScrapText** function and the **SavePICT** operation.

## pwd

### pwd

The pwd operation prints the full path of the current data folder to the history area. It is equivalent to Print GetDataFolder(1).

pwd is named after the UNIX "print working directory" command.

### See Also

GetDataFolder, cd, Dir, Data Folders on page II-107

## q

### q

The q function returns the current column index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled column index is available as the y function.

### Details

Unlike p, outside of a wave assignment statement, q does not act like a normal variable.

### See Also

Waveform Arithmetic and Assignments on page II-74.

For other dimensions, the p, r, and s functions.

For scaled dimension indices, the x, y, z and t functions.

## qcsr

**qcsr**(*cursorName* [, *graphNameStr*])

The qcsr function can be used with cursors on images or waterfall plots to return the column number. It can also be used with free cursors to return the relative Y coordinate.

### Parameters

*cursorName* identifies the cursor, which can be cursor A through J.

*graphNameStr* specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### See Also

The hcsr, pcsr, vcsr, xcsr, and zcsr functions.

Programming With Cursors on page II-309.

## Quit

**Quit** [/N/Y]

The Quit operation quits Igor Pro.

### Flags

|    |                                                                                                             |
|----|-------------------------------------------------------------------------------------------------------------|
| /N | Quits without saving changes and without dialog.                                                            |
| /Y | Saves current experiment before quitting without putting up dialog unless current experiment is "Untitled". |

## r

### r

The r function returns the current layer index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled layer index is available as the z function.

### Details

Unlike p, outside of a wave assignment statement, r does not act like a normal variable.

## r2polar

---

### See Also

**Waveform Arithmetic and Assignments** on page II-74. For other dimensions, the **p**, **q**, **s**, and **t** functions. For scaled dimension indices, the **x**, **y**, **z**, and **t** functions.

## r2polar

### r2polar (z)

The r2polar function returns a complex value in polar coordinates derived from the complex value *z*, which is assumed to be in rectangular coordinates. The magnitude is stored in the real part and the angle (in radians) is stored in the imaginary part of the returned complex value.

### Examples

Assume waveIn and waveOut are complex.

```
waveOut= r2polar(waveIn)
```

sets each point of waveOut to the polar coordinates derived from the real and imaginary parts of waveIn.

You may get unexpected results if the number of points in waveIn differs from the number of points in waveOut.

### See Also

The functions **cmplx**, **conj**, **imag**, **p2rect**, and **real**.

## RatioFromNumber

### RatioFromNumber [flags] num

The RatioFromNumber operation computes two integers whose ratio is equal to  $num \pm maxError$  (/MERR flag). The ratio is returned in V\_numerator and V\_denominator.

### Parameters

*num* is the number to approximate by V\_numerator/V\_denominator.

### Flags

- /MERR=*maxError* Specifies the maximum tolerable error. The computed ratio differs from *num* by no more than *maxError* (default value is  $num * 1e-6$ ).  
*maxError* must be a value between 0 and *num*. See Details about setting *maxError* to 0.
- /MITS = *maxIterations* Keeps returned values small by specifying a small number for *maxIterations*.  
*maxIterations* must be a value between 1 and 32767 (default is 100).
- /V[=*v*] Prints output variables to history.  
*v*=1: Prints variables (same as /V).  
*v*=0: Nothing printed (same as no /V).

### Details

The ratio is computed by continued fraction expansion and recurrence relations for the convergents and checking  $num - (V\_numerator/V\_denominator)$  against *maxError*.

Setting *maxError* = 0 computes a maximally accurate ratio. The returned values can be surprisingly large:

```
RatioFromNumber/V/MERR=0 (1/1666)
 V_numerator= 4398046511104; V_denominator= 7.3271454874993e+15;
 ratio= 0.00060024009603842; V_difference= 0;
```

Using the default /MERR returns the expected 1 and 1666. The difference is attributable to floating-point roundoff errors.

The ratio is computed by continued fraction expansion and recurrence relations for the convergents and checking  $num - (V\_numerator/V\_denominator)$  against /MERR.

### Output Variables

RatioFromNumber sets the following output variables:

V\_difference    V\_numerator/V\_denominator - *num* (positive if the approximation is too big).

`V_flag`            0: `V_difference` less than or equal to `/MERR`.  
                       1: `V_difference` greater than `/MERR`.

`V_numerator, V_denominator`

                      Values for the numerator and denominator. The ratio of `V_numerator/V_denominator` approximates *num*.

`V_iterations`     The number of iterations actually used.

### Examples

```
RatioFromNumber/V pi
 V_numerator= 355; V_denominator= 113; ratio= 3.141592920354;
 V_difference= 2.6676418940497e-07; V_iterations= 3;

RatioFromNumber/V/MITS=2 pi
 V_numerator= 22; V_denominator= 7; ratio= 3.1428571428571;
 V_difference= 0.0012644892673497; V_iterations= 1;
```

### See Also

The `gcd` and `trunc` functions.

## Rect

The `Rect` structure is used as a substructure usually to store the coordinates of a window or control.

```
Structure Rect
 Int16 top
 Int16 left
 Int16 bottom
 Int16 right
EndStructure
```

## RectF

The `RectF` structure is the same as `Rect` but with floating point fields.

```
Structure RectF
 float top
 float left
 float bottom
 float right
EndStructure
```

## ReadVariables

### ReadVariables

The `ReadVariables` operation reads variables into an experiment.

`ReadVariables` is used automatically when you open an experiment. You need not invoke it.

## real

### real(z)

The `real` function returns the real component of the complex value `z`.

### See Also

The functions `cmplx`, `conj`, `imag`, `p2rect`, and `r2polar`.

## Redimension

`Redimension [flags] waveName [, waveName]...`

The `Redimension` operation remakes the named waves, preserving their contents as much as possible.

### Flags

`/B`            Converts waves to 8-bit signed integer or unsigned integer if `/U` is present.

`/C`            Converts real waves to complex.

## Remez

---

|                                  |                                                                                                                                                                                                                                                                                                          |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/D</code>                  | Converts single precision waves to double precision.                                                                                                                                                                                                                                                     |
| <code>/E=e</code>                | Controls the redimension mode:<br><code>e=0</code> : No special action (default).<br><code>e=1</code> : Force reshape without converting or moving data.<br><code>e=2</code> : Perform endian swap. See <b>FBinRead</b> for a discussion of endian byte ordering.                                        |
| <code>/I</code>                  | Converts waves to 32-bit signed integer or unsigned integer if <code>/U</code> is present.                                                                                                                                                                                                               |
| <code>/L</code>                  | Converts waves to 64-bit signed integer or unsigned integer if <code>/U</code> is present. Requires Igor Pro 7.00 or later.                                                                                                                                                                              |
| <code>/N=n</code>                | <code>n</code> is the new number of points each wave will have. Multidimensional waves are converted to 1 dimension. If <code>n=-1</code> , the wave is converted to a 1-dimensional wave with the original number of rows.                                                                              |
| <code>/N=(n1, n2, n3, n4)</code> | <code>n1, n2, n3, n4</code> specify the number of rows, columns, layers, and chunks each wave will have. Trailing zeros can be omitted (e.g., <code>/N=(n1, n2, 0, 0)</code> can be abbreviated as <code>/N=(n1, n2)</code> ). If any dimension size is to remain unchanged, pass -1 for that dimension. |
| <code>/R</code>                  | Converts complex waves to real by discarding the imaginary part.                                                                                                                                                                                                                                         |
| <code>/S</code>                  | Converts double precision waves to single precision.                                                                                                                                                                                                                                                     |
| <code>/U</code>                  | Converts integer waves to unsigned.                                                                                                                                                                                                                                                                      |
| <code>/W</code>                  | Converts waves to 16-bit integer (unsigned integer if <code>/U</code> is present).                                                                                                                                                                                                                       |
| <code>/Y=type</code>             | Specifies wave data type. See details below.                                                                                                                                                                                                                                                             |

### Wave Data Types

As a replacement for the above number type flags you can use `/Y=numType` to set the number type as an integer code. See the **WaveType** function for code values. Do not use `/Y` in combination with other type flags. This technique cannot be used to change the number type without changing the real/complex setting.

### Details

The waves must already exist. New points in waves that are extended are zeroed.

In general, Redimension does not move data from one dimension to another. For instance, if you have a 6x6 matrix wave, and you would like it to be 3x12, the rows have been shortened and the data for the last three rows is lost.

As a special case, if converting to or from a 1D wave, Redimension will leave the data in place while changing the dimensionality of the wave. For example, you can use Redimension to convert a 36-element 1D wave into a 6x6 matrix in which the elements in the first column (column 0) are the first 6 elements of the 1D wave, the elements of the second column are the next 6, etc. When redimensioning from a 1D wave, columns are filled first, then layers, followed by chunks.

### Examples

Reshaping a 1D wave having 4 elements to make a 2x2 matrix:

```
Make/N=4 vector=x
Redimension/N=(2,2) vector
```

## Remez

Remez [`/N=num` `/Q=[iter]`] *frWave, wtWave, gridWave, coefsWave*

The Remez operation calculates the coefficients for digital filters given a desired frequency response as input.

Remez is primarily used for the MPR filter feature of the Igor Filter Design Laboratory (IFDL) package.

**Parameters**

*frWave* contains the desired response.

*wtWave* contains the weight function array. For a differentiator, the weight function is inversely proportional to frequency.

*gridWave* contains the frequencies corresponding to each point in *frWave* and *wtWave*. Its values range from 0 to 0.5 with gaps where the band edges occur.

*coefsWave* receives the resulting coefficients. Its length defines the number of coefficients (nfil in the IEEE program referenced below).

**Flags**

*/N=mode*                    *mode=0*: Selects multiple passband/stopband filter (default).  
                               *mode=1*: Selects differentiator or Hilbert transform filter.

*/Q[=iter]*                    Determines if execution stops if the filter doesn't converge.  
                               If you omit */Q*, execution stops if the filter doesn't converge.  
                               If you specify */Q* or */Q=0*, execution continues if the filter doesn't converge, regardless of the number of iterations.  
                               For *iter*>=1, execution stops if the filter fails to converge in *iter* iterations or less. If the filter does converge after *iter* iterations, execution does stop.  
                               Use */Q=3* to stop execution for serious errors (after only 1, 2, or 3 iterations) but not for minor errors (after 4 or more iterations).

**Details**

Remez returns symmetrical coefficients suitable for use with **FilterFIR** in *coefsWave*.

The algorithm is based upon the McClellan-Parks-Rabiner Fortran program as found in the IEEE and Elliot references cited below.

If the filter converged, Remez sets *V\_Flag* to 0. Otherwise it sets it to the number of iterations before it failed.

**Example**

This example specifies a length 41 lowpass filter with passband 0 to 0.14 x *fs* and stopband 0.18 x *fs* to 0.5 x *fs*. The passband weight is equal to the stopband weight.

```
Make/O/N=41 coefs = NaN
Make/O/N=(41*16) fr, wt, grid
grid = 0.5*p/numpts(grid) // Frequencies where fr and wt define desire response
wt = 1
fr[0,0.14*numpts(fr)] = 1 // Low pass from 0 to 0.14 x fs
// Remove transition frequencies
DeletePoints 0.14*numpts(fr), 0.04*numpts(fr), fr, wt, grid
// Compute filter coefs
Remez fr, wt, grid, coefs
// Analyze the filter's frequency response
FFT/OUT=3/PAD={256}/DEST=coefs_FFT coefs
// Display filter response for 1Hz sample rate
Display coefs_FFT
```

## Remove

---

### See Also

FMaxFlat, FilterFIR

## Remove

### Remove

When interpreting a command, Igor treats the Remove operation as **RemoveFromGraph**, **RemoveFromTable**, or **See Also**, depending on the target window. This does not work when executing a user-defined function. Therefore, we recommend that you use **RemoveFromGraph**, **RemoveFromTable**, or **RemoveLayoutObjects** rather than Remove.

## RemoveByKey

**RemoveByKey**(*keyStr*, *kwListStr* [, *keySepStr* [, *listSepStr* [, *matchCase*]])

The RemoveByKey function returns *kwListStr* after removing the keyword-value pair specified by *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1, KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use RemoveByKey to remove information from a string containing a "key1:value1;key2:value2;" or "key1=value1, key2=value2," style list such as those returned by functions like **AxisInfo** or **TraceInfo**.

If *keyStr* is not found then *kwListStr* is returned unchanged.

*keySepStr*, *listSepStr*, and *matchCase* are optional; their defaults are ":", ";", and 0 respectively.

### Details

*kwListStr* is searched for an instance of the key string bound by *listSepStr* on the left and a *keySepStr* on the right. The key, the *keySepStr*, and the text up to and including the next *listSepStr* (if any) are removed from the returned string.

If the resulting string contains only *listSepStr* characters, then an empty string (" ") is returned.

*kwListStr* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are usually case-insensitive. Setting the optional *matchCase* parameter to 1 makes the comparisons case sensitive.

In Igor6, only the first byte of *keySepStr* and *listSepStr* was used. In Igor7 and later, all bytes are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *matchCase* is specified, *keySepStr* and *listSepStr* must be specified.

### Examples

```
Print RemoveByKey("AKEY", "AKEY:123;BKEY:val") // prints "BKEY:val"
Print RemoveByKey("AKEY", "akey=1;BK=b;", "=") // prints "BK=b;"
Print RemoveByKey("AKEY", "AKEY=1,BK=b,", "=", ",") // prints "BK=b,"
Print RemoveByKey("ckey", "CKEY:1;BKEY:2") // prints "BKEY:2"
Print RemoveByKey("ckey", "CKEY:1;BKEY:2", ":", ";", 1) // prints "CKEY:1;BKEY:2"
```

## RemoveContour

**RemoveContour** [/W=*winName*] *contourInstanceName* [, *contourInstanceName*]

The RemoveContour operation removes the traces, and releases memory associated with the contour plot of *contourInstanceName* in the target or named graph.

### Parameters

*contourInstanceName* is usually simply the name of a wave. More precisely, *contourInstanceName* is a wave name, optionally followed by the # character and an instance number to identify which contour plot of a given wave is to be removed.

**Flags**

|                                |                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/ALL</code>              | Removes all contour plots from the graph. Any contour name parameters listed are ignored. <code>/ALL</code> was added in Igor Pro 9.00.                                                                                                                                                                                                                                  |
| <code>/W=<i>winName</i></code> | Removes contours from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |

**Details**

If the axes used by the contour plot are no longer in use, they will also be removed.

A contour instance name in a string can be used with the `$` operator to specify *contourInstance*.

**Examples**

```
Display;AppendMatrixContour zw //new graph, contour of zw matrix
AppendMatrixContour zw //two contours of zw
RemoveContour zw#1 //remove the second contour
```

**See Also**

The **AppendMatrixContour** and **AppendXYZContour** operations.

## RemoveEnding

**RemoveEnding**(*str* [, *endingStr*])

The RemoveEnding function removes one character from the end of *str*, or it removes the *endingStr* from the end of *str*.

The RemoveEnding function returns *str* with *endingStr* removed from the end. If you omit *endingStr*, it returns *str* with one grapheme removed from the end.

**Details**

If you specify *endingStr*, RemoveEnding compares it to the end of *str* using case-insensitive comparison. If there is a match, RemoveEnding returns the contents of *str* up to *endingStr*. If there is no match, RemoveEnding returns the entirety of *str*.

If you omit *endingStr*, RemoveEnding returns *str* with the last grapheme removed. A grapheme is whatever visually appears to be one character even if it consists of more than one character. In "ABC", the last grapheme is "C" which is also the last character. In "ABÇ", "Ç" consists of two characters: a C character and a "combining cedilla" character; RemoveEnding removes "Ç" which is the last grapheme.

**Examples**

```
Print RemoveEnding("123") // Prints "12"
Print RemoveEnding("ABÇ") // Prints "AB"
Print RemoveEnding("no semi" , ";") // Prints "no semi"
Print RemoveEnding("trailing semi;" , ";") // Prints "trailing semi"
Print RemoveEnding("file.txt" , ".TXT") // Prints "file"
```

**See Also**

The **CmpStr** and **ParseFilePath** functions.

## RemoveFromGizmo

**RemoveFromGizmo** [*flags*]

The RemoveFromGizmo operation removes the specified object from the specified list and optionally performs an update.

Documentation for the RemoveFromGizmo operation is available in the Igor online help files only. In Igor, execute:

```
DisplayHelpTopic "RemoveFromGizmo"
```

### RemoveFromGraph

`RemoveFromGraph [/W=winName/Z] traceName [, traceName]...`

The `RemoveFromGraph` operation removes the specified wave traces from the target or named graph. A trace is a representation of the data in a wave, usually connected line segments.

#### Parameters

*traceName* is usually just the name of a wave.

More generally, *traceName* is a wave name, optionally followed by the # character and an instance number - for example, `wave0#1`. See **Instance Notation** on page IV-20 for details.

#### Flags

|                                |                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/ALL</code>              | Removes all non-contour traces from the graph. Any trace name parameters listed are ignored. <code>/ALL</code> was added in Igor Pro 9.00.                                                                                                                                                                                                                             |
| <code>/W=<i>winName</i></code> | Removes traces from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |
| <code>/Z</code>                | Suppresses errors if specified trace or image is not on the graph.                                                                                                                                                                                                                                                                                                     |

#### Details

Up to 100 *traceNames* may be specified, subject to the 2500 byte command length limit.

If the axes used by the given trace are not in use after removing the trace, they will also be removed.

A string containing a trace name can be used with the \$ operator to specify *traceName*.

Specifying  `$"#0"`  for *traceName* removes the first trace in the graph.  `$"#1"`  removes the second trace in the graph, and so on.  `$""`  is equivalent to  `$"#0"` .

Note that removing all the contour traces from a contour plot is not the same as removing the contour plot itself. Use the **RemoveContour** operation.

#### Examples

The command:

```
Display myWave,myWave;Modify mode(myWave#1)=6
```

appends two instances of `myWave` to the graph. The first/backmost instance of `myWave` is instance 0, and its trace name is just `myWave` as a synonym for `myWave#0`. The second or frontmost instance of `myWave` is `myWave#1` and it is displayed with the cityscape mode.

To remove the second instance from the graph requires the command:

```
RemoveFromGraph myWave#1
```

or

```
String MyTraceName="myWave#1"
RemoveFromGraph $MyTraceName
```

#### See Also

**Trace Names** on page II-270, **Programming With Trace Names** on page IV-87.

### RemoveFromLayout

`RemoveFromLayout objectSpec [, objectSpec]...`

Deprecated — use **RemoveLayoutObjects**.

The `RemoveFromLayout` operation removes the specified objects from the top layout.

#### Parameters

*objectSpec* is either an object name (e.g., `Graph0`) or an *objectName* with an instance (e.g., `Graph0#1`). An instance is needed only if the same object appears in the layout more than one time. `Graph0` is equivalent to `Graph0#0` and `Graph0#1` refers to the second instance of `Graph0` in the layout.

**See Also**

The **RemoveLayoutObjects** operation.

**RemoveFromList**

```
RemoveFromList(itemOrListStr, listStr [, listSepStr [, matchCase]])
```

The **RemoveFromList** function returns *listStr* after removing the item or items specified by *itemOrListStr*. *listStr* should contain items separated by *listSepStr* which typically is ";".

If *itemOrListStr* contains multiple items, they should be separated by the *listSepStr* character, too.

Use **RemoveFromList** to remove item(s) from a string containing a list of items separated by a string (usually a single ASCII character), such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

If all items in *itemOrListStr* are not found or if any of the arguments is "" then *listStr* is returned unchanged (unless *listStr* contains only list separators, in which case an empty string is returned).

*listSepStr* and *matchCase* are optional; their defaults are ";" and 1 respectively.

**Details**

*itemStr* may have any length.

*listStr* is searched for an instance of the item string(s) bound by *listSepStr* on the left and right. All instances of the item(s) and any trailing *listSepStr* (if any) are removed from the returned string.

If the resulting string contains only *listSepStr* characters, then an empty string ("") is returned.

*listStr* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *listSepStr* are case-sensitive. Searches for *items* in *itemOrListStr* are usually case-sensitive. Setting the optional *matchCase* parameter to 0 makes the comparisons case insensitive.

In Igor6, only the first byte of *listSepStr* was used. In Igor7 and later, all bytes are used.

If *matchCase* is specified, then *listSepStr* must also be specified.

**Examples**

```
Print RemoveFromList("wave1", "wave0;wave1;") // prints "wave0;"
Print RemoveFromList("wave1", ";wave1;;;") // prints ""
Print RemoveFromList("KEY=joy", "AX=3,KEY=joy", ",") // prints "AX=3,"
Print RemoveFromList("fred", "fred\twilma", "\t") // prints "wilma"
Print RemoveFromList("fred;barney", "fred;wilma;barney") // prints "wilma;"
Print "X"+RemoveFromList("", ";;;")+"Y" // prints "XY"
Print RemoveFromList("FRED", "fred;wilma") // prints "fred;wilma"
Print RemoveFromList("FRED", "fred;wilma", ";", 0) // prints "wilma"
```

**See Also**

The **FindListItem**, **FunctionList**, **ItemsInList**, **RemoveByKey**, **RemoveListItem**, **StringFromList**, **StringList**, **TraceNameList**, **UpperStr**, **VariableList**, and **WaveList** functions.

**RemoveFromTable**

```
RemoveFromTable [/W=winName] columnSpec [, columnSpec]...
```

The **RemoveFromTable** operation removes the specified columns from the top table.

**Parameters**

*columnSpecs* are the same as for the **Edit** operation; usually they are just the names of waves.

**Flags**

|                   |                                                                                                                                                                                                                                                                              |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/W=winName</i> | Removes columns from the named table window or subwindow. When omitted, action will affect the active window or subwindow.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**See Also**

**Edit** about *columnSpecs*, and **AppendToTable**.

## RemoveImage

---

### RemoveImage

**RemoveImage** [/W=*winName*/Z] *imageInstance* [, *imageInstance*]...

The RemoveImage operation removes the given image from the target or named graph.

#### Parameters

*imageInstance* is usually simply the name of a wave. More precisely, *imageInstance* is a wave name, optionally followed by the # character and an instance number to identify which image of a given wave is to be removed.

#### Flags

- |                    |                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /ALL               | Removes all image plots from the graph. Any image name parameters listed are ignored. /ALL was added in Igor Pro 9.00.                                                                                                                                                                                                                                              |
| /W= <i>winName</i> | Removes an image from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. Must be the first flag specified when used in a Proc or Macro or on the command line.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |
| /Z                 | Suppresses errors if specified image is not on the graph.                                                                                                                                                                                                                                                                                                           |

#### Details

If the axes used by the given image are not in use after removing the image, they will also be removed.

An image name in a string can be used with the \$ operator to specify *imageInstance*.

#### See Also

The **AppendImage** operation.

### RemoveLayoutObjects

**RemoveLayoutObjects** [/PAGE=*page*/W=*winName*/Z] *objectSpec* [, *objectSpec*]

The RemoveLayoutObjects operation removes the specified object or objects from the top page layout, or from the layout specified by the /W flag. It targets the active page or the page specified by the /PAGE flag.

Unlike the RemoveFromLayout operation, RemoveLayoutObjects can be used in user-defined functions. Therefore, RemoveLayoutObjects should be used in new programming.

#### Parameters

*objectSpec* is either an object name (e.g., Graph0) or an *objectName* with an instance (e.g., Graph0#1). An instance is needed only if the same object appears in the layout more than one time. Graph0 is equivalent to Graph0#0 and Graph0#1 refers to the second instance of Graph0 in the layout.

#### Flags

- |                    |                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /PAGE= <i>page</i> | Removes the object from the specified page.<br><br>Page numbers start from 1. To target the active page, omit /PAGE or use <i>page</i> =0.<br><br>The /PAGE flag was added in Igor Pro 7.00. |
| /W= <i>winName</i> | <i>winName</i> is the name of the page layout window from which the object is to be removed. If /W is omitted or if <i>winName</i> is \$ " ", the top page layout is used.                   |
| /Z                 | Does not report errors if the specified layout object does not exist.                                                                                                                        |

#### See Also

**NewLayout**, **AppendLayoutObject**, **ModifyLayout**, **LayoutPageAction**

### RemoveListItem

**RemoveListItem**(*index*, *listStr* [, *listSepStr* [, *offset*]])

The RemoveListItem function returns *listStr* after removing the item specified by the list index *index*.

RemoveListItem removes an item from a string containing a list of items separated by a separator, such as strings returned by functions like **TraceNameList** and **AnnotationList**.

#### Parameters

*index* is the zero-based index of the list item that you want to remove.

*listStr* contains a series of text items separated by *listSepStr*. The trailing separator is optional though recommended.

*listSepStr* is optional. If omitted it defaults to ";". Prior to Igor Pro 7.00, only the first byte of *listSepStr* was used. Now all bytes are used.

*offset* is optional and requires Igor Pro 7.00 or later. If omitted it defaults to 0. The search begins *offset* bytes into *listStr*. When iterating through lists containing large numbers of items, using the *offset* parameter provides dramatically faster execution. For an example using the offset parameter, see **StringFromList**.

#### Details

RemoveListItem differs from **RemoveFromList** in that it specifies the item to be removed by index and removes only that item, while RemoveFromList specifies the item to be removed by value, and removes all matching items.

If *index* less than 0 or greater than `ItemsInList(listStr) - 1`, or if *listSepStr* is "" then *listStr* is returned unchanged (unless *listStr* contains only list separators, in which case an empty string is returned).

If the resulting string contains only *listSepStr* characters, then an empty string ("") is returned.

#### Examples

```
Print RemoveListItem(1, "wave0;wave1;w2;") // Prints "wave0;w2;"
```

## RemovePath

**RemovePath** [/A/Z] *pathName*

The RemovePath operation removes a path from the list of symbolic paths. RemovePath is an old name for the new **KillPath** operation, which we recommend you use instead.

## Rename

**Rename** *oldName*, *newName*

The Rename operation renames waves, strings, or numeric variables from *oldName* to *newName*.

#### Parameters

*oldName* may be a simple object name or a data folder path and name. *newName* must be a simple object name.

#### Details

You can not rename an object using a name that already exists. The following will result in an error:

```
Make wave0, wave1
// Rename wave0 and overwrite wave1.
Rename wave0, wave1 // This will not work.
```

However, you can achieve the desired effect as follows:

```
Make wave0, wave1
Duplicate/O wave0, wave1; KillWaves wave0
```

#### See Also

The **Duplicate** operation.

### RenameDataFolder

**RenameDataFolder** *sourceDataFolderSpec, newName*

The `RenameDataFolder` operation changes the name of the source data folder to the new name.

*sourceDataFolderSpec* can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

*newName* is just the new name for the data folder, without any path.

#### Details

`RenameDataFolder` generates an error if the new name is already in use as a data folder contained within the source data folder.

#### Examples

```
RenameDataFolder root:foo,foo2 // Change name of foo to foo2
```

#### See Also

Chapter II-8, **Data Folders**.

### RenamePath

**RenamePath** *oldName, newName*

The `RenamePath` operation renames an existing symbolic path from *oldName* to *newName*.

#### See Also

**Symbolic Paths** on page II-22

### RenamePICT

**RenamePICT** *oldName, newName*

The `RenamePICT` operation renames an existing picture to from *oldName* to *newName*.

#### See Also

**Pictures** on page III-509.

### RenameWindow

**RenameWindow** *oldName, newName*

The `RenameWindow` operation renames an existing window or subwindow from *oldName* to *newName*.

#### Parameters

*oldName* is the name of an existing window or subwindow.

When identifying a subwindow with *oldName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

#### See Also

The **DoWindow** operation.

## ReorderImages

**ReorderImages** [/W=*winName*] *anchorImage*, {*imageA*, *imageB*, ...}

The ReorderImages operation changes the ordering of graph images to that specified in the braces.

### Flags

*/W=winName* Reorders images in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Details

Igor keeps a list of images in a graph and draws the images in the listed order. The first image drawn is consequently at the bottom. All other images are drawn on top of it. The last image is the top one; no other image obscures it.

ReorderImages works by removing the images in the braces from the list and then reinserting them at the location specified by *anchorImage*. If *anchorImage* is not in the braces, the images in braces are placed before *anchorImage*.

If the list of images is A, B, C, D, E, F, G and you execute the command

```
ReorderImages F, {B,C}
```

images B and C are placed just before F: A, D, E, **B, C, F**, G.

The result of

```
ReorderImages E, {D,E,C}
```

is to reorder C, D and E and put them where E was. Starting from the initial ordering this gives A, B, **D, E, C**, F, G.

ReorderImages generates an error if the same trace is in the list twice.

In Igor7 or later, *anchorImage* can be `_front_` or `_back_`. To move A to the front, you can write:

```
ReorderImage _front_, {A}
```

### See Also

The **ReorderTraces** operation.

### ReorderTraces

```
ReorderTraces [/W=winName /L[=axisName] /R[=axisName]] anchorTrace, {traceA,
traceB, ...}
```

The ReorderTraces operation changes the ordering of graph traces to that specified in the braces.

#### Flags

- /W=*winName** Reorders traces in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
- When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.
- /L[=*axisName*]* Moves traces to a new or existing axis. This feature was added in Igor Pro 8.00.
- /R[=*axisName*]* To reference the built-in left or right axes, you can use /L or /R without specifying the axis name. To reference a free axis, you must specify the axis name.
- If the specified axis does not already exist, a new axis is created by cloning the axis controlling *traceA*.
- If the move results in no traces assigned to an axis, then that axis is deleted.
- Reordering is optional. Specify *\_none\_* for *anchorTrace* for no reordering.
- You can move a trace manually by right-clicking a trace and choosing Move to Opposite Axis.

#### Details

Igor keeps a list of traces in a graph and draws the traces in the listed order. The first trace drawn is consequently at the bottom. All other traces are drawn on top of it. The last trace is the top one; no other trace obscures it.

ReorderTraces works by removing the traces in the braces from the list and then reinserting them at the location specified by *anchorTrace*. If *anchorTrace* is not in the braces, the traces in braces are placed before *anchorTrace*.

If the list of traces is A, B, C, D, E, F, G and you execute the command

```
ReorderTraces F, {B,C}
```

traces B and C are placed just before F: A, D, E, **B, C, F**, G.

The result of

```
ReorderTraces E, {D,E,C}
```

is to reorder C, D and E and put them where E was. Starting from the initial ordering results in A, B, **D, E, C, F, G**.

ReorderTraces generates an error if the same trace is in the list twice.

In Igor7 or later, *anchorImage* can be *\_front\_* or *\_back\_*. To move A to the front, you can write:

```
ReorderTraces _front_, {A}
```

The **ReorderImages** operation.

### ReplaceNumberByKey

```
ReplaceNumberByKey(keyStr, kwListStr, newNum [, keySepStr
[, listSepStr [, case]]])
```

The ReplaceNumberByKey function returns *kwListStr* after replacing the numeric value of the keyword-value pair specified by *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1, KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use ReplaceNumberByKey to add or modify numeric information in a string containing a "key1:value1;key2:value2;" style list such as those returned by functions like **AxisInfo** or **TraceInfo**.

If *keyStr* is not found in *kwListStr*, then the key and the value are appended to the end of the returned string.

*keySepStr*, *listSepStr*, and *case* are optional; their defaults are ":", ";", and 0 respectively.

### Details

The actual string appended is:

```
[listSepStr] keyStr keySepStr newNum listSepStr
```

The optional leading list separator *listSepStr* is added only if *kwListStr* does not already end with a list separator.

*kwListStr* is searched for an instance of the key string bound by *listSepStr* on the left and a *keySepStr* on the right. The text up to the next ";" is replaced by *newNum* after conversion to text using the %.15g format (see **printf** for format conversion specifications).

*kwListStr* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are usually case-insensitive. Setting the optional *case* parameter to 0 makes the comparisons case sensitive.

In Igor6, only the first byte of *keySepStr* and *listSepStr* was used. In Igor7 and later, all bytes are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *case* is specified, *keySepStr* and *listSepStr* must be specified.

### Examples

```
Print ReplaceNumberByKey("K1", "K1:7;", 4) // prints "K1:4;"
Print ReplaceNumberByKey("k2", "K2=8;", 5, "=") // prints "K2=5;"
Print ReplaceNumberByKey("K3", "K3:9", 6, ":", ",") // prints "K3:6,"
Print ReplaceNumberByKey("k3", "K0:9", 6, ":", ",") // prints "K0:9,k3:6,"
Print ReplaceNumberByKey("k3", "K3:9", 6, ":", ",") // prints "K3:6,"
Print ReplaceNumberByKey("k3", "K3:9", 6, ":", ",", 1) // prints "K3:9,k3:6,"
```

### See Also

The **ReplaceStringByKey**, **NumberByKey**, **StringByKey**, **RemoveByKey**, **ItemsInList**, **AxisInfo**, **IgorInfo**, **SetWindow**, and **TraceInfo** functions.

## ReplaceString

**ReplaceString**(*replaceThisStr*, *inStr*, *withThisStr* [, *caseSense* [, *maxReplace*]])

The **ReplaceString** function returns *inStr* after replacing any instance of *replaceThisStr* with *withThisStr*.

The comparison of *replaceThisStr* to the contents of *inStr* is case-insensitive. Setting the optional *caseSense* parameter to nonzero makes the comparison case-sensitive.

Usually all instances of *replaceThisStr* are replaced. Setting the optional *maxReplace* parameter limits the replacements to that number.

### Details

If *replaceThisStr* is not found, *inStr* is returned unchanged.

If *maxReplace* is less than 1, then no replacements are made. Setting *maxReplace* = Inf is the same as omitting it.

### Examples

```
Print ReplaceString("hello", "say hello", "goodbye") // prints "say goodbye"
Print ReplaceString("\r\n", "line1\r\nline2", "") // prints "line1line2"
Print ReplaceString("A", "an Ack-Ack", "a", 1) // prints "an ack-ack"
Print ReplaceString("A", "an Ack-Ack", "a", 1, 1) // prints "an ack-Ack"
Print ReplaceString("", "input", "whatever") // prints "input" (no change)
```

### See Also

**ReplaceStringByKey**, **CmpStr**, **StringMatch**, **strsearch**, **TrimString**, **ReplaceString**

### ReplaceStringByKey

```
ReplaceStringByKey(keyStr, kwListStr, newTextStr [, keySepStr
[, listSepStr [, matchCase]])
```

The `ReplaceStringByKey` function returns *kwListStr* after replacing the text value of the keyword-value pair specified by *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use `ReplaceStringByKey` to add or modify text information in a string containing a "key1:value1;key2:value2;" style list such as those returned by functions like `AxisInfo` or `TraceInfo`.

If *keyStr* is not found in *kwListStr*, then the key and the value are appended to the end of the returned string. *keySepStr*, *listSepStr*, and *matchCase* are optional; their defaults are ":", ";", and 0 respectively.

#### Details

The actual string appended is:

```
[listSepStr] keyStr keySepStr newTextStr listSepStr
```

The optional leading list separator *listSepStr* is added only if *kwListStr* does not already end with a list separator.

*kwListStr* is searched for an instance of the key string bound by a ";" on the left and a ":" on the right. The text up to the next ";" is replaced by *newTextStr*.

If *newTextStr* is "", any existing value is deleted, but the key, the key separator, and the list separator are retained. To remove a keyword-value pair, use the `RemoveByKey` function.

*kwListStr* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are case-insensitive. Setting the optional *matchCase* parameter to 1 makes the comparisons case-sensitive.

In Igor6, only the first byte of *keySepStr* and *listSepStr* was used. In Igor7 and later, all bytes are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *matchCase* is specified, *keySepStr* and *listSepStr* must be specified.

#### Examples

```
Print ReplaceStringByKey("KY", "KY:a;KZ:c", "b") // prints "KY:b;KZ:c"
Print ReplaceStringByKey("KY", "ky=a;", "b", "=") // prints "ky=b;"
Print ReplaceStringByKey("KY", "KY:a", "b", ":", ",") // prints "KY:b,"
Print ReplaceStringByKey("ky", "ZZ:a", "b", ":", ",") // prints "ZZ:a,ky:b,"
Print ReplaceStringByKey("kz", "KZ:a", "b", ":", ",") // prints "KZ:b,"
Print ReplaceStringByKey("kz", "KZ:a", "b", ":", ",", 1) // prints "KZ:a,kz:b,"
```

#### See Also

The `ReplaceString`, `ReplaceNumberByKey`, `NumberByKey`, `StringByKey`, `ItemsInList`, `RemoveByKey`, `AxisInfo`, `IgorInfo`, `SetWindow`, and `TraceInfo` functions.

## ReplaceText

**ReplaceText** [/W=*winName*/N=*name*] *textStr*

The ReplaceText operation replaces the text in the most recently created or changed annotation or in the annotation specified by /W=*winName* and/N=*name*.

### Parameters

*textStr* can contain escape codes to set the font, size, style, color and other properties. See **Annotation Escape Codes** on page III-53 for details.

If the annotation is a color scale, this command replaces the text of the color scale's main axis label.

### Flags

|                    |                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /N= <i>name</i>    | Replaces the text of the named tag or textbox.                                                                                                                                                                                                                                                                                                                      |
| /W= <i>winName</i> | Replaces text in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |

| /W= <i>winName</i> | Replaces the wave in the named graph window or subwindow. When omitted, action will affect the active window or subwindow.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |
| /X                 | Replaces the wave supplying X coordinates.<br><br>If the trace represents a category plot, the wave must be either a text wave or the special keyword '_labels_' to use dimension labels from the Y wave controlling the axis.                                               |
| /Y                 | Replaces the wave supplying Y data.                                                                                                                                                                                                                                          |

### Keywords

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>allinCDF</b>                    | Searches the current data folder for waves with the same names as waves used in the graph. If found and if the waves are of the correct type, they replace the existing waves. Thus, if you have several data folders with identically-named waves containing data from different experimental runs, you can browse through the runs by moving from one data folder to another, using ReplaceWave <b>allinCDF</b> to update the graph. |
| <b>contour=</b> <i>contourName</i> | Replaces the wave supplying the Z data for <i>contourName</i> . If /X or /Y is used, replaces the wave used to set the X or Y data spacing (if the Z data are in a matrix) or the wave used to supply the X or Y positions if XYZ triplets were specified with three separate waves.                                                                                                                                                   |

## ReplicateString

---

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>image=imageName</code> | Replaces the wave supplying the Z data for <i>imageName</i> . If /X or /Y is used, replaces the wave used to set the X or Y data spacing.                                                                                                                                                                                                                                                                                                                                                                              |
| <code>trace=traceName</code> | Replaces the wave associated with <i>traceName</i> . With the /X flag, <i>waveName</i> will replace the X wave associated with <i>traceName</i> , otherwise it will replace the Y wave. Note that <i>traceName</i> is derived from the Y wave name; if you created a graph using <code>Display jack vs sam</code> , you would use <code>ReplaceWave/X trace=jack, newsam</code> to replace the X wave.<br><br>For traces, the <code>ReplaceWave/Y</code> flag is equivalent to <code>ReplaceWave</code> with no flags. |

### Details

Waves are replaced in the graph specified by `/W=winName` otherwise waves are replaced in the top graph.

Updating a contour plot in response to replacing a wave can be time-consuming. If you must replace more than one wave, put all the commands separated by semicolons on a single line. In a macro, use **DelayUpdate** to prevent updates between command lines.

When using the `allinCDF` keyword, `ReplaceWave` cannot find waves buried in dynamic annotation text (for instance, using the `\{ }` syntax in an annotation). `ReplaceWave` will not replace waves used for error bars, either.

Subsets of data, including individual rows or columns from a matrix, may be specified using **Subrange Display Syntax** on page II-309.

### Examples

Make XY plot, then replace the waves:

```
Make fred=x, sam=log(x)
Display fred vs sam
Make fred2=2*x, sam2=ln(x)
ReplaceWave/X trace=fred, sam2
ReplaceWave trace=fred, fred2 // trace is now named fred2
```

Make contour plot with XYZ triplet waves, then replace the waves. Note the `DelayUpdate` commands after the first two `ReplaceWave` commands:

```
Make/N=100 junkx, junky, junkz // Waves for XYZ triplets
junkx=trunc(x/10) // X wave for XYZ triplets
junky=mod(x,10) // Y wave for XYZ triplets
junkz=sin(junkx[p])*cos(junky[p]) // Z wave for XYZ triplets
Display; AppendXYZContour junkz vs {junkx, junky} // Make contour plot
Make/O/N=150 junkx2, junky2, junkz2 // Make replacement waves
junkx2=trunc(x/15)
junky2=mod(x,15)
junkz2=sin(junkx2[p])*cos(junky2[p])
ReplaceWave/X contour=junkz, junkx2; DelayUpdate
ReplaceWave/Y contour=junkz, junky2; DelayUpdate
ReplaceWave contour=junkz, junkz2
```

This example is suitable for copying all the lines and pasting into the command line, or for use in a macro. If you are typing on the command line, you would want to put the `ReplaceWave` commands all on one line:

```
ReplaceWave/X contour=junkz, junkx2; ReplaceWave/Y contour=...
```

**Trace Names** on page II-270, **Programming With Trace Names** on page IV-87.

## ReplicateString

**ReplicateString**(*str*, *totalNumCopies*)

The `ReplicateString` function returns a string containing *str* repeated *totalNumCopies* times.

The `ReplicateString` function was added in Igor Pro 9.00.

### Example

```
String in = "αβγ"
String out = ReplicateString(in, 3) // Returns "αβγαβγαβγαβγ"
```

### See Also

**PadString**, **ReplaceString**

## Resample

**Resample** [*flags*] *waveName* [, *waveName*]...

The Resample operation resamples *waveName* by interpolating or up-sampling (set by */UP=upSample*), lowpass filtering, and decimating or down-sampling (set by */DOWN=downSample*).

Lowpass filtering is specified with */N* and */WINF* or with */COEF=coefsWaveName*.

The sampling frequency ( $1/\text{DimDelta}$ ) of a resampled output wave *waveName* is changed by the ratio of *upSample/downSample*. For example, if *upSample=4* and *downSample=3*, then the final sampling rate is  $4/3$  of the original value.

Straight interpolation can be accomplished by setting *upSample* to the interpolation factor and *downSample=1*, in which case the sample rate is multiplied by *upSample*.  $\text{DeltaX}(\text{waveName})$  will be proportionally smaller. Linear interpolation is accomplished by setting *numReconstructionSamples=3* and *windowKind=None*.

For decimation only, set *upSample=1* and *downSample* to the decimation factor. The sample rate is divided by *downSample*, and  $\text{DeltaX}(\text{waveName})$  will be proportionally larger.

Use **RatioFromNumber** to choose appropriate values for *upSample* and *downSample*, or use */SAME=sWaveName* or */RATE=sampRate*. See **Resampling Rates Example** for details.

When using */COEF=coefsWaveName*, the filter coefficients should implement a low-pass filter appropriate for the *upSample* and *downSample* values or aliasing (filtering errors) will result. See **Advanced Externally-Supplied Low Pass Filter Example** for details.

### Resampling Rates Flags

The *upSample* and *downSample* values define how much interpolation and decimation to perform. They can be set directly with */UP* and */DOWN* or indirectly with */SAME* or */RATE*

*/DOWN=downSample* Down-samples or decimates the filtered result by this integer factor after up-sampling and lowpass filtering. The default is 1 (no down-sampling).

For example, */DOWN=3* places only every third value in the output wave.

Down-sampling divides the sampling rate of the filtered data by a factor of *downSample*. The  $\text{DimDelta}(\text{waveName}, \text{dim})$  value is multiplied by the same factor.

*/RATE=sampRate* Converts the output *waveName* to the specified sampling rate frequency (normally Hz).

The necessary *upSample* and *downSample* values for each *waveName* are computed internally as if you had executed:

```
RatioFromNumber (deltaX(waveName) * sampRate)
upSample = V_numerator
downSample = V_denominator
```

*/RATE* returns *V\_numerator* and *V\_denominator* set to these automatically-determined values for the last *waveName*.

*/SAME=sWaveName*

Converts the output *waveName* to the same sampling rate as *sWaveName*,  $1/\text{DimDelta}(\text{sWaveName}, \text{dim})$ . The necessary *upSample* and *downSample* values are computed internally as if you had executed:

```
Variable dd = DimDelta(waveName, dim)
RatioFromNumber dd/DimDelta(sWaveName, dim)
upSample = V_numerator
downSample = V_denominator
```

*/SAME* returns *V\_numerator* and *V\_denominator* set to these automatically-determined values for the last *waveName*.

## Resample

---

*/UP=upSample* Up-samples or interpolates the input by this integer factor. The default is 1 (no up-sampling).

For example, */UP=4* inserts three extra points between each input point (producing 4 times as many values) before the lowpass filtering and down-sampling occurs.

Up-sampling multiplies the sampling rate of the input data by a factor of *upSample*, though no additional signal information is created. The `DimDelta(waveName, dim)` value is divided by the same factor.

### Internal Sinc Reconstruction Filter Flags

If */COEF=coefsWaveName* is not specified, Resample computes a windowed sinc filter from */N*, */DOWN*, */UP*, and */WINF* flag values.

If */COEF=coefsWaveName* is specified, then *coefsWaveName* supplies the filter, and */N* and */WINF* are ignored. See **Externally-Supplied Low Pass Filter Flags**.

*/COEF* Replaces the first *waveName* with coefficients generated by *downSample*, *upSample*, *numReconstructionSamples*, and *windowKind*, a windowed sinc impulse response.

When resampling multiple *waveNames* with different filters (because */RATE* or */SAME* were specified and the multiple *waveNames* had different sampling rates), the filter used to resample the last *waveName* is returned.

*/N=numReconstructionSamples*

Specifies the number of input values used to create the up-sampled values (default is 21).

The value of *numReconstructionSamples* must be odd.

The size of the computed filter is  $(numReconstructionSamples-1) * upSample + 1$ .

Bigger is better: 15 is usually on the low side for yielding reasonably accurate results, and although 101 will nearly always give very good results, it will be slow.

Use */COEF* to output the impulse response, and the FFT to display the frequency response of the interpolator:

```
Make/O coefs
```

```
Variable numReconstructionSamples= 51, upSample= 5
```

```
Resample/COEF/N=(numReconstructionSamples)/UP=(upSample) coefs
```

```
Variable evenNum= 2*floor((numpts(coefs)+1)/2)
```

```
FFT/OUT=3/PAD={evenNum}/DEST=coefs_FFT coefs
```

```
Display coefs_FFT
```

Bigger is also slower: the filtering is computed in the time-domain, and execution time is linearly related to

$upSample/downSample * numReconstructionSamples$ .

*/WINF=windowKind*

Applies the window, *windowKind*, to the computed filter coefficients. If */WINF* is omitted, the Hanning window is used. For no coefficient windowing, use */WINF=None*, though this is discouraged unless you want linear interpolation, in which case it should be paired with */N=3*.

Windows alter the frequency response of the filter in obvious and subtle ways, enhancing the stop-band rejection or steepening the transition region between passed and rejected frequencies. They matter less when *numReconstructionSamples* is large.

Choices for *windowKind* are:

Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, Riemann and None.

See **FFT** for window equations and details.

## Externally-Supplied Low Pass Filter Flags

*/COEF=coefsWaveName*

Identifies the wave, *coefsWaveName*, containing filter coefficients that implement a low-pass filter with a cutoff frequency of the lesser of  $0.5/upSample$  and  $0.5/downSample$ , where 0.5 corresponds to the Nyquist frequency of the up-sampled data.

For example, if *upSample=2*, then the filter must contain the classic “half-band” filter, which stops the higher half of the frequencies and passes the lower half. If *upSample=10*, then the filter must pass only the lowest 1/10th of the frequencies.

For *downSample > upSample*, the low-pass filter’s cutoff frequency must be  $0.5/downSample$ . This prevents the decimation from introducing aliasing to the resampled data.

To avoid shifting the output with respect to the input, *coefsWaveName* must have an odd length with the “center” coefficient in the middle of the wave.

The length of *coefsWaveName* must be  $1+upSample*n$ , where *n* is any even integer.

**Note:** Instead of using */N=numReconstructionSamples* with */COEF=coefsWaveName*, *numReconstructionSamples* is computed from *upSample* and the number of points in *coefsWaveName*:

$numReconstructionSamples=1+(numpts(coefsWaveName)-1)/upSample$ .

Coefficients are usually symmetrical about the middle point, but this is not enforced.

*coefsWaveName* must not be a destination *waveName*.

*coefsWaveName* must be single- or double-precision numeric and one-dimensional.

## Data Range Flags

*/DIM=d*

Specifies the wave dimension to resample.

For *d=0, 1, ...*, resampling is along rows, columns, etc.

The default is */DIM=0*, which resamples each individual column (each one a channel, say left and right) in a multidimensional *waveName* where each row comprises all sound samples at a particular time.

To resample in multiple dimensions, execute the command once for each dimension. For example, use */DIM=0* followed by another command with */DIM=1* to resample a two-dimensional wave in each direction.

*E=endEffect*

Determines how to handle the ends of the resampled wave(s) (*w*) when fabricating missing neighbor values.

*endEffect=0:* Bounce method. Uses  $w[i]$  in place of the missing  $w[-i]$  and  $w[n-i]$  in place of the missing  $w[n+i]$ .

*endEffect=1:* Wrap method. Uses  $w[n-i]$  in place of the missing  $w[-i]$  and vice versa.

*endEffect=2:* Zero method (default). Uses 0 for any missing value.

*endEffect=3:* Repeat method. Uses  $w[0]$  in place of the missing  $w[-i]$  and  $w[n]$  in place of the missing  $w[n+i]$ .

## Parameters

*waveName* can be a wave with any number of dimensions. Only one dimension is resampled. Use multiple Resample calls to resample across multiple dimensions.

Without */DIM*, resampling is done along the row (first) dimension. Each column is resampled as if it were a separate one-dimensional row. This allows multichannel audio to be resampled to another frequency.

If */DIM=1*, then resampling proceeds across all the columns of each row.

## Resample

---

If /COEF is specified without *coefsWaveName*, then the first *waveName* is overwritten by the filter coefficients instead of being resampled.

### Details

The filtering convolution is performed in the time-domain. That is, the FFT is not employed to filter the data. For this reason the coefficients length (/N or the length of *coefsWaveName*) should be small in comparison to the resampled waves.

Resample assumes that the middle point of *coefsWaveName* corresponds to the delay=0 point. The “middle” point number =  $\text{trunc}(\text{numpts}(\text{coefsWaveName})-1)/2$ . *coefsWaveName* usually contains the two-sided impulse response of a filter, an odd number of points, and implements a low-pass filter whose cutoff frequency is the lesser of  $0.5/\text{upSample}$  and  $0.5/\text{downSample}$  (0.5 corresponds to the Nyquist frequency =  $1/2$  sampling frequency).

When /COEF creates a coefficients wave it sets the wave's X scaling *deltax* property to the *deltax* of the input wave multiplied by the /DOWN factor and divided by the /UP factor. It also sets the *x0* property so that the zero-phase (center) coefficient is located at  $x=0$ .

### Simple Examples

```
// Interpolation by factor of 4, default filter
Resample/UP=4 data

// Interpolation by factor of 7, linear interpolation
Resample/UP=7/N=3/WINF=None data

// Decimation by factor of 3, default filter
Resample/DOWN=3 data

// Match sampling rates, default filter
Resample/SAME=dataAtDesiredRate dataAtWrongRate1, dataAtWrongRate2,...

// Resample waves to 10 KHz sampling rate
Resample/RATE=10e3 dataAtWrongRate1, dataAtWrongRate2,...

// Interpolate an image by a factor of 2
Resample/UP=2 image // default is /DIM=0, resample rows
Resample/UP=2/DIM=1 image // resample across columns
```

**Note:** Interpolating by a factor of two does not produce an image with twice as many rows and columns. The new number of rows =  $(\text{original rows}-1)*\text{upSample} + 1$ , and a similar computation applies to columns.

### Resampling Rates Example

Suppose we have an audio wave sampled at 44,100 Hz and we wish to resample it to a higher 192,000 Hz frequency.

We can use /RATE= 192000 and let Resample determine the correct values (provided *waveName* has its X scaling set properly to reflect sampling at 44100 Hz), but let's compute *upSample* and *downSample* ourselves.

Because the sampling rate =  $1/\text{deltax}(\text{wave})$ , we can recast the /SAME formula to *RatioFromNumber* (*desiredSamplingRate/currentSamplingRate*):

```
•RatioFromNumber/V (192000 / 44100)
 V_numerator= 640; V_denominator= 147;
 ratio= 4.3537414965986;
 V_difference= 0;
```

Then *upSample*=640 and *downSample*=147.

The 44100 Hz input data will be interpolated by 640 to 28,224,000 Hz.

The result is low-pass filtered with a “cutoff frequency” of  $1/640$ th of the interpolated Nyquist frequency =  $(28224000/2)/640 = 22,050$  Hz, the same as the input signal's original Nyquist frequency.

The result will be decimated by 147 to 192,000 Hz, which is the desired output sampling frequency.

**Note:** If *downSample* had been greater than *upSample*, then the low-pass filter's cutoff frequency would have been  $1/\text{downSample}$ th of the interpolated Nyquist frequency =  $(28224000/2)/\text{downSample}$ . This prevents the decimation from introducing aliasing to the resampled data.

```
Resample/UP=640/DOWN=147 sound // convert 44.1 KHz to 192 KHz
```

### Advanced Externally-Supplied Low Pass Filter Example

You can generate an appropriate filter by executing commands like these:

```
// Compute a filter for after the input is upsampled
// to restore the frequency content to the original range.
Variable fc = min(0.5 / upSample, 0.5 * upSample / downSample)
// Transition width, small widths need big n
Variable tw= fc/10
// Set end of pass band
Variable f1= fc-tw/2
// Set start of stop band
Variable f2= fc+tw/2
// Use bigger values of n to make the filter smoother
Variable nReconstruct= 31
Variable n= (nReconstruct-1)*upSample+1 // odd = no phase shift
// Create a wave to hold the coefficients; it gets resized to n
Make/O/N=0 coeffsWaveName
FilterFIR/COEF/LO={f1,f2,n} coeffsWaveName
```

However, FilterFIR does not create windowed sinc lowpass filters that have the endearing property that the original input values are unaltered in the filtered output, though only if *upSample* > *downSample*. This is called a “Nyquist filter” or “Kth-band filter” in the literature.

If *upSample* > *downSample*, you can enforce the Nyquist criterion by “zeroizing” the designed filter by setting every *upSample*th value to 0 except the center one.

```
// coeffsWaveName length must be 1+upSample*n, where n is any even integer
Function Zeroize(w, upSample)
 Wave w // coeffsWaveName
 Variable upSample // upSample value

 Variable n= DimSize(w,0)
 Variable centerP= floor((n-1)/2) // if n=101, centerP= 50
 Variable i
 for (i=0; i<n; i+=upSample)
 if(i != centerP)
 w[i] = 0
 endif
 endfor
End
```

Resample zeroizes the internally-generated low pass filter when *upSample* > *downSample*.

Additionally, the FilterFIR command generates a low-pass filter whose gain needs to be multiplied by *upsample*:  
*coeffsWaveName* \*= *upSample*

When designing an externally supplied filter, you should also consider the filter’s “polyphase” nature; *coeffsWaveName* is actually a set of *upSample* interleaved filters, each with its own response. It makes sense to adjust these filters to produce consistent responses. If you don’t, the results will contain ringing with a period of *upSample/downSample*. This is most apparent when *downSample* is 1.

Using the filter we’ve designed so far with *upSample*=4, here’s the output of a constant-input wave:

```
Make/O constantData= 1
Resample/COEF=coeffsWaveName/UP=4 constantData
```

The graph shows that the filter response at 0 Hz for the first of 4 filters is 1.0010, the second and fourth filter’s responses are very close to 1.0, and the third filter’s response at 0 Hz is a little less than 1.0.

## ResumeUpdate

---

These variations can be eliminated by normalizing the sum of each polyphase filter to 1.0:

```
Function PolyphaseNormalize(w, upSample)
 Wave w // coeffsWaveName
 Variable upSample // upSample value

 Variable n= DimSize(w,0)
 Variable filt
 // for each filter (0..upSample-1)
 for (filt=0; filt<upSample; filt+=1)
 Variable total=0
 Variable pt
 // compute total for this filter
 for (pt=filt; pt<n; pt+=upSample)
 total += w[pt]
 endfor
 // divide by total to normalize total to 1
 for (pt=filt; pt<n; pt+=upSample)
 w[pt] /= total
 endfor
 endfor
End
```

Now the filter is ready to be used to filter data:

```
Resample/COEF=coeffsWaveName/UP=(upSample)/DOWN=(downSample) dataWave
```

You can see that designing an externally-supplied lowpass filter is much more complicated than using the internal sinc reconstruction filter, which does all this zeroizing, scaling, and polyphase normalization for you.

## ResumeUpdate

### ResumeUpdate

The ResumeUpdate operation cancels the corresponding **PauseUpdate**.

This operation is of use in macros. It is not allowed from the command line. It is allowed but has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the DoUpdate operation.

### See Also

The **DelayUpdate**, **DoUpdate**, and **PauseUpdate** operations.

## return

```
return [expression]
```

The return flow control keyword immediately stops execution of the current procedure. If called by another procedure, it returns *expression* and control to the calling procedure.

Functions can return only a single value directly to the calling procedure with a return statement. The return value must be compatible with the function type. A function may contain any number of return statements; only the first one encountered during procedure execution is evaluated.

A macro has no return value, so return simply quits the macro.

#### See Also

**The Return Statement** on page IV-35.

## Reverse

**Reverse** [*type flags*] [/DIM=*d* /P] *waveA* [/D = *destWaveA*] [, *waveB* [/D = *destWaveB*] [, ...]]

The Reverse operation reverses data in a wave in a specified dimension. It does not accept text waves.

#### Flags

|                 |                                                                                                                                                              |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /DIM = <i>d</i> | Specifies the wave dimension to reverse.<br><i>d</i> =-1: Treats entire wave as 1D (default).<br>For <i>d</i> =0, 1, ..., operates along rows, columns, etc. |
| /P              | Suppresses adjustment of dimension scaling. Without /P the scaled dimension value of reversed points remains the same.                                       |

#### Type Flags (*used only in functions*)

Reverse also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it is needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See **WAVE Reference Types** on page IV-73 and **WAVE Reference Type Flags** on page IV-73 for a complete list of type flags and further details.

#### Wave Parameters

**Note:** *All* wave parameters must follow *wave* in the command. All wave parameter flags and type flags must appear immediately after the operation name (Reverse).

/D=*destWave* Specifies the name of the wave to hold the reversed data. It creates *destWave* if it does not already exist or overwrites it if it exists.

#### Details

If the optional /D = *destWave* flag is omitted, then the wave is reversed in place.

## RGBColor

The RGBColor structure is used as a substructure usually to store various color settings.

```
Structure RGBColor
 UInt16 red
 UInt16 green
 UInt16 blue
EndStructure
```

## RGBAColor

The RGBAColor structure is the same as RGBColor but with an alpha field to represent translucency.

```
Structure RGBAColor
 UInt16 red
 UInt16 green
 UInt16 blue
 UInt16 alpha
EndStructure
```

## rightx

**rightx** (*waveName*)

The **rightx** function returns the X value corresponding to point N of the named 1D wave of length N.

### Details

Note that the point numbers in a wave run from 0 to N-1 so there is no point with this X value. To get the X value of the last point in a wave (point N-1), use the following:

```
pnt2x(waveName, numpnts(waveName) - 1) // N = numpnts(waveName)
```

which is more accurate than:

```
rightx(waveName) - deltax(waveName)
```

The **rightx** function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details. The equivalent information for any dimension can be calculated this way:

$$IndexN = DimSize(wave, dim) * DimDelta(wave, dim) + DimOffset(wave, dim)$$

Here *IndexN* is the value of the scaled dimension index corresponding to element N of the dimension *dim* in a wave named *wave* that has N elements in that dimension.

### See Also

The **deltax** and **leftx** functions, also the **pnt2x** and **numpnts** functions.

For an explanation of waves and dimension scaling, see **Changing Dimension and Data Scaling** on page II-68.

For multidimensional waves, see **DimDelta**, **DimOffset**, and **DimSize**.

## root

**root** [ : *dataFolderName* [ : *dataFolderName* [ : ... ] ] ] [ : *objectName* ]

Igor's data folder hierarchy starts with the root folder as its basis. The root data folder always exists and it contains all other objects (waves, variables, strings, and data folders). By default, the root data folder is the current data folder in a new experiment. In commands, **root** is used as part of a path specifying the location of a data object in the folder hierarchy.

### See Also

Chapter II-8, **Data Folders**.

## Rotate

**Rotate** *rotPoints*, *waveName* [, *waveName*] ...

The **Rotate** operation rotates the Y values of waves in *wavelist* by *rotPoints* points.

### Parameters

If *rotPoints* is positive then values are rotated from the start of the wave toward the end and *rotPoints* values from the end of a wave wrap around to the start of the wave.

If *rotPoints* is negative then values are rotated from the end of the wave toward the start and *rotPoints* values from the start of a wave wrap around to the end of the wave.

### Details

The X scaling of the named waves is changed so that the X values for the Y values remains the same except for the points that wrap around.

The **Rotate** operation is not multidimensional aware. To rotate rows or columns of 2D waves, see the **rotateRows**, **rotateCols**, **rotateLayers** and **rotateChunks** keywords for **MatrixOp** and the **rotateRows** and **rotateCols** keywords for **ImageTransform**.

For general information about multidimensional analysis, see **Analysis on Multidimensional Waves** on page II-95.

### See Also

The *shift* parameter of the **WaveTransform** operation.

## round

**round** (*num*)

The round function returns the integer value closest to *num*.

The rounding method is “away from zero”.

The result for INF and NAN is undefined.

### See Also

The **ceil**, **floor**, and **trunc** functions.

## rtGlobals

**#pragma rtGlobals = 0, 1, 2, or 3**

**#pragma rtglobals=<n>** is a compiler directive that controls compiler and runtime behaviors for the procedure file in which it appears.

This statement must be flush against the left edge of the procedure file with no indentation. It is usually placed at the top of the file.

**#pragma rtglobals=0** turns off runtime creation of globals. This is obsolete.

**#pragma rtglobals=1** is a directive that turns on runtime lookup of globals. This is the default behavior if **#pragma rtGlobals** is omitted from a given procedure file.

**#pragma rtGlobals=2** turns off compatibility mode. This is mostly obsolete. See **Legacy Code Issues** on page IV-113 for details.

**#pragma rtglobals=3** turns on runtime lookup of globals, strict wave reference mode and wave index bounds checking.

**rtGlobals=3** is recommended.

See **The rtGlobals Pragma** on page IV-51 for a detailed explanation of **rtGlobals**.

## S

**s**

The **s** function returns the current chunk index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled chunk index is available as the **t** function.

### Details

Unlike **p**, outside of a wave assignment statement, **s** does not act like a normal variable.

### See Also

**Waveform Arithmetic and Assignments** on page II-74.

For other dimensions, the **p**, **r**, and **q** functions.

For scaled dimension indices, the **x**, **y**, **z** and **t** functions.

## Save

**Save** [*flags*] *waveList* [**as** *fileNameStr*]

The Save operation saves the named waves to disk as text (/F, /G or /J) or as Igor binary.

### Parameters

*waveList* is either a list of wave names or, if the /B flag is present, a string list of references to waves. For example, the following commands are equivalent, assuming that the waves in question are in the root data folder and root is the current data folder:

```
Save/J wave0,wave1 as "Test.dat"
Save/J root:wave0,root:wave1 as "Test.dat"
Save/J/B "wave0;wave1;" as "Test.dat"
Save/J/B "root:wave0;root:wave1;" as "Test.dat"
String list="root:wave0;root:wave1;"; Save/J/B list as "Test.dat"
```

The form using the /B flag and a string containing a list of references to waves saves a very large number of waves using one command. This is not possible using a list of wave names because of the 2500 byte

command line length limit. When using this form, the string must contain semicolon-separated wave names or data folder paths leading to waves. Liberal names in the string may be quoted or unquoted.

The file to be written is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If it cannot determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

**Flags**

- /A[=a]* Appends to the file rather than overwriting it (with */T*, */G* or */J*).

  - a=0*: Does not append.
  - a=1*: Appends to the file with a blank line before the appended data (same as */A* only).
  - a=2*: Appends to the file with no blank line before the appended data.
- /B* The *waveList* parameter is a string containing a list of references to waves instead of a literal list of waves.
- /C* Saves a copy of the wave when saving as Igor binary.
- /DLIM=delimStr* Specifies the string to use as a column delimiter. This flag affects general text saves (*/G*) and delimited text saves (*/J*) only.

*delimStr* defaults to tab. It can consist of multiple characters.

If you choose a delimiter that also appears in the data you are saving, for example if you choose to save text waves containing commas using comma as the separator, the resulting file is likely to be misinterpreted by any software loading it.

*/DLIM* was added in Igor Pro 7.00.
- /DSYM=dsStr* Specifies a string containing the character to use as the decimal symbol for all numbers (default is a period). If *dsStr* is empty (" "), then the decimal symbol is as defined in system preferences as of when Igor was launched.
- /E=useEscapeCodes* Determines whether to use escape sequences for special characters.

  - /E=1*: Converts carriage-return, linefeed, tab, and backslash characters to escape sequences when writing general or delimited text files (default; same as no */E*).
  - /E=0*: No escape sequences used in general or delimited text files. When saving text waves containing backslashes (such as Windows paths) in a file intended for another program, you probably should use */E=0*.
- /F* Writes delimited and general text files with numeric formatting as it appears in the top table. Has no effect if there is no top table or if the wave being saved does not appear in the top table.

**Note:** The text written to the file is exactly as displayed in the table. Set the table to display as many digits of precision as you want in the file.

**Note:** Fractional and out-of-range floating point wave data can not be formatted as octal or hex. See **Octal Numeric Formats** on page II-245 and **Hexadecimal Numeric Formats** on page II-245 for details.

**Note:** When saving a multi-column wave (1D complex wave or multidimensional wave), all columns of the wave are saved using the table format for the first table column from the wave.
- /G* Saves waves in general text format.

---

|                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/H</i>                                                                        | <p>"Adopts" the waves specified by <i>waveList</i>.</p> <p>"Adopt" means that any connection between the waves and external files is severed. The waves become part of the current experiment. When the experiment is next saved, the waves are saved in the experiment file (for an packed experiment) or in the experiment folder (for an unpacked experiment).</p> <p>When you use the <i>/H</i> flag, all other flags and the <i>fileNameStr</i> parameter are ignored. The wave is not actually saved but rather is marked for saving as part of the current experiment.</p> <p>You would normally do this to make an experiment more self-contained which makes it easier to send to other people. See <b>Sharing Versus Copying Igor Binary Wave Files</b> on page II-147 and the <b>LoadWave</b> <i>/H</i> flag.</p>                                                                                                                                                                                                                                         |
| <i>/I</i>                                                                        | Presents a dialog from which you can specify file name and folder.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>/J</i>                                                                        | <p>Saves waves in delimited text format.</p> <p>The delimiter defaults to tab unless you specify another delimiter using <i>/DLIM</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>/M=termStr</i>                                                                | <p>Specifies the terminator character or characters to use at the end of each line of text. The default is <i>/M="\r"</i>, which uses a carriage return character. This is the Macintosh convention. To use the Windows convention, carriage return plus linefeed, specify <i>/M="\r\n"</i>. To use the Unix convention, just a linefeed, specify <i>/M="\n"</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>/O</i>                                                                        | Overwrites file if it exists already.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>/P=pathName</i>                                                               | Specifies the folder to store the file in. <i>pathName</i> is the name of an existing symbolic path.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>/T</i>                                                                        | Saves waves in Igor Text format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>/U={writeRowLabels, rowPositionAction, writeColLabels, colPositionAction}</i> | <p>These parameters affect the saving of a matrix (2D wave) to a delimited text (<i>/J</i>) or general text (<i>/G</i>) file. They are accepted no matter what the save type is but are ignored when they don't apply.</p> <p>If <i>writeRowLabels</i> is nonzero, Save writes the row labels of the matrix as the first column of data in the file.</p> <p><i>rowPositionAction</i> has one of the following values:</p> <ul style="list-style-type: none"> <li>0: Don't write a row position column.</li> <li>1: Writes a row position column based on the row scaling of the matrix wave.</li> <li>2: Writes a row position column based on the contents of the row position wave for the matrix. The row position wave is an optional 1D wave whose name is the same as the matrix wave but with the prefix "RP_".</li> </ul> <p><i>writeColumnLabels</i> and <i>columnPositionAction</i> have analogous meanings. The prefix used for the column position wave is "CP_".</p> <p>See Chapter II-9, <b>Importing and Exporting Data</b>, for further details.</p> |
| <i>/W</i>                                                                        | Saves wave names (with <i>/G</i> or <i>/J</i> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### Details

The Save operation saves only the named waves; it does not save the entire experiment.

Waves saved in Igor binary format are saved one wave per file. If you are saving more than one wave, you must not specify a *fileNameStr*. Save will give each file a name which consists of the wave name concatenated with ".ibw".

When you save a wave as Igor binary, unless you use the */C* flag to save a copy, the current experiment subsequently references the file to which the wave was saved. See **References to Files and Folders** on page II-24 for details.

## Save

---

In a general text file (/G), waves with different numbers of points are saved in different groups. Waves with different precisions and number types are saved in same group if they have the same number of points.

In a delimited text file (/J), all waves are saved in one group whether or not they have the same number of points.

If you save multiple 2D waves, the blocks of data are written one after the other.

If you save 3D waves, the data for each wave is written as a contiguous block having as many columns as there are columns in the wave, and R\*L rows, where R is the number of rows in the multidimensional wave and L is the number of layers. All rows for layer 0 are saved followed by all rows for layer 1, and so on.

If you save 4D waves, the data for each wave is written as a contiguous block having R\*L\*C rows, where R is the number of rows, L is the number of layers and C is the number of chunks. Igor writes all data for chunk 0 followed by all data for chunk 1, and so on.

The Save operation will always present a save dialog if you try to save to an existing file without using the overwrite flag.

Here are some details about saving an Igor binary wave file.

If you omit the path or the file name, the Save operation will normally present a save dialog. However, if the wave has already been saved to a stand-alone file and if you use the overwrite flag, it will save the wave to the same file without a dialog. Also, if the wave has never been saved and the current experiment is an unpacked experiment, it will save to the home folder without a dialog.

If you use /P=*pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-22 for details.

### Examples

This function uses the string list of references to waves to save some or all of the waves in the current data folder:

```
Function SaveWavesFromCurrentDF(matchStr)
 String matchStr // As for the WaveList function.
 String list
 list = WaveList(matchStr, ";", "")
 Save/O/J/W/I/B list
End
```

For example, to save all of the waves in the current data folder, execute:

```
SaveWavesFromCurrentDF("*")
```

To save those waves in the current data folder whose name starts with "wave", execute:

```
SaveWavesFromCurrentDF("wave*")
```

This function saves all of the waves used in a particular graph:

```
Function SaveWavesFromGraph(graphName) // Saves all waves in graph.
 String graphName // "" for top graph.

 String list, traceList, traceName
 Variable index = 0
 list = ""
 traceList = TraceNameList(graphName, ";", 1)
 do
 traceName = StringFromList(index, traceList, ";")
 if (strlen(traceName) == 0)
 break
 endif
 Wave w = TraceNameToWaveRef(graphName, traceName)
 list += GetWavesDataFolder(w,2) + ";"
 index += 1
 while(1)

 if (strlen(list) > 0)
 Save/O/J/W/I/B list
 endif
End
```

## SaveData

**SaveData** [*flags*] *fileOrFolderNameStr*

The SaveData operation writes data from the current data folder of the current experiment to a packed experiment file on disk or to a file system folder. “Data” means Igor waves, numeric and string variables, and data folders containing them. The data is written as a packed experiment file or as unpacked Igor binary wave files in a file-system folder.

**Warning:** If you make a mistake using SaveData, it is possible to overwrite critical data, even entire folders containing critical data. It is your responsibility to make sure that any file or folder that you can not afford to lose is backed up. If you provide procedures for use by other people, you should warn them as well.

SaveData provides a way to save data for archival storage or unload data from memory during a lengthy process like data acquisition. The file or files that SaveData writes are disassociated from the current experiment.

Use SaveData to save experiment data using Igor procedures. To save experiment data interactively, use the Save Copy button in the Data Browser (Data menu).

### Parameters

*fileOrFolderNameStr* specifies the packed experiment file (if /D is omitted) or the file system folder (if /D is present) in which the data is to be saved. The documentation below refers to this file or folder as the “target”.

If you use a full or partial path for *fileOrFolderNameStr*, see **Path Separators** on page III-453 for details on forming the path.

If *fileOrFolderNameStr* is omitted or is empty (" "), SaveData displays a dialog from which you can select the target. You also get a dialog if the target is not fully specified by *fileOrFolderNameStr* or the /P=*pathName* flag.

If you are saving to a packed experiment file (/D omitted or /D=0), SaveData writes an HDF5 packed experiment file if the file name extension is ".h5xp". Otherwise it writes a standard packed experiment file (.pxp format). The .h5xp format requires Igor Pro 9 or later.

### Flags

/COMP={*minWaveElements*, *gzipLevel*, *shuffle*}

Specifies that compression is to be applied to numeric waves saved when saving as an HDF5 packed experiment file. The /COMP flag was added in Igor Pro 9.00.

*minWaveElements* is the minimum number of elements that a numeric wave must have to be eligible for compression. Waves with fewer than this many total elements are not compressed.

*gzipLevel* is a value from 0 to 9. 0 means no GZIP compression.

*shuffle* is 0 to turn shuffle off or 1 to turn shuffle on.

When compression is applied by SaveData, the entire wave is saved in one chunk. See **HDF5 Layout Chunk Size** on page II-201 for background information and **SaveExperiment Compression** on page II-202 for details.

/D [=*d*]

Writes to a file-system folder (a directory). If omitted, SaveData writes to an Igor packed experiment file.

*d*=1: If the target folder already exists, the new data is “mixed-in” with the data already there (same as /D).

*d*=2: If the target folder already exists, **it is completely deleted before the writing of data starts.**

If in doubt, use /D=1. See **Details** below.

/I

Presents a dialog in which you can interactively choose the target.

*/J=objectNamesStr* Saves only the objects named in the semicolon-separated list of object names. When saving as an HDF5 packed experiment file (.h5xp), */J* is not supported and returns an error if you use it and provide a non-empty string as *objectNamesStr*. See **Saving Specific Objects** below for further discussion of */J*.

*/L=saveFlags* Controls what kind of data objects are saved with a bit for each data type:

| <i>saveFlags</i> | Bit Number | Saves this Type of Object |
|------------------|------------|---------------------------|
| 1                | 0          | Waves                     |
| 2                | 1          | Numeric variables         |
| 4                | 2          | String variables          |

To save multiple data types, sum the values shown in the *saveFlags* column. For example, */L=1* saves waves only, */L=2* saves numeric variables only and */L=3* saves both waves and numeric variables.

If */L* is not specified, all of these object types are saved. This is equivalent to */L=7*. All other bits are reserved and must be set to zero. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

*/M=modDateTime* Saves waves modified on or after the specified modification date/time. Waves modified before *modDateTime* will not be saved. Applies to waves only (not variables or strings).

*modDateTime* is in standard Igor time format — seconds since 1/1/1904. If *modDateTime* is zero, all waves will be saved, as if there were no */M* flag at all.

*/O* Overwrites existing files or folders on disk.

**Warning:** If you use the */O* flag and if the target already exists, it will be overwritten without any warning. If you use */O* with */D=2*, **you will completely overwrite the target folder and all of its contents, including subfolders**. Do not use */O* with */D* unless you are absolutely sure you know what your doing.

*/P=pathName* Specifies the folder in which to save the specified file or folder.

*pathName* is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-22 for details.

When used with the */D* flag, if */P=pathName* is present and *fileOrFolderNameStr* is ":", the target is the directory specified by */P=pathName*.

*/Q* Suppresses normal messages in the history area.

*/R* Recursively saves subdata folders.

*/T [=topLevelName]* Creates an enclosing data folder in the target with the specified name, *topLevelName*, and writes the data to the new data folder.

If just */T* is specified, it creates an enclosing data folder in the target using the name of the data folder being saved. However, if the data folder being saved is the root data folder, the name Data is used instead of root. In packed experiment files and unpacked experiment folders, the root data folder is implicit.

If */T* is omitted, the contents of the current data folder are saved with no enclosing data folder.

### Saving Specific Objects

If */J=objectNamesStr* is used, then only the objects named in *objectNamesStr* are saved. For example, specifying */J="wave0 ; wave1 ; "* will save only the two named waves, ignoring any other data in all data folders.

The list of object names used with */J* must be semicolon-separated. A semicolon after the last object name in the list is optional. The object names must not be quoted even if they are liberal. The list is limited to 1000 characters.

Using `/J=""` acts like no `/J` at all.

When saving as an HDF5 packed experiment file (.h5xp), `/J` is not supported and returns an error if you use it and provide a non-empty string as *objectNamesStr*.

### Details

The `/M=modDateTime` flag can be used in data acquisition projects to save only those waves modified since the previous save. For example, assume that we have a global variable in the root data folder named `gLastWaveSaveDateTime`. Then this function will write out only those waves modified since the previous save:

```
Function SaveModifiedWaves(savePath)
 String savePath // Symbolic path pointing to output directory
 NVAR lastSave = root:gLastWaveSaveDateTime
 SaveData/O/P=$savePath/D=1/L=1/M=(lastSave) ":"
 lastSave = datetime
End
```

Because the `datetime` function and the wave modification date have a coarse resolution (one second), this function may sometimes save the same wave twice.

The `/M` flag makes sense only in conjunction with the `/D=1` flag because `/D=1` is the only way to mix-in new data with existing data.

### Writing to a Packed Experiment File

When writing to a packed file, `SaveData` creates a standard packed Igor experiment file which you can open as an experiment, browse using the Data Browser, or access using the **LoadData** operation.

If you do not use the `/O` (overwrite) flag and the packed file already exists on disk, `SaveData` will present a dialog to confirm which file you want to write to. If you use the `/O` flag, `SaveData` will overwrite without presenting a dialog. When writing a packed file, `SaveData` always completely overwrites the preexisting packed file.

Appending to a packed experiment file is not supported because dealing with the possibility of name conflicts (e.g., two waves with the same name in the same data folder in the packed experiment file) would be technically difficult, very slow and errors would result in corrupted files.

### Writing to a File-System Folder

When saving to a folder on disk, `SaveData` writes wave files, variables files, and subfolders. This resembles the experiment folder of an unpacked experiment, but it does not contain other unpacked experiment files, such as history or procedures. You can browse the folder using the Data Browser or access it using the **LoadData** operation.

If the target directory does not exist, `SaveData` creates it.

If you do not use the `/O` (overwrite) flag and the target folder already exists on disk, `SaveData` will present a dialog to confirm that you want to write to it. `SaveData` checks for the existence of the top file system folder only. For example, if you write data to `hd:Data:Run1`, `SaveData` will display a dialog if `hd:Data:Run1` exists. But `SaveData` will not display a dialog for any folders inside `hd:Data:Run1`.

If you use the `/O` flag, `SaveData` will write without presenting a dialog.

When writing to a directory, `SaveData` can operate in one of two modes. If you use `/D=1` or just `/D`, `SaveData` operates in “mix-in” mode. If you use `/D=2`, `SaveData` operates in “delete” mode.

**Warning:** If the target directory exists and delete mode is used, `SaveData` deletes the target directory and all of its contents. Then `SaveData` creates the target directory and writes the data to it. This is a complete overwrite operation.

If the target directory exists and mix-in mode is used, `SaveData` does not do any explicit deletion. It writes data to the target directory and any subdirectories. Conflicting files in any directory are overwritten but other files are left intact.

To prevent you from inadvertently deleting an entire volume, `SaveData` will not permit you to target the root directory of any volume. You must target a subdirectory.

The `/J` flag will not work as expected when writing numeric and string variables in mix-in mode. Instead of mixing-in the specified variables, `SaveData` will overwrite all variables already in the target. This is because all numeric and string variables in a particular data folder are stored in a single file-system folder (named “variables”), so it is not possible to mix-in. Since waves are written one-to-a-file, `/J` will work as expected for waves.

## SaveData

---

When SaveData writes a wave to a file-system folder, the file name for the wave is the same as the wave name, with the extension “.ibw” added. This is true even if the wave in the experiment was loaded from a file with a different name.

### Limitations of SaveData

SaveData does not save free waves, free data folders, wave waves or DFREF waves all of which are ignored by SaveData.

When saving as HDF5 packed (.h5xp), the entire experiment must use UTF-8 text encoding. If the experiment uses non-UTF8 text encoding, SaveData displays an alert directing you to Misc→Text Encoding→Convert to UTF-8 Text Encoding and returns an error.

When saving as HDF5 packed (.h5xp), the /J flag is not supported and returns an error if you use it and provide a non-empty string as objectNamesStr.

### Outputs

SaveData sets the variable V\_flag to zero if the operation succeeded or to nonzero if it failed. The main use for this is to determine if the user clicked Cancel during an interactive save. This would occur if you use the /I flag or if you omit /O and the target already exists. V\_flag will also be nonzero if an error occurs during the save.

SaveData sets the string variable S\_path to the full file system path to the file or folder that was written. S\_path uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. When saving unpacked, S\_path includes a trailing colon.

### Examples

Write the contents of the current data folder and all subdata folders to a packed experiment file:

```
Function SaveDataInPackedFile(pathName, fileName)
 String pathName // Name of symbolic path
 String fileName // Name of packed file to be written

 SaveData/R/P=$pathName fileName
End
```

Write the contents of the current data folder and all subdata folders to an unpacked file-system folder:

```
Function SaveDataInUnpackedFolder(pathName, folderName)
 String pathName // Name of symbolic path
 String folderName // Name of file-system folder

 SaveData/D=1/R/P=$pathName folderName
End
```

Copy the contents of an unpacked file-system folder to a packed experiment file:

```
Function TransferUnpackedToPacked(path1, folderName, path2, fileName)
 String path1 // Points to parent of unpacked folder
 String folderName // Name of folder containing unpacked data
 String path2 // Points to folder where file is to be written
 String fileName // Name of packed file to be written

 DFREF savedDF = GetDataFolderDFR()
 NewDataFolder/O/S :TempTransfer
 // Load all data from the unpacked folder.
 LoadData/D/Q/R/P=$path1 folderName

 // Save all data to the packed file.
 SaveData/R/P=$path2 fileName

 KillDataFolder : // Kill TempTransfer
 SetDataFolder savedDF
End
```

## SaveExperiment

**SaveExperiment** [**flags**] [**as fileName**]

The SaveExperiment operation saves the current experiment.

**Warning:** SaveExperiment overwrites any previously-existing file named fileName.

### Parameters

The optional *fileName* string contains the name of the experiment to be saved. *fileName* can be the currently open experiment, in which case it overwrites the experiment file.

If *fileName* and *pathName* are omitted and the experiment is Untitled, you will need to locate where the experiment file will be saved interactively via a dialog.

If you use a full or partial path for *pathName*, see **Path Separators** on page III-453 for details on forming the path.

### Flags

**/C** Saves an experiment copy (valid only when *fileName* or *pathName* is provided or both if experiment is Untitled).

**/COMP={minWaveElements, gzipLevel, shuffle}**

Specifies that compression is to be applied to numeric waves saved when saving as an HDF5 packed experiment file. The **/COMP** flag was added in Igor Pro 9.00.

*minWaveElements* is the minimum number of elements that a numeric wave must have to be eligible for compression. Waves with fewer than this many total elements are not compressed.

*gzipLevel* is a value from 0 to 9. 0 means no GZIP compression.

*shuffle* is 0 to turn shuffle off or 1 to turn shuffle on.

When compression is applied by SaveExperiment, the entire wave is saved in one chunk. See **HDF5 Layout Chunk Size** on page II-201 for background information and **SaveExperiment Compression** on page II-202 for details.

**/F={format, unpackedExpFolderNameStr, unpackedExpFolderMode}**

Specifies the experiment file format.

See **Experiment File Format** below for details.

**/P=pathName** Specifies folder in which to save the experiment. *pathName* is the name of an existing symbolic path.

### Details

SaveExperiment acts like the Save menu command in the File menu. If the experiment is associated with an already saved file, then SaveExperiment with no parameters will simply save the current experiment. If the experiment resides only in memory and has not yet been saved, then a dialog will be presented unless the path and file name are specified.

If you use a full path in the name you will not need the **/P** flag. If instead you use **/P=pathName**, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-22 for details.

### Experiment File Format

For background information on experiment file formats, see **Experiments** on page II-16.

The **/F** flag provides control of the file format of a previously-unsaved experiment independent of the user's preferences as set in the Experiment Settings section of the Miscellaneous Settings dialog. It also allows you to save a previously-saved experiment using a different experiment file format.

If you just want to save the current experiment in its current format, you don't need to use **/F**.

If you use **/F**, you must fully-specify the location of the experiment file through the **/P** flag and the *fileName* parameter or through *fileName* alone if it contains a full path.

The **format** parameter controls the experiment file format used by SaveExperiment:

## SaveGizmoCopy

---

*format* =-1: Default format  
*format* =0: Unpacked experiment file  
*format* =1: Packed experiment file  
*format* =2: HDF5 packed experiment file

If */F* is omitted or if *format* is -1 then the experiment is saved in its current format or, if it was never saved to disk, as a packed experiment file (.pxp).

If *format* = 0, the experiment is saved in unpacked experiment file format. *fileName* must end with ".uxp" or ".uxt".

If *format* = 1, the experiment is saved in packed experiment file format. *fileName* must end with ".pxp" or ".pxt".

If *format* = 2, the experiment is saved in HDF5 packed experiment file format. *fileName* must end with ".h5xp" or ".h5xt". This format requires Igor Pro 9.00 or later.

### Unpacked Experiment Folder

The unpacked experiment folder is the folder in which wave files, the history file, the variables file, and other experiment files are stored for an unpacked experiment. See **Saving as an Unpacked Experiment File** on page II-17 for details.

The */F unpackedExpFolderNameStr* parameter specifies the name of the experiment folder for an unpacked experiment. It contains a folder name, not a full or partial path. It is ignored unless saving in unpacked experiment format.

The unpacked experiment folder is created in the same directory as the experiment file.

If */F=0* is used and *unpackedExpFolderNameStr* is "" then the experiment folder name is the same as the experiment file name with the extension removed and a space and "Folder" added.

If the specified unpacked experiment folder already exists and is the current experiment's unpacked experiment folder, it is reused. "Reuse" means that SaveExperiment saves files in the unpacked experiment folder, possibly overwriting files already in it, but does not delete any files or folders already in it.

The *unpackedExpFolderMode* parameter controls what happens if the folder to be used as the unpacked experiment folder already exists and is not the current experiment's unpacked experiment folder:

*unpackedExpFolderMode*=0 : SaveExperiment returns an error.  
*unpackedExpFolderMode*=1 : SaveExperiment displays a dialog asking the user if it is OK to reuse the folder. If the user answers yes, the operation proceeds. Otherwise, it returns an error.  
*unpackedExpFolderMode*=2 : SaveExperiment reuses the folder without asking the user.

**Warning:** If you pass 2 for *unpackedExpFolderMode*, files and folders in the unpacked experiment folder may be overwritten without the user's express permission.

## SaveGizmoCopy

**SaveGizmoCopy** [*flags*] [*as fileNameStr*]

The SaveGizmoCopy operation saves a Gizmo window and its waves in an Igor packed experiment file.

SaveGizmoCopy was added in Igor Pro 8.00.

### Parameters

The file to be written is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor

can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

### Flags

|                     |                                                                                                                                                                                                                                                                        |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /I                  | Presents a dialog from which you can specify file name and folder.                                                                                                                                                                                                     |
| /O                  | Overwrites file if it exists already.                                                                                                                                                                                                                                  |
| /P= <i>pathName</i> | Specifies the folder to store the file in. <i>pathName</i> is the name of an existing symbolic path.                                                                                                                                                                   |
| /T= <i>saveType</i> | Specifies the file format of the saved file.<br><i>saveType</i> =0: Packed experiment file.<br><i>saveType</i> =1: HDF5 packed experiment file. If <i>fileNameStr</i> is specified the file name extension must be ".h5xp".<br>The /T flag was added in Igor Pro 9.00. |
| /W= <i>winName</i>  | <i>winName</i> is the name of the Gizmo window to be saved. If /W is omitted or if <i>winName</i> is "", the top Gizmo window is saved.                                                                                                                                |
| /Z                  | Errors are not fatal and error dialogs are suppressed. See Details.                                                                                                                                                                                                    |

### Details

The main uses for saving as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see **Merging Experiments** on page II-19). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the Gizmo window starting from the root data folder. Only the Gizmo window, its waves as well as the objects on Gizmo's object list and attribute list are saved in the packed experiment file. Associated procedures including hook functions are not saved.

SaveGizmoCopy does not know about dependencies. If a Gizmo window contains a wave, *wave0*, that is dependent on another wave, *wave1* which is not used in the Gizmo window, SaveGizmoCopy will save *wave0* but not *wave1*. When the saved experiment is open, there will be a broken dependency.

SaveGizmoCopy sets the variable *V\_flag* to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the /Z flag and check *V\_flag* after calling SaveGizmoCopy.

## SaveGraphCopy

**SaveGraphCopy** [*flags*] [*as fileNameStr*]

The SaveGraphCopy operation saves a graph and its waves in an Igor packed experiment file.

### Parameters

The file to be written is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

### Flags

|                     |                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------|
| /I                  | Presents a dialog from which you can specify file name and folder.                                   |
| /O                  | Overwrites file if it exists already.                                                                |
| /P= <i>pathName</i> | Specifies the folder to store the file in. <i>pathName</i> is the name of an existing symbolic path. |

## SaveGraphCopy

---

|                    |                                                                                                                                                                                                                                                                                 |

| <i>/W= winName</i> | <i>winName</i> is the name of the graph to be saved. If <i>/W</i> is omitted or if <i>winName</i> is "", the top graph is saved.                                                                                                                                                |
| <i>/Z</i>          | Errors are not fatal and error dialogs are suppressed. See Details.                                                                                                                                                                                                             |

### Details

The main uses for saving as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see **Merging Experiments** on page II-19). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the graph starting from the "top" data folder, which is the data folder that encloses all waves displayed in the graph. The top data folder becomes the root data folder of the resulting experiment file. Only the graph, its waves, dashed line settings, and any pictures used in the graph are saved in the packed experiment file, not procedures, variables, strings or any other objects in the experiment.

SaveGraphCopy does not work well with graphs containing controls. First, the controls may depend on waves, variables or FIFOs (for chart controls) that SaveGraphCopy will not save. Second, controls typically rely on procedures which are not saved by SaveGraphCopy.

SaveGraphCopy does not know about dependencies. If a graph contains a wave, wave0, that is dependent on another wave, wave1 which is not in the graph, SaveGraphCopy will save wave0 but not wave1. When the saved experiment is open, there will be a broken dependency.

SaveGraphCopy sets the variable *V\_flag* to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the */Z* flag and check *V\_flag* after calling SaveGraphCopy.

The **SaveData** operation also has the ability to save data from a graph to a packed experiment file. SaveData is more complex but a bit more flexible than SaveGraphCopy.

### Examples

This function saves all graphs in the experiment to individual packed experiment files.

```
Function SaveAllGraphsToPackedFiles(pathName)
 String pathName // Name of an Igor symbolic path.

 String graphName
 Variable index

 index = 0
 do
 graphName = WinName(index, 1)
 if (strlen(graphName) == 0)
 break
 endif

 String fileName
 sprintf fileName, "%s.pxp", graphName

 SaveGraphCopy/P=$pathName/W=$graphName as fileName

 index += 1
 while(1)
End
```

### See Also

**SaveTableCopy**, **SaveGizmoCopy**, **SaveData**, **Merging Experiments** on page II-19

## SaveNotebook

**SaveNotebook** [*flags*] *notebookName* [*as fileNameStr*]

The SaveNotebook operation saves the named notebook.

### Parameters

*notebookName* is either `kwTopWin` for the top notebook window, the name of a notebook window or a host-child specification (an `hcSpec`) such as `Panel0#nb0`. See **Subwindow Syntax** on page III-92 for details on host-child specifications.

If *notebookName* is an host-child specification, `/S` must be used and *saveType* must be 3 or higher.

The file to be written is specified by *fileNameStr* and `/P=pathName` where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case `/P` is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

### Flags

`/ENCG=textEncoding`

Specifies text encoding in which the notebook is to be saved.

This flag was added in Igor Pro 7.00.

This is relevant for plain text notebooks only and is ignored for formatted notebooks because they can contain multiple text encodings. See **Plain Text File Text Encodings** on page III-468 and **Formatted Text Notebook File Text Encodings** on page III-474 for details.

If omitted, the file is saved in its original text encoding. Normally you should omit `/ENCG`. Use it only if you have some reason to change the file's text encoding.

Passing 0 for *textEncoding* acts as if `/ENCG` were omitted.

See **Text Encoding Names and Codes** on page III-492 for a list of accepted values for *textEncoding*.

This flag does not affect HTML export. Use `/H` instead.

`/H={encodingName, writeParagraphProperties, writeCharacterProperties, PNGOrJPEG, quality, bitDepth}`

Controls the creation of an HTML file.

*encodingName* specifies the HTML file text encoding. The recommended value is "UTF-8".

*writeParagraphProperties* determines what paragraph properties SaveNotebook will write to the HTML file. This is a bitwise parameter with the bits defined as follows:

Bit 0: Write paragraph alignment.

Bit 1: Write first indent.

Bit 2: Write minimum line spacing.

Bit 3: Write space-before and space-after paragraph.

All other bits are reserved for future use and should be set to zero.

*writeCharacterProperties* determines what character properties SaveNotebook will write to the HTML file. This is a bitwise parameter with the bits defined as follows:

- Bit 0: Write font families.
- Bit 1: Write font sizes.
- Bit 2: Write font styles.
- Bit 3: Write text colors.
- Bit 4: Write text vertical offsets.

All other bits are reserved for future use and should be set to zero.

If you set bit 2, SaveNotebook exports only the bold, underline, and italic styles because other character styles are not supported by HTML.

*PNGOrJPEG* determines whether SaveNotebook will write picture files as PNG or JPEG:

- 0: PNG (default).
- 1: JPEG.
- 2: JPEG.

In Igor7 and later, there is no difference between *PNGOrJPEG*=1 and *PNGOrJPEG*=2.

See **Details** for more on HTML picture files.

*quality* specifies the degree of compression or image quality when writing pictures as JPEG files. Legal values are in the range 0.0 to 1.0.

In Igor7 or later, the quality used is 0.9 regardless of what you pass for this parameter.

*bitDepth* specifies the color depth when writing pictures as JPEG files. Legal values are legal: 1, 8, 16, 24, and 32.

In Igor7 or later, the bit depth used is 32 regardless of what you pass for this parameter.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/I</i>            | Saves interactively. A dialog is displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>/M=messageStr</i> | Specifies prompt message used in save dialog.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>/O</i>            | Overwrites existing file without asking permission.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>/P=pathName</i>   | Specifies the folder to store the file in. <i>pathName</i> is the name of an existing symbolic path.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>/S=saveType</i>   | Controls the type of save. <ul style="list-style-type: none"><li><i>saveType</i>=1: Normal save (default).</li><li><i>saveType</i>=2: Save-as.</li><li><i>saveType</i>=3: Save-a-copy.</li><li><i>saveType</i>=4: Export as RTF (Rich Text Format).</li><li><i>saveType</i>=5: Export as HTML (Hypertext Markup Language).</li><li><i>saveType</i>=6: Export as plain text.</li><li><i>saveType</i>=7: Export as formatted notebook.</li><li><i>saveType</i>=8: Export as plain text with line breaks.</li></ul> |

### Details

Interactive (*/I*) means that Igor displays the Save, Save As, or Save a Copy dialog.

The save will be interactive under the following conditions:

- You include the */I* flag and the *saveType* is 2, 3, 4, 5, 6, 7 or 8.
- *saveType* is 2, 3, 4, 5, 6, 7 or 8 and you do not specify the path or filename.

If the *saveType* is normal and the notebook has previously been saved to a file then the */I* flag, the path and file name that you specify, if any, are ignored and the notebook is saved to its associated file without user intervention.

The full path to the saved file is stored in the string *S\_path*. If the save was unsuccessful, *S\_path* will be "".

If you use */P=pathName*, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See **Symbolic Paths** on page II-22 for details.

*saveType=8* applies to formatted notebooks only. It exports the notebook as plain text with line breaks where text wraps in the formatted notebook. This feature was added in Igor Pro 8.00. Special characters such as pictures are skipped. If the notebook is plain text then *saveType=8* acts like *saveType=6*.

### Exporting as RTF

For background information on writing RTF files, see **Import and Export Via Rich Text Format Files** on page III-20.

### Exporting as HTML

For background information on writing HTML files, see **Exporting a Notebook as HTML** on page III-21.

You can pass "UTF-8" or "UTF-2" for the *encodingName* parameter. In virtually all cases, you should use "UTF-8".

When creating an HTML file, SaveNotebook can write pictures using the PNG or JPEG graphics formats. PNG is recommended because it is lossless.

**Setting Bit Parameters** on page IV-12 for further details about bit settings.

## SavePackagePreferences

```
SavePackagePreferences [/FLSH=flush /KILL /P=pathName] packageName,
 prefsFileName, recordID, prefsStruct
```

The SavePackagePreferences operation saves preference data in the specified structure so that it can be accessed later via the **LoadPackagePreferences** operation.

**Note:** The package preferences structure must not use fields of type Variable, String, WAVE, NVAR, SVAR or FUNCREF because these fields refer to data that may not exist when LoadPackagePreferences is called.

The structure can use fields of type char, uchar, int16, uint16, int32, uint32, int64, uint64, float and double as well as fixed-size arrays of these types and substructures with fields of these types.

The data is stored in memory and by default flushed to disk when the current experiment is saved or closed and when Igor quits.

If the */P* flag is present then the location on disk of the preference file is determined by *pathName* and *prefsFileName*. However in the usual case the */P* flag will be omitted and the preference file is located in a file named *prefsFileName* in a directory named *packageName* in the Packages directory in Igor's preferences directory.

**Note:** You must choose a very distinctive name for *packageName* as this is the only thing preventing collisions between your package and someone else's package.

See **Saving Package Preferences** on page IV-249 for background information and examples.

### Parameters

*packageName* is the name of your package of Igor procedures. It is limited to 31 bytes and must be a legal name for a directory on disk. This name must be very distinctive as this is the only thing preventing collisions between your package and someone else's package.

*prefsFileName* is the name of a preference file to be saved by SavePackagePreferences. It should include an extension, typically ".bin".

*prefsStruct* is the structure containing the data to be saved in the preference file on disk.

*recordID* is a unique positive integer that you assign to each record that you store in the preferences file. If you store more than one structure in the file, you would use distinct *recordIDs* to identify which structure you want to save. In the simple case you will store just one structure in the preference file and you can use 0 (or any positive integer of your choice) as the *recordID*.

## SavePICT

### Flags

|                    |                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/FLSH=flush</i> | Controls when the data is actually written to the preference file:<br><i>flush=0</i> : The data will be flushed to disk when the current experiment is saved, reverted or closed or when Igor quits. This is the default behavior used when <i>/FLSH</i> is omitted and is recommended for most purposes.<br><i>flush=1</i> : The data is flushed to disk immediately. |
| <i>/KILL</i>       | Instead of saving <i>prefsStruct</i> under the specified record ID, that record is deleted from the package's preference if it exists. If it does not exist, nothing is done and no error is returned.                                                                                                                                                                 |
| <i>/P=pathName</i> | Specifies the directory in which to save the file specified by <i>prefsFileName</i> .<br><i>pathName</i> is the name of an existing symbolic path. See <b>Symbolic Paths</b> on page II-22 for details.<br><i>/P=\$&lt;empty string variable&gt;</i> acts as if the <i>/P</i> flag were omitted.                                                                       |

### Details

SavePackagePreferences sets the following output variables:

|                     |                                                                                                                                                                                                                                 |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>V_flag</i>       | Set to 0 if preferences were successfully saved or to a nonzero error code if they were not saved. The latter case is unlikely and would indicate some kind of corruption such as if Igor's preferences directory were deleted. |
| <i>V_structSize</i> | Set to the size in bytes of <i>prefsStruct</i> . This may be useful in handling structure version changes.                                                                                                                      |

### Example

See the example under **Saving Package Preferences in a Special-Format Binary File** on page IV-250.

## SavePICT

**SavePICT** [*flags*] [*as fileNameStr*]

The SavePICT operation creates a picture file representing the top graph, table or layout. The picture file can be opened by many word processing, drawing, and page layout programs.

### Parameters

The file to be written is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

If you omit *fileNameStr* but include */P=pathName*, SavePICT writes the file using a default file name. The default file name is the window name followed by an extension, such as ".png", ".emf" or ".svg", that depends on the graphic format being exported.

If you specify the file name as "Clipboard", and do *not* specify a */P=pathName*, Igor copies the picture to the Clipboard, rather than to a file. EPS is a file-only format and can not be stored in the clipboard.

If you specify the file name as "\_string\_" the output will be saved into a string variable named *S\_Value*, which is used with the **ListBox** binary bitmap display mode.

If you use the special name `_PictGallery_` with the `/P` flag, then the picture will be stored in Igor's picture gallery (see **Pictures** on page III-509) with the name you provide via `fileNameStr`. This feature was added in support of making movies using the `/PICT` flag with **NewMovie**.

|                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/B=<i>dpi</i></code>                            | Controls image resolution in dots-per-inch ( <i>dpi</i> ). The legal values for <i>dpi</i> are $n*72$ where <i>n</i> can be from 1 to 8. The actual image <i>dpi</i> is not used. Igor calculates <i>n</i> from your value of <i>dpi</i> and then multiplies <i>n</i> by your computer's screen resolution. This is because bitmap images that are not an integer multiple of the screen resolution look quite bad.<br>Also see the <code>/RES</code> flag.                                                                       |
| <code>/C=<i>c</i></code>                              | Specifies color mode.<br><i>c</i> =0: Black and white.<br><i>c</i> =1: RGB color (default).<br><i>c</i> =2: CMYK color (EPS and native TIFF only).                                                                                                                                                                                                                                                                                                                                                                                |
| <code>/D=<i>d</i></code>                              | Obsolete in Igor Pro 7 or later.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>/E=<i>e</i></code>                              | Sets graphics format used when exporting a graphic. See <b>Details</b> for formats. See also Chapter III-5, <b>Exporting Graphics (Macintosh)</b> , or Chapter III-6, <b>Exporting Graphics (Windows)</b> , for a description of these modes and when to use them.                                                                                                                                                                                                                                                                |
| <code>/EF=<i>e</i></code>                             | Sets font embedding.<br><i>e</i> =0: No font embedding. Not honored in Igor Pro 7 or later.<br><i>e</i> =1: Embed nonstandard fonts.<br><i>e</i> =2: Embed all fonts.                                                                                                                                                                                                                                                                                                                                                             |
| <code>/I</code>                                       | Specifies that <code>/W</code> coordinates are inches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>/M</code>                                       | Specifies that <code>/W</code> coordinates are centimeters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>/N=<i>winSpec</i></code>                        | <code>/N</code> is antiquated but still supported. Use <code>/WIN</code> instead.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>/O</code>                                       | Overwrites file if it exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>/P=<i>pathName</i></code>                       | Saves file into a folder specified by <i>pathName</i> , which is the name of an existing symbolic path.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>/PGR=(<i>firstPage</i>, <i>lastPage</i>)</code> | Controls which pages in a multi-page layout are saved.<br><i>firstPage</i> and <i>lastPage</i> are one-based page numbers. All pages from <i>firstPage</i> to <i>lastPage</i> are saved if the file format supports it.<br>The special value 0 refers to the current page and -1 refers to the last page in the layout.<br>Currently only the PDF formats support saving multiple pages. Other file formats save only <i>firstPage</i> and ignore the value of <i>lastPage</i> .<br><code>/PGR</code> was added in Igor Pro 7.00. |
| <code>/PICT=<i>pic</i></code>                         | Saves specified named picture rather than the target window. Native format of the picture is used and all format flags are ignored.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>/PLL=<i>p</i></code>                            | Specifies Postscript language level when used in conjunction with EPS export.<br><i>p</i> =1: For very old Postscript printers.<br><i>p</i> =2: For all other uses (default).                                                                                                                                                                                                                                                                                                                                                     |
| <code>/Q=<i>q</i></code>                              | Sets quality factor (0.0 is lowest, 1.0 is highest). Default is dependent on individual format. Used only by lossy formats such as JPEG.                                                                                                                                                                                                                                                                                                                                                                                          |

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/R=resID</i>                   | Obsolete in Igor Pro 7 or later.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>/RES=dpi</i>                   | Controls the resolution of image formats in dots-per-inch. Unlike the similar <i>/B</i> flag, the value for <i>/RES</i> is the actual output resolution and is useful when your publisher demands a specific resolution.                                                                                                                                                                                                                                                                                                                                                                               |
| <i>/S</i>                         | Suppresses the preview that is normally included with an EPS file.<br>Obsolete in Igor Pro 7 or later.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>/SNAP=s</i>                    | Saves a snapshot (screen dump) of a graph or panel window.<br>s=1: Include all controls in capture.<br>s=2: Capture only window data content.<br><br>Snapshot mode is available only for graphs and panels and only for bitmap export formats PNG, JPEG, and TIFF at screen resolution. When using <i>/W</i> to specify the size of a graph, the capture is sized to fit within the specified rectangle while maintaining the window aspect ratio. Coordinates used with <i>/W</i> are in pixels.                                                                                                      |
| <i>/T=t</i>                       | Obsolete QuickTime export type. Not supported in Igor Pro 7 or later.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>/TRAN[=1 or 0]</i>             | Makes white background areas transparent using an RGBA type PNG when used with native PNG export of graphs or page layouts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>/W=(left,top,right,bottom)</i> | Specifies the size of the picture when exporting a graph. If <i>/W</i> is omitted, it uses the graph window size.<br><br>When exporting a page layout, specifies the part of the page to export. Only objects that fall completely within the specified area are exported. If <i>/W</i> is omitted, the area of the layout containing objects is exported.<br><br>When exporting a page layout in Igor Pro 7.00 or later, you can specify <i>/W=(0,0,0,0)</i> to use the full page size.<br><br>Coordinates for <i>/W</i> are in points unless <i>/I</i> or <i>/M</i> are specified before <i>/W</i> . |
| <i>/WIN=winSpec</i>               | Saves the named window or subwindow. <i>winSpec</i> can be just a window name, or a window name following by a “#” character and the name of the subwindow, as in <i>/WIN=Panel0#G0</i> .                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>/Z</i>                         | Errors are not fatal. <i>V_flag</i> is set to zero if no error, else nonzero if error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### Details

SavePICT sets the variable *V\_flag* to 0 if the operation succeeds or to a nonzero error code if it fails.

If you specify a path using the */P=pathName* flag, then Igor saves the file in the folder identified by the path. Note that *pathName* is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like “hd:Folder1:” or “C:\\Folder1\\”. See **Symbolic Paths** on page II-22 for details. Otherwise, with no path specified, Igor presents a standard save dialog to let you specify where the file is to be saved.

Graphics formats, specified via */E*, are as follows:

| <i>/E</i> Value | Macintosh File Format                                                                                                                                                                                                                                                            | Windows File Format |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| -9              | SVG file.                                                                                                                                                                                                                                                                        | SVG file.           |
| -8              | PDF file.                                                                                                                                                                                                                                                                        | PDF file.           |
| -7              | TIFF file. Lossless but larger file than PNG; best for text, graph traces, and simple images with sharp edges. The default resolution is 72 dpi. You can specify the resolution with the <i>/B</i> or <i>/RES</i> flag. Cross-platform compatible.                               |                     |
| -6              | JPEG file. Lossy compression; best used for grayscale and color images with smooth tones. The <i>/Q</i> flag specifies compression quality and the <i>/B</i> or <i>/RES</i> flag sets the resolution. Cross-platform compatible. PNG is a better choice for scientific graphics. |                     |

| 1        | Low resolution Quartz PDF at 1x normal size.                                                                                                                                                                                      | High-resolution Enhanced Metafile (EMF).                                                                                  |
| 2        | Low resolution Quartz PDF at 2x normal size.                                                                                                                                                                                      | High-resolution Enhanced Metafile (EMF).                                                                                  |
| 4        | Low resolution Quartz PDF at 4x normal size.                                                                                                                                                                                      | High-resolution Enhanced Metafile (EMF).                                                                                  |
| 8        | Low resolution Quartz PDF at 8x normal size.                                                                                                                                                                                      | High-resolution Enhanced Metafile (EMF).                                                                                  |

The low resolution PDF formats on Macintosh are probably not useful and are just placeholders for compatibility with old procedures.

#### See Also

The **ImageSave** operation for saving waves as PICTs and other image file formats. The **LoadPICT** operation.

See Chapter III-5, **Exporting Graphics (Macintosh)**, or Chapter III-6, **Exporting Graphics (Windows)**, for a description of the /E modes.

## SaveTableCopy

**SaveTableCopy** [*flags*] [*as fileNameStr*]

The SaveTableCopy operation saves a copy of the data displayed in a table on disk. The saved file can be an Igor packed experiment file, a tab-delimited text file, or a comma-separated values text file.

When saving as text, by default the data format matches the format shown in the table. This causes truncation if the underlying data has more precision than shown in the table. If you specify /F=1, SaveTableCopy uses as many digits as needed to represent the data with full precision.

The point column is never saved.

To save data as text with full precision, use the **Save** operation.

When saving 3D and 4D waves as text, only the visible layer is saved. To save the entirety of a 3D or 4D wave, use the **Save** operation.

#### Parameters

The file to be written is specified by *fileNameStr* and /P=*pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

### Flags

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/A=a</i>        | Appends data to the file rather than overwriting.<br><i>a=0</i> : Does not append.<br><i>a=1</i> : Appends to the file with a blank line before the appended data.<br><i>a=2</i> : Appends to the file with no blank line before the appended data.<br><i>/A</i> applies when saving text files and is ignored when saving packed experiment files.<br>If the file does not exist, a new file is created and <i>/A</i> has no effect.                    |
| <i>/F=f</i>        | Controls the precision of saved numeric data.<br><i>f=0</i> : Numeric data is written exactly as shown in the table. This may cause truncation. This is the default behavior if <i>/F</i> is omitted.<br><i>f=1</i> : Numeric data is written with as many digits as needed to represent the data with full precision.<br><br>The <i>/F</i> flag was added in Igor Pro 7.00                                                                              |
| <i>/I</i>          | Presents a dialog from which you can specify file name and folder.                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>/M=termStr</i>  | Specifies the terminator character or characters to use at the end of each line of text. The default is <i>/M="\r"</i> on Macintosh and <i>/M="\r\n"</i> on Windows; it is used when <i>/M</i> is omitted. To use the Unix convention, just a linefeed, specify <i>/M="\n"</i> .                                                                                                                                                                         |
| <i>/N=n</i>        | Specifies whether to use column names, titles, or dimension labels.<br><i>n</i> is a bitwise parameter with the bits defined as follows:<br>Bit 0: Include column names or titles. The column title is included if it is not empty. If it is empty, the column name is included.<br>Bit 1: Include horizontal dimension labels if they are showing in the table.<br>The default setting for <i>n</i> is 1. All other bits are reserved and must be zero. |
| <i>/O</i>          | Overwrites file if it exists already.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>/P=pathName</i> | Specifies the folder to store the file in. <i>pathName</i> is the name of an existing symbolic path.                                                                                                                                                                                                                                                                                                                                                     |
| <i>/S=s</i>        | Saves all of the data in the table ( <i>s=0</i> ; default) or the selection only ( <i>s=1</i> ).<br><i>/S</i> applies when saving text files and is ignored when saving packed experiment files.                                                                                                                                                                                                                                                         |
| <i>/T=saveType</i> | Specifies the file format of the saved file.<br><i>saveType=0</i> : Packed experiment file.<br><i>saveType=1</i> : Tab-delimited text file.<br><i>saveType=2</i> : Comma-separated values text file.<br><i>saveType=3</i> : Space-delimited values text file.<br><i>saveType=4</i> : HDF5 packed experiment file (requires Igor Pro 9 or later). If <i>fileNameStr</i> is specified the file name extension must be ".h5xp".                             |
| <i>/W=winName</i>  | <i>winName</i> is the name of the table to be saved. If <i>/W</i> is omitted or if <i>winName</i> is "", the top table is saved.                                                                                                                                                                                                                                                                                                                         |
| <i>/Z</i>          | Errors are not fatal and error dialogs are suppressed. See Details.                                                                                                                                                                                                                                                                                                                                                                                      |

### Details

The main uses for saving a table as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see **Merging Experiments** on page II-19). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the table starting from the "top" data folder, which is the data folder that encloses all waves displayed in the table. The top data folder becomes the root data folder of the resulting experiment file. Only the table and its waves are saved in the packed experiment file, not variables or strings or any other objects in the experiment.

SaveTableCopy does not know about dependencies. If a table contains a wave, wave0, that is dependent on another wave, wave1 which is not in the table, SaveTableCopy will save wave0 but not wave1. When the saved experiment is open, there will be a broken dependency.

The main use for saving as a tab or comma-delimited text file is for exporting data to another program.

When calling SaveTableCopy from a procedure, you should call DoUpdate before calling SaveTable copy. This insures that the table is up-to-date if your procedure has redimensioned or otherwise changed the number of points in the waves in the table.

SaveTableCopy sets the variable V\_flag to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the /Z flag and check V\_flag after calling SaveTableCopy.

The **SaveData** operation also has the ability to save a table to a packed experiment file. SaveData is more complex but a bit more flexible than SaveTableCopy.

### Examples

This function saves all tables to a single tab-delimited text file.

```
Function SaveAllTablesToTextFile(pathName, fileName)
 String pathName // Name of an Igor symbolic path.
 String fileName

 String tableName
 Variable index

 index = 0
 do
 tableName = WinName(index, 2)
 if (strlen(tableName) == 0)
 break
 endif

 SaveTableCopy/P=$pathName/W=$tableName/T=1/A=1 as fileName

 index += 1
 while(1)
End
```

## sawtooth

### sawtooth(*num*)

The sawtooth function returns  $((num + n2\pi) \bmod 2\pi) / 2\pi$  where *n* is used to correct if *num* is negative. Sawtooth is used to create arbitrary periodic waveforms like sine and cosine.

### Examples

```
wave1 = sawtooth(x)
```

creates a sawtooth in wave1 whose Y values range from 0 to 1 as its X values go through  $2\pi$  units.

```
wave1 = exp(sawtooth(x))
```

creates a series of exponentials in wave1 of amplitude exp(1) and period  $2\pi$ .

You can also use sawtooth to create periodic repetitions of a given part of a wave:

```
wave1 = wave2(sawtooth(x))
```

creates a periodic repetition of wave2 in wave1 given the correct X scaling for the waves.

## ScaleToIndex

### ScaleToIndex(*wave, coordValue, dim*)

The ScaleToIndex function returns the number of the element in the requested dimension whose scaled index value is closest to *coordValue*.

The ScaleToIndex function was added in Igor Pro 7.00.

### Parameters

*dim* is a dimension number: 0 for rows, 1 for columns, 2 for layers, 3 for chunks.

## ScreenResolution

---

*coordValue* is a scaled index in that dimension.

### Details

The ScaleToIndex function returns the value of the expression:

```
round((coordValue - DimOffset(wave,dim)) / DimDelta(wave,dim))
```

With *dim*=0, ScaleToIndex is equivalent to **x2pnt**.

If *coordValue* is NaN or +/-INF, ScaleToIndex returns NaN. Otherwise, the result is computed based on the **DimOffset** and **DimDelta** of the specified dimension of the wave. The result is not clipped to a valid element number for the wave dimension.

### See Also

**IndexToScale**, **x2pnt**, **DimDelta**, **DimOffset**

**Waveform Model of Data** on page II-62 for an explanation of wave scaling.

## ScreenResolution

### ScreenResolution

The ScreenResolution function returns the logical resolution of your video display screen in dots per inch (dpi). On Macintosh this is always 72. On Windows it is usually 96 (small fonts) or 120 (large fonts).

### Examples

```
// 72 is the number of points in an inch which is constant.
Variable pixels = numPoints * (ScreenResolution/72) // Convert points to pixels
Variable points = numPixels * (72/ScreenResolution) // Convert pixels to points
```

### See Also

**PanelResolution**

## sec

### sec(*angle*)

The sec function returns the secant of *angle* which is in radians:

$$\sec(x) = \frac{1}{\cos(x)}$$

In complex expressions, *angle* is complex, and sec(*angle*) returns a complex value.

### See Also

**sin**, **cos**, **tan**, **csc**, **cot**

## sech

### sech(*x*)

The sech function returns the hyperbolic secant of *x*.

$$\operatorname{csch}(x) = \frac{1}{\cosh(x)} = \frac{2}{e^x + e^{-x}}$$

In complex expressions, *x* is complex, and sech(*x*) returns a complex value.

### See Also

**cosh**, **tanh**, **coth**, **csch**

## Secs2Date

**Secs2Date**(*seconds*, *format* [, *sep*])

The Secs2Date function returns a string containing a date.

With *format* values 0, 1, and 2, the formatting of dates depends on operating system settings entered in the Language & Region control panel (*Macintosh*) or the Region control panel (*Windows*). These date formats do not work with dates before 0001-01-01 in which case Date2Secs returns an empty string.

If *format* is -1, the format is independent of operating system settings. The fixed-length format is “*day /month /year (dayOfWeekNum)*”, where *dayOfWeekNum* is 1 for Sunday, 2 for Monday... and 7 for Saturday.

If *format* is -2, the format is YYYY-MM-DD.

The optional *sep* parameter affects format -2 only. If *sep* is omitted, the separator character is “-”. Otherwise, *sep* specifies the separator character.

### Parameters

*seconds* is the number of seconds from 1/1/1904 to the date to be returned.

*seconds* is limited to the range -1094110934400 (-32768-01-01) to 973973807999 (32768-12-31). For *seconds* outside that range, Secs2Date returns an empty string.

*format* is a number between -2 and 2 which specifies how the date is to be constructed.

### Examples

```
Print Secs2Date(DateTime,-2) // 1993-03-14
Print Secs2Date(DateTime,-2,"/") // 1993/03/14
Print Secs2Date(DateTime,-1) // 15/03/1993 (2)
Print Secs2Date(DateTime,0) // 3/15/93 (depends on system settings)
Print Secs2Date(DateTime,1) // Monday, March 15, 1993 (depends on system settings)
Print Secs2Date(DateTime,2) // Mon, Mar 15, 1993 (depends on system settings)
```

### See Also

For further discussion of how Igor represents dates, see **Date/Time Waves** on page II-85.

The **date**, **date2secs** and **DateTime** functions.

## Secs2Time

**Secs2Time**(*seconds*, *format*, [*fracDigits*])

The Secs2Time function returns a string containing a time.

### Parameters

*seconds* is the number of seconds from 1/1/1904 to the time to be returned.

*format* is a number between 0 and 5 that specifies how the time is to be constructed. It is interpreted as follows:

- 0: Normal time, no seconds.
- 1: Normal time, with seconds.
- 2: Military time, no seconds.
- 3: Military time, with seconds and optional fractional seconds.
- 4: Elapsed time, no seconds.
- 5: Elapsed time, with seconds and optional fractional seconds.

“Normal” formats (0 and 1) follow the preferred formatting of the short time format as set in the International control panel (*Macintosh*) or in the Regional and Language Options control panel (*Windows*).

“Military” means that the hour is a number from 0 to 23. Hours greater than 23 are wrapped.

“Elapsed” means that the hour is a number from -9999 to 9999. The result for hours outside that range is undefined.

The *fracDigits* parameter is optional and specifies the number of digits of fractional seconds. The default value is 0. The *fracDigits* parameter is ignored for *format*=0, 1, 2, and 4.

## SelectNumber

---

### Examples

```
Print Secs2Time(DateTime,0) // prints 1:07 PM
Print Secs2Time(DateTime,1) // prints 1:07:28 PM
Print Secs2Time(DateTime,2) // prints 13:07
Print Secs2Time(DateTime,3) // prints 13:07:29
Print Secs2Time(30*60*60+45*60+55,4) // Prints 30:45
Print Secs2Time(30*60*60+45*60+55,5) // Prints 30:45:55
```

### See Also

For a discussion of how Igor represents dates, see **Date/Time Waves** on page II-85.

The **Secs2Date**, **date**, **date2secs** and **DateTime** functions. Also, **Operators** on page IV-6 for ? details.

## SelectNumber

**SelectNumber**(*whichOne*, *val1*, *val2* [, *val3*])

The SelectNumber function returns one of *val1*, *val2*, or (optionally) *val3* based on the value of *whichOne*.

SelectNumber(*whichOne*, *val1*, *val2*) returns *val1* if *whichOne* is zero, else it returns *val2*.

SelectNumber(*whichOne*, *val1*, *val2*, *val3*) returns *val1* if *whichOne* is negative, *val2* if *whichOne* is zero, or *val3* if *whichOne* is positive.

### Details

SelectNumber works with complex (or real) *val1*, *val2*, and *val3* when the result is assigned to a complex wave or variable. (Print expects a real result, see the "causes error" example, below).

If *whichOne* is NaN, then NaN is returned.

*whichOne* must always be a real value.

Unlike the ? : conditional operator, SelectNumber always evaluates all of the numeric expression parameters *val1*, *val2*, ...

SelectNumber works in a macro, whereas the conditional operator does not.

### Examples

```
Print SelectNumber(0,1,2) // prints 1
Print SelectNumber(0,1,2,3) // prints 2
wv=SelectNumber(numtype(wv[p])==2,wv[p],0) // replace NaNs with zeros

// chooses among complex values
Variable/C cx= SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1))

// causes error because Print expects a real value (not complex)
Print SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1))

// The real function expects a complex result
Print real(SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1)))
```

### See Also

The **SelectString** and **limit** functions, and **Waveform Arithmetic and Assignments** on page II-74. Also, **Operators** on page IV-6 for details about the ? : operator.

## SelectString

**SelectString**(*whichOne*, *str1*, *str2* [, *str3*])

The SelectString function returns one of *str1*, *str2*, or (optionally) *str3* based on the value of *whichOne*.

SelectString(*whichOne*, *str1*, *str2*) returns *str1* if *whichOne* is zero, else it returns *str2*.

SelectString(*whichOne*, *str1*, *str2*, *str3*) returns *str1* if *whichOne* is negative, *str2* if *whichOne* is zero, or *str3* if *whichOne* is positive.

### Details

If *whichOne* is NaN, then "" is returned.

*whichOne* must always be a real value.

Unlike the ? : conditional operator, SelectString always evaluates all of the string expression parameters *str1*, *str2*, ...

SelectString works in a macro, whereas the conditional operator does not.

### Examples

```
Print SelectString(0,"hello","there") // prints "hello"
Print SelectString(1,"hello","there") // prints "there"
Print SelectString(-3,"hello","there","jack") // prints "hello"
Print SelectString(0,"hello","there","jack") // prints "there"
Print SelectString(100,"hello","there","jack") // prints "jack"
```

### See Also

The **SelectNumber** function and **String Expressions** on page IV-13. Also, **Operators** on page IV-6 for details about the ?: operator.

## SetActiveSubwindow

### SetActiveSubwindow *subWinSpec*

The SetActiveSubwindow operation specifies the subwindow that is to be activated. This operation is mainly for use by recreation macros.

### Parameters

*subWinSpec* specifies an existing subwindow. See **Subwindow Syntax** on page III-92 for details on subwindow specifications.

Use `_endfloat_` for *subWinSpec* to make a newly-created floating panel not be the default target.

### See Also

**GetWindow** with the activeSW keyword.

## SetAxis

### SetAxis [*flags*] *axisName* [, *num1*, *num2*]

The SetAxis operation sets the extent (or “range”) of the named axis.

### Parameters

*axisName* is usually “left”, “right”, “top” or “bottom”, but it can also be the name of a free axis, such as “vertCrossing”.

If *axisName* is a vertical axis such as “left” or “right” then *num1* sets the bottom end of the axis and *num2* sets the top end of the axis.

If *axisName* is a horizontal axis such as “top” or “bottom” then *num1* sets the left end of the axis and *num2* sets the right end of the axis.

You can flip the graph by reversing *num1* and *num2* (or by using /A/R). This is particularly useful for images, because Igor plots an image inverted.

If you pass \* (asterisk) for *num1* and/or *num2* then the corresponding end of the axis will be autoscaled.

### Flags

|                 |                                                                                                                                                                          |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /A[= <i>a</i> ] | Autoscale axis (when used, <i>num1</i> , <i>num2</i> should be omitted).                                                                                                 |
| <i>a</i> =0:    | No autoscale. Same as no /A flag.                                                                                                                                        |
| <i>a</i> =1:    | Normal autoscale. Same as /A.                                                                                                                                            |
| <i>a</i> =2:    | Autoscale Y axis to a subset of the data defined by the current X axis range.                                                                                            |
| /E= <i>z</i>    | Sets the treatment of zero when the axis is in autoscale mode.                                                                                                           |
| <i>z</i> =0:    | Normal mode where zero is not treated special.                                                                                                                           |
| <i>z</i> =1:    | Forces the smaller end of the axis to be set to zero (autoscale from zero).                                                                                              |
| <i>z</i> =2:    | Axis is symmetric about zero.                                                                                                                                            |
| <i>z</i> =3:    | If the data is unipolar (all positive or all negative), this behaves like /E=1 (autoscale from zero). If the data is bipolar, it behaves like /E=0 (normal autoscaling). |

## SetBackground

---

|                                |                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/N=<i>n</i></code>       | Sets the algorithm for axis autoscaling.<br><i>n</i> =0: Normal mode; sets the axis limits equal to the data limits.<br><i>n</i> =1: Picks nice values for the axis limits.<br><i>n</i> =2: Picks nice values; also ensures that the data is inset from the axis ends.                                                                                          |
| <code>/R</code>                | Reverses the autoscaled axis (smaller values at the left for horizontal axes, at the top for vertical axes) when used with <code>/A</code> . Although it only has an effect for autoscale, it can be used with nonautoscale version of <code>SetAxis</code> so that the next time the Axis Range tab is used the “reverse axis” checkbox will already be set.   |
| <code>/W=<i>winName</i></code> | Sets axes in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |
| <code>/Z</code>                | No error reporting if named axis doesn't exist in a style macro.                                                                                                                                                                                                                                                                                                |

## SetBackground

### **SetBackground** *numericExpression*

The `SetBackground` operation sets *numericExpression* as the current unnamed background task.

`SetBackground` works only with the unnamed background task. New code should use named background tasks instead. See **Background Tasks** on page IV-316 for details.

The background task runs while Igor is not busy with other things. Normally, there won't be a background task. The most common use for the background task is to monitor or drive a continuous data acquisition process.

### **Parameters**

*numericExpression* is a single precision numeric expression that Igor executes when it isn't doing anything else.

### **Details**

*numericExpression* is expected to return one of three numeric values:

- 0: Background task executed normally.
- 1: Background task wants to stop.
- 2: Background task encountered error and wants to stop.

Usually the expression will be a call to a user-defined numeric function or external function to drive or monitor data acquisition. The expression should be designed to execute very quickly and it should not present a dialog to the user nor should it create or destroy windows. Generally, it should do nothing more than store data into waves or variables. You can use Igor's dependency mechanism to perform more extensive tasks.

`SetBackground` designates the background task but you must use `CtrlBackground` to start it. You can also use `KillBackground` to stop it. You can not call `SetBackground` from the background function itself.

### **See Also**

The **BackgroundInfo**, **CtrlBackground**, **CtrlNamedBackground**, **KillBackground**, and **SetProcessSleep** operations, and **Background Tasks** on page IV-316.

## SetDashPattern

### **SetDashPattern** *dashNumber*, {*d1*, *s1* [, *d2*, *s2*]...}

The `SetDashPattern` operation defines a dashed-line pattern for a user-defined dashed line. These dashed lines are used by the drawing tools and the Modify Waves Appearance dialog, and are elsewhere referred to as “line styles”.

**Parameters**

*dashNumber* specifies which dash pattern is to be set. It must be between 1 and 17. Dash pattern 0 is reserved for a solid line.

|   |       |    |       |
|---|-------|----|-------|
| 0 | _____ | 9  | ----- |
| 1 | ..... | 10 | ----- |
| 2 | ..... | 11 | ----- |
| 3 | ----- | 12 | _____ |
| 4 | ..... | 13 | _____ |
| 5 | ----- | 14 | _____ |
| 6 | ..... | 15 | _____ |
| 7 | ----- | 16 | _____ |
| 8 | ----- | 17 | _____ |

$\{d1,s1 [d2,s2]...\}$  defines the dash pattern. The dash pattern consists of 1 to 8 “dash,skip” pairs. Each pair consists of the number of drawn points followed by the number of skipped points.

*d1* specifies the number of drawn points and *s1* specifies the number of skipped points in the first “dash,skip” pair. *d2* and *s2* specify the number of drawn and skipped points in the second pair and so on. Each draw or skip value must be between 1 and 127.

**Details**

SetDashPattern updates *all* graphs, panels and layouts so that any dashed lines will be updated with the new pattern. If you repeatedly call SetDashPattern from within a macro, you should precede the commands with the PauseUpdate operation to prevent multiple updates (which would be slow).

Dashed lines may also be redefined by the Dashed Lines dialog which you can choose from the Misc menu.

The dashed line patterns are saved as part of the experiment. When a new experiment is opened, the preferred dash patterns are restored.

Some programs and printer drivers do not properly render dashed lines with many “dash,skip” pairs.

**Examples**

```
Make test; Display test
SetDashPattern 17, {20,3,15,8} // sets last dashed line pattern
ModifyGraph lstyle(test)=17 // apply pattern to trace
```

**See Also**

PauseUpdate and ResumeUpdate operations, and Dashed Lines on page III-498.

**SetDataFolder****SetDataFolder** *dataFolderSpec*

The SetDataFolder operation sets the current data folder to the specified data folder.

**Parameters**

*dataFolderSpec* can be a simple name (MyDataFolder), a path (root:MyDataFolder) or a string expression containing a name or path. It can also be a data folder reference created by the DFREF keyword or returned by GetDataFolderDFR.

If *dataFolderSpec* is a path it can be a partial path relative to the current data folder (:MyDataFolder) or an absolute path starting from root (root:MyDataFolder).

**Examples**

```
SetDataFolder foo // Sets CDF to foo in the current data folder
SetDataFolder :bar:foo // Sets CDF to foo in bar current data folder
SetDataFolder root:foo // Sets CDF to foo in the root data folder
DFREF savedDF= GetDataFolderDFR() // Remember current data folder
NewDataFolder/O/S root:MyDataFolder // Set CDF to a new data folder
Variable/G newVariable=1 // Do work in the new data folder
SetDataFolder savedDF // Restore current data folder
```

Chapter II-8, Data Folders and Data Folder References on page IV-78.

### SetDimLabel

**SetDimLabel** *dimNumber, dimIndex, label, wavelist*

The SetDimLabel operation sets the dimension label or dimension element label to the specified label.

#### Parameters

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers and 3 for chunks.

If *dimIndex* is -1, it sets the label for the entire dimension. For *dimIndex*  $\geq$  0, it sets the dimension label for that element of the dimension.

*label* is a name (e.g., time), not a string (e.g., "time").

*label* is limited to 255 bytes. If you use more than 31 bytes, your wave will require Igor Pro 8.00 or later.

#### Details

Dimension labels can contain up to 255 bytes and may contain spaces and other normally-illegal characters if you surround the name in single quotes or if you use the \$ operator to convert a string expression to a name.

Dimension labels have the same characteristics as object names. See **Object Names** on page III-503 for a discussion of object names in general.

**Dimension Labels** on page II-93 and **Example: Wave Assignment and Indexing Using Labels** on page II-82 for further usage details and examples.

### SetDrawEnv

**SetDrawEnv** [/W=*winName*] *keyword* [=value] [, *keyword* [=value]]...

The SetDrawEnv operation sets properties of the drawing environment.

If one or more draw objects are selected in the top window then the SetDrawEnv command will apply only to those objects.

If no objects are selected *and* if the keyword *save* is *not* used *then* the command applies only to the next object drawn.

If no objects are selected *and* if the keyword "save" is used *then* the command sets the environment for all following objects.

Each draw layer has its own draw environment settings.

#### Parameters

SetDrawEnv can accept multiple *keyword=value* parameters on one line.

|                      |                                                                                                                                                                                                               |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>arrow=arr</i>     | Specifies the arrow head position on lines.<br><i>arr</i> =0: No arrowhead (default).<br><i>arr</i> =1: Arrowhead at end.<br><i>arr</i> =2: Arrowhead at start.<br><i>arr</i> =3: Arrowhead at start and end. |
| <i>arrowfat=afat</i> | Sets ratio of arrowhead width to length (default is 0.5).                                                                                                                                                     |
| <i>arrowlen=alen</i> | Sets length of arrowhead in points (default is 10).                                                                                                                                                           |
| <i>arrowSharp=s</i>  | Specifies the continuously variable barb sharpness between -1.0 and 1.0.<br><i>s</i> =1: No barb; lines only.<br><i>s</i> =0: Blunt (default).<br><i>s</i> =-1: Diamond.                                      |
| <i>arrowframe=f</i>  | Specifies the stroke outline thickness of the arrow in points (default is <i>f</i> =0 for solid fill).                                                                                                        |

|                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>astyle=s</code>                            | <p>Specifies which side of the line has barbs relative to a right-facing arrow.</p> <p><code>s=0</code>: None.<br/> <code>s=1</code>: Top.<br/> <code>s=2</code>: Bottom.<br/> <code>s=3</code>: Both (default).</p>                                                                                                                                                                                                                                                                                                                                                          |
| <code>clipRect=(left, top, right, bottom)</code> | <p>Clips drawing to the specified rectangle. The <code>clipRect</code> keyword was added in Igor Pro 8.00.</p> <p><i>left</i>, <i>top</i>, <i>right</i>, and <i>bottom</i> are specified in the current coordinate system of the drawing environment.</p> <p>If a save is in effect, you can use values of all 0 to cancel the clipping or, better, you can use a push, <code>clipRect</code>, save, drawing, pop sequence. When a save is in effect, the clipping is set once and remains unchanged for the remaining objects even if the coordinate system is changed.</p>  |
| <code>dash=dsh</code>                            | <p><i>dsh</i> is a dash pattern number between 0 and 17 (see <b>SetDashPattern</b> for patterns). 0 (solid line) is the default.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>fillbgc=(r,g,b[,a])</code>                 | <p>Specifies fill background color. <i>r</i>, <i>g</i>, <i>b</i>, and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b>. The default is the window's background color.</p>                                                                                                                                                                                                                                                                                                                                                                                |
| <code>fillfgc=(r,g,b[,a])</code>                 | <p>Specifies fill foreground color. <i>r</i>, <i>g</i>, <i>b</i>, and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b>. The default is opaque white.</p>                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>fillpat=fpatt</code>                       | <p>Specifies fill pattern density.</p> <p><code>fpatt=-1</code>: Erase to background color.<br/> <code>fpatt=0</code>: No fill.<br/> <code>fpatt=1</code>: 100% (solid pattern, default).<br/> <code>fpatt=2</code>: 75% gray.<br/> <code>fpatt=3</code>: 50% gray.<br/> <code>fpatt=4</code>: 25% gray.</p>                                                                                                                                                                                                                                                                  |
| <code>fillRule=fr</code>                         | <p>Determines how polygons and Bezier curves with intersecting edges are filled:</p> <p><code>fr=0</code>: Winding rule (default)<br/> <code>fr=1</code>: Even-odd rule</p> <p>The <code>fillRule</code> keyword applies only to polygons created with <b>DrawPoly</b> and <b>DrawBezier</b>, not to those created manually.</p> <p>See <b>Polygon and Bezier Curve Fill Rules</b> on page III-72 for a discussion of the rules used for filling polygons and Bezier curves with intersecting edges.</p> <p>The <code>fillRule</code> keyword was added in Igor Pro 9.00.</p> |
| <code>fname="fontName"</code>                    | <p>Sets font name, default is the default font or the graph font.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>gedit=flag</code>          | Supplies optional edit flag for a group of objects. Use with <code>gstart</code> .<br><code>flag=0</code> : Select entire group, moveable (default).<br><code>flag=1</code> : Individual components editable as if not grouped. Allows objects to be grouped by name but still be editable.                                                                                                                                                                             |
| <code>gname=name</code>          | Supplies optional <i>name</i> for an object group. Use with <code>gstart</code> .                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>gstart</code>              | Marks the start of a group of objects.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>gstop</code>               | Marks the end of a group of objects.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>gradient</code>            | See <b>Gradient Fills</b> on page III-500 for details.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>gradientExtra</code>       | See <b>Gradient Fills</b> on page III-500 for details.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>linebgc=(r,g,b[,a])</code> | Specifies line background color. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> . The default is the window's background color.                                                                                                                                                                                                                                                                             |
| <code>linecap=cap</code>         | Sets the line end cap style:<br><code>cap=0</code> : Flat caps<br><code>cap=1</code> : Round caps<br><code>cap=2</code> : Square caps (default)<br><br>See <b>Line Join and End Cap Styles</b> on page III-498 for further information.<br><code>linecap</code> was added in Igor Pro 8.00.                                                                                                                                                                             |
| <code>linefgc=(r,g,b[,a])</code> | Specifies line foreground color. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> . The default is opaque black.                                                                                                                                                                                                                                                                                              |
| <code>linejoin=j</code>          | Sets the line join style:<br><code>j=0</code> : Miter joins<br><code>j=1</code> : Round joins<br><code>j=2</code> : Bevel joins (default)<br><br>For a miter join, you can also set the miter limit using the <code>lineMiterLimit</code> keyword.<br>See <b>Line Join and End Cap Styles</b> on page III-498 for further information.<br><code>linejoin</code> was added in Igor Pro 8.00.                                                                             |
| <code>lineMiterLimit=ml</code>   | Applies only to a miter line join style. See the <code>linejoin</code> keyword.<br><code>ml &gt;= 1</code> : Sets miter limit to <i>ml</i><br><code>ml = INF</code> : Sets miter limit to unlimited<br><code>ml = 0</code> : Leaves miter limit unchanged<br><code>ml = -1</code> : Sets miter limit to default (10)<br><br>See <b>Line Join and End Cap Styles</b> on page III-498 for further information.<br><code>lineMiterLimit</code> was added in Igor Pro 8.00. |
| <code>linepat=patt</code>        | Specifies the line pattern/density.<br><code>patt=1</code> : 100% (solid pattern, default).<br><code>patt=2</code> : 75% gray.<br><code>patt=3</code> : 50% gray.<br><code>patt=4</code> : 25% gray.                                                                                                                                                                                                                                                                    |
| <code>linethick=thick</code>     | <i>thick</i> is a line thickness $\geq 0$ , default is 1 point.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>origin= x0,y0</code>       | Moves coordinate system origin to <i>x0,y0</i> . Unlike <code>translate</code> , <code>rotate</code> , and <code>scale</code> , this survives a change in coordinate system and is most useful that way. See <b>Coordinate Transformation</b> .                                                                                                                                                                                                                         |

---

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pop                          | Pops a draw environment from the stack. Pops should always match pushes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| push                         | Pushes the current draw environment onto a stack (limited to 10).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| rotate= <i>deg</i>           | Rotates coordinate system by <i>deg</i> degrees. Only makes sense if X and Y coordinate systems are the same. See <b>Coordinate Transformation</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| rounding= <i>rnd</i>         | Radius for rounded rectangles in points, default is 10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| rsabout                      | Redefines coordinate system rotation or scaling to occur at the translation point instead of the current origin. To use, combine rotate or scale with translate and rsabout parameters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| save                         | Stores the current drawing environment as the default environment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| scale= <i>sx,sy</i>          | Scales coordinate system by <i>sx</i> and <i>sy</i> . Affects only coordinates — not line thickness or arrow head sizes. See <b>Coordinate Transformation</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| subpaths= <i>sp</i>          | Controls the way polygon and Bezier curve segments separated by NaN values are drawn.:<br><i>sp=0</i> : Each segment is drawn as a separate polygon or Bezier curve, and any arrows are added to each segment as if they are separate polygons or Bezier curves. This is the default if you omit the subpaths keyword.<br><i>sp=1</i> : The segments are treated as subpaths within a single polygon or Bezier curve, making it possible to define a shape with holes. Any arrows are added only to the first or last points in the entire shape.<br><br>The subpaths keyword applies only to polygons created with <b>DrawPoly</b> and <b>DrawBezier</b> , not to those created manually.<br>Also see the fillRule keyword.<br>The subpaths keyword was added in Igor Pro 9.00. |
| textrgb=( <i>r,g,b[,a]</i> ) | Specifies text color. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> . The default is opaque black.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| textrot= <i>rot</i>          | Text rotation in degrees.<br><i>rot</i> is a value from -360 to 360.<br>0 is normal (default) horizontal left-to-right text,<br>90 is vertical bottom-to-top text, etc.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| textxjust= <i>xj</i>         | Sets horizontal text alignment.<br><i>xj=0</i> : Left aligned text (default).<br><i>xj=1</i> : Center aligned text.<br><i>xj=2</i> : Right aligned text.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| textyjust= <i>yj</i>         | Sets vertical text alignment.<br><i>yj=0</i> : Bottom aligned text (default).<br><i>yj=1</i> : Middle aligned text.<br><i>yj=2</i> : Top aligned text.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| translate= <i>dx,dy</i>      | Shifts coordinate system by <i>dx</i> and <i>dy</i> . Units are in the current coordinate system. See <b>Coordinate Transformation</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| xcoord=abs                   | X coordinates are absolute window coordinates (default for all windows except graphs where the default is xcoord=prel). The unit of measurement is <b>Control Panel Units</b> if the window is a panel, otherwise they are points. The left edge of the window (or of the printable area in a layout) is at x=0. See <b>Drawing Coordinate Systems</b> on page III-66 for details.                                                                                                                                                                                                                                                                                                                                                                                               |

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| ycoord=axisName | <p>Y coordinates are in terms of the named axis (graphs only).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Flags**

|                   |                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/W=winName</i> | <p>Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.</p> <p>When identifying a subwindow with <i>winName</i>, see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.</p> |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Coordinate Transformation**

The execution order for the translate, rotate, scale, and origin parameters is important. Translation followed by rotation is different than rotation followed by translation. When using multiple keywords in one SetDrawEnv operation, the order in which they are applied is origin, translate, rotate followed by scale regardless of the command order (with the exception of the rsabout parameter). Before using origin with

the save keyword, you should use push to save the current draw environment and then use pop after drawing objects using the new origin.

### Examples

Following is a simple example of arrow markers:

```
NewPanel
SetDrawEnv arrow= 1,arrowlen= 30,save
SetDrawEnv arrowsharp= 0.3
DrawLine 61,67,177,31
SetDrawEnv arrowsharp= 1
DrawLine 65,95,181,59
SetDrawEnv astyle= 1
DrawLine 69,123,185,87
SetDrawEnv arrowframe= 1
DrawLine 73,151,189,115
```

You can position objects in one coordinate system and then draw them in another with the origin keyword. In the following coordinate transformation example, we position arrows in axis units but size them in absolute units.

```
Make/O jack=sin(x/8)
Display jack
SetDrawEnv xcoord=bottom,ycoord=left,save
SetDrawEnv push
SetDrawEnv origin=50,0
SetDrawEnv xcoord=abs,ycoord=abs,arrow=1,arrowlen=20,arrowsharp=0.2,save
DrawLine 0,0,50,0 // arrow 50 points long pointing to the right
DrawLine 0,0,0,50 // arrow 50 points long pointing down
// now let's move over, rotate a bit and draw the same arrows:
SetDrawEnv translate=100,0
SetDrawEnv rotate=30,save
DrawLine 0,0,50,0
DrawLine 0,0,0,50
SetDrawEnv pop
```

Now try zooming in on the graph. You will see that the first pair of arrows always starts at 50 on the bottom axis and 0 on the left axis whereas the second pair is 100 points to the right of the first.

## SetDrawLayer

**SetDrawLayer** [/K/W=*winName*] *layerName*

The SetDrawLayer operation makes all future drawing operations use the named layer.

### Parameters

Valid *layerNames* for graphs:

|          |          |          |          |           |           |         |
|----------|----------|----------|----------|-----------|-----------|---------|
| ProgBack | UserBack | ProgAxes | UserAxes | ProgFront | UserFront | Overlay |
|----------|----------|----------|----------|-----------|-----------|---------|

Valid *layerNames* for page layouts:

|          |          |           |           |         |
|----------|----------|-----------|-----------|---------|
| ProgBack | UserBack | ProgFront | UserFront | Overlay |
|----------|----------|-----------|-----------|---------|

Valid *layerNames* for control panels:

|          |          |           |           |         |
|----------|----------|-----------|-----------|---------|
| ProgBack | UserBack | ProgFront | UserFront | Overlay |
|----------|----------|-----------|-----------|---------|

There are really only three layers for control panels. ProgFront is treated as an alias for ProgBack and UserFront is treated as an alias for UserBack.

## SetEnvironmentVariable

---

### Flags

|                                |                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/K</code>                | Kills (erases) the given layer.                                                                                                                                                                                                                                                                                                                               |
| <code>/W=<i>winName</i></code> | Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |

### Details

The Overlay layer is drawn above all else. It is not included when printing or exporting graphics and is provided for programmers who wish to add user-interface drawing elements without disturbing graphics drawing elements. Overlay was added in Igor Pro 7.00.

The back-to-front order of the layers is shown by the layer pop-up menu obtained by clicking the Layer icon in the drawing palette: . A checkmark indicates the current layer. Non-drawing layers are indicated with gray text.

### Output Variables

SetDrawLayer sets `S_Name` to the name of the previously-selected drawing layer. You can use this to restore the active drawing layer after programmatic drawing.

### See Also

**Drawing Layers** on page III-68 and the **DrawAction** operation.

## SetEnvironmentVariable

### **SetEnvironmentVariable**(*varName*, *varValue*)

The SetEnvironmentVariable function creates an environment variable in Igor's process and sets its value to *varValue*. If a variable named *varName* already exists, its value is set to *varValue*.

The function returns 0 if it succeeds or a nonzero value if it fails.

The SetEnvironmentVariable function was added in Igor Pro 7.00.

### Parameters

|                 |                                                                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>varName</i>  | The name of an environment variable which does not need to actually exist. It must not be an empty string and may not contain an equals sign (=).                                         |
| <i>varValue</i> | The new contents for the variable.<br><br>On Windows, if <i>varValue</i> is an empty string, the variable is removed. On other platforms, the variable is always set to <i>varValue</i> . |

### Details

The environment of Igor's process is composed of a set of key=value pairs that are known as environment variables. Any child process created by calling ExecuteScriptText inherits the environment variables of Igor's process.

SetEnvironmentVariable changes the environment variables present in Igor's process and any future process created by ExecuteScriptText but does not affect any other processes already created.

On Windows, environment variable names are case-insensitive. On other platforms, they are case-sensitive.

### Examples

```
Variable result
result = SetEnvironmentVariable("SOME_VARIABLE", "15")
result = SetEnvironmentVariable("SOME_OTHER_VARIABLE", "string value")
```

### See Also

**GetEnvironmentVariable**, **UnsetEnvironmentVariable**

## SetFileFolderInfo

**SetFileFolderInfo** [*flags*] [*fileOrFolderNameStr*]

The SetFileFolderInfo operation changes the properties of a file or folder.

### Parameters

*fileOrFolderNameStr* specifies the file or folder to be changed.

If you use a full or partial path for *fileOrFolderNameStr*, see **Path Separators** on page III-453 for details on forming the path.

Folder paths should not end with single Path Separators. See the **MoveFolder Details** section.

If Igor can not determine the location of the file or folder from *fileOrFolderNameStr* and */P=pathName*, it displays a dialog allowing you to specify the file to be deleted. Use */D* to select a folder in this event, otherwise Igor prompts your for a file.

### Flags

At least one of the seven following flags is required, or nothing is actually accomplished:

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/CDAT=cdate</i> | Specifies the number of seconds since midnight January 1, 1904 when the file or folder was first created. <i>cDate</i> is interpreted as local time or UTC depending on the <i>/UTC</i> flag.                                                                                                                                                                                                                                                       |
| <i>/INV[=inv]</i>  | Sets the visibility of a file.<br><i>inv=0</i> : File is visible.<br><i>inv=1</i> : Default; file is invisible ( <i>Macintosh</i> ) or Hidden ( <i>Windows</i> ).                                                                                                                                                                                                                                                                                   |
| <i>/MDAT=mDate</i> | Specifies the number of seconds since midnight January 1, 1904 when the file or folder was modified most recently. <i>mDate</i> is interpreted as local time or UTC depending on the <i>/UTC</i> flag.                                                                                                                                                                                                                                              |
| <i>/RO[=ro]</i>    | Sets the read/write state of a file or folder.<br><i>ro=0</i> : File or folder is writable.<br><i>ro=1</i> : File or folder is locked (default).<br><br>On Macintosh, locking the file or folder is equivalent to setting the locked property manually using the Get Info window in the Finder.<br>On Windows, locking the file or folder is equivalent to setting the read-only property manually using the Properties window in Windows Explorer. |

If *fileOrFolderNameStr* refers to a file (not a folder), SetFileFolderInfo updates the file properties to reflect values given with the following keywords:

|                         |                                                                                                                                                                                                                                                                                            |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/CRE8=creatorStr</i> | Sets the four-character creator code string, such as 'IGR0' (Igor Pro creator code).<br><br>Ignored on Windows, where files have no "creator code"; instead file extensions are "registered" or "owned" by one, and only one, application. You cannot change that ownership from Igor Pro. |
| <i>/FTYP=fTypeStr</i>   | Sets the four-character file type code, such as 'TEXT' or 'IGsU' (packed experiment).<br>Ignored on Windows. Use <b>MoveFile</b> to change the file extension.                                                                                                                             |
| <i>/STA[=st]</i>        | Specifies whether the file is a stationery file or not.<br><i>st=1</i> : Stationery file (default).<br><i>st=0</i> : Normal file.<br><br>Ignored on Windows. Use <b>MoveFile</b> to change the file extension.                                                                             |

### Optional Flags

|           |                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/D</i> | Uses the Select Folder dialog rather than Open File dialog when <i>pathName</i> and <i>fileOrFolderNameStr</i> do not specify an existing file or folder. |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|

## SetFileFolderInfo

---

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/P=<i>pathName</i></code> | Specifies the folder to look in for the file. <i>pathName</i> is the name of an existing symbolic path.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>/R[=<i>r</i>]</code>      | Recursively applies change(s) to all files or folders in the folder specified by <code>/P=<i>pathName</i></code> or <code>fileOrFolderNameStr</code> , and the folder itself:<br><code>r=0:</code> No recursion. Same as no <code>/R</code> .<br><code>r=1:</code> Recursively apply changes to files.<br><code>r=2:</code> Recursively apply changes to folders, including the folder specified by <code>pathName</code> or <code>fileOrFolderNameStr</code> .<br><code>r=3:</code> Recursively apply changes to both files and folders (default).<br><code>/R</code> requires <code>/D</code> and a folder specification. |
| <code>/UTC[=<i>u</i>]</code>    | If you include <code>/UTC</code> or <code>/UTC=1</code> , <code>SetFileFolderInfo</code> interprets the creation and modification dates as UTC (coordinated universal time). If you omit <code>/UTC</code> or specify <code>/UTC=0</code> , <code>SetFileFolderInfo</code> interprets the creation and modification dates as local time.<br>The default, used if you omit <code>/UTC</code> , is local time.<br>The <code>/UTC</code> flag was added in Igor Pro 9.00.                                                                                                                                                      |
| <code>/Z[=<i>z</i>]</code>      | Prevents procedure execution from aborting if <code>SetFileFolderInfo</code> tries to set information about a file or folder that does not exist. Use <code>/Z</code> if you want to handle this case in your procedures rather than having execution abort.<br><code>/Z=0:</code> Same as no <code>/Z</code> at all.<br><code>/Z=1:</code> Used for setting information for a file or folder only if it exists. <code>/Z</code> alone has the same effect as <code>/Z=1</code> .<br><code>/Z=2:</code> Used for setting information for a file or folder if it exists and displaying a dialog if it does not exist.        |

### Variables

`SetFileFolderInfo` returns information about the file or folder in the following variables:

|                     |                                                                                                                                                         |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>V_flag</code> | 0: File or folder was found.<br>-1: User cancelled the Open File dialog.<br>>0: An error occurred, such as the specified file or folder does not exist. |
| <code>S_path</code> | File system path of the selected file or folder.                                                                                                        |

### Examples

Change the file creator code; no complaint if it doesn't exist:

```
SetFileFolderInfo/Z /CRE8="CWIE", "Macintosh HD:folder:afile.txt"
```

Set the file modification date:

```
Variable mDate= Date2Secs(2000,12,25) + hrs*3600+mins*60+secs
SetFileFolderInfo/P=myPath/MDAT=(mDate), "afile.txt"
```

Remove read-only property from a folder and everything within it:

```
SetFileFolderInfo/P=myPath/D/R/RO=0
```

### See Also

The `GetFileFolderInfo`, `MoveFile`, and `FStatus` operations. The `IndexedFile`, `date2secs`, and `ParseFilePath` functions.

## SetFormula

**SetFormula** *waveName*, *expressionStr*

**SetFormula** *variableName*, *expressionStr*

The SetFormula operation binds the named wave, numeric or string variable to the expression or, if the expression is "", unbinds it from any previous expression. In user functions, SetFormula must be used to create dependencies.

### Parameters

*expressionStr* is a string containing a numeric or string expression, depending on the type of the bound object.

Pass an empty string ("") for *expressionStr* to clear any previous dependency expression associated with the wave or variable.

### Details

The dependent object (the wave or variable) will depend on the objects referenced in the string expression. The expression will be reevaluated any time an object referred to in the expression is modified.

Besides being set from a string expression this differs from just typing:

```
name := expression
```

in that syntax errors in *expressionStr* are not reported and are not fatal. You end up with a dependency assignment that is marked as needing to be recompiled. The recompilation will be attempted every time an object is created or when the procedure window is recompiled.

Use the Object Status dialog in the Misc menu to check up on dependent objects.

### Examples

This command makes the variable `v_sally` dependent on the user-defined function `anotherFunction`, waves `wave_fred` and `wave_sue`, and the system variable `K2`:

```
SetFormula v_sally, "anotherFunction(wave_fred[1]) + wave_sue[0] + K2"
```

This is equivalent to:

```
v_sally := anotherFunction(wave_fred[1]) + wave_sue[0] + K2
```

except that no error will be generated for the SetFormula if, for instance, `wave_fred` does not exist.

A string variable dependency can be created by a command such as:

```
SetFormula myStringVar, "note(wave_joe)"
```

observe that *expressionStr* is a string *containing* a string expression, and that:

```
SetFormula myStringVar, note(wave_joe)
```

is not the same thing. In this case the note of `wave_joe` would contain the expression that `myStringVar` would depend on! Also, `wave_joe` would have to exist for Igor to understand the statement.

### See Also

Chapter IV-9, **Dependencies**, and the **GetFormula** function.

## SetIdlePeriod

**SetIdlePeriod** *period*

The SetIdlePeriod operation changes and reports the period of Igor's main idle loop. The units of *period* are milliseconds. Setting *period* to zero does not change the period.

SetIdlePeriod was added in Igor Pro 8.00.

The default idle period is 20 milliseconds. Setting the period higher may make a slight improvement in the performance of some computation-heavy tasks.

Setting the period lower can make some parts of Igor more responsive. In particular, background tasks can be made to run more often, as the minimum period between runs of a background task is determined by Igor's idle period. Reducing the period too far increases the likelihood that your background task will run too long. Setting the period to very low values can make Igor very sluggish.

## SetIgorHook

---

### Output Variables

SetIdlePeriod creates the output variable `V_value` and sets it to the idle period before the call was made. You can use this value to restore the idle period after temporarily changing it. If period is zero, the idle period is not changed, but the current value is returned in `V_value`.

## SetIgorHook

**SetIgorHook** [/K/L] [*hookType* = [*procName*]]

The SetIgorHook operation tells Igor to call a user-defined "hook" function at the following times:

- After procedures have been successfully compiled (**AfterCompiledHook**)
- After a file is opened (**AfterFileOpenHook**)
- After the MDI frame window is resized on Windows (**AfterMDIframeSizedHook**)
- After a window is created (**AfterWindowCreatedHook**)
- Before the debugger is opened (**BeforeDebuggerOpensHook**)
- Before an experiment is saved (**BeforeExperimentSaveHook**)
- Before a file is opened (**BeforeFileOpenHook**)
- Before a new experiment is opened (**IgorBeforeNewHook**)
- Before Igor quits (**IgorBeforeQuitHook**)
- When a menu item is selected (**IgorMenuHook**)
- During Igor's quit processing (**IgorQuitHook**)
- When Igor starts or a new experiment is created (**IgorStartOrNewHook**)

The term "hook" is used as in the phrase "to hook into", meaning to intercept or to attach.

Hook functions are typically used by a sophisticated procedure package to make sure that the package's private data is consistent.

In addition to using SetIgorHook, you can designate hook functions using fixed function names (see **User-Defined Hook Functions** on page IV-278). The advantage of using SetIgorHook over fixed hook names is that you don't have to worry about name conflicts.

You can designate hook functions for specific windows using window hooks (see **SetWindow** on page V-863).

### Flags

- /K* Removes *procName* from the list of functions called for the *hookType* events.  
If *procName* is not specified all *hookType* functions are removed.  
If *hookType* is not specified all functions are removed for all *hookType* events, returning Igor to the pre-SetIgorHook state.
- /L* Executes *procName* last. Without */L*, a newly added hook function runs before previously registered hook functions.  
A function that has been previously registered with SetIgorHook can be moved from being called first to being called last by calling SetIgorHook again with */L*.  
To move a function from being called last to being called first requires removing the hook function with */K* and then calling SetIgorHook without */L*.

### Parameters

*hookType* Specifies one of the fixed-name hook function names:

**AfterCompiledHook**

**AfterFileOpenHook**

**AfterMDIframeSizedHook**

**AfterWindowCreatedHook**

**BeforeDebuggerOpensHook**

**BeforeExperimentSaveHook**

**BeforeFileOpenHook**

**IgorBeforeNewHook**

**IgorBeforeQuitHook**

**IgorMenuHook**

**IgorQuitHook**

**IgorStartOrNewHook**

See the note below about these *hookType* names.

*hookType* is required except with /K.

*procName* Names the user-defined hook function that is called for the *hookType* event.

### Details

The parameters and return type of the user-defined function *procName* varies depending on the *hookType* it is registered for.

For example, a function registered for the **AfterFileOpenHook** type must have the same parameters and return type as the shown for the **AfterFileOpenHook** on page IV-280.

The *procName* function is called *after* any window-specific hook for these *hookTypes*, and the *procName* function is called *before* any other hook functions previously registered by calling **SetIgorHook** *unless the /L flag is given*, in which case it still runs after window-specific hook functions, but also *after* all other previously registered hook functions.

The *procName* function should return a nonzero value (1 is typical) to prevent later functions from being called. Returning 0 allows successive functions to be called.

**SetIgorHook** does not work at Igor start or new experiment time, so **SetIgorHook IgorStartOrNewHook** is disallowed. Define a global or static fixed-name **IgorStartOrNewHook** function (see page IV-290).

The saved Igor experiment file remembers the **SetIgorHooks** that are in effect when the experiment is saved:

### Hook Function Interactions

After all the **SetIgorHook** functions registered for *hookType* have run (and all have returned 0), any static fixed-name hook functions are called and then the (only) fixed-name user-defined hook function, if any, is called. As an example, when a menu event occurs, Igor handles the event by calling routines in this order:

## SetIgorHook

---

1. The top window's hook function as set by **SetWindow**
2. Any SetIgorHook-registered hook functions
3. Any static fixed-named IgorMenuHook functions (in any independent module)
4. The one-and-only non-static fixed-named IgorMenuHook function (in only the ProcGlobal independent module)

| 1. SetWindow event<br>(called first) | 2. SetIgorHook hookType<br>(called second) | 3. User-defined Hook Function(s)<br>(called last) |
|--------------------------------------|--------------------------------------------|---------------------------------------------------|
| enableMenu                           | IgorMenuHook                               | IgorMenuHook                                      |
| menu                                 | IgorMenuHook                               | IgorMenuHook                                      |

**Note:** Although you can technically use one of the fixed-name functions, as described in **User-Defined Hook Functions** on page IV-278, for *procName*, the result would be that the function will be called twice: once as a registered named hook function and once as the fixed-named hook function. That is, don't use SetIgorHook this way:

```
SetIgorHook AfterFileOpenHook=AfterFileOpenHook // NO
```

### Variables

SetIgorHook returns information in the following variables:

**S\_info** Semicolon-separated list of all current hook functions associated with *hookType*, listed in the order in which they are called. **S\_info** includes the full independent module paths (e.g., "ProcGlobal#MyMenuHook;MyIM#MyModule#MyMenuHook;").

### Examples

This hook function invokes the Export Graphics menu item when Command-C (*Macintosh*) or Ctrl+C (*Windows*) is selected for a graph, preventing the usual Copy.

```
SetIgorHook IgorMenuHook=CopyIsExportHook
Function CopyIsExportHook(isSelection,menuName,itemName,itemNo,win,wType)
 Variable isSelection
 String menuName,itemName
 Variable itemNo
 String win
 Variable wType

 Variable handledIt= 0
 if(isSelection && wType==1) // menu was selected, window is graph
 if(CmpStr(menuName,"Edit")==0 && CmpStr(itemName,"Copy")==0)
 DoIgorMenu "Edit", "Export Graphics" // dialog instead
 handledIt= 1 // don't call other IgorMenuHook functions.
 endif
 endif
 return handledIt
End
```

To unregister CopyIsExportHook as a hook procedure:

```
SetIgorHook/K IgorMenuHook=CopyIsExportHook // unregister CopyIsExportHook
```

To discover which functions are associated with a *hookType*, use a command such as:

```
SetIgorHook IgorMenuHook // inquire about names registered for IgorMenuHook
Print S_info // list of functions
```

To remove (or "unregister") named hooks:

```
SetIgorHook/K // removes all hook functions for all hookTypes
SetIgorHook/K IgorMenuHook // removes all IgorMenuHook functions
SetIgorHook/K IgorMenuHook=CopyIsExportHook// removes only this hook function
```

The **SetWindow** operation and **User-Defined Hook Functions** on page IV-278.

**Independent Modules** on page IV-236.

## SetIgorMenuMode

**SetIgorMenuMode** *MenuNameStr*, *MenuItemStr*, *Action*

The SetIgorMenuMode operation allows an Igor programmer to disable or enable Igor's built-in menus and menu items. This is useful for building applications that will be used by end-users who shouldn't have access to all Igor's extensive and confusing functionality.

### Parameters

|                    |                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>MenuNameStr</i> | The name of an Igor menu, like "File", "Graph", or "Load Waves".                                                                                                                                                                                                                                                                                                               |
| <i>MenuItemStr</i> | The text of an Igor menu item, like "Copy" (in the Edit menu) or "New Graph" (in the Windows menu). For menu items in submenus, such as the "Load Waves" submenu in the "Data" menu, <i>MenuItemStr</i> is the name of the submenu.                                                                                                                                            |
| <i>Action</i>      | One of DisableItem, EnableItem, DisableAllItems, or EnableAllItems.<br>DisableItem and EnableItem disable or enable just the single item named by <i>MenuNameStr</i> and <i>MenuItemStr</i> . If <i>MenuItemStr</i> is " ", then the menu itself is disabled.<br>DisableAllItems and EnableAllItems disable and enable all the items in the menu named by <i>MenuNameStr</i> . |

### Details

All menu names and menu item text are in English. This ensures that code developed for a localized version of Igor will run on all versions. Note that no trailing "..." is used in *MenuItemStr*.

The SetIgorMenuModeProc.ipf procedure file includes procedures and commands that disable or enable every menu and item possible. It is in your Igor Pro folder, in WaveMetrics Procedures:Utilities. It is not intended to be used as-is. You should make a copy and edit the copy to include just the parts you need.

The text of some items in the File menu changes depending on the type of the active window. In these cases you must pass generic text as the *MenuItemStr* parameter. Use "Save Window", "Save Window As", "Save Window Copy", "Adopt Window" and "Revert Window" instead of "Save Notebook" or "Save Procedure", etc. Use "Page Setup" instead of "Page Setup For All Graphs", etc. Use "Print" instead of "Print Graph", etc.

The Edit→Insert File menu item was previously named Insert Text. For compatibility reasons, you can specify either "Insert File" or "Insert Text" as *MenuItemStr* to modify this item.

### See Also

The SetIgorMenuModeProc.ipf WaveMetrics procedure file contains SetIgorMenuMode commands for every menu and menu item. You can load it using

```
#include <SetIgorMenuModeProc>
```

## SetIgorOption

**SetIgorOption** [*mainKeyword*,] *keyword= value*

**SetIgorOption** [*mainKeyword*,] *keyword= ?*

The SetIgorOption operation makes unusual and temporary changes to Igor Pro's behavior. The behavior changes are of interest to advanced users only and last only until you end the Igor session.

The details of the syntax depend on the keyword and are documented where the alternate behaviors are described.

SetIgorOption is not compilable. To use it in a user-defined function, you need to use **Execute**.

In most cases the current value of a setting can be read using the keyword=? syntax.

For example, the IndependentModuleDev keyword is used to enable editing of procedure files that implement independent modules:

```
SetIgorOption IndependentModuleDev=?; Print V_Flag // Query
SetIgorOption IndependentModuleDev=1 // Set
```

## SetMarquee

---

Most SetIgorOption keywords are obscure and rarely of use. Here are the some of the more commonly-used SetIgorOption keywords:

|                      |                                                                |
|----------------------|----------------------------------------------------------------|
| IndependentModuleDev | See <b>SetIgorOption IndependentModuleDev=1</b> on page IV-237 |
| PoundDefine          | See <b>Conditional Compilation</b> on page IV-108              |
| GraphicsTechnology   | See <b>Graphics Technology</b> on page III-507                 |
| PanelResolution      | See <b>SetIgorOption PanelResolution</b> on page III-458       |
| DisableThreadSafe    | See <b>Debugging ThreadSafe Code</b> on page IV-224            |

It is rarely necessary, but you can find the more obscure applications using Help→Search Igor Files to search for "SetIgorOption".

## SetMarquee

**SetMarquee** [ /HAX=*hAxisName* /VAX=*vAxisName* /W=*winName*] *left, top, right, bottom*

The SetMarquee operation creates a marquee on the target graph or layout window or the specified window or subwindow.

### Parameters

The *left, top, right, and bottom* coordinates are in units of points unless you specify /HAX or /VAX in which case they are in axis units. Axis units are allowed for graphs only, not for layouts.

If the coordinates are all 0, the marquee, if it exists, is killed.

### Flags

|                        |                                                                                                                                                                                                                                                             |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /HAX= <i>hAxisName</i> | Specifies that the <i>left</i> and <i>right</i> parameters are in units of the axis named by <i>hAxisName</i> . The /HAX flag was added in Igor Pro 9.00.                                                                                                   |
| /VAX= <i>vAxisName</i> | Specifies that the <i>top</i> and <i>bottom</i> parameters are in units of the axis named by <i>vAxisName</i> . The /VAX flag was added in Igor Pro 9.00.                                                                                                   |
| /W= <i>winName</i>     | Specifies the named window or subwindow. When omitted, action will affect the active window or subwindow.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |

### Details

Igor stores marquee coordinates internally as integers in units of points. If you specify coordinates in axis units, there will be some roundoff error when Igor converts to integer points. This results in a small discrepancy between the coordinates you set using /HAX or /VAX and the coordinates returned by GetMarquee.

### See Also

GetMarquee

## SetProcessSleep

**SetProcessSleep** *sleepTicks*

The SetProcessSleep operation is obsolete and does nothing as of Igor Pro 7.00. It is documented here in case you come across it in old Igor procedure code. Do not use it in new code.

The SetProcessSleep operation determines how much time Igor will give to background tasks or other Macintosh applications executing in the background. This operation does nothing on Windows.

### Parameters

*sleepTicks* is the amount of time given to background tasks in sixtieths of a second. *sleepTicks* values between 0 and 60 are valid.

**Details**

Igor starts up with sleepTicks = 1. Use 0 to give Igor maximum time, use a larger number to give other applications more time.

Background tasks are used mainly by data acquisition programs.

**See Also**

**Background Tasks** on page IV-316 and the **SetBackground** operation.

## SetRandomSeed

**SetRandomSeed** *seed*

The SetRandomSeed operation seeds the random number generator used for the **ennoise** and **gnoise** functions. Use SetRandomSeed if you need “random” numbers that are reproducible. If you don’t use SetRandomSeed, the random number generator is initialized using the system clock when Igor starts. This almost guarantees that you will never get the same sequence twice unless you use SetRandomSeed.

**Flags**

`/BETR[=better]`      If better is absent or non-zero, a better method is used for seeding the Mersenne Twister random number generator.

**Parameters**

*seed* should be a number in the interval (0, 1]. For any given *seed*, ennoise or gnoise or any of the other random-number generator functions generates a particular sequence of pseudorandom numbers. Calling SetRandomSeed with the same seed restarts and repeats the sequence.

**Details**

Internally *seed* is scaled to a 32-bit unsigned integer. Consequently, the number of different values for the internally-scaled seed is less than the resolution of the double-precision numbers in the (0, 1] range.

You should use /BETR unless you need consistency with older versions of Igor. /BETR was introduced in Igor Pro 6.20.

The Mersenne Twister random number generator is used for most of Igor’s noise functions (and optionally for ennoise and gnoise), and internally for operations that need random sequences, such as **StatsSample** or **StatsResample**.

Without the /BETR flag, SetRandomSeed maps *seed* to an internal 16-bit integer for seeding the Mersenne Twister random number generator. With /BETR it maps to an internal 32-bit integer seed. So using /BETR reduces the chance that two values of *seed* will map to the same internal integer seed.

**See Also**

The **ennoise** and **gnoise** functions. **Noise Functions** on page III-390.

## SetScale

**SetScale** [/I/P] *dim*, *num1*, *num2* [, *unitsStr*], *waveName* [, *waveName*]...

**SetScale** *d*, *num1*, *num2* [, *unitsStr*], *waveName* [, *waveName*]...

The SetScale operation sets the dimension scaling or the data full scale for the named waves.

**Parameters**

The first parameter *dim* must be one of the following:

| Character | Signifies                                     |
|-----------|-----------------------------------------------|
| d         | Data full scale.                              |
| t         | Scaling of the chunks dimension (t scaling).  |
| x         | Scaling of the rows dimension (x scaling).    |
| y         | Scaling of the columns dimension (y scaling). |
| z         | Scaling of the layers dimension (z scaling).  |

## SetVariable

---

If setting the scaling of any dimension ( $x$ ,  $y$ ,  $z$ , or  $t$ ),  $num1$  is the starting index value — the scaled index for the first point in the dimension. The meaning of  $num2$  changes depending on the /I and /P flags. If you use /P, then  $num2$  is the delta value — the difference in the scaled index from one point to the next. If you use /I,  $num2$  is the “ending value” — the index value for the last element in the dimension. If you use neither flag,  $num2$  is the “right value” — the index value that the element *after the last element in the dimension* would have.

These three methods are just three different ways to specify the two scaling values, the starting value and the delta value, that are stored for each dimension of each wave.

If setting the data full scale ( $d$ ), then  $num1$  is the nominal minimum and  $num2$  is the nominal maximum data value for the waves. The data full scale values are not used. They serve only to document the minimum and maximum values the waves are expected to attain. No flags are used when setting the data full scale.

The *unitsStr* parameter is a string that identifies the natural units for the  $x$ ,  $y$ ,  $z$ ,  $t$ , or data values of the named waves. Igor will use this to automatically label graph axes. This string must be one to 49 bytes such as “m” for meters, “g” for grams or “s” for seconds. If the waves have no natural units you can pass “ ” for this parameter.

Setting *unitsStr* to “dat” (case-sensitive) tells Igor that the wave is a date/time wave containing data in Igor date/time format (seconds since midnight on January 1, 1904). Date/time waves must be double-precision.

### Flags

At most one flag is allowed, and then only if dimension scaling (not data full scale) is being set:

- |    |                                                                                                                         |
|----|-------------------------------------------------------------------------------------------------------------------------|
| /I | Inclusive scaling. $num2$ is the ending index — the index value for the very last element in the dimension.             |
| /P | Per-point scaling. $num2$ is the delta index value — the difference in scaled index value from one element to the next. |

### Details

SetScale will not allow the delta scaling value to be zero. If you execute a SetScale command with a delta value of zero, it will set the delta value to 1.0.

If you do not use the /P flag, SetScale converts  $num1$  and  $num2$  into a starting index value and a delta index value. If you call SetScale on a dimension with fewer than two elements, it does this conversion as if the dimension had two elements.

Prior to Igor Pro 3.0, Igor supported only 1D waves. “SetScale x” was used to set the scaling for the rows dimensions and “SetScale y” was used to set the data full scale. With the addition of multidimensional waves, “SetScale y” is now used to set the scaling of the columns dimension and “SetScale d” is used to set the data full scale. For backward compatibility, “SetScale y” on a 1D wave sets the data full scale.

When setting the dimension scaling of a numeric wave, you can omit the *unitsStr* parameter. Igor will set the wave’s scaling but not change its units. However, when setting the dimension scaling of a text wave, you must supply a *unitsStr* parameter (use “ ” if the wave has no units). If you don’t, Igor will think that the text wave is the start of a string expression and will attempt to treat it as the *unitsStr*.

For an explanation of waves and dimension scaling, see **Changing Dimension and Data Scaling** on page II-68.

For further discussion of how Igor represents dates, see **Date/Time Waves** on page II-85.

## SetVariable

**SetVariable** [/Z] *ctrlName* [**keyword** = *value* [, **keyword** = *value* ...]]

The SetVariable operation creates or modifies a SetVariable control in the target window.

A SetVariable control sets the value of a global numeric or string variable or a point in a wave when you type or click in the control. A SetVariable can also hold its own value without the need for a global or wave.

For information about the state or status of the control, use the **ControlInfo** operation.

**Parameters**

*ctrlName* is the name of the SetVariable control to be created or changed.

The following keyword=value parameters are supported:

|                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| activate                                       | Activates the control and selects the text that sets the value. Use <b>ControlUpdate</b> to deactivate the control and deselect the text.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| align= <i>alignment</i>                        | <p>Sets the alignment mode of the control. The alignment mode controls the interpretation of the <i>leftOrRight</i> parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.</p> <p>If <i>alignment=0</i> (default), <i>leftOrRight</i> specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.</p> <p>If <i>alignment=1</i>, <i>leftOrRight</i> specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.</p>                                                       |
| appearance={ <i>kind</i> [, <i>platform</i> ]} | <p>Sets the appearance of the control. <i>platform</i> is optional. Both parameters are names, not strings.</p> <p><i>kind</i> can be one of <i>default</i>, <i>native</i>, or <i>os9</i>.</p> <p><i>platform</i> can be one of <i>Mac</i>, <i>Win</i>, or <i>All</i>.</p> <p>See <b>Button</b> and <b>DefaultGUIControls</b> for more appearance details.</p>                                                                                                                                                                                                                                                                      |
| bodyWidth= <i>width</i>                        | Specifies an explicit size for the body (nontitle) portion of a SetVariable control. By default (bodyWidth=0), the body portion is the amount left over from the specified control width after providing space for the current text of the title portion. If the font, font size or text of the title changes, then the body portion may grow or shrink. If you supply a bodyWidth>0, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed. |
| disable= <i>d</i>                              | <p>Sets user editability of the control.</p> <p><i>d=0</i>: Normal.</p> <p><i>d=1</i>: Hide.</p> <p><i>d=2</i>: No user input.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| fColor=( <i>r,g,b[,a]</i> )                    | <p>Sets the initial color of the title. <i>r</i>, <i>g</i>, <i>b</i>, and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b>. The default is opaque black.</p> <p>To further change the color of the title text, use escape sequences as described for <i>title=titleStr</i>.</p>                                                                                                                                                                                                                                                                                                                                |
| focusRing= <i>fr</i>                           | <p>Enables or disables the drawing of a rectangle indicating keyboard focus:</p> <p><i>fr=0</i>: Focus rectangle will not be drawn.</p> <p><i>fr=1</i>: Focus rectangle will be drawn (default).</p> <p>On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.</p>                                                                                                                                                                                                                                                     |
| font=" <i>fontName</i> "                       | Sets the font used to display the value of the variable, e.g., font="Helvetica".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| format= <i>formatStr</i>                       | Sets the numeric format of the displayed value, e.g., format="%g". Not used with string variables. Never use leading text or the "%W" formats, because Igor reads the value back without interpreting the units. For a description of <i>formatStr</i> , see the <b>printf</b> operation.                                                                                                                                                                                                                                                                                                                                           |

## SetVariable

---

|                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>frame=f</code>                                    | Sets the frame for the value readout.<br><code>f=0:</code> Value unframed.<br><code>f=1:</code> Value framed (default).                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>fsize=s</code>                                    | Sets the size of the type used to display the variable's value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>fstyle=fs</code>                                  | <code>fs</code> is a bitwise parameter with each bit controlling one aspect of the font style as follows:<br>Bit 0: Bold<br>Bit 1: Italic<br>Bit 2: Underline<br>Bit 4: Strikethrough<br><br>See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings.                                                                                                                                                                                                                                                                                                   |
| <code>help={helpStr}</code>                             | Sets the help for the control.<br><code>helpStr</code> is limited to 1970 bytes (255 in Igor Pro 8 and before).<br>You can insert a line break by putting “\r” in a quoted string.                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>labelBack=(r,g,b[,a])</code> or<br><code>0</code> | Specifies the background fill color for labels. <code>r</code> , <code>g</code> , <code>b</code> , and <code>a</code> specify the color and optional opacity as <b>RGBA Values</b> . The default is 0, which uses the window's background color.                                                                                                                                                                                                                                                                                                                               |
| <code>limits={low,high,inc}</code>                      | Sets the limits of the allowable values ( <code>low</code> and <code>high</code> ) for the variable. <code>inc</code> sets the amount by which the variable is incremented if you click the control's up/down arrows. This applies to numeric variables, not to string variables. If <code>inc</code> is zero then the up/down arrows will not be drawn.                                                                                                                                                                                                                       |
| <code>live=l</code>                                     | Determines when the readout is updated.<br><code>l=0:</code> Update only after variable changes (default).<br><code>l=1:</code> Update as variable changes.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>noedit=val</code>                                 | <code>noedit=1</code> prevents the user from clicking (or tabbing into) a SetVariable control to directly edit its value. This is useful when you want to make a string read-only or when you want to restrict a numeric setting to those available only via the control's up or down arrow buttons.<br><code>noedit=0</code> reactivates user editing.<br><code>noedit=2</code> is deprecated as of Igor Pro 6.34 but still supported. It allows the use of formatting escape codes described under <b>Annotation Escape Codes</b> . Use <code>styledText=1</code> , instead. |
| <code>noproc</code>                                     | No procedure is to execute when the control's value is changed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>pos={leftOrRight,top}</code>                      | Sets the position in <b>Control Panel Units</b> of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.                                                                                                                                                                                                                                                                                                                                                   |
| <code>pos+={dx,dy}</code>                               | Offsets the position of the control in <b>Control Panel Units</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>proc=procName</code>                              | Sets the procedure to execute when the control's value is changed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>rename=newName</code>                             | Gives control a new name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>styledText=val</code>                             | <code>styledText=1</code> allows the use of formatting escape codes described under <b>Annotation Escape Codes</b> on page III-53. This works for string SetVariable controls only, not for numeric controls.<br><br>For example:<br><pre>SetVariable sv0 value=_STR:"\\JC\\K(65535,0,0)Centered Red Text"</pre>                                                                                                                                                                                                                                                               |

styledText=0 treats escape codes as plain text.

The styledText keyword was added in Igor Pro 6.34. For compatibility with earlier versions of Igor, the combination of noedit=1 and styledText=1 is recorded as noedit=2 in recreation macros.

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| size={width,height}        | Sets width of control in <b>Control Panel Units</b> . <i>height</i> is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| title=titleStr             | Sets the title of the control to the specified string expression. The title is displayed to the left of the control. If <i>titleStr</i> is empty (" "), the name of the controlled variable is displayed as the title. Use title=" " (put a space within the quotation marks) to create a "blank" title.<br><br>Using escape codes you can change the font, size, style, and color of the title. See <b>Annotation Escape Codes</b> on page III-53 or details.                                                                                                                                                                                |
| userdata(UDName)=UDStr     | Sets the unnamed user data to <i>UDStr</i> . Use the optional ( <i>UDName</i> ) to specify a named user data to create.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| userdata(UDName)+=UDStr    | Appends <i>UDStr</i> to the current unnamed user data. Use the optional ( <i>UDName</i> ) to append to the named <i>UDStr</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| value=varOrWaveName        | Sets the numeric or string variable or wave element to be controlled.<br><br>If <i>varOrWaveName</i> references a wave, the point is specified using standard bracket notation with either a numeric point number or a row label, for example: value=awave [4] or value=awave [%alabel] .<br><br>You may also use a 2D, 3D, or 4D wave and specify a column, layer, and chunk index or dimension label in addition to the row index.<br><br>You can have the control store the value internally rather than in a global variable. In place of varName, use _STR:str or _NUM:num. For example:<br><br>NewPanel; SetVariable sv1,value=_NUM:123 |
| valueColor=(r,g,b[,a])     | Sets the color of the value text. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> . The default is opaque black.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| valueBackColor=(r,g,b[,a]) | Sets the background color under the value text. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| valueBackColor=0           | Sets the background color under the value text to the default color, the standard document background color used on the current operating system, which is usually white.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| win=winName                | Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.                                                                                                                                                                                                                                                                                                                                              |

## Flags

/Z No error reporting.

## Details

The target window must be a graph or panel.

## SetVariable Action Procedure

The action procedure for a SetVariable control takes a predefined WMSetVariableAction structure as a parameter to the function:

```
Function ActionProcName(SV_Struct) : SetVariableControl
 STRUCT WMSetVariableAction &SV_Struct
```

## SetVariableControl

---

```
...
return 0
End
```

The “: SetVariableControl” designation tells Igor to include this procedure in the Procedure pop-up menu in the SetVariable Control dialog.

See **WMSetVariableAction** for details on the WMSetVariableAction structure.

Although the return value is not currently used, action procedures should always return zero.

You may see an old format SetVariable action procedure in old code:

```
Function procName(ctrlName, varNum, varStr, varName) : SetVariableControl
String ctrlName
Variable varNum // value of variable as number
String varStr // value of variable as string
String varName // name of variable
...
return 0
End
```

This old format should not be used in new code.

### Examples

Executing the commands:

```
Variable/G globalVar=99
SetVariable setvar0 size={120,20}
SetVariable setvar0 font="Helvetica", value=globalVar
```

creates a SetVariable control that displays the value of globalVar.

## SetVariableControl

### SetVariableControl

SetVariableControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined SetVariable control. See **Procedure Subtypes** on page IV-204 for details. See **SetVariable** for details on creating a SetVariable control.

## SetWaveLock

### SetWaveLock *lockVal, waveList*

The SetWaveLock operation locks a wave or waves and protects them from modification. Such protection is not absolute, but it should prevent most common attempts to change or kill a wave.

### Parameters

*lockVal* can be 0, to unlock, or 1, to lock the wave(s).

*waveList* is a list of waves or it can be *all in CDF* to act on all waves in the current data folder.

### See Also

**WaveInfo** to check if a wave is locked.

## SetWaveTextEncoding

### SetWaveTextEncoding [*flags*] *newTextEncoding, elements, [wave, wave, ...]*

The SetWaveTextEncoding operation changes the text encoding of the specified waves and/or the text encoding of all waves in the specified data folder.

Wave text encodings are mostly an issue in dealing with pre-Igor Pro 7 experiments containing non-ASCII text. Most users will have no need to worry about or change them. You should not use this operation unless you have a thorough understanding of text encoding issues or are instructed to use it by someone who has a thorough understanding.

See **Wave Text Encodings** on page III-474 for essential background information.

SetWaveTextEncoding can work on a list of specific waves or on all of the waves in a data folder (/DF flag). When working on a data folder, it can work on just the data folder itself or recursively on sub-data folders as well.

If /CONV is present, SetTextWaveEncoding actually converts the text to a different text encoding. You would use this, for example, to convert text stored as Shift JIS (Japanese non-Unicode) into UTF-8 (Unicode).

If /CONV is omitted, SetTextWaveEncoding merely causes Igor to reinterpret text. You would do this to tell Igor what text encoding is used for a wave created by Igor Pro 6 if Igor gets it wrong.

Conversion does not change the characters that make up text - it merely changes the numeric codes used to represent those characters. Reinterpretation does not change the numeric codes but does change the characters by changing the interpretation of the numeric codes.

In some cases it may be necessary to fix text encoding issues in Igor Pro 6.3x before opening an experiment in later versions.

### Parameters

*newTextEncoding* specifies the text encoding to set the wave element to. See **Text Encoding Names and Codes** on page III-492 for a list of codes.

*newTextEncoding* can be the special value 255 which marks a text wave's content as really containing binary data, not text. See **Text Waves Containing Binary Data** on page III-477 below for details.

*elements* is a bitwise parameter that specifies one or more elements of a wave, as follows:

| Bit | Value | Meaning               |
|-----|-------|-----------------------|
| 0   | 1     | Wave name             |
| 1   | 2     | Wave units            |
| 2   | 4     | Wave note             |
| 3   | 8     | Wave dimension labels |
| 4   | 16    | Text wave content     |

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

*wave, wave, ...* is a list of the targeted waves. The list is optional and typically should be omitted if you use the /DF flag. However, if you specify a data folder via /DF and you also list specific waves, SetWaveTextEncoding works on all waves in the data folder as well as the specifically listed waves.

### Flags

/BINA={*markAsBinary, diagnosticsFlags*}

If *markAsBinary* is 1, SetWaveTextEncoding marks the content of any text wave as binary if the data contains control characters (codes less than 32) other than carriage return (13), linefeed (10), and tab (9). The number of waves so marked is returned via *V\_numMarkedAsBinary*.

If *markAsBinary* is 0, SetWaveTextEncoding acts as if /BINA were omitted.

*diagnosticsFlags* is optional and defaults to 1. If you omit it you can also omit the braces (/BINA=1).

*diagnosticsFlags* is a bitwise parameter defined as follows:

Bit 0: Emit diagnostic message for each wave marked as binary.

All other bits are reserved for future use.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

The /BINA=1 flag works with the content of text waves only. It skips non-text waves. It is also independent of the *elements* parameter. That is, it marks the text wave content and only the text wave content as binary even if *elements* is something other than 16.

If you pass 255 for *newTextEncoding* when using the /BINA flag, this tells SetWaveTextEncoding to stop processing after marking binary waves. No further conversion or reinterpretation is done.

See **Text Waves Containing Binary Data** on page III-477 for further discussion.

*/CONV={errorMode [, defaultTextEncoding, diagnosticsFlags, conversionFlags]}*

Causes the text data to be converted to the specified text encoding. If /CONV is present, SetTextWaveEncoding actually converts the text. If it is omitted, SetTextWaveEncoding merely causes Igor to reinterpret it.

*defaultTextEncoding*, *diagnosticsFlags* and *conversionFlags* are optional and are further discussed below. If you omit them you can also omit the braces (/CONV=1).

If /CONV is specified and the original text encoding is binary (255) then SetWaveTextEncoding does nothing, because all conversions involving binary are NOPs.

If /CONV is specified and *newTextEncoding* is binary (255) then no conversion is done, because all conversions involving binary are NOPs, but the wave is marked as binary. Thus this amounts to the same thing as reinterpreting the wave's text data as binary.

If /CONV is specified, *defaultTextEncoding* is omitted or is -1, and the original text encoding is unknown (0) then SetWaveTextEncoding does nothing. That is, it does no reinterpretation or conversion.

*errorMode* determines how SetWaveTextEncoding behaves if the conversion can not be done because the text can not be mapped to the specified text encoding. This will occur if the text contains characters that can not be represented in the specified text encoding or if Igor's notion of the original text encoding is wrong. In the latter case, call SetWaveTextEncoding without /CONV to correct Igor's interpretation of the text and then call SetWaveTextEncoding with /CONV to do the conversion.

*errorMode* takes one of these values:

- 1: Generate error. SetWaveTextEncoding returns an error to Igor.
- 2: Use a substitute character for any unmappable characters. The substitute character for Unicode is the Unicode replacement character, U+FFFD. For most non-Unicode text encodings it is either control-Z or a question mark.
- 3: Skip unmappable input characters. Any unmappable characters will be missing in the output.
- 4: Use escape sequences representing any unmappable characters or invalid source text.

If the source text is valid in the source text encoding but can not be represented in the destination text encoding, unmappable characters are replaced with `\uXXXX` where `XXXX` specifies the UTF-16 code point of the unmappable character in hexadecimal.

If the conversion can not be done because the source text is not valid in the source text encoding, invalid bytes are replaced with `\xXX` where `XX` specifies the value of the invalid byte in hexadecimal.

*defaultTextEncoding* is optional. If it is present, not -1, and if the wave text element's original encoding is unknown (0), then the wave text element is treated as if it were the specified *defaultTextEncoding*. This allows you to convert the text of Igor Pro 6 waves that are set to unknown when you know that they are really some other text encoding. For example, if you know a wave's text data text encoding is Shift JIS, you can convert it to UTF-8 in one step, like this:

```
SetWaveTextEncoding /CONV={1,4} 1, 16, textWave0
```

Without the *defaultTextEncoding*, you would have to do two steps - the first to tell Igor what the real text encoding is and the second to do the conversion:

```
// Text encoding is Shift JIS
SetWaveTextEncoding 4, 16, textWave0

// Convert to UTF-8
SetWaveTextEncoding /CONV=1 1, 16, textWave0
```

Passing -1 for *defaultTextEncoding* acts the same as omitting it.

*diagnosticsFlags* is an optional bitwise parameter defined as follows:

- Bit 0: Emit diagnostic message if text conversion succeeds.
- Bit 1: Emit diagnostic message if text conversion fails.
- Bit 2: Emit diagnostic message if text conversion is skipped.
- Bit 3: Emit summary diagnostic message.

All other bits are reserved for future use and must be 0.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

*diagnosticsFlags* defaults to 2 (bits 1 set) if the /DF flag is not present and to 10 (bits 1 and 3 set) if the /DF flag is present.

Text conversion may be skipped because the wave element is marked as unknown text encoding, because it is marked as binary, because of the /ONLY or /SKIP flags, or because *newTextEncoding* is the same as the wave element's original text encoding.

*conversionFlags* is an optional bitwise parameter defined as follows:

Bit 0: Do a dry run only.

All other bits are reserved for future use and must be 0.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

The *conversionFlags* parameter was added in Igor Pro 9.00.

*conversionFlags* defaults to 0. If *conversionFlags* is 1, SetWaveTextEncoding goes through the entire conversion process but does not actually do any conversions. This feature was added to provide a way to determine if conversions are needed to create a pure UTF-8 experiment. For most purposes you can omit the *conversionFlags* parameter.

*/DF={dfr, recurse, excludedDFR}*

*dfr* is a reference to a data folder. SetWaveTextEncoding operate on all waves in the specified data folder. If *dfr* is null ("") SetWaveTextEncoding acts as if */DF* was omitted.

If *recurse* is 1, SetWaveTextEncoding works recursively on all sub-data folders. Otherwise it affects only the data folder referenced by *dfr*.

*excludedDFR* is an optional reference to a data folder to be skipped by SetWaveTextEncoding. For example, this command sets the text encoding of text wave data for all waves in all data folders except for root:Packages and its sub-data folders:

```
SetWaveTextEncoding /DF={root:,1,root:Packages} 1, 16
```

If *excludedDFR* is null ("") SetWaveTextEncoding acts as if *excludedDFR* was omitted and no data folders are excluded.

*/KIND=kind*

SetWaveTextEncoding changes only waves of the specified kind. *kind* is:

- 1: Home waves only
- 2: Shared waves only
- 3: Home and shared waves (default)

A "home wave" is a wave that is stored in the experiment file for packed experiment or in the disk folder corresponding to the wave's data folder for an unpacked experiment.

A "shared wave" is a wave that is stored in a standalone file for packed experiment or in a standalone file outside the disk folder corresponding to the wave's data folder for an unpacked experiment.

See **References to Files and Folders** on page II-24 for an explanation of shared versus home waves.

*/ONLY=targetedTextEncoding*

SetWaveTextEncoding changes only wave elements that are currently set to *targetedTextEncoding*. For example, this command converts the content of all waves that are currently set to unknown text encoding (0) to UTF-8 (1), treating the waves originally marked as unknown as Shift JIS (4) waves:

```
SetWaveTextEncoding /DF={root:,1} /ONLY=0 /CONV={1,4} 1, 16
```

Passing -1 for *targetedTextEncoding* acts as if you omitted */ONLY* altogether.

*/SKIP=skipTextEncoding*

SetWaveTextEncoding skips all wave elements that are currently set to *skipTextEncoding*. For example, this command converts the content of all waves to UTF-8 (1) except those that are set to Japanese (4):

```
SetWaveTextEncoding /DF={root:,1} /SKIP=4 /CONV=1 1, 16
```

As explained under /CONV, binary (255) wave elements are always skipped and unknown (0) wave elements are skipped if the /CONV defaultTextEncoding parameter is omitted.

Passing -1 for *skipTextEncoding* acts as if you omitted /SKIP altogether.

/TYPE=*type*

SetWaveTextEncoding changes only waves of the specified type.

*type* is:

- 1: Text waves only
- 2: Non-text waves only
- 3: All waves (default)

/Z[=*z*]

Prevents procedure execution from aborting if SetWaveTextEncoding generates an error. Use /Z or the equivalent, /Z=1, if you want to handle errors in your procedures rather than having execution abort.

/Z does not suppress invalid parameter errors. It suppresses only errors in doing text encoding reinterpretation or conversion.

### Details

Because SetWaveTextEncoding is intended for use by experts or by users instructed by experts, it does not respect the lock state of waves. That is, it will change waves even if they are locked using SetWaveLock.

For background information on wave text encodings, see **Wave Text Encodings** on page III-474.

A wave's text wave content text encoding can also be set to the special value 255. This marks a text wave as really containing binary data, not text. See **Text Waves Containing Binary Data** on page III-477 for details.

### Using SetWaveTextEncoding

One of the main uses for SetWaveTextEncoding is to set the encoding settings to some value other than 0 (unknown) so that Igor's idea of the text encoding used for the items accurately reflects the actual text encoding. We call this "reinterpreting" the item. It does not change the numeric codes representing the text but rather just changes the setting that controls Igor's idea of how the text is encoded. This does change the meaning of the underlying numeric codes. In other words, it changes the characters represented by the text.

You would do reinterpretation if you load an Igor6 experiment and Igor interprets the waves using the wrong text encoding. For example, if you load an experiment that you know uses Shift JIS encoding but Igor interprets it as Windows-1252, you get garbage for Japanese text. Reinterpreting it as Shift JIS fixes this. An example is provided below.

The other use for SetWaveTextEncoding is to actually change the numeric codes representing the text - i.e., to convert the content to a different text encoding. For example, if you have text waves from Igor Pro 6 that are encoded in Japanese (Shift JIS), you may want to convert the text to UTF-8 (a form of Unicode) so that you can combine Japanese and non-Japanese characters or use other features that require Unicode. This also applies to western text containing non-ASCII characters encoded as MacRoman or Windows-1252.

Converting changes the underlying numeric codes but does not change the characters represented by the text.

The main use for converting text is to convert Igor Pro 6 waves from whatever encoding they use, which typically will be MacRoman, Windows-1252, or Shift JIS, to UTF-8 (a form of Unicode) which is a more modern representation but is not backward compatible with Igor Pro 6.

If the /CONV flag is omitted SetWaveTextEncoding does reinterpretation. If the /CONV flag is present then SetWaveTextEncoding does text conversion except if the original text encoding is unknown (0) or binary (255) in which case it does nothing.

If a wave has mistakenly been marked as containing binary, use SetTextWaveEncoding without /CONV to set it to the correct text encoding.

## SetWaveTextEncoding

---

If a wave's text encoding is set to unknown (0) but you know that it really contains text in some specific encoding, you can use `SetTextWaveEncoding` without `/CONV` to set it to the correct text encoding and then use `SetTextWaveEncoding` with `/CONV` to convert it to the desired final text encoding. Alternately you can combine these two steps by using `/CONV` and providing a value for the optional *defaultTextEncoding* parameter.

### Output Variables

The `SetWaveTextEncoding` operation returns information in the following variables:

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>V_numConversionsSucceeded</code> | Set only when the <code>/CONV</code> flag is used. Zero otherwise.<br><code>V_numConversionsSucceeded</code> is set to the number of successful text element conversions.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>V_numConversionsFailed</code>    | Set only when the <code>/CONV</code> flag is used. Zero otherwise.<br><code>V_numConversionsFailed</code> is set to the number of unsuccessful text conversions. Because <code>SetWaveTextEncoding</code> quits when any error occurs, <code>V_numConversionsFailed</code> will be either 0 or 1.                                                                                                                                                                                                                                                                             |
| <code>V_numConversionsSkipped</code>   | Set only when the <code>/CONV</code> flag is used. Zero otherwise.<br><code>V_numConversionsSkipped</code> is set to the number of skipped text element conversions. Text conversion may be skipped because the wave element is marked as unknown text encoding, because it is marked as binary, because of the <code>/ONLY</code> or <code>/SKIP</code> flags or because <code>newTextEncoding</code> is the same as the wave element's original text encoding.<br><code>V_numConversionsSkipped</code> does not count waves skipped because of the <code>/TYPE</code> flag. |
| <code>V_numMarkedAsBinary</code>       | Set only when the <code>/BINA</code> flag is used. Zero otherwise.<br><code>V_numMarkedAsBinary</code> is set to the number of text waves whose text wave content was marked as binary.<br><code>V_numMarkedAsBinary</code> was added in Igor Pro 9.00.                                                                                                                                                                                                                                                                                                                       |
| <code>V_numWavesAffected</code>        | <code>V_numWavesAffected</code> is set to the number of waves modified in any way, whether through reinterpretation, conversion of one or more elements, or marking as binary.<br><code>V_numWavesAffected</code> was added in Igor Pro 9.00.                                                                                                                                                                                                                                                                                                                                 |

### Examples

```
// Keep in mind that, if /CONV is present, SetWaveTextEncoding does nothing
// for wave text elements currently set to binary (255).
// Also, if /CONV is present, SetWaveTextEncoding does nothing
// for wave text elements currently set to unknown (0) if the /CONV
// optional defaultTextEncoding parameter is omitted.
// In the following examples 1 means UTF-8, 4 means Shift JIS, and 16
// means text wave content.

// Reinterpret specific text waves as Shift JIS if they are currently set to unknown
SetWaveTextEncoding /ONLY=0 4, 16, textWave0, textWave1

// Convert specific waves' content to UTF-8
SetWaveTextEncoding /CONV=1 1, 16, textWave0, textWave1

// Reinterpret all text waves as Shift JIS if they are currently set to unknown
SetWaveTextEncoding /DF={root:,1} /ONLY=0 4, 16

// Convert all waves' content to UTF-8
SetWaveTextEncoding /DF={root:,1} /CONV=1 1, 16

// Convert all text waves' content from Shift JIS to UTF-8
// if it is currently set to unknown
SetWaveTextEncoding /DF={root:,1} /ONLY=0 /TYPE=1 /CONV={1,4} 1, 16

// Same as before but exclude the root:Packages data folder
```

```

SetWaveTextEncoding /DF={root:,1,root:Packages} /ONLY=0 /TYPE=1 /CONV={1,4} 1, 16

// Mark a text wave as really containing binary data
SetWaveTextEncoding 255, 16, textWaveContainingBinaryData

// Convert Chinese, Japanese and Korean text wave data to UTF-8.
// This example illustrates how to do a conversion based on criteria
// that require inspecting each wave.
Function ConvertCJKToUTF8(dfr, recurse)
 DFREF dfr

**WaveTextEncoding**, **ConvertTextEncoding**, **ConvertGlobalStringTextEncoding**

**SetWindow**

**SetWindow** *winName* [, *keyword* = *value*]...

The SetWindow operation sets the window note and user data for the named window or subwindow. SetWindow can also set hook functions for a base window or exterior subwindow (interior subwindows not supported).

**Parameters**

*winName* can be the name of any target window (graph, table, page layout, notebook, control panel, Gizmo, camera, or XOP target window). It can also be the keyword *kwTopWin* to specify the topmost target window.

## SetWindow

---

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>activeChildFrame=f</code>      | <p>Determines if the frame indicating the active subwindow in the named window or subwindow is drawn.</p> <p><i>f=-1</i>: Default. Recursively check ancestors of this window. If one is found with a value of either 0 or 1, use that value. If the topmost window has a value of -1, then the frame is drawn.</p> <p><i>f=1</i>: If this subwindow or one of its descendants becomes active, then the frame is drawn.</p> <p><i>f=0</i>: If this subwindow or one of its descendants becomes active, then the frame is not drawn.</p>                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>doScroll=mode</code>           | <p>Controls scrolling mode for top-level graph and panel windows only. The <code>doScroll</code> keyword was added in Igor Pro 9.00.</p> <p><i>mode=1</i>: Turns scrolling mode on for the graph or panel.</p> <p>When scrolling mode is on, the size of the content area of the graph or panel is fixed and the window no longer grows or shrinks when you resize the window. If you shrink the window smaller than the size of the content area, scroll bars appear which allow you to view different parts of the content area.</p> <p>When scrolling mode is on, you can change the size of the content area of the graph or panel window using <code>doScroll=(width, height)</code>.</p> <p><i>mode=0</i>: Turns scrolling mode off for the graph or panel.</p> <p>When scrolling mode is off, scroll bars are not shown and the size of the content area of the graph or panel grows or shrinks when you resize the window.</p> |
| <code>doScroll=(width,height)</code> | <p>Controls scrolling mode for top-level graph and panel windows only. The <code>doScroll</code> keyword was added in Igor Pro 9.00.</p> <p>Turns scrolling mode on if it is off. Sets the size of the content area of the graph or panel. <i>width</i> and <i>height</i> are in units of points.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>graphicsTech=t</code>          | <p>Sets the graphics technology used to draw the window. This flag may be useful in rare cases to work around graphics limitations. See <b>Graphics Technology</b> (see page III-507) for background information.</p> <p><i>t=0</i>: Default: The graphics technology specified in Miscellaneous Settings dialog, Miscellaneous category. This is Qt Graphics by default.</p> <p><i>t=1</i>: Native: Core Graphics on Macintosh, GDI+ on Windows.</p> <p><i>t=2</i>: Old: Core Graphics on Macintosh, GDI on Windows.</p>                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>hide=h</code>                  | <p>Hides or unhides windows or subwindows.</p> <p><i>h=0</i>: Unhides a subwindow or base window.</p> <p><i>h=1</i>: Hides a subwindow or base window.</p> <p><i>h=2</i>: Unhides without restoring minimized windows (<i>Windows</i> only).</p> <p>When un hiding subwindows, you should combine with <code>needUpdate=1</code> if conditions require the subwindow to be redrawn since the window was hidden.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>hook=procName</code>           | <p>Sets the window hook function that Igor will call when certain events happen. Use <code>SetWindow hook=\$"</code> to specify no hook function.</p> <p>See <b>Unnamed Window Hook Functions</b> on page IV-303 for further details.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>hook(hName)=procName</code>    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

The marker range can be any positive integers less than 1000 and can overlap built-in marker numbers. See <b>Custom Marker Hook Functions</b> on page IV-306 for details.</p> <p>Use "\$" for <i>hookFuncName</i> to specify no hook.</p>                                                                                                                                                                                                                                                                        |
| needUpdate= <i>n</i>                                                                   | <p>Marks a window as needing an update (<i>n</i>=1) or takes no action (<i>n</i>=0).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| note= <i>noteStr</i>                                                                   | <p>Sets the window note to <i>noteStr</i>, replacing any existing note.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| note+= <i>noteStr</i>                                                                  | <p>Appends <i>noteStr</i> to current contents of the window note.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| sizeLimit= { <i>minWidth</i> , <i>minHeight</i> , <i>maxWidth</i> , <i>maxHeight</i> } |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

Imposes limits on a window's size when resized with the mouse or by calling **MoveWindow**. The units of the limits are the same as those returned by **GetWindow** `wsize`.

The `sizeLimit` keyword was added in Igor Pro 7.00.

To allow the window width to grow essentially without bound, pass `INF` for `maxWidth`.

To allow the window height to grow essentially without bound, pass `INF` for `maxHeight`.

If  $minWidth > maxWidth$  or  $minHeight > maxHeight$ , the maximum dimensions are set to the minimum, effectively fixing the size of the window in that dimension. For control panels, it is better to use `ModifyPanel fixedSize=1`.

Combining these limits with `ModifyGraph` width and height modes leads to unexpected results and is discouraged.

If you first use `sizeLimit` and then execute `ModifyPanel fixedSize=1` on the same window, the `fixedSize` command takes precedence. If you execute `SetWindow sizeLimit` on a control panel that has `fixedSize=1`, Igor generates an error.

Igor includes a `SetWindow sizeLimit` command in a window recreation macro if necessary. Igor6 does not support `SetWindow sizeLimit` so this causes an error when recreating the window in Igor6. If you never set the `sizeLimit` property for a window, or if the minimum dimensions are very small and maximum dimensions are `INF`, then no `SetWindow` command is generated.

`tooltipHook(hName)=procName`

A tooltip hook function is like a window hook function (see **Named Window Hook Functions** on page IV-293), except that it allows you to alter the text of a tooltip in a graph or table. At present, a tooltip hook function is called for a graph when the mouse hovers over a trace or image, and for a table when the mouse hovers over the data for a wave.

Unlike a window hook function, a tooltip hook function can be set for either a top-level window or a subwindow.

For details, see **Tooltip Hook Functions** on page IV-307.

`userdata=UDStr`

`userdata(UDName)=UDStr`

Sets the window or subwindow user data to `UDStr`. Use the optional (`UDName`) to specify a named user data to create.

`userdata+=UDStr`

`userdata(UDName)+=UDStr`

Appends `UDStr` to the current window or subwindow user data. Use the optional (`UDName`) to append to the named user data.

### Details

For details on named window hooks, see **Window Hook Functions** on page IV-291.

Unnamed window hook functions are supported for backward compatibility only. New code should use named window hook functions. For details on unnamed window hooks, see **Unnamed Window Hook Functions** on page IV-303.

For details on marker hooks, see **Custom Marker Hook Functions** on page IV-306.

You can also attach user data to traces in graphs using the `userData` keyword of the `ModifyGraph` operation and to controls using the `userData` keyword of the various control operations.

**See Also**

The **GetWindow**, **SetIgorHook**, and **SetIgorMenuMode** operations and **AxisValFromPixel**, **NumberByKey**, **PopupContextualMenu**, and **TraceFromPixel** functions. The **GetUserData** operation for retrieving named user data.

**ShowIgorMenus**

**ShowIgorMenus** [*MenuNameStr* [, *MenuNameStr*] ...

The ShowIgorMenus operation shows the named built-in menus or, if none are explicitly named, shows all built-in menus in the menu bar.

User-defined menus attached to built-in menus are also affected by this operation.

**Parameters**

*MenuNameStr*      The name of an Igor menu, like "File", "Data", or "Graph".

**Details**

See **HideIgorMenus** for details.

**See Also**

**HideIgorMenus**, **DoIgorMenu**, **SetIgorMenuMode**, **User-Defined Menus** on page IV-125

**ShowInfo**

**ShowInfo** [/CP=*num* /W=*winName*]

The ShowInfo operation puts an information panel on the target or named graph. The information panel contains cursors and readouts of values associated with waves in the graph.

**Flags**

*/CP=num*      Selects a cursor pair to display in the info panel.

*num=0:*      Selects cursor A and cursor B.

*num=1:*      Selects cursor C and cursor D.

*num=2:*      Selects cursor E and cursor F.

*num=3:*      Selects cursor G and cursor H.

*num=4:*      Selects cursor I and cursor J.

*/CP={n1,n2,...}*      Allows you to select multiple cursor pairs to be displayed in the info panel. The numbers n1, n2, etc., are the same as the single-pair version of this flag.

This form of */CP* was added in Igor Pro 7.00.

*/W=winName*      Displays info panel in the named window.

**See Also**

**Info Panel and Cursors** on page II-307.

The **HideInfo** operation.

**Programming With Cursors** on page II-309.

### ShowTools

**ShowTools** [/A/W=*winName*] [*toolName*]

The ShowTools operation puts a tool palette for drawing along the left hand side of the target or named graph or control panel, and optionally activates the named tool.

#### Flags

- /A* Sizes window automatically to make extra room for the tool palette. This preserves the proportion and size of the actual graph area.
- /W=winName* Shows tool palette in the named window. This must be the first flag specified when used in a Proc or Macro or on the command line.
- winName* must be either the name of a top-level window or a path leading to an exterior panel window (see **Exterior Control Panels** on page III-443).

#### Parameters

If you specify a *toolName* (which can be one of: normal, arrow, text, line, rect, rrect, oval, or poly) the named tool is activated. Specifying the "normal" tool has the same effect as issuing the GraphNormal command for a graph that has the drawing tools selected.

#### Details

The activated tool is not highlighted until the top graph or control panel becomes the topmost (activated) window. Use DoWindow/F to bring a window to the top (or "front").

#### See Also

The DoWindow, GraphNormal, GraphWaveDraw, GraphWaveEdit, and HideTools operations.

### SinIntegral

**SinIntegral** (*z*)

The SinIntegral(*z*) function returns the sine integral of *z*.

If *z* is real, a real value is returned. If *z* is complex then a complex value is returned.

The SinIntegral function was added in Igor Pro 7.00.

#### Details

The sine integral is defined by

$$Si(z) = \int_0^z \frac{\sin(t)}{t} dt.$$

IGOR computes the SinIntegral using the expression:

$$Si(z) = z {}_1F_2 \left( \frac{1}{2}; \frac{3}{2}, \frac{3}{2}; -\frac{z^2}{4} \right).$$

### sign

**sign** (*num*)

The sign function returns -1 if *num* is negative or 1 if it is not negative.

## Silent

### **Silent** *num*

The Silent operation is largely obsolete. Only very obscure uses remain and most users can ignore this operation.

Prior to Igor Pro 7, Silent was used to enable or disable the display of macro commands in the command line as they were executed. It was also used to enable compatibility modes for very old experiments.

### **Parameters**

If *num* is 2, commands issued by AppleEvents or ActiveX Automation are not shown in the history are of the command window. Use 3 to re-enable.

If *num* is 100, 101 or 102, all procedures are recompiled. For 102, the time to recompile is displayed in the history.

## sin

### **sin** (*angle*)

The sin function returns the sine of *angle* which is in radians.

In complex expressions, *angle* is complex, and  $\sin(\text{angle})$  returns a complex value:

$$\sin(x + iy) = \sin(x)\cosh(y) + i\cos(x)\sinh(y).$$

### **See Also**

**asin, cos, tan, sec, csc, cot**

## sinc

### **sinc** (*num*)

The sinc function returns  $\sin(\text{num})/\text{num}$ . The sinc function returns 1.0 when *num* is zero. *num* must be real.

## sinh

### **sinh** (*num*)

The sinh function returns the hyperbolic sine of *num*:

$$\sinh(x) = \frac{e^x - e^{-x}}{2}.$$

In complex expressions, *num* is complex, and  $\sinh(\text{num})$  returns a complex value.

### **See Also**

**cosh, tanh, coth**

## Sleep

### **Sleep** [*flags*] *timeSpec*

The Sleep operation puts Igor to sleep for a while. After the while is up, Igor continues execution.

You could use Sleep, for example, to give an instrument time to perform an action or to allow a user to admire a graph before proceeding.

More advanced programmers may prefer to use a background task as an alternative. See **Background Tasks** on page IV-316.

### **Parameters**

The format of *timeSpec* depends on which flags, if any, are present.

If no flags are present, then *timeSpec* is in *hh:mm:ss* format and specifies the number of elapsed hours, minutes and seconds to sleep.

## Sleep

| <code>/T</code>                                                              | <code>timeSpec</code> is a numeric expression in ticks (about 1/60 of a second).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### Details

The Sleep operation does *not* let the user choose menus, move cursors, run procedures, draw in graphs, or do any other interactive task.

Normally `timeSpec` specifies an amount of elapsed time. If the `/A` flag is present, then `timeSpec` is an absolute time when sleep is to end. If the specified absolute time has already passed, no sleep occurs unless you also use `/W`, which makes it wait until tomorrow.

If you specify time in hh:mm:ss format, you can also specify the time indirectly through a string variable. See the examples.

You can end sleep by pressing the **User Abort Key Combinations**. Normally when you do this, it aborts any procedure that is running. However, if you use the /Q flag, the procedure continues running normally.

### Displaying a Progress Dialog

When you specify /C=6 or if you use the /PROG flag, Sleep displays a progress dialog with a progress bar showing how much of the sleep time has passed. The dialog displays a prompt which you can control using the /M flag.

If you use /PROG, then /Q and /B are ignored.

If you use /C=6, then /Q and /B have special meanings:

|          |                                                                                                                                                                                                                                                            |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /C=6     | Progress dialog with Cancel button which aborts running procedures.<br>The Abort key combinations abort running user procedures.                                                                                                                           |
| /C=6/B   | Progress dialog with Abort button which aborts running procedures.<br>The Abort key combinations abort running user procedures.                                                                                                                            |
| /C=6/Q   | Progress dialog with Continue button which terminates the current sleep operation but allows procedures to continue.<br>Abort key combinations allow running procedures to continue.                                                                       |
| /C=6/B/Q | Progress dialog with Continue and Abort buttons. The Continue button terminates the current sleep operation but allows procedures to continue. The Abort button aborts running procedures.<br>Abort key combinations allow running procedures to continue. |

If you use the /PROG flag, you can provide your own titles for the Cancel and Continue buttons.

### Examples

These examples assume the current time is 4 PM:

```
Sleep 00:01:30 // sleeps for 1 minute, 30 seconds
Sleep/A 23:30:00 // sleeps until 11:30 PM
Sleep/A 03:00:00 // doesn't sleep at all because time is past
Sleep/A/W 03:00:00 // sleeps until 3 AM tomorrow
String str1= "03:00:00" // put wakeup call time in string
Sleep/A/W $str1 // sleeps until 3 AM tomorrow
Sleep/B/C=2/S/Q 60 // sleep 60 seconds, or until user clicks,
 // and keep going (don't abort)
```

The following function creates a graph and then periodically updates the displayed data. By default, it sleeps for a number of seconds specified by the sleepTime parameter.

```
Function SleepDemo(sleepTime, displayProgressDialog)
 Variable sleepTime // In seconds
 Variable displayProgressDialog // 1 for progress dialog

 Make/N=200/O junk
 SetScale/I x 0, 2*pi, junk
 junk=sin(x)
 DoWindow/F SleepDemoGraph
 if (V_Flag == 0)
 Display/N=SleepDemoGraph junk
 endif
 DoUpdate

 try
 Variable i
 for (i = 0; i < 10; i+=1)
 if (displayProgressDialog)
 // Because the abortMode is 0, pressing the user abort key combinations
 // or pressing the Done button generates an abort instead of merely
 // terminating the current Sleep call.
 int abortMode = 0
 Sleep/S/PROG={"Done", "Continue", abortMode} sleepTime
 else
 // /B makes Sleep terminate if the user clicks.
```

## Slider

---

```
 // Because the /Q flag is omitted, pressing the user abort key combinations
 // or pressing Igor's Abort button generates an abort instead of merely
 // terminating the current Sleep call.
 Sleep/S/C=2/B sleepTime
 endif
 junk = sin(x*(i+2))
 DoUpdate
endfor
catch
 Printf "An abort occurred with V_abortCode=%d\r", V_abortCode
endtry
End
```

## Slider

**Slider** [/Z] *controlName* [*key* [= *value*]] [, *key* [= *value*]]...

The Slider operation creates or modifies a Slider control in the target window.

A Slider control sets or displays a single numeric value. The user can adjust the value by dragging a thumb along the length of the Slider.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*ctrlName* is the name of the Slider control to be created or changed.

The following keyword=value parameters are supported:

- align=alignment** Sets the alignment mode of the control. The alignment mode controls the interpretation of the *leftOrRight* parameter to the *pos* keyword. The *align* keyword was added in Igor Pro 8.00.
- If *alignment=0* (default), *leftOrRight* specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.
- If *alignment=1*, *leftOrRight* specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.
- appearance={kind [, platform]}**
- Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.
- kind* can be one of *default*, *native*, or *os9*.
- platform* can be one of *Mac*, *Win*, or *All*.
- Note:** The Slider control reverts to *os9* appearance on Macintosh if *thumbColor* isn't the default blue (0,0,65535).
- See **Button** and **DefaultGUIControls** for more appearance details.
- disable=d** Sets user editability of the control.
- d=0:* Normal.
- d=1:* Hide.
- d=2:* Draw in gray state; disable control action.
- fColor=(r,g,b[,a])** Sets the color of the tick marks. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. The default is opaque black.
- focusRing=fr** Enables or disables the drawing of a rectangle indicating keyboard focus:
- fr=0:* Focus rectangle will not be drawn.
- fr=1:* Focus rectangle will be drawn (default).
- On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.
- font="fontName "** Sets the font used to display the tick labels, e.g., *font="Helvetica"*.

| <code>proc=procName</code>                               | Specifies the action procedure for the slider.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>rename=newName</code>                              | Gives control a new name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>repeat={style,springback,rate,restingValue}</code> | Set the control to call its action procedure repeatedly at timed intervals while the user clicks the thumb.<br><br>style can take one of the following values:<br>0: No repeat (default). Use this to turn the repeat feature off.<br>1: Slider repeats at a constant rate.<br>2: Slider repeats at a rate proportional to the distance from the <i>restingValue</i> .<br><br><i>springback</i> controls what happens to the slider value when the user releases the mouse. If <i>springback</i> is 1, the slider returns to the resting value. If it is 0, it remains at the last set value.<br><br><i>rate</i> specifies the rate at which the action procedure is called in calls per second. The maximum rate accepted rate is 1000. If <i>rate</i> is 0, it sets style to 0 which turns the repeating feature off.<br><br><i>restingValue</i> specifies the value to which the slider returns when the user releases the mouse. If <i>springback</i> is 1, the thumb automatically returns to <i>restingValue</i> when the mouse button is released. If <i>springback</i> is 0, <i>restingValue</i> has no effect. |
| <code>side=s</code>                                      | Controls slider thumb.<br><i>s</i> =0: Thumb is blunt and tick marks are suppressed.<br><i>s</i> =1: Thumb points right or down (default).<br><i>s</i> =2: Thumb points up or left.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>size={width,height}</code>                         | Sets width or height of control in <b>Control Panel Units</b> . <i>height</i> is ignored if <i>vert</i> =0 and <i>width</i> is ignored if <i>vert</i> =1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>thumbColor=(r,g,b[,a])</code>                      | Sets dominant foreground color of thumb. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> . Alpha ( <i>a</i> ) is accepted but ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ticks=t</code>                     | Controls slider ticks.<br><code>t=0:</code> No ticks.<br><code>t=1:</code> Number of ticks is calculated from limits (no ticks drawn if calculated value is less than 2 or greater than 100). Default value.<br><code>t&gt;1:</code> $t$ is the number of ticks distributed between the start and stop position. Ticks are labeled using the same automatic algorithm used for graph axes. Use negative tick values to force ticks to not be labeled. Ticks are shown on the side specified by the side keyword and are not drawn if <code>side=0</code> . |
| <code>tkLblRot= deg</code>               | Rotates tick labels. <i>deg</i> is a value between -360 and 360.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>userdata(UDName)=UDStr</code>      | Sets the unnamed user data to <i>UDStr</i> . Use the optional ( <i>UDName</i> ) to specify a named user data to create.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>userdata(UDName)+=UDStr</code>     | Appends <i>UDStr</i> to the current unnamed user data. Use the optional ( <i>UDName</i> ) to append to the named <i>UDStr</i> .                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>userTicks={tvWave,tlblWave}</code> | User-defined tick positions and labels. <i>tvWave</i> contains the tick positions, and text wave <i>tlblWave</i> contains the labels. See <code>ModifyGraph userticks</code> for more info. Overrides normal ticking specified by <code>ticks</code> keyword.                                                                                                                                                                                                                                                                                              |
| <code>value=v</code>                     | $v$ is the new value for the Slider.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>valueColor=(r,g,b[, a])</code>     | Sets the color of the tick labels. $r$ , $g$ , $b$ , and $a$ specify the color and optional opacity as <b>RGBA Values</b> . The default is opaque black.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>variable= var</code>               | Sets the variable ( <i>var</i> ) that the slider will update. It is not necessary to connect a Slider to a variable — you can get a Slider's value using the <b>ControlInfo</b> operation.                                                                                                                                                                                                                                                                                                                                                                 |
| <code>vert=v</code>                      | Set vertical ( $v =1$ ; default) or horizontal ( $v =0$ ) orientation of the slider.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>win=winName</code>                 | Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.<br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.                                                                                                                                                                                                                                                               |

### Flags

`/Z` No error reporting.

### Details

The target window must be a graph or panel.

If you use negative ticks to suppress automatic labeling, you can label tick marks using drawing tools (panels only).

### Slider Action Procedure

The action procedure for a Slider control takes a predefined `WMSliderAction` structure as a parameter to the function:

```
Function ActionProcName(S_Struct) : SliderControl
 STRUCT WMSliderAction &S_Struct
 ...
 return 0
End
```

The “: SliderControl” designation tells Igor to include this procedure in the Procedure pop-up menu in the Slider Control dialog.

See **WMSliderAction** for details on the WMSliderAction structure.

See **Handling Slider Events** on page III-430 for a demonstration of slider event handling.

Although the return value is not currently used, action procedures should always return zero.

This old format for a slider action procedure should not be used in new code:

```
Function MySliderProc(name, value, event) : SliderControl
 String name // name of this slider control
 Variable value // value of slider
 Variable event // bit field:bit 0:value set; 1:mouse down,
 // 2:mouse up, 3:mouse moved

 return 0 // other return values reserved
End
```

### Repeating Sliders

A repeating slider calls your action procedure periodically while the user is clicking the thumb. See **Repeating Sliders** on page III-418 for an overview.

When the repeat style is set to 2, the call rate is proportional to the slider value. See the Slider reference documentation in the online help for the formula.

Whereas the rate can be set as high as 1000 calls per second, if your action procedure takes more time to execute than the period of the slider repeat, you will simply lose repeats. It is unlikely that a rate of more than about 50 calls per second can realistically be achieved.

### Examples

```
Function SliderExample()
 NewPanel /W=(150,50,501,285)
 Variable/G var1
 Execute "ModifyPanel cBRGB=(56797,56797,56797)"
 SetVariable setvar0,pos={141,18},size={122,17},limits={-Inf,Inf,1},value=var1
 Slider foo,pos={26,31},size={62,143},limits={-5,10,1},variable=var1
 Slider foo2,pos={173,161},size={150,53}
 Slider foo2,limits={-5,10,1},variable=var1,vert=0,thumbColor=(0,1000,0)
 Slider foo3,pos={80,31},size={62,143}
 Slider foo3,limits={-5,10,1},variable=var1,side=2,thumbColor=(1000,1000,0)
 Slider foo4,pos={173,59},size={150,13}
 Slider foo4,limits={-5,10,1},variable=var1,side=0,vert=0
 Slider foo4,thumbColor=(1000,1000,1000)
 Slider foo5,pos={173,90},size={150,53}
 Slider foo5,limits={-5,10,1},variable= var1,side=2,vert=0
 Slider foo5,ticks=5,thumbColor=(500,1000,1000)
End
```

## SliderControl

### SliderControl

SliderControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined slider control. See **Procedure Subtypes** on page IV-204 for details. See **Slider** for details on creating a slider control.

## Slow

### Slow ticks

The Slow operation is obsolete. Prior to Igor Pro 7 it slowed down execution of macros for debugging purposes. It now does nothing.

## Smooth

---

### Smooth

**Smooth** [*flags*] *num*, *wave0* [, *wave1*]...

The Smooth operation smooths the named waves using binomial (Gaussian) smoothing, boxcar (sliding average) smoothing, Savitzky-Golay (polynomial) smoothing, or running-median filtering.

#### Parameters

*num* is the number of smoothing operations to be applied for binomial smoothing or the integer number of points in the smoothing window for boxcar, Savitzky-Golay, and running-median smoothing, or, if you use /BLPF, the low-pass cutoff frequency.

Each wave, which may be floating point or integer, is smoothed in-place, overwriting the values with the smoothed result.

If an input wave is complex, the real and imaginary parts are smoothed independently.

If an input wave contains NaNs, the results are undefined. (The **Loess** and **Interpolate2** operations can fill in NaNs).

**Flags**

**/B [=b]** Invokes boxcar smoothing algorithm. If given, *b* specifies the number of passes to use when smoothing the data with smoothing factor *num* (box width). The number of passes can be any value between 1 and 32767.

**/BLPF[=*roundMode*]** Calculates the integer number of smoothing operations to be applied for binomial smoothing based on interpreting the *num* parameter as the low-pass cutoff frequency and then performs the smoothing. /BLPF was added in Igor Pro 8.00.

The calculated number of smoothing operations is returned in *V\_iterations*:

$$V\_iterations = \ln(\sqrt{2}) \left( \frac{1}{(\pi f_{cn})^2} - \frac{1}{6} \right)$$

where  $f_{cn} = num * DimDelta(wave0, dim)$

If *roundMode* is 1, *V\_iterations* is rounded down to an integer value. This is the default if you use /BLPF by itself without *roundMode*.

If *roundMode* is 2, *V\_iterations* is rounded up to an integer value.

$f_{cn}$  is the Nyquist-normalized cutoff frequency and should be  $\leq 0.182028$ , which results in *V\_iterations* = 1.

The cutoff frequency, also known as the "half power point", is the frequency at which the magnitude response of the smoothing filter declines to  $1/\sqrt{2} \approx 0.707107$ .

**/DIM=*dim***

Specifies the wave dimension to smooth.

*dim*=-1: Treats entire wave as 1D (default)  
*dim*=0: Operates along rows  
*dim*=1: Operates along columns  
*dim*=2: Operates along layers  
*dim*=3: Operates along chunks

**/E=*endEffect***

Determines how to handle the ends of the wave (*w*) when fabricating missing neighbor values.

*endEffect*=0: Bounce method (default). Uses *w*[*i*] in place of the missing *w*[-*i*] and *w*[*n-i*] in place of the missing *w*[*n+i*].  
*endEffect*=1: Wrap method. Uses *w*[*n-i*] in place of the missing *w*[-*i*] and vice versa.  
*endEffect*=2: Zero method. Uses 0 for any missing value.  
*endEffect*=3: Repeat method. Uses *w*[0] in place of the missing *w*[-*i*] and *w*[*n*] in place of the missing *w*[*n+i*].

**/EVEN [=evenAllowed]**

Specifies the smoothing increment for boxcar smoothing (/B). Values are:

0: Increments even values of *num* to the next odd value. Default when /EVEN omitted.  
1: Uses even values of *num* for boxcar smoothing despite the half-sample shifting this introduces in the smoothed output (prior to version 6, this shift was prevented). Same as /EVEN alone.

**/F [=f]**

Selects the boxcar or multipass binomial smoothing method:

*f*=0: Slow, but accurate, method (default).  
*f*=1: Fast method. Same as /F alone.

- /M=threshold* Invokes running-median smoothing and specifies an absolute numeric threshold used to optionally replace "outliers". Points that differ from the central median by an amount exceeding *threshold* are replaced, either with the *replacement* value specified by */R*, or otherwise with the median value.
- Special *threshold* values are:
- 0: Replace all values with running-median values or the *replacement* value.
  - (NaN): Replace only NaN input values with running-median values or the *replacement* value.
- The smoothing factor *num* is the number of points in the smoothing window used to compute each median.
- /MPCT=percentile* Used with */M* to compute a smoothed value that is a different percentile than the median. */M* must be present if */MPCT* is used.
- percentile* is a value from 0 to 100.
- Roughly speaking, the smoothed value returned is the smallest value in the smoothing window that is greater than the smallest *percentile* % of the values. See "Median and Percentile Smoothing Details", below.
- percentile=0*: The smoothed value is the minimum value in the smoothing window.
  - percentile=50*: The smoothed value is the median of the values in the smoothing window. This is the default if */MPCT* is omitted.
  - percentile=100*: The smoothed value is the maximum value in the smoothing window.
- /R=replacement* Specifies the value that replaces input values that exceed the central median by *threshold* (requires */M*). *replacement* can be any value (including NaN or  $\pm\text{Inf}$  if *waveName* is floating point).
- /S=sgOrder* Invokes Savitzky-Golay smoothing algorithm and specifies the smoothing order. *sgOrder* must be either 2 or 4.

### Binomial Smoothing Details

For binomial smoothing, use no flags other than */BLPF*, */DIM*, */E*, and */F*.

If you are not using */BLPR*, *num* is the number of smoothing operations between 1 and 32767.

If you are using */BLPF*, *num* is the low-pass cutoff frequency which must be less than 0.182028 times the sampling frequency of *wave0*. The computed smoothing factor is returned in *V\_iterations*. Very small values of  $f_{\text{cn}}$  ( $\approx 0.0007$  or less) will fail with errors due to excessive number of smoothing operations or to insufficient range (too few wave points).

In Igor Pro 6 and later, the binomial smooth algorithm automatically switches to a nearly-equivalent but much faster multipass box smooth when  $num \geq 50$ . You can prevent the switch to box smoothing by setting this global variable:

```
Variable/G root:V_doOrigBinomSmooth=1
```

The binomial smoothing algorithm does not detect and ignore NaNs in the input data. Use **Loess** or **Interpolate2** to fill in NaNs.

### Boxcar Smoothing Details

For boxcar smoothing, use the */B* flag and a *num* value from 1 to 32767.

For  $num < 2$ , no smoothing is done.

If *num* is even and */EVEN* is not specified, *num* is incremented to the next (odd) integer.

If *num* is even and */EVEN* is specified, each smoothed output is formed from one more previous value than future values.

The fast boxcar smoothing (/F) algorithm creates small errors when the data has a large offset. For some data sets you may want to subtract the mean of the data before smoothing and add it back in afterwards.

The boxcar smoothing algorithm detects and ignores NaNs in the input data. If *num* is less than the number of NaNs near the output point, then the result is NaN. Otherwise the average of the non-NaN neighboring points is used to compute the smoothed result.

### Savitzky-Golay Smoothing Details

For Savitzky-Golay smoothing, use the /S flag and an odd *num* value from 5 to 25. An even value for *num* returns an error. If *sgOrder=4*, then *num=5* gives no smoothing at all so *num* should be at least 7.

The Savitzky-Golay smoothing algorithm does not detect and ignore NaNs in the input data.

### Median and Percentile Smoothing Details

For running-median smoothing, use the /M flag and a *num* value from 1 to 32767. When *num* is 1, no smoothing is done.

If *num* is even, the median is the average of the two middle values.

For example, the median of 6 values around data[i] is the median of data[i-3], data[i-2], data[i-1], data[i], data[i+1], and data[i+2], and if these values were already sorted, the median would be the average of data[i-1] and data[i].

Use /M=0 to replace all values with the median over the smoothing window or use /M=*threshold*/R=(NaN) to replace outliers with NaNs.

Use /M=(NaN) to replace only NaN input values with the running-median values or the *replacement* value.

The running-median smoothing algorithm detects and ignores NaNs in the input data. If *num* is less than the number of NaNs near the output point, then the result is NaN. Otherwise the median of the non-NaN neighboring points is used to compute the smoothed result.

The running-median is a special case of running-percentile, with *percentile=50*.

The /M and /MPCT algorithm uses an interpolated rank to compute the value of percentiles other than 0 and 100.

Using Example 1 from <<http://cnx.org/content/m10805/latest/>> ("A Third Definition"), the 25th percentile (/MPCT=25) of the 8 values:

```
Make/O sortedData={3,5,7,8,9,11,13,15} // Already sorted, rank 1 to 8
```

The first step is to compute the rank (R) of the 25th percentile. This is done using the following formula:  $R = (\text{percentile}/100) * (\text{num} + 1)$ , where *percentile* is 25 and *num* is 8, so here  $R = 2.25$ .

If R were an integer, the Pth percentile would be the number with rank R; if R were 2 the result would be the 2nd value = 5.

Since R is not an integer, we compute the Pth percentile by interpolation as follows:

1. Define IR as the integer portion of R (the number to the left of the decimal point). For this example, IR=2.
2. Define FR as the fractional portion of R. For this example, FR=0.25
3. Find the values with Rank IR and with Rank IR+1. For this example, this means the values with Rank 2 and the score with Rank 3. The values are 5 and 7.
4. Interpolate by multiplying the difference between the values by FR and add the result to the lower values. For these data, this is  $0.25(7-5)+5=5.5$

Therefore, the 25th percentile is 5.5:

```
Smooth/M=0/MPCT=(percentile) 8, sortedData // 8-point smoothing window
Print sortedData[3] // prints 5.5, the 25th percentile of all 8 values
```

### Smoothing Window and End Effects Details

These smoothing algorithms compute the output value for a given point using each point's neighbors. Except for running-median smoothing, each algorithm combines neighboring points before and after the point being smoothed. At the start or end of a wave some points will not have enough neighbors so some method for fabricating neighbor values must be implemented. The /E flag specifies the method.

The running-median filter, however, ignores /E. At each end of the data fewer values are included in the median calculation, so that values "beyond" the end of data are not needed.

## Smooth

The first output value is the median of `wave[0, floor((num-1)/2)]`. For example, if `num = 7`, then the first output value is the median of `wave[0]`, `wave[1]`, `wave[2]`, and `wave[3]`. Because that is an even number of points, the median is the average of the two middle values. Continuing the example, if the values were 3, 1, 7, and 5, the two middle values are 3 and 5. The computed median would be  $(3+5)/2=4$ .

### Examples

Box smoothing example:

```
Make/N=100 wv; Display wv
wv=gnoise(1)
Smooth/B/E=3 3,wv // output[p] = average of wv[p-1], wv[p] and wv[p+1]
// /E=3 causes wv[0] = (w[0]+w[0]+w[1])/3
// and wv[n-1] = (w[n-2]+w[n-1]+w[n-1])/3
```

Demonstrate the impulse response of Savitzky-Golay Smoothing:

```
Make/O/N=100 wv
wv= p==50 // 1 at center of wave, 0 elsewhere; an impulse
SetScale/P x, 0, 1/1000, "s", wv // 1000 Hz sampling rate
Smooth/S=2 5,wv
Display wv
ModifyGraph mode=8,marker=19
FFT/MAG/DEST=fftMag wv
Display fftMag
```

Replace NaN with median:

```
Make/O/N=100 data= enoise(1)>.9 ? NaN : sin(x/8) // signal with NaNs
Duplicate/O data, dataMedian
Smooth/M=(NaN) 5, dataMedian // replace (only) NaNs with 5-point median
```

**See Also**

See the **Loess**, **MatrixConvolve**, and **MatrixFilter** operations for true 2D smoothing.

**FilterFIR, FilterIIR, Loess, Interpolate2**

Also see the “Smooth Operation Responses” example experiment.

**SmoothCustom**

**SmoothCustom** [/E=*endEffect*] *coefsWaveName*, *waveName* [, *waveName*]...

**Note:** SmoothCustom is obsolete. Use the **FilterFIR** operation instead. For multidimensional data use the **MatrixConvolve** or **MatrixFilter** operations.

The SmoothCustom operation smooths waves by convolving them with *coefsWaveName*.

**Parameters**

*coefsWaveName* must be single or double floating point, must not be one of the destination *waveNames*, must not be complex.

*waveName* is a numeric destination wave that is overwritten by the convolution of itself and *coefsWaveName*.

**Flags**

/E=*endEffect*            End effect method, a value between 0 and 3. See the **Smooth** operation for a description of the /E flag.

**Details**

The convolution is in the time domain. That is, the FFT is not employed. For this reason the length of *coefsWaveName* should be small or small in comparison to the destination waves.

SmoothCustom presumes that the middle point of *coefsWaveName* corresponds to the delay = 0 point. The “middle” point number =  $\text{trunc}(\text{numpts}(\text{coefsWaveName}-1)/2)$ . *coefsWaveName* usually contains the two-sided impulse response of a filter, and contains an odd number of points. This is the type of wave created by FilterFIR.

SmoothCustom ignores the X scaling of all the waves.

The SmoothCustom operation is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-95 for details.

**Sort**

**Sort** [ /A /DIML /C /R ] *sortKeyWaves*, *sortedWaveName* [, *sortedWaveName*]...

The Sort operation sorts the *sortedWaveNames* by rearranging their Y values to put the data values of *sortKeyWaves* in order.

**Parameters**

*sortKeyWaves* is either the name of a single wave, to use a single sort key, or the name of multiple waves in braces, to use multiple sort keys.

All waves must be of the same length.

The *sortKeyWaves* must not be complex.

**Flags**

/A[=*a*]            Alphanumeric sort. When *sortKeyWaves* includes text waves, the normal sorting places “wave1” and “wave10” before “wave9”.

The optional *a* parameter requires Igor Pro 7.00 or later.

Use /A or /A=1 to sort the number portion numerically, so that “wave9” is sorted before “wave10”.

Use /A=2 to ignore + and - characters in the text so that “Text-09” sorts before “Text-10”.

## SortColumns

---

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /C    | Case-sensitive sort. When <i>sortKeyWaves</i> includes text waves, the sort is case-insensitive unless you use the /C flag to make it case-sensitive.                                                                                                                                                                                                                                                                                                                  |
| /DIML | Moves the dimension labels with the values (keeps any row dimension label with the row's value).                                                                                                                                                                                                                                                                                                                                                                       |
| /LOC  | Performs a locale-aware sort.<br><br>When <i>sortKeyWaves</i> includes text waves, the text encoding of the text waves' data is taken into account and sorting is done according to the sorting conventions of the current system locale. This flag is ignored if the text waves' data encoding is unknown, binary, Symbol, or Dingbats. This flag cannot be used with the /A flag. See Details for more information.<br><br>The /LOC flag was added in Igor Pro 7.00. |
| /R    | Reversed sort; sort from largest to smallest.                                                                                                                                                                                                                                                                                                                                                                                                                          |

### Details

*sortKeyWaves* are not actually sorted unless they also appear in the list of destination waves.

The sort algorithm does not maintain the relative position of items with the same key value.

When the /LOC flag is used, the bytes stored in the text wave at each point are converted into a Unicode string using the text encoding of the text wave data. These Unicode strings are then compared using OS specific text comparison routines based on the locale set in the operating system. This means that the order of sorted items may differ when the same sort is done with the same data under different operating systems or different system locales.

When /LOC is omitted the sort is done on the raw text without regard to the waves' text encoding.

### Examples

```
Sort/R myWave,myWave // sorts myWave in decreasing order
Sort xWave,xWave,yWave // sorts x wave in increasing order,
// corresponding yWave values follow.
Make/O/T myWave={"1st","2nd","3rd","4th"}
Make/O key1={2,1,1,1} // places 2nd, 3rd, 4th before 1st.
Make/O key2={0,1,3,2} // arranges 2nd, 3rd, 4th as 2nd, 4th, 3rd.
Sort {key1,key2},myWave // sorts myWave in increasing order by key1.
// For equal key1 values, sorted by key2.
// Result is myWave={"2nd","4th","3rd","1st"}
Make/O/T tw={"w1","w10","w9","w-2.1"}
Sort/A tw,tw // sorts tw in increasing number-aware order:
// Result is tw={"w-2.1","w1","w9","w10"}
```

## SortColumns

**SortColumns** [*flags*] *keyWaves*={*waveList*}, *sortWaves*={*waveList*}

The SortColumns operation rearranges data in columns of the *sortWaves* using the data movements that would sort the values of the *keyWaves* if they were sorted.

The SortColumns operation was added in Igor Pro 7.00.

### Parameters

*keyWaves* is a lists of 1 or more wave references in braces separated by commas. The first listed wave is the primary sort key, the second is the secondary sort key, and so on. The *keyWaves* list can contain a maximum of 10 waves. The key waves can be either text or real numeric waves but all key waves must be of the same type and have the same number of points. Complex waves, wave reference waves and data folder reference waves can not be used as key waves.

*sortWaves* is a lists of one or more wave references in braces separated by commas. The *sortWaves* list can contain a maximum of 100 waves.

**Flags**

- /A**                   Alphanumeric sort.
- When *keyWaves* includes text waves, or the /KNDX flag is used and the first wave in the *sortWaves* list is a text wave, the normal sorting places "wave1" and "wave10" before "wave9". Use /A to sort the number portion numerically, so that "wave9" is sorted before "wave10". /A cannot be used with the /LOC flag.
- /C**                   Case-sensitive sort. When *keyWaves* includes text waves, or the /KNDX flag is used and the first wave in the *sortWaves* list is a text wave, the sort is case-insensitive unless you use the /C flag to make it case-sensitive.
- /DIML**               Moves the row dimension labels with the data values. Column dimension labels remain unchanged.
- /KNDX={c0, c1, ... c9}**
- Specifies up to 10 columns of the first wave in the *sortWaves* list to use as the sort keys. This flag and the *keyWaves* keyword are mutually exclusive. If this flag is used then the first wave in the *sortWaves* list must be either a real numeric or text wave.
- /LOC**               Locale aware sort.
- When *keyWaves* includes text waves, or the /KNDX flag is used and the first wave in the *sortWaves* list is a text wave, the text encoding of the text waves' data is taken into account and sorting is done according to the sorting conventions of the current system locale.
- /LOC is ignored if the text waves' data encoding is unknown, binary, Symbol, or Dingbats.
- /LOC can not be used with the /A flag.
- See Details for more information.
- /R**                   Reverses the sort, sorting from largest to smallest.

**Details**

Waves in the *keyWaves* list are not actually sorted unless they also appear in the *sortWaves* list.

All waves must have the same number of rows but can have different numbers of columns, layers and chunks.

*keyWaves*, or the first wave in the *sortWaves* list when /KNDX is used, must be either numeric or text waves.

When the *sortWaves* list includes 3D or 4D waves, the operation sorts all columns of all layers/chunks.

The sorting algorithm used does not maintain the relative position of rows with the same key value.

When the /LOC flag is used, the bytes stored in the text wave at each point are converted into a Unicode string using the text encoding of the text wave data. These Unicode strings are then compared using OS-specific text comparison routines based on the current locale as set in the operating system. This means that the order of sorted items may differ when the same sort is done with the same data under different operating systems or different system locales.

**Examples**

```
// Define a function that creates sample data
Function CreateSampleData()
 Make/O key1={3,1,0,2}
 Make/O/T text1={"Jack", "Fred", "Robin", "Bob"}
 Make/O w1={{1,2,3,4}, {11,12,13,14}}
End

// Create sample data and display in a table
CreateSampleData()
Edit key1,text1,w1

// Sort based on a numeric key
SortColumns keyWaves=key1,sortWaves=w1
```

## SortList

---

```
// Revert the data
CreateSampleData()

// Sort based on text key
SortColumns keyWaves=text1,sortWaves=w1

// Revert the data
CreateSampleData()

// Sort using key index
SortColumns/kndx=0 sortWaves={text1,w1}
```

### See Also

Sorting on page III-132, [Sort](#), [Reverse](#), [SortList](#)

## SortList

**SortList(listStr [, listSepStr [, options]])**

The SortList function returns *listStr* after sorting it according to the default or *listSepStr* and *options* parameters. *listStr* should contain items separated by *listSepStr*, such as "the first item;second item;".

Use SortList to sort the items in a string containing a list of items separated by a string, such as those returned by functions like [TraceNameList](#) or [WaveList](#), or a line of text from a delimited text file, where *listSepStr* can be "\r" or "\r\n".

*listSepStr* and *options* are optional; their defaults are ";" and 0 (ascending alphabetic sort), respectively.

### Details

*listStr* is treated as if it ends with a *listSepStr* even if it doesn't. The returned list will always have an ending *listSepStr* string.

In Igor6, SortList used only the first byte of *listSepStr*. As of Igor7, it uses the whole string.

*options* controls the sorting method, as follows:

- 0: Default sort (ascending case-sensitive alphabetic ASCII sort).
- 1: Descending sort.
- 2: Numeric sort.
- 4: Case-insensitive sort.
- 8: Case-sensitive alphanumeric sort.
- 16: Case-insensitive alphanumeric sort that sorts wave0 and wave9 before wave10.
- 32: Unique sort in which duplicates are removed. Added in Igor Pro 7.00.
- 64: Ignore + and - in the alphanumeric sort so that "Text-09" sorts before "Text-10". Set options to 80 or 81. Added in Igor Pro 7.00.

*options* may also be a bitwise combination of these values with the following restriction: only one of 2, 4, 8, or 16 may be specified. Thus the legal values are thus 0, 1, 2, 3, 4, 5, 8, 9, 16, 17, 32, 33, 34, 35, 36, 40, 41, 48, 49, 80 or 81. Other values will produce undefined sorting.

In a case-insensitive, unique sort (options=4+32), if two items differ only in case, which one is retained is not specified.

### Examples

```
// Alphabetic sorts
Print SortList("c;a;a;b") // prints "a;a;b;c;"
Print SortList("you,me,More", ",", 0) // prints "More,me,you,"
Print SortList("you,me,More", ",", 4) // prints "me,More,you,"
Print SortList("9,93,91,33,15,3", ",", 16) // prints "15,3,33,9,91,93,"
Print SortList("Zx;abc;All;", ";", 0) // prints "All;Zx;abc;"
Print SortList("Zx;abc;All;", ";", 8) // prints "abc;All;Zx;"
Print SortList("w9;w10;w02;", ";", 16) // prints "w02;w9;w10;"

// Unique sort
Print SortList("b;c;a;a;", ";", 32) // prints "a;b;c;"
```

```
Print SortList("b;c;A;a;", ";", 4+32) // prints "A;b;c;"
Print SortList("b;c;a;A;", ";", 4+32) // prints "a;b;c;"

// Numeric sorts
Print SortList("9,93,91,33,15,3", ",", 2) // prints "3,9,15,33,91,93,"
Print SortList("9,93,91,33,15,3", ",", 3) // prints "93,91,33,15,9,3,"
```

**See Also****Sort, StringFromList, WaveList, RemoveEnding**See **Setting Bit Parameters** on page IV-12 for details about bit settings.

## SoundInRecord

**SoundInRecord** [/BITS=*bits* /Z] *wave*

The SoundInRecord operation records audio input at the sample rate obtained from the wave's X scaling and for the number of points determined by the length of the wave. The recording is done synchronously.

The number type of the wave must be a type supported by the sound input hardware as reported by the SoundInStatus operation. Use **SoundInStatus** with the format keyword to check if a particular format is supported.

On Windows 8-bit or 16-bit integer are typically supported. On Macintosh, 16-bit integer or 32-bit floating point (the Mac OS native type for sound) are typically supported.

To record in stereo, provide a 2 column wave. (The software is designed to handle any number of channels but has not been tested on more than 2.)

**Flags**

/BITS=*bits* Controls the number of bits used for each recorded sound sample.

Use /BITS=24 with a 32-bit integer wave for 24-bit sound data capable of representing values from -8,388,608 to +8,388,607.

If you omit /BITS or use /BITS=0, SoundInRecord uses the wave's data type and size to determine how many bits are recorded for each sound sample.

The /BITS flag was added in Igor Pro 9.00.

/Z Errors are not fatal. V\_flag is set to zero if no error, else nonzero if error.

**Details**

SoundInRecord requires a computer with sound inputs. Several sample experiments using sound input can be found in your Igor Pro Folder in the Examples folder.

**See Also****SoundInSet, SoundInStartChart, SoundInStatus**

## SoundInSet

**SoundInSet** [/Z] [gain=*g*, agc=*a*]

The SoundInSet operation is used to setup the input device for recording.

**Parameters**

SoundInSet can accept multiple *keyword =value* parameters on one line.

agc=*a* Turns automatic gain control mode on (*a*=1) or off (*a*=0). Will generate an error if device does not support setting agc. Use SoundInStatus to check or use /Z flag to make errors nonfatal.

*Windows:* This is not supported and V\_SoundInAGC from the SoundInStatus command always returns -1.

gain=*g* Sets input gain, 0 is lowest gain and 1 is highest. Will generate an error if device does not support setting gain. Use SoundInStatus to check or use /Z flag to make errors nonfatal.

## SoundInStartChart

---

*Windows:* SoundInSet attempts to adjust the master gain of the sound input device but not all sound cards have a master gain. If V\_SoundInGain from the SoundInStatus command returns -1, you will have to use your sound card software to adjust the input gain for the particular input source you are using. On some cards there are separate line-in and microphone-in sources.

### Flags

/Z Errors are not fatal. V\_flag is set to zero if no error, else nonzero if error.

### Details

SoundInSet requires a computer with sound inputs. Several sample experiments using sound inputs are in your Igor Pro Folder in the Examples folder.

### See Also

The **SoundInRecord**, **SoundInStartChart**, and **SoundInStatus** operations.

## SoundInStartChart

**SoundInStartChart** [/Z] *bufferSize* , *destFIFOname*

The SoundInStartChart operation starts audio data acquisition into the given FIFO.

### Parameters

*bufferSize* is the number of bytes to allocate for the interrupt time buffer which then feeds into the given Igor named FIFO *destFIFOname*. The FIFO must be set up with the correct number of channels and number type - use **SoundInStatus** to find legal values. The sample rate is read from the FIFO also, so that also needs to be correct.

### Flags

/Z Errors are not fatal. V\_flag is set to zero if no error, else nonzero if error.

### Details

SoundInStartChart requires a computer with sound inputs. Several sample experiments using sound inputs are in your Igor Pro Folder in the Examples folder.

On systems where 32-bit floating point data is supported, you can use NewFIFOChan with no flags and a range of -1 to 1.

### See Also

The **SoundInRecord**, **SoundInSet**, **SoundInStatus** and **SoundInStopChart** operations, and **FIFOs and Charts** on page IV-310.

## SoundInStatus

**SoundInStatus** [format={*intOrFloat*, *channels*, *bits*, *frequency*}]

The SoundInStatus operation creates and sets a set of variables and strings with information about the current sound input device.

### Keywords

format={*intOrFloat*, *channels*, *bits*, *frequency*}

Checks if a specific sound input format is supported. This is useful because it is often the case that more sound input formats are supported than are reported via the V\_SoundInSampSize and W\_SoundInRates outputs.

V\_Flag is set to 0 if the specified format is supported by the input device or to a non-zero error code otherwise.

The format keyword was added in Igor Pro 9.00.

*intOrFloat* is a keyword (unquoted), either int or float.

*channels* is 1 for mono, 2 for stereo. Additional channels may also work with some sound hardware.

*bits* may be any value between 8 and 64, though 8, 16, 24, and 32 are most likely to be supported by the operating system. CD audio samples use 16 bits.

*frequency* is the sampling rate in Hertz, with a minimum of 4800. CD audio is sampled at 44100 Hz. A practical upper limit is 192000.

## Outputs

|                   |                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_Flag            | Set to 0 if the device is available or to a non-zero error code.<br>Also, if you use the format keyword and the specified format is not supported then V_Flag is set to a non-zero error code.<br>If V_Flag is non-zero then none of the following outputs are valid.                                                                                |
| S_SoundInName     | String with name of device.                                                                                                                                                                                                                                                                                                                          |
| V_SoundInAGC      | Automatic gain control on or off (1 or 0). This is an optional item and if the current device does not support AGC then V_SoundInAGC will be set to -1.                                                                                                                                                                                              |
| V_SoundInChansAv  | Available number of channels (e.g., 1 for mono, 2 for stereo).                                                                                                                                                                                                                                                                                       |
| V_SoundInGain     | Current input gain. Ranges from 0 (lowest) to 1. This is an optional item and if the current device does not support gain then V_SoundInGain will be set to -1.                                                                                                                                                                                      |
| V_SoundInSampSize | Bits set depending on number of bits available in a sample.<br>Bit 0: Set if 8-bit integer is supported.<br>Bit 1: Set if 16-bit integer is supported.<br>Bit 2: Set if 32-bit integer is supported.<br>Bit 3: Set if 32-bit floating point is supported (range is -1 to 1).<br>Bit 4: Set if 64-bit floating point is supported (range is -1 to 1). |
| W_SoundInRates    | Wave containing sample rate information: If point 0 contains 0 then points 1 and 2 contain the lower and upper limits of a continuous range; otherwise point 0 contains the number of discrete rates which follow in the wave. The usual rates are 44100 Hz and 4800 Hz.                                                                             |

## See Also

SoundInSet, SoundInRecord, SoundInStartChart

## SoundInStopChart

**SoundInStopChart** [/Z]

The SoundInStopChart operation stops audio data acquisition started by SoundInStartChart.

### Flags

/Z Errors are not fatal. V\_flag is set to zero if no error, else nonzero if error.

### Details

SoundInStopChart requires a computer equipped with sound input hardware.

## SoundLoadWave

---

Audio data acquisition also stops automatically when an experiment is closed.

### See Also

The **SoundInStartChart** and **SoundInStatus** operations.

## SoundLoadWave

**SoundLoadWave** [**flags**] **waveName** [ , **fileNameStr** ]

The SoundLoadWave operation loads sound data from the named file into a wave. Mono, stereo, surround-sound, and high-resolution sound formats are supported.

The SoundLoadWave operation was added in Igor Pro 7.00.

### Parameters

*waveName* is the name of the wave to load the sound into.

If *fileNameStr* is omitted or is "", SoundLoadWave displays an Open File dialog.

The file to be loaded is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If SoundLoadWave can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to choose the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

### Flags

|                                 |                                                                                                                                                                                                                                                         |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/I</i> [= <i>filterStr</i> ] | Force interactive mode. Use optional filter string to limit allowable file extensions. See <b>Open File Dialog File Filters</b> on page IV-149.                                                                                                         |
| <i>/O</i>                       | Overwrite existing waves in case of a name conflict.                                                                                                                                                                                                    |
| <i>/P=pathName</i>              | Specifies the folder to load the file from. <i>pathName</i> is the name of an Igor symbolic path, created via <b>NewPath</b> . It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See <b>Symbolic Paths</b> on page II-22 for details. |
| <i>/Q</i>                       | Quiet: Doesn't print message to history area, and doesn't abort, if the sound can not be loaded. <i>V_Error</i> is set to the returned error code, which will be zero if there was no error.                                                            |
| <i>/S=(startT,endT)</i>         | Load a subrange of the sound resource. <i>startT</i> and <i>endT</i> are in seconds, clipped to the duration of the loaded sound.                                                                                                                       |
| <i>/TMOT= timeOut</i>           | Aborts load if <i>timeOut</i> , in seconds, is exceeded.                                                                                                                                                                                                |

### Details

SoundLoadWave uses Core Audio on Macintosh and Qt framework calls on Windows. Note that some files can not be loaded due to digital rights management issues even though they can be played.

If *waveName* specifies a wave that does not exist, it is created. The wave is redimensioned to a wave type that maintains the numeric precision of the sound data. If the wave can not be created or resized to fit the loaded data then SoundLoadWave returns an error.

If *waveName* does exist, the wave is overwritten only if the */O* flag is specified. Without the */O* flag SoundLoadWave returns an error.

Multi-channel audio is loaded into sequential columns of the destination wave.

On Macintosh, Igor uses Core Audio to produce 32-bit or 64-bit floating point waves. The *BITS* value in *S\_info*, described below, may be zero for some formats.

On Windows, SoundLoadWave uses the smallest Igor wave data type that preserves the number of bits in the audio. Igor doesn't have a 24-bit data type, so these values are stored in a 32-bit integer wave.

**Output Variables**

SoundLoadWave sets these output variables:

|             |                                                                                                                                                                                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_flag      | Set to 1 if a sound is loaded and fits into available memory, 0 otherwise.                                                                                                                                                                                                       |
| V_Error     | Set if /Q is specified, V_Error is set to a non-zero error code if something went wrong or to zero on success. Negative returned codes are system-dependent, positive are Igor-defined errors.<br>V_Error = 1 means there wasn't enough memory to load the (uncompressed) sound. |
| S_path      | Set to the full file path of the loaded file, not including the file name.                                                                                                                                                                                                       |
| S_fileName  | Set to the name of the loaded file.                                                                                                                                                                                                                                              |
| S_waveNames | Set to the name of loaded wave.                                                                                                                                                                                                                                                  |
| S_info      | Information about the loaded sound.                                                                                                                                                                                                                                              |

If the sound file exists, SoundLoadWave sets the string variable S\_info to:

```
"FILE:nameOfFile;FORMAT:soundFileFormat;CHANNELS:numChannels;CHANNEL_LAYOUT:channelLayoutDescription;CHANNEL_ORDER:channelsList;BITS:numBits;SAMPLES:numSamples;RATE:samplesPerSec;"
```

The *soundFileFormat* and *channelLayoutDescription* values are text descriptions of the sound data in the file, and are written in the localized language. This information is available only on Macintosh and may or may not be present in a given sound file.

The *channelsList* value is a comma-separated list of channel names, always in English abbreviations, such as "L,R" or "L,R,C,LFE,Ls,Rs". The meaning of the abbreviations:

| <b>channelList Abbreviation</b> | <b>Channel or Speaker Names</b>           |
|---------------------------------|-------------------------------------------|
| L                               | Front Left                                |
| R                               | Front Right                               |
| C                               | Front Center                              |
| LFE                             | Low Frequency Effects                     |
| Ls                              | Left Surround (Back Left)                 |
| Rs                              | Right Surround (Back Right)               |
| Lc                              | Left Center (Front Left of Center)        |
| Rc                              | Right Center (Front Right of Center)      |
| Cs                              | Center Surround (Back Center)             |
| Lsd                             | Left Surround Direct (Side Left)          |
| Rsd                             | Right Surround Direct (Side Right)        |
| Ts                              | Top Center Surround (Top Center)          |
| Vhl                             | Vertical Height Left (Top Front Left)     |
| Vhc                             | Vertical Height Center (Top Front Center) |
| Vhr                             | Vertical Height Right (Top Front Right)   |
| Rls                             | Rear Left Surround (Top Back Left)        |
| Rcs                             | Rear Center Surround (Top Back Center)    |
| Rrs                             | Rear Right Surround (Top Back Right)      |

## SoundSaveWave

---

### Examples

```
// Display an Open File dialog and load the chosen file.
// Use file's name for wave, overwrite any pre-existing wave, print information to history
SoundLoadWave/O myDestWave

// SoundLoadWave stores following in S_Info and prints it to the history area
FILE:<file name>;FORMAT:MPEG Layer 3;CHANNELS:2;BITS:0;SAMPLES:524416;RATE:44100;

// Rename the wave to a cleaned up version of the file name
Rename myDestWave, $CleanupName(S_fileName,1)
```

### See Also

**SoundSaveWave, PlaySound**

## SoundSaveWave

**SoundSaveWave** [*flags*] *typeStr*, *waveName* [ , *fileNameStr* ]

The SoundSaveWave operation saves the named wave on disk as an Audio Interchange File Format (AIFF-C) or Microsoft WAVE sound file. AIFF-C is primarily used on Macintosh.

### Parameters

*typeStr* must be either "AIFC" or "WAVE".

*fileNameStr* contains the name of the file in which the named wave is saved. If you omit *fileNameStr*, SoundSaveWave uses the wave name with the appropriate extension.

The file to be written is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If SoundSaveWave can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

### Flags

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/BITS=bits</i>  | Controls the number of bits used for each sound sample written to the file.<br>Use <i>/BITS=24</i> with a 32-bit integer wave to save 24-bit sound data capable of representing values from -8,388,608 to +8,388,607.<br>If you omit <i>/BITS</i> or use <i>/BITS=0</i> , SoundSaveWave uses the wave's data type and size to determine how many bits are written for each sound sample.<br>The <i>/BITS</i> flag was added in Igor Pro 9.00. |
| <i>/I</i>          | Presents a Save File dialog in which you can specify the file to be saved.                                                                                                                                                                                                                                                                                                                                                                    |
| <i>/O</i>          | Overwrites the file if it already exists.<br>If you omit <i>/O</i> and the file exists, SoundSaveWave displays a Save File dialog.                                                                                                                                                                                                                                                                                                            |
| <i>/P=pathName</i> | Specifies the folder to store the file in. <i>pathName</i> is the name of an Igor symbolic path, created via <b>NewPath</b> . It is not a file system path like "hd:Folder1:" or "C:\\Folder1\\". See <b>Symbolic Paths</b> on page II-22 for details.                                                                                                                                                                                        |
| <i>/Q</i>          | Suppresses the normal messages in the history area of the command window. At present nothing is written to the history even if <i>/Q</i> is omitted.                                                                                                                                                                                                                                                                                          |

### Details

The sound file is always an uncompressed AIFF-C or WAVE file, with as many channels as the wave contains columns.

The sound file format is determined by the wave's data type, *typeStr*, and the */BITS* flag. Signed 8-, 16- and 24-bit integers are supported as are 32-bit and 64-bit floating point. When writing floating point waves, the wave data should be scaled to +/- 1.0 as full scale.

The SoundSaveWave operation was added in Igor Pro 7.00. 24-bit integer and 64-bit floating point support were added in Igor Pro 9.00.

### Output Variables

SoundSaveWave sets these automatically created variables:

|            |                                                                                      |
|------------|--------------------------------------------------------------------------------------|
| V_flag     | Set to 0 if the wave was successfully saved to the file or to a non-zero error code. |
| S_fileName | Set to the name of the saved file.                                                   |
| S_path     | Set to the full path to the file's directory.                                        |

### Examples

```
// Create a simple sound (1000 Hz tone burst)
Make/O/N=10000 mySound // Single-precision wave, 10,000 values
SetScale/P x, 0, 1/8000, "" mySound // 8000 Hz sampling frequency (1.25 seconds)
mySound= sin(2*pi*1000*x) // 1000 Hz tone
Hanning mySound // Fade in and out

// Save it to a file, chosen from the Save File dialog
SoundSaveWave "AIFC", mySound, "my sound.aif"

// Create a floating point stereo frequency sweep
Make/O/N=(20000,2) stereoSineSoundF32 // 32-bit float data
SetScale/P x, 0, 1e-4, stereoSineSoundF32 // Set sample rate to 10KHz
stereoSineSoundF32= sin(2*Pi*(1000 + (1-2*q)*150*x)*x)
NewPath sound // Create a symbolic path via dialog
SoundSaveWave/P=sound/O "WAVE", stereoSineSoundF32
```

## SpecialCharacterInfo

**SpecialCharacterInfo**(*notebookNameStr*, *specialCharacterNameStr*, *whichStr*)

The SpecialCharacterInfo function returns a string containing information about the named special character in the named notebook window.

### Parameters

If *notebookNameStr* is "", the top visible notebook is used. Otherwise *notebookNameStr* contains either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0#nb0. See **Subwindow Syntax** on page III-92 for details on host-child specifications.

*specialCharacterNameStr* is the name of a special character in the notebook.

If *specialCharacterNameStr* is "" and if exactly one special character is selected, the selected special character is used. If other than exactly one special character is selected, an error is returned.

*whichStr* identifies the information item you want. Because SpecialCharacterInfo can return several items that may contain semicolons, it does not return a semicolon-separated keyword-value list like other info functions. Instead it returns just one item as specified by *whichStr*.

### Details

Here are the supported values for *whichStr*.

| Keyword | Returned Information                                        |
|---------|-------------------------------------------------------------|
| NAME    | The name of the special character.                          |
| FRAME   | 0: None<br>1: Single<br>2: Double<br>3: Triple<br>4: Shadow |

## SpecialCharacterInfo

---

| Keyword | Returned Information                                                                                                                            |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| LOC     | Paragraph and character position (e.g., 1,3).                                                                                                   |
| SCALING | Horizontal and vertical scaling in units of one tenth of a percent (e.g., 1000,1000).                                                           |
| TYPE    | Special character type is: Picture, Graph, Table, Layout, Action, ShortDate, LongDate, AbbreviatedDate, Time, Page, TotalPages, or WindowTitle. |

---

These keywords apply to Igor-object pictures only. If the specified character is not an Igor-object picture, "" is returned.

| Keyword    | Returned Information                                                   |
|------------|------------------------------------------------------------------------|
| WINTYPE    | 1 for graphs, 2 for tables, 3 for layouts.                             |
| OBJECTNAME | The name of the window with which the special character is associated. |

---

The remaining keywords apply to notebook action characters only. If the specified special character is not a notebook action character, "" is returned.

| Keyword      | Returned Information                                                                                                                                        |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BGRGB        | Background color in RGB format (e.g., 65535,65534,49151).                                                                                                   |
| COMMANDS     | Command string.                                                                                                                                             |
| ENABLEBGRGB  | 1 if the action's background color is enabled, 0 if not.                                                                                                    |
| HELPTXT      | Help text string.                                                                                                                                           |
| IGNOREERRORS | 0 or 1.                                                                                                                                                     |
| LINKSTYLE    | 0 or 1.                                                                                                                                                     |
| PADDING      | The value of the left, right, top, bottom and internal padding properties, in that order (e.g, 4,4,4,4,8).                                                  |
| PICTURE      | 1 if the action has a picture, 0 if not.                                                                                                                    |
| PROCPICNAME  | The name of the action Proc Picture or "" if none.                                                                                                          |
| QUIET        | 0 or 1.                                                                                                                                                     |
| SHOWMODE     | 1: Title only<br>2: Picture only<br>3: Picture below title<br>4: Picture above title<br>5: Picture to the left of title<br>6: Picture to the right of title |
| TITLE        | Title string.                                                                                                                                               |

---

If *whichStr* is an unknown keyword, SpecialCharacterInfo returns "" but does not generate an error.

### Examples

```
Function PrintSpecialCharacterInfo(notebookName, specialCharacterName)
 String notebookName, specialCharacterName

 String typeStr=SpecialCharacterInfo(notebookName, specialCharacterName, "TYPE")
 String locStr=SpecialCharacterInfo(notebookName, specialCharacterName, "LOC")

 Printf "TYPE: %s\r", typeStr
 Printf "LOC: %s\r", locStr
End
```

### See Also

The **Notebook** and **NotebookAction** operations; the **SpecialCharacterList** function; **Using Igor-Object Pictures** on page III-18.

## SpecialCharacterList

**SpecialCharacterList**(*notebookNameStr*, *separatorStr*, *mask*, *flags*)

The SpecialCharacterList function returns a string containing a list of names of special characters in a formatted text notebook.

### Parameters

If *notebookNameStr* is "", the top visible notebook is used. Otherwise *notebookNameStr* contains either *kwTopWin* for the top notebook window, the name of a notebook window or a host-child specification (an *hcSpec*) such as `Panel0#nb0`. See **Subwindow Syntax** on page III-92 for details on host-child specifications.

*separatorStr* should contain a single ASCII character, usually semicolon, to separate the names.

*mask* determines which types of special characters are included. *mask* is a bitwise parameter with values:

- 1: Pictures including graphs, tables and layouts.
- 2: Notebook actions.
- 4: All other special characters such as dates and times.

or a bitwise combination of the above for more than one type. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

*flags* is a bitwise parameter. Pass 0 to include all special characters or 1 to include only selected special characters. All other bits are reserved and should be passed as zero.

### Details

Only formatted text notebooks have special characters. When called for a plain text notebook, SpecialCharacterList always returns "".

### Examples

Print a list of all special characters in the top notebook:

```
Print SpecialCharacterList("", ";", -1, 0)
```

Prints a list of notebook action characters in Notebook0:

```
Print SpecialCharacterList("Notebook0", ";", 2, 0)
```

Print a list of selected notebook action characters in Notebook0:

```
Print SpecialCharacterList("Notebook0", ";", 2, 1)
```

### See Also

The **Notebook** and **NotebookAction** operations; the **SpecialCharacterInfo** function.

## SpecialDirPath

**SpecialDirPath**(*dirIDStr*, *domain*, *flags*, *createDir*)

The SpecialDirPath function returns a full path to a file system directory specified by *dirIDStr* and *domain*. It provides a programmer with a way to access directories of special interest, such as the preferences directory and the desktop directory.

The path returned always ends with a separator character which may be a colon, backslash, or forward slash depending on the operating system and the *flags* parameter.

SpecialDirPath depends on operating system behavior. The exact path returned depends on the locale, the operating system, the specific installation, the current user, and possibly other factors.

### Parameters

*dirIDStr* is one of the following strings:

- "Packages" Place for advanced programmers to put preferences for their procedure packages.
- "Documents" The OS-defined place for users to put documents.
- "Preferences" The OS-defined place for applications to put preferences.
- "Desktop" The desktop.

## SpecialDirPath

---

|                       |                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| "Temporary"           | The OS-defined place for applications to put temporary files.                                                                                                                                                                                                                                                                           |
| "Igor Application"    | The Igor installation folder. This is typically:<br>/Applications/Igor Pro X Folder (Macintosh)<br>or<br>C:\Program Files\WaveMetrics\Igor Pro X Folder (Windows)<br>where "X" is the major version number.<br>Use only with domain = 0 (the current user).                                                                             |
| "Igor Executable"     | The folder containing the current Igor executable. On Macintosh, this is the path to the executable itself, not to the application bundle.<br>Use only with domain = 0 (the current user).<br>Requires Igor Pro 7.00 or later.                                                                                                          |
| "Igor Preferences"    | The folder in which Igor's own preference files are stored.                                                                                                                                                                                                                                                                             |
| "Igor Pro User Files" | A guaranteed-writable folder for the user to store their own Igor files, and to activate extensions, help, and procedure files by creating shortcuts or aliases in the appropriate subfolders. Use only with domain = 0 (the current user).<br>This is the folder opened using the Show Igor Pro User Files menu item in the Help menu. |

*domain* permits discriminating between, for example, the preferences folder for all users versus the preferences folder for the current user. It is supported only for certain *dirIDStrs*. It is one of the following:

- 0: The current user (recommended value for most purposes).
- 1: All users (may generate an error or return the same path as 0).
- 2: System (may generate an error or return the same path as 1).

*flags* a bitwise parameter:

- Bit 0: If set, the returned path is a native path (Macintosh-style on Mac OS 9, Unix-style on Mac OS X, Windows-style on Windows). If cleared, the returned path is a Macintosh-style path regardless of the current platform. In most cases you should set this bit to zero since Igor accepts Macintosh-style paths on all operating systems. You must set this bit to one if you are going to pass the path to an external script.

All other bits are reserved and must be set to zero.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

*createDir* is 1 if you want the directory to be created if it does not exist or 0 if you do not want it to be created. This flag will not work if the current user does not have sufficient privileges to create the specified directory. In almost all cases it is not needed, you can't count on it, and you should pass 0.

### Details

The *domain* parameter has no effect in most cases. In almost all cases you should pass 0 (current user) for this parameter. For values other than 0, *SpecialDirPath* might return an error which you must be prepared to handle.

In the event of an error, *SpecialDirPath* returns a NULL string and sets a runtime error code. You can check for an error like this:

```
String fullPath = SpecialDirPath("Packages", 0, 0, 0)
Variable len = strlen(fullPath) // strlen(NULL) returns NaN
if (numtype(len) == 2) // fullPath is NULL?
 Print "SpecialDirPath returned error."
endif
```

Here is sample output from *SpecialDirPath*("Packages", 0, 0, 0):

**Mac OS X**      hd:Users:<user>:Library:Preferences:WaveMetrics:Igor Pro X:Packages:

**Windows** C:\Documents and Settings:<user>\Application Data\WaveMetrics\Igor Pro X\Packages:

where <user> is the name of the current user and "X" is the major version number..

#### Example

For an example using SpecialDirPath, see **Saving Package Preferences** on page IV-249.

## sphericalBessJ

**sphericalBessJ**(*n*, *x* [, *accuracy*])

The sphericalBessJ function returns the spherical Bessel function of the first kind and order *n*.

$$j_n(x) = \sqrt{\frac{\pi}{2x}} J_{n+1/2}(x).$$

For example:

$$j_0(x) = \frac{\sin(x)}{x}$$

$$j_1(x) = \frac{\sin(x)}{x^2} - \frac{\cos(x)}{x}$$

$$j_2(x) = \left( \frac{3}{x^3} - \frac{1}{x} \right) \sin(x) - \frac{3}{x^2} \cos(x).$$

## SphericalInterpolate

**SphericalInterpolate** *triangulationDataWave, dataPointsWave, newLocationsWave*

The SphericalInterpolate operation works in conjunction with the SphericalTriangulate operation to calculate interpolated values on a surface of a sphere. Given a set of  $\{x_i, y_i, z_i\}$  points on the surface of a sphere with their associated values  $\{v_i\}$ , the SphericalTriangulate operation performs the Delaunay triangulation and creates an output that is used by the SphericalInterpolate operation to calculate values at any other point on the surface of a sphere. The interpolation calculation uses Voronoi polygons to weigh the contribution of the nearest neighbors to any given location on the sphere.

### Parameters

*triangulationDataWave* is a 13 column wave that was created by the SphericalTriangulate operation.

*dataPoints* is a 4 column wave. The first 3 columns are the  $\{x_i, y_i, z_i\}$  locations that were used to create the triangulation, and the last column corresponds to the  $\{v_i\}$  values at the triangulation locations.

*newLocationsWave* is a 3 column wave that specifies the x, y, z locations on the sphere at which the interpolated values are calculated. Note that internally, each triplet is normalized to a point on the unit sphere before it is used in the interpolation.

### Details

You will always need to use the SphericalTriangulate operation first to generate the *triangulationDataWave* input for this operation.

The result of the operation are put in the wave W\_SphericalInterpolation.

## SphericalTriangulate

**SphericalTriangulate** [/Z] *tripletWaveName*

The SphericalTriangulate operation triangulates an arbitrary XYZ triplet wave on a surface of a sphere.

It starts by normalizing the data to make sure that  $\sqrt{x^2+y^2+z^2}=1$ , and then proceeds to calculate the Delaunay triangulation.

### Flags

/Z            No error reporting.

### Details

The result of the triangulation is the wave M\_SphericalTriangulation. This 13 column wave is used in SphericalInterpolate to obtain the interpolated values.

### Example

```
// Generates output waves that can be used in Gizmo to display the triangulation.
// triangulationData is the M_TriangulationData output from SphericalTriangulation.
// tripletWave is the source wave input to SphericalTriangulation.
// Output wave sphereTrianglesPath can be used to display the triangulation as a path.
// Output wave sphereTrianglesSurf can be used to display the triangulation as a surface.
Function BuildTriangleWaves(triangulationData,tripletWave)
 Wave triangulationData, tripletWave

 // Extract 3 columns from triangulationData that contain the index of the row.
 Duplicate/O/FREE/r=[] [1,3] triangulationData,triIndices
 Variable finalNumTriangles=dimSize(triIndices,0),i,j,k

 // Initialize both waves to NaN so any unassigned point would appear as a hole.
 Make/O/N=(5*finalNumTriangles,3) sphereTrianglesPath=NaN
 Make/O/N=(3*finalNumTriangles,3) sphereTrianglesSurf=NaN

 // Assign the values of the vertices to the two waves:
 Variable rowIndex,rowIndex0,outRowCount=0,outcount2=0
 for(i=1;i<finalNumTriangles;i+=1)
```

## SplitString

---

```
 for(j=0;j<3;j+=1)
 rowIndex=triIndices[i][j]
 for(k=0;k<3;k+=1)
 sphereTrianglesPath[outRowCount][k]=tripletWave[rowIndex][k]
 sphereTrianglesSurf[outcount2][k]=tripletWave[rowIndex][k]
 endfor
 outRowCount+=1
 outcount2+=1
 endfor

 // Close the triangle path by returning to the first vertex:
 rowIndex0=triIndices[i][0]
 sphereTrianglesPath[outRowCount][0]=tripletWave[rowIndex0][0]
 sphereTrianglesPath[outRowCount][1]=tripletWave[rowIndex0][1]
 sphereTrianglesPath[outRowCount][2]=tripletWave[rowIndex0][2]
 outRowCount+=2 // Increment row count and skip the NaN
endfor
End
```

## SplitString

**SplitString** /E=*regExprStr* *str* [, *substring1* [, *substring2*,... *substringN*]

The SplitString operation uses the regular expression *regExprStr* to split *str* into subpatterns. See **Subpatterns** on page IV-186 for details. Each matched subpattern is returned sequentially in the corresponding substring parameter.

### Parameters

*str* is the input string to be split into subpatterns.

The *substring1*...*substringN* output parameters must be the names of existing string variables if you need to use the matched subpatterns. The first matched subpattern is returned in *substring1*, the second in *substring2*, etc.

### Flags

/E=*regExprStr* Specifies the Perl-compatible regular expression string containing subpattern definition(s).

### Details

*regExprStr* is a regular expression with successive subpattern definitions, such as shown in the examples. (Subpatterns are regular expressions within parentheses.)

For unmatched subpatterns, the corresponding substring is set to "". If you specify more substring parameters than subpatterns, the extra parameters are also set to "".

The number of matched subpatterns is returned in *V\_flag*.

The part of *str* that matches *regExprStr* (often all of *str*) is stored in *S\_value*.

### Examples

```
// Split the output of the date() function:
Print date()
 Mon, May 2, 2005

String expr="([[:alpha:]]+), ([[:alpha:]]+) ([[:digit:]]+), ([[:digit:]]+)"
String dayOfWeek, monthName, dayNumStr, yearStr
SplitString/E=(expr) date(), dayOfWeek, monthName, dayNumStr, yearStr
Print V_flag
 4
Print dayOfWeek
 Mon
Print monthName
 May
Print dayNumStr
 2
Print yearStr
```

```

2005
Print S_value
 Mon, May 2, 2005

// Get the part of str that matches regExprStr
SplitString/E=",*," "stuff in front,second value,stuff at end"
Print S_value
 ,second value,

```

## SplitWave

**SplitWave** [*flags*] *srcWave*

The SplitWave operation creates new waves containing subsets of the data in *srcWave* which must be 2D or greater.

The newly generated waves have lower dimensionality than *srcWave*. The operation is ideal for splitting 2D waves into constituent columns, 3D waves into their layers, etc.

Added in Igor Pro 7.00.

**Flags**

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/DDF=destDataFolder</i> | Specifies the data folder where the generated waves are created. If the data folder does not exist the operation creates it. If the <i>/DDF</i> flag is not used, output goes into the current data folder.                                                                                                                                                                                                                                            |
| <i>/FREE</i>               | Generates free output waves. The <i>/OREF</i> flag must also be used when the <i>/FREE</i> flag is used. When you use this flag there is no need to use either <i>/N</i> or <i>/NAME</i> .                                                                                                                                                                                                                                                             |
| <i>/N=baseName</i>         | Provides the base name for all output waves. The waves will be named sequentially, i.e., <i>baseName0</i> , <i>baseName1</i> ...                                                                                                                                                                                                                                                                                                                       |
| <i>/NAME=strList</i>       | <i>strList</i> is a semicolon-separated list of wave names to be used as the names of the output waves.<br><br>If <i>strList</i> contains fewer names than the number needed, the operation terminates and returns an error.<br><br>If the output data folder is the data folder containing <i>srcWave</i> then <i>strList</i> must not contain the name of <i>srcWave</i> .<br><br>Only simple names, not full paths, are allowed in <i>strList</i> . |
| <i>/NOTE</i>               | Copies the wave note, if any, from <i>srcWave</i> to the output waves. The <i>/NOTE</i> flag was added in Igor Pro 8.00.                                                                                                                                                                                                                                                                                                                               |
| <i>/O</i>                  | Permits overwriting of existing destination waves. Overwriting <i>srcWave</i> is not permitted.                                                                                                                                                                                                                                                                                                                                                        |
| <i>/OREF=waveRefWave</i>   | <i>waveRefWave</i> is a wave reference wave. SplitWave stores a wave reference for each of the output waves in <i>waveRefWave</i> .<br><br>If the specified <i>waveRefWave</i> already exists it is overwritten and its size is changed as appropriate. If it does not already exist, it is created by the operation.                                                                                                                                  |
| <i>/SDIM=n</i>             | Specifies the dimensionality of the output waves. By default this is 1 less than the dimensionality of <i>srcWave</i> . The minimum value is <i>n=1</i> which results in 1D output waves.                                                                                                                                                                                                                                                              |
| <i>/Z[=z]</i>              | <i>/Z</i> or <i>/Z=1</i> prevents procedure execution from aborting if there is an error. Use <i>/Z</i> if you want to handle this case in your procedures rather than having execution abort.<br><br><i>/Z=0</i> : Same as no <i>/Z</i> at all. This is the default.<br><i>/Z=1</i> : Same as <i>/Z</i> alone.                                                                                                                                        |

## sprintf

---

### Details

The SplitWave operation is in some ways the inverse of the Concatenate operation. *srcWave* is decomposed into waves of lower dimensionality.

Splitting a 2D 10x15 wave results in 15 waves of 10 rows each.

Splitting a 3D 10x15x4 using /SDIM=2 results in 4 2D waves of dimension 10x15.

Splitting a 3D 10x15x4 using /SDIM=1 results in 60 1D waves of 10 rows each.

The SplitWave operation works on all wave types. *srcWave* must be 2D or greater.

The operation creates the string variable S\_waveNames which contains a semicolon separated list of the names of the output waves. However if you use /FREE then S\_waveNames will be empty as free waves can not be accessed by name; use /OREF to access the created waves.

### Examples

```
// Create sample input
Make/N=(5,4,3,2) wave1 = p + 10*q + 100*r + 1000*s

// Split chunks into 2 3D waves and store them in data folder Chunks
SplitWave/DDF=Chunks/N=chunk wave1

// Split layers into 6 2D waves and store them in data folder Layers
SplitWave/DDF=Layers/N=Layers/SDIM=2 wave1

// Split into 24 1D waves and store them in data folder Columns
SplitWave/DDF=Columns/N=Columns/SDIM=1 wave1
```

### See Also

## sprintf

**sprintf** *stringName, formatStr [, parameter]...*

The sprintf operation is the same as printf except it prints the formatted output to the string variable *stringName* rather than to the history area.

### Parameters

|                   |                                                       |
|-------------------|-------------------------------------------------------|
| <i>formatStr</i>  | See printf.                                           |
| <i>parameter</i>  | See printf.                                           |
| <i>stringName</i> | Results are “printed” into the named string variable. |

### See Also

The **printf** operation for complete format and parameter descriptions and **Creating Formatted Text** on page IV-257.

## sqrt

**sqrt** (*num*)

The sqrt function returns the square root of *num* or NaN if *num* is negative.

In complex expressions, *num* is complex, and sqrt(*num*) returns the complex value  $x + iy$ .

## sscanf

**sscanf** *scanStr, formatStr, var [, var]*

The sscanf operation is useful for parsing text that contains numeric or string data. It is based on the C sscanf function and provides a subset of the features available in C.

Here is a trivial example:

```
Variable v1
sscanf "Value= 1.234", "Value= %f", v1
```

This skips the text “Value=” and the following space and then converts the text “1.234” (or whatever number appeared there) into a number and stores it in the local variable v1.

The `sscanf` operation sets the variable `V_flag` to the number of values read. You can use this as an initial check to see if the `scanStr` is consistent with your expectations.

**Note:** The `sscanf` operation is supported in user functions only. It is not available using the command line, using a macro, or using the Execute operation.

### Parameters

`scanStr` contains the text to be parsed.

`formatStr` is a format string which describes how the parsing is to be done.

`formatStr` is followed by the names of one or more local numeric or string variables or NVARs (references to global numeric variables) or SVARs (references to global string variables), which are represented by `var` above.

`sscanf` can handle a maximum of 100 `var` parameters.

### Details

The format string consists of the following:

- Normal text, which is anything other than a percent sign (“%”) or white space.
- White space (spaces, tabs, linefeeds, carriage returns).
- A percent (“%”) character, which is the start of a conversion specification.

The trivial example illustrates all three of these components.

```
Variable v1
sscanf "Value= 1.234", "Value= %f", v1
```

`sscanf` attempts to match normal text in the format string to the identical normal text in the scan string. In the example, the text “Value=” in the format string skips the identical text in the scan string.

`sscanf` matches a single white space character in the format string to 0 or more white space characters in the scan string. In the example, the single space skips the single space in the scan string.

When `sscanf` encounters a percent character in the format string, it attempts to convert the corresponding text in the scan string into a number or string, depending on the conversion character following the percent, and stores the resulting number or string in the corresponding variable in the parameter list. In the example, “%f” converts the text “1.234” into a number which it stores in the local variable `v1`.

A conversion specification consists of:

- A percent character (“%”).
- An optional “\*”, which is a conversion suppression character.
- An optional number, which is a maximum field width.
- A conversion character, which specifies how to interpret text in the scan string.

Don’t worry about the suppression character and the maximum width specification for now. They will be explained later.

The `sscanf` operation supports a subset of the conversion characters supported by the C `sscanf` operation. The supported conversion characters, which are case-sensitive, are:

|   |                                                                                                                                                                                                                                                                                |
|---|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| d | Converts text representing a decimal number into an integer numeric value.                                                                                                                                                                                                     |
| i | Converts text representing a decimal, octal or hexadecimal number into an integer value. If the text starts with “0x” (zero-x), it is interpreted as hexadecimal. Otherwise, if it starts with “0” (zero), it is interpreted as octal. Otherwise it is interpreted as decimal. |
| o | Converts text representing an octal number into an integer numeric value.                                                                                                                                                                                                      |
| u | Converts text representing an unsigned decimal number into an integer numeric value.                                                                                                                                                                                           |
| x | Converts text representing a hexadecimal number into an integer numeric value.                                                                                                                                                                                                 |
| c | Converts a single character into an integer value which is the ASCII code representing that character.                                                                                                                                                                         |
| e | Converts text representing a decimal number into a floating point numeric value.                                                                                                                                                                                               |
| f | Same as e.                                                                                                                                                                                                                                                                     |

|   |                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| g | Same as e.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| s | Stores text up to the next white space into a string.                                                                                                                                                                                                                                                                                                                                                                      |
| [ | Stores text that matches a list of specific characters into a string. The list consists of the characters inside the brackets ("%[abc]"). If the first character is "^", this means to match any character that is <b>not</b> in the list. You can specify a range of characters to match. For example "% [A-Z] " matches all of the upper case letters and "% [A-Za-z] " matches all of the upper and lower case letters. |

---

Here are some simplified examples to illustrate each of these conversions.

```
Variable v1
String s1
```

Convert text representing a decimal number to an integer value:

```
sscanf "1234", "%d", v1
```

Convert text representing a decimal, octal, or hexadecimal number:

```
sscanf "1.234", "%i", v1 // Convert from decimal.
sscanf "01234", "%i", v1 // Convert from octal.
sscanf "0x123", "%i", v1 // Convert from hex.
```

Convert text representing an octal number:

```
sscanf "1234", "%o", v1
```

Convert text representing an unsigned decimal number:

```
sscanf "1234", "%u", v1
```

Convert text representing a hexadecimal number:

```
sscanf "1FB9", "%x", v1
```

Convert a single ASCII character:

```
sscanf "A", "%c", v1
```

Convert text representing a decimal number to a floating point value:

```
sscanf "1.234", "%e", v1
sscanf "1.234", "%f", v1
sscanf "1.234", "%g", v1
```

Copy a string of text up to the first white space:

```
sscanf "Hello There", "%s", s1
```

Copy a string of text matching the specified characters:

```
sscanf "+4.27", "%[+-]", s1
```

In a C program, you will sometimes see the letters "l" (ell) or "h" between the percent and the conversion character. For example, you may see "%lf" or "%hd". These extra letters are not needed or tolerated by Igor's sscanf operation.

When sscanf matches the format string to the scan string, it reads from the scan string until a character that would be inappropriate for the section of the format string that sscanf is trying to match. In the following example, sscanf stops reading characters to be converted into a number when it hits the first character that is not appropriate for a number.

```
Variable v1
String s1, s2
sscanf "1234Volts DC", "%d%s %s", v1, s1, s2
```

sscanf stops matching text for "%d" when it hits "V" and stores the converted number in v1. It stops matching text for the first "%s" when it hits white space and stores the matched text in s1. It then skips the space in the scan string because of the corresponding space in the format string. Finally, it matches the remaining text to the second "%s" and stores the text in s2.

The maximum field width must appear just before the conversion character ("d" in this case).

```
Variable v1, v2
sscanf "12349876", "%4d%4d", v1, v2
```

The suppression character ("\*") is used in a conversion specification to skip values in the scan string. It parses the value, but sscanf does not store the value in any variable. In the following example, we read one

number into local variable `v1`, skip a colon, and read another number into local variable `v2`, skip a colon, and read another number into local variable `v3`.

```
Variable v1, v2, v3
sscanf "12:30:45", "%d%*[:] %d%*[:] %d", v1, v2, v3
```

Here “%\*[:]” means “read a colon character but don’t store it anywhere”. The “\*” character must appear immediately after the percent. Note that there is nothing in the parameter list corresponding to the suppressed strings.

If the text in the scan string is not consistent with the text in the format string, `sscanf` may not read all of the values that you expected. You can check for this using the `V_flag` variable, which is set to the number of values read. This kind of inconsistency does not cause `sscanf` to return an error to Igor, which would cause procedure execution to abort. It is a situation that you can deal with in your procedure code.

The `sscanf` operation returns the following kinds of errors:

- Out-of-memory.
- The number of parameters implied by *formatStr* does not match the number of parameters in the *var* list.
- *formatStr* calls for a numeric variable but the parameter list expects a string variable.
- *formatStr* calls for a string variable but the parameter list expects a numeric variable.
- *formatStr* includes an unsupported, unknown or incorrectly constructed conversion specification.
- The *var* list references a global variable that does not exist.

### Examples

Here is a simple example to give you the general idea:

```
Function SimpleExample()
 Variable v1, valuesRead
 sscanf "Value=1.234", "Value=%g", v1
 valuesRead = V_flag
 if (valuesRead != 1)
 Printf "Error: Expected 1 value, got %d values\r", valuesRead
 else
 Printf "Value read = %g\r", v1
 endif
End
```

For an example that uses `sscanf` to load data from a text file, choose File→Example Experiments→Programming→Load File Demo.

## Stack

**Stack** [*flags*] [*objectName*] [, *objectName*]...

The Stack operation stacks the named layout objects in the top page layout.

### Parameters

*objectName* is the name of a graph, table, picture or annotation object in the top page layout.

### Flags

|                       |           |                    |                                   |
|-----------------------|-----------|--------------------|-----------------------------------|
| <i>/A=(rows,cols)</i> | <i>/I</i> | <i>/O=objTypes</i> | <i>/S</i>                         |
| <i>/G=grout</i>       | <i>/M</i> | <i>/R</i>          | <i>/W=(left,top,right,bottom)</i> |

### See Also

The **Tile** operation for details on the flags and parameters.

### StackWindows

**StackWindows** [*flags*] [*windowName* [, *windowName*]...]

The StackWindows operation stacks the named windows on the desktop.

#### Flags

*/A*=(*rows,cols*)    */G*=*grout*    */O*=*objTypes*    */P*    */W*=(*left,top,right,bottom*)  
*/C*                    */I*                    */M*                    */R*

#### See Also

See the **TileWindows** operation for details on the flags and parameters.

### StartMSTimer

**StartMSTimer**

The StartMSTimer function creates a new microsecond timer and returns a timer reference number.

#### Details

You can create up to ten different microsecond timers using StartMSTimer. A valid timer reference number is a number between 0 and 9. If StartMSTimer returns -1, there are no free timers available. StartMSTimer works in conjunction with StopMSTimer.

#### See Also

StopMSTimer, ticks, DateTime

### Static

**Static constant** *objectName* = *value*

**Static strconstant** *objectName* = *value*

**Static Function** *funcName*()

**Static Structure** *structureName*

**Static Picture** *pictName*

The Static keyword specifies that a constant, user-defined function, structure, or Proc Picture is local to the procedure file in which it appears. Static objects can only be used by other functions; they cannot be accessed from macros; they cannot be accessed from other procedure files or from the command line.

#### See Also

Static Functions on page IV-105, Proc Pictures on page IV-56, and Constants on page IV-50.

### StatsAngularDistanceTest

**StatsAngularDistanceTest** [*flags*] [*srcWave1*, *srcWave2*, *srcWave3*...]

The StatsAngularDistanceTest operation performs nonparametric tests on the angular distance between sample data and reference directions for two or more samples in individual waves. The angular distance is the shortest distance between two points on a circle (in radians). Specify the sample waves using /WSTR or by listing them following the flags. Set reference directions with /ANG, /ANGW, or the sample mean direction.

#### Flags

*/ALPH*=*val*                Sets the significance level (default 0.05).  
*/ANG*={*d1*, *d2*}        Sets reference directions (in radians) for two samples; for more than two samples use /ANGW.  
*/ANGM*                    Computes the mean direction of each sample and uses it as the reference direction.  
*/ANGW*=*dWave*            Sets reference directions (in radians) for more than two samples using directions in *dWave*, which must be single or double precision.  
*/APRX*=*m*                Controls the approximation method for computing the P-value in the case of two samples (Mann-Whitney Wilcoxon). See **StatsWilcoxonRankTest** for more details. The default value is 0, which may require long computation times if your sample size is large. Use /APRX=1 if you have a large sample and you expect ties in the data.

|                                          |                                                                                                                                                                                                             |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/Q</code>                          | No results printed in the history area.                                                                                                                                                                     |
| <code>/T=k</code>                        | Displays results in a table. <i>k</i> specifies the table behavior when it is closed.<br><i>k</i> =0: Normal with dialog (default).<br><i>k</i> =1: Kills with no dialog.<br><i>k</i> =2: Disables killing. |
| <code>/TAIL=tail</code>                  | <i>tail</i> is a bitwise parameter that specifies the tails tested.<br>Bit 0: Lower tail.<br>Bit 1: Upper tail (default).<br>Bit 2: Two tail.                                                               |
|                                          | See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings.<br>The P value corresponding to the last tail calculated will be entered in the table.                                      |
| <code>/WSTR=<i>waveListString</i></code> | Specifies a string containing a semicolon-separated list of waves that contain sample data. Use <i>waveListString</i> instead of listing each wave after the flags.                                         |
| <code>/Z</code>                          | Ignores errors. <code>V_flag</code> will be set to -1 for any error and to zero otherwise.                                                                                                                  |

### Details

The inputs for `StatsAngularDistanceTest` are two or more waves each corresponding to individual sample. The waves must be single or double precision expressing the angles in radians. There is no restriction on the number of points or dimensionality of the waves but the data should not contain NaNs or INFs. We recommend that you use double precision waves, especially if there are ties in the data. The reference directions should also be in radians. For two samples, `StatsAngularDistanceTest` computes the angular distances between the input data and the reference directions and then uses the Mann-Whitney-Wilcoxon test (**StatsWilcoxonRankTest**). Results are stored in the `W_WilcoxonTest` wave and in the corresponding table. For more than two samples, `StatsAngularDistanceTest` uses the Kruskal-Wallis test, storing results in the wave `W_KWTestResults` wave in the current data folder.

`V_flag` will be set to -1 for any error and to zero otherwise.

## StatsANOVA1Test

**StatsANOVA1Test** [*flags*] [*wave1, wave2, ... wave100*]

The `StatsANOVA1Test` operation performs a one-way ANOVA test (fixed-effect model). The standard ANOVA test results are stored in the `M_ANOVA1` wave in the current data folder.

### Flags

|                               |                                                                                                                                                                |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/ALPH=<i>val</i></code> | Sets the significance level (default 0.05).                                                                                                                    |
| <code>/BF</code>              | Performs the Brown and Forsythe test computing $F''$ and degrees of freedom. The <code>W_ANOVA1BnF</code> wave in the current data folder contains the output. |
| <code>/Q</code>               | No results printed in the history area.                                                                                                                        |
| <code>/T=k</code>             | Displays results in a table; additional tables are created with <code>/BF</code> and <code>/W</code> .                                                         |

|                             |                                                                                                                                                                     |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             | <i>k</i> specifies the table behavior when it is closed.                                                                                                            |
| <i>k=0:</i>                 | Normal with dialog (default).                                                                                                                                       |
| <i>k=1:</i>                 | Kills with no dialog.                                                                                                                                               |
| <i>k=2:</i>                 | Disables killing.                                                                                                                                                   |
| <i>/W</i>                   | Performs the Welch test F' and computes degrees of freedom. The W_ANOVA1Welch wave in the current data folder contains the output.                                  |
| <i>/WSTR=waveListString</i> | Specifies a string containing a semicolon-separated list of waves that contain sample data. Use <i>waveListString</i> instead of listing each wave after the flags. |
| <i>/Z</i>                   | Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.                                                                                       |

### Details

Inputs to StatsANOVA1Test are two or more 1D numerical waves containing (one wave for each group of samples). Use NaN for missing entries or use waves with different numbers of points. The standard ANOVA results are in the M\_ANOVA1 wave with corresponding row and column labels. Use /T to display the results in a table. In each case you will get the two degrees of freedom values, the F value, the critical value Fc for the choice of alpha and the degrees of freedom, and the P-value for the result. V\_flag will be set to -1 for any error and to zero otherwise.

In some cases the ANOVA test may not be appropriate. For example, if groups do not exhibit sufficient homogeneity of variances. Although this may not be fatal for the ANOVA test, you may get more insight by performing the variances test in **StatsVariancesTest**.

If there are only two groups this test should be equivalent to **StatsTTest**.

You can evaluate the power of an ANOVA test for a given set of degrees of freedom and noncentrality parameter using:

```
power=1-StatsNCFCDF(StatsInvFCDF((1-alpha),n1,n2),n1,n2,delta)
```

Here n1 is the Groups' degrees of freedom, n2 is the Error degrees of freedom, and delta is the noncentrality parameter. For more information see ANOVA Power Calculations Panel and the associated example experiment.

## StatsANOVA2NRTest

**StatsANOVA2NRTest** [*flags*] *srcWave*

The StatsANOVA2NRTest operation performs a two-factor analysis of variance (ANOVA) on the data that has no replication where there is only a single datum for every factor level. *srcWave* is a 2D wave of any numeric type. Output is to the M\_ANOVA2NRResults wave in the current data folder or optionally to a table.

### Flags

|                  |                                                                                                                                                                                                                                                                                  |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/ALPH=val</i> | Sets the significance level (default 0.05).                                                                                                                                                                                                                                      |
| <i>/FOMD</i>     | Estimates one missing value. You will also have to use a single or double precision wave for <i>srcWave</i> and designate the single missing value as NaN. The estimated value is printed to the history as well as the bias used to correct the sum of the squares of factor A. |
| <i>/INT=val</i>  | Sets the degree of interactivity.                                                                                                                                                                                                                                                |

Sets the degree of interactivity.

*val*=0: No interaction between the factors (default).

*val*=1: Significant interaction effect between factors.

Combination with /MODL determines which factors to test:

| <i>val</i> | Model 1 | Model 2 | Model 3 |
|------------|---------|---------|---------|
| 1          |         | A&B     | A       |
| 0          | A&B     | A&B     | A&B     |

As indicated in the table, factor B is not tested for significant interaction under Model 3 and neither factor A nor factor B are tested for Model 1. If you are willing to accept an increase in Type II error you can obtain the relevant values by specifying Model 2. None of the models support a test for interaction A x B.

/MODL=*m*

Sets the model number.

*m*=1: Factor A and factor B are fixed.

*m*=2: Both factors are random.

*m*=3: Factor A is fixed and factor B is random (default).

/Q

No results printed in the history area.

/T=*k*

Displays results in a table. *k* specifies the table behavior when it is closed.

*k*=0: Normal with dialog (default).

*k*=1: Kills with no dialog.

*k*=2: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/Z

Ignores errors. *V\_flag* will be set to -1 for any error and to zero otherwise.

### Details

Input to StatsANOVA2NRTest is a 2D wave in which the Factor A corresponds to rows and Factor B corresponds to columns. *H0* provides that there is no difference in the means of the respective populations, i.e., if *H0* is rejected for Factor A but accepted for Factor B that means that there is no difference in the means of the columns but the means of the rows are different.

NaN and INF entries are not supported although you may use a single NaN value in combination with the /FOMD flag. If *srcWave* contains dimension labels they will be used to designate the two factors in the output.

The contents of the *M\_ANOVA2NRResults* output wave columns are as follows:

|          |                                                                   |
|----------|-------------------------------------------------------------------|
| Column 0 | Sum of the squares (SS) values                                    |
| Column 1 | Degrees of freedom (DF)                                           |
| Column 2 | Mean square (MS) values                                           |
| Column 3 | Computed F value for this test                                    |
| Column 4 | Critical F value ( <i>F<sub>c</sub></i> ) for the specified alpha |
| Column 5 | Conclusion with 0 to reject <i>H0</i> or 1 to accept it           |

The variable *V\_flag* is set to zero if the operation succeeds or to -1 otherwise.

### StatsANOVA2RMTTest

**StatsANOVA2RMTTest** [*flags*] *srcWave*

The StatsANOVA2RMTTest operation performs analysis of variance (ANOVA) on *srcWave* where replicates consist of multiple measurements on the same subject (repeated measures). *srcWave* is a 2D wave of any numeric type. Output is to the M\_ANOVA2RMResults wave in the current data folder or optionally to a table.

#### Flags

|                  |                                                                                                                                                                                                                                                                                                                                                         |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/ALPH=val</i> | Sets the significance level (default 0.05).                                                                                                                                                                                                                                                                                                             |
| <i>/Q</i>        | No results printed in the history area.                                                                                                                                                                                                                                                                                                                 |
| <i>/T=k</i>      | Displays results in a table. <i>k</i> specifies the table behavior when it is closed.<br><i>k=0</i> : Normal with dialog (default).<br><i>k=1</i> : Kills with no dialog.<br><i>k=2</i> : Disables killing.<br><br>The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results. |
| <i>/Z</i>        | Ignores errors. <i>V_flag</i> will be set to -1 for any error and to zero otherwise.                                                                                                                                                                                                                                                                    |

#### Details

Input to StatsANOVA2RMTTest is the 2D *srcWave* in which the factor A (Groups) are columns and the different subjects are rows. It does not support NaNs or INFs.

The contents of the M\_ANOVA2RMResults output wave columns are: the first contains the sum of the squares (SS) values, the second contains the degrees of freedom (DF), the third contains the mean square (MS) values, the fourth contains the single F value for this test, the fifth contains the critical F value for the specified alpha and degrees of freedom, and the last column contains the conclusion with 0 to reject  $H_0$  or 1 to accept it. In each case  $H_0$  corresponds to the mean level, which is the same for all subjects.

*V\_flag* will be set to -1 for any error and to zero otherwise.

### Details

Input to `StatsANOVA2Test` is the single or double precision 3D `srcWave` in which the factor A levels are columns, the factor B levels are rows, and the replicates are layers. If `srcWave` contains dimension labels they will be used to designate the factors in the output.

Ideally, the number of replicates must be equal for each factor and each level. `StatsANOVA2Test` supports both equal replication and proportional replication. Proportional replication allows for different number of data in each cell with missing data represented as NaN and the number of points in each cell is given by  $N_{ij} = (\text{sum of data in row } i) * (\text{sum of data in column } j) / \text{number of samples}$ .

If you have no replicates (a single datum per cell) use `StatsANOVA2NRTest` instead. If the number of replicates in your data does not satisfy these conditions you may be able to “estimate” additional replicates using various methods. In that case use the `/FAKE` flag so that the operation can account for the estimated data by reducing the total and error degrees of freedom. `/FAKE` only accounts for the number of estimates being used. You must provide an appropriate number of estimated values.

The contents of the `M_ANOVA2Results` output wave columns are: the first contains the sum of the squares (SS) values, the second the degrees of freedom (DF), the third contains the mean square (MS) values, the fourth contains the computed F value for this test, the fifth contains the critical  $F_c$  value for the specified alpha and degrees of freedom, and the last contains the conclusion with 0 to reject  $H_0$  or 1 to accept it. In each case  $H_0$  corresponds to the mean level, which is the same for all populations.

`V_flag` will be set to -1 for any error and to zero otherwise.

## StatsBetaCDF

`StatsBetaCDF(x, p, q [, a, b])`

The `StatsBetaCDF` function returns the beta cumulative distribution function

$$F(x,p,q,a,b) = \frac{1}{B(p,q)} \int_0^{\frac{x-a}{b-a}} t^{p-1} (1-t)^{q-1} dt, \quad \begin{array}{l} p, q > 0 \\ a \leq x \leq b \end{array}$$

where  $B(p,q)$  is the beta function

$$B(p,q) = \int_0^1 t^{p-1} (1-t)^{q-1} dt.$$

The defaults ( $a=0$  and  $b=1$ ) correspond to the standard beta distribution where  $a$  is the location parameter,  $(b-a)$  is the scale parameter, and  $p$  and  $q$  are shape parameters.

Evans, M., N. Hastings, and B. Peacock, *Statistical Distributions*, 3rd ed., Wiley, New York, 2000.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; `StatsBetaPDF` and `StatsInvBetaCDF`.

## StatsBetaPDF

**StatsBetaPDF(x, p, q [, a, b])**

The StatsBetaPDF function returns the beta probability distribution function

$$f(x; p, q, a, b) = \frac{(x-a)^{p-1} (b-x)^{q-1}}{B(p, q)(b-a)^{p+q-1}}, \quad \begin{array}{l} a \leq x \leq b \\ p, q > 0 \end{array}$$

where  $B(p, q)$  is the beta function

$$B(p, q) = \int_0^1 t^{p-1} (1-t)^{q-1} dt.$$

The defaults ( $a=0$  and  $b=1$ ) correspond to the standard beta distribution where  $a$  is the location parameter,  $(b-a)$  is the scale parameter, and  $p$  and  $q$  are shape parameters. When  $p < 1$ ,  $f(x=a)$  returns Inf.

**StatsCauchyCDF**

**StatsCauchyCDF**( $x$ ,  $\mu$ ,  $\sigma$ )

The StatsCauchyCDF function returns the Cauchy-Lorentz cumulative distribution function

$$F(x; \mu, \sigma) = \frac{1}{2} + \frac{1}{\pi} \tan^{-1} \left( \frac{x - \mu}{\sigma} \right).$$

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsCauchyCDF** and **StatsCauchyPDF**.

**StatsCauchyPDF**

**StatsCauchyPDF**( $x$ ,  $\mu$ ,  $\sigma$ )

The StatsCauchyPDF function returns the Cauchy-Lorentz probability distribution function

$$f(x; \mu, \sigma) = \frac{1}{\sigma\pi} \frac{1}{1 + \left( \frac{x - \mu}{\sigma} \right)^2},$$

where  $\mu$  is the location parameter and  $\sigma$  is the scale parameter. Use  $\mu=0$  and  $\sigma=1$  for the standard form of the Cauchy-Lorentz distribution.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsCauchyCDF** and **StatsInvCauchyCDF**.

**StatsChiCDF**

**StatsChiCDF**( $x$ ,  $n$ )

The StatsChiCDF function returns the chi-squared cumulative distribution function for the specified value and degrees of freedom  $n$ .

$$F(x; n) = \frac{\gamma\left(\frac{n}{2}, \frac{x}{2}\right)}{\Gamma\left(\frac{n}{2}\right)}.$$

where  $\gamma(a,b)$  the incomplete gamma function. The distribution can also be expressed as

$$F(x; n) = 1 - \text{gammq}\left(\frac{n}{2}, \frac{x}{2}\right).$$

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsChiPDF**, **StatsInvChiCDF**, and **gammq**.

**StatsChiPDF**

**StatsChiPDF**( $x$ ,  $n$ )

The StatsChiPDF function returns the chi-squared probability distribution function for the specified value and degrees of freedom as

$$f(x;n) = \frac{\exp\left(-\frac{x}{2}\right)x^{\frac{n}{2}-1}}{2^{\frac{n}{2}}\Gamma\left(\frac{n}{2}\right)}.$$

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsChiCDF** and **StatsChiPDF**.

**StatsChiTest**

**StatsChiTest** [*flags*] *srcWave1*, *srcWave2*

The StatsChiTest operation computes a  $\chi^2$  statistic for comparing two distributions or a  $\chi^2$  statistic for comparing a sample distribution with its expected values. In both cases the comparison is made on a bin-by-bin basis. Output is to the W\_StatsChiTest wave in the current data folder or optionally to a table.

**Flags**

- /ALZR*                      Allows zero entries in source waves. If you are using */S* zero entries in *srcWave2* are skipped.
- /NCON=nCon*                Specifies the number of constraints (0 by default), which reduces the number degrees of freedom and the critical value by *nCon*.
- /S*                              Sets the calculation mode to a single distribution where *srcWave1* represents an array of binned measurements and *srcWave2* represents the corresponding expected values.
- /T=k*                         Displays results in a table. *k* specifies the table behavior when it is closed.
  - k=0*:                      Normal with dialog (default).
  - k=1*:                      Kills with no dialog.
  - k=2*:                      Disables killing.
- /Z*                             Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

**Details**

The source waves, *srcWave1* and *srcWave2*, must have the same number of points and can be any real numeric data type. Any nonpositive values (including NaN) in either wave removes the entry in both waves from consideration and reduces the degrees of freedom by one. The number degrees of freedom is initially the number of points in *srcWave1-1-nCon*. By default it is assumed that *srcWave1* and *srcWave2* represent two distributions of binned data.

When you specify */S*, *srcWave1* must consist of binned values of measured data and *srcWave2* must contain the corresponding expected values. The calculation is:

$$\chi^2 = \sum_{i=0}^{n-1} \frac{(Y_i - V_i)^2}{V_i}.$$

Here  $Y_i$  is the sample point from *srcWave1*,  $V_i$  is the expected value of  $Y_i$  based on an assumed distribution (*srcWave2*), and  $n$  is the number of points in the each wave. If you do not use */S*, it calculates:

$$\chi^2 = \sum_{i=0}^{n-1} \frac{(Y_{1i} - Y_{2i})^2}{Y_{1i} + Y_{2i}},$$

where  $Y_{1i}$  and  $Y_{2i}$  are taken from *srcWave1* and *srcWave2* respectively.

V\_flag will be set to -1 for any error and to zero otherwise.

**StatsCircularCorrelationTest**

**StatsCircularCorrelationTest** [*flags*] *waveA*, *waveB*

The StatsCircularTwoSampleTest operation performs a number of tests for two samples of circular data. Using the appropriate flags you can choose between parametric or nonparametric, unordered or paired tests. The input consists of two waves that contain one or two columns. The first column contains angle data expressed in radians and an optional second column contains associated vector lengths. The waves must be either single or double precision floating point. Results are stored in the W\_StatsCircularCorrelationTest wave in the current data folder and optionally displayed in a table. Some flags generate additional outputs, described below.

**Flags**

|                   |                                                                                                                                                                                                             |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /ALPH= <i>val</i> | Sets the significance level (default 0.05).                                                                                                                                                                 |
| /NAA              | Performs a nonparametric angular-angular correlation test.                                                                                                                                                  |
| /PAA              | Performs a parametric angular-angular correlation test.                                                                                                                                                     |
| /PAL              | Performs a parametric angular-linear correlation test. In this case the angle wave is <i>waveA</i> and the linear data corresponds to <i>waveB</i> .                                                        |
| /Q                | No results printed in the history area.                                                                                                                                                                     |
| /T= <i>k</i>      | Displays results in a table. <i>k</i> specifies the table behavior when it is closed.<br><i>k</i> =0: Normal with dialog (default).<br><i>k</i> =1: Kills with no dialog.<br><i>k</i> =2: Disables killing. |
| /Z                | Ignores errors.                                                                                                                                                                                             |

**Details**

The nonparametric test (/NAA) follows Fisher and Lee's modification of Mardia's statistic, which is an analogue of Spearman's rank correlation. The test ranks the angles of each sample and computes the quantities  $r'$  and  $r''$  as follows:

$$r' = \frac{\left\{ \sum_{i=0}^{n-1} \cos \left[ \frac{2\pi}{n} (r_{ai} - r_{bi}) \right] \right\}^2 + \left\{ \sum_{i=0}^{n-1} \sin \left[ \frac{2\pi}{n} (r_{ai} - r_{bi}) \right] \right\}^2}{n^2},$$

$$r'' = \frac{\left\{ \sum_{i=0}^{n-1} \cos \left[ \frac{2\pi}{n} (r_{ai} + r_{bi}) \right] \right\}^2 + \left\{ \sum_{i=0}^{n-1} \sin \left[ \frac{2\pi}{n} (r_{ai} + r_{bi}) \right] \right\}^2}{n^2}.$$

Here  $n$  is the number of data pairs and  $r_{ai}$  and  $r_{bi}$  are the ranks of the  $i$ th member in the first and second samples respectively.

The test statistic is  $(n-1)(r'-r'')$ , which is compared with the critical value (for one and two tails). The CDF of the statistic is a highly irregular function. The critical value is computed by a different methods according to  $n$ . For  $3 \leq n \leq 8$ , a built-in table of CDF transitions gives a "conservative" estimate of the critical value. For  $9 \leq n \leq 30$ , the CDF is approximated by a 7th order polynomial in the region  $x > 0$ . For  $n \geq 30$ , the CDF is from the asymptotic expression. For  $3 \leq n \leq 30$ , CDF values are obtained by Monte-Carlo simulations using  $1e6$  random samples for each  $n$ .

The parametric test for angular-angular correlation (/PAA) involves computation of a correlation coefficient  $r_{aa}$  and then evaluating the mean  $\overline{r_{aa}}$  and variance  $s_{r_{aa}}^2$  of equivalent correlation coefficients computed

## StatsCircularCorrelationTest

from the same data but by deleting a different pair of angles each time. The mean and variance are then used to compute confidence limits L1 and L2:

$$L1 = nr_{aa} - (n-1)\overline{r_{aa}} - Z_{\alpha(2)}\sqrt{\frac{S_{r_{aa}}^2}{n}},$$

$$L2 = nr_{aa} - (n-1)\overline{r_{aa}} + Z_{\alpha(2)}\sqrt{\frac{S_{r_{aa}}^2}{n}}$$

where  $Z_{\alpha(2)}$  is the normal distribution two-tail critical value at the  $\alpha$  level of significance.  $H_0$  (corresponding to no correlation) is rejected if zero is not contained in the interval [L1,L2].

The parametric test for angular-linear correlation (/PAL) involves computation of the correlation coefficient  $r_{al}$  which is then compared with a critical value from  $\chi^2$  for alpha significance and two degrees of freedom.

$$r_{al} = \sqrt{\frac{r_{xc}^2 + r_{xs}^2 - 2r_{xc}r_{xs}r_{cs}}{1 - r_{cs}^2}},$$

where:

$$r_{xc} = \frac{\sum_{i=0}^{n-1} X_i \cos(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} X_i \sum_{i=0}^{n-1} \cos(a_i)}{\sqrt{\left( \sum_{i=0}^{n-1} X_i^2 - \frac{1}{n} \left( \sum_{i=0}^{n-1} X_i \right)^2 \right) \left( \sum_{i=0}^{n-1} \cos^2(a_i) - \frac{1}{n} \left( \sum_{i=0}^{n-1} \cos(a_i) \right)^2 \right)}},$$

$$r_{xs} = \frac{\sum_{i=0}^{n-1} X_i \sin(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} X_i \sum_{i=0}^{n-1} \sin(a_i)}{\sqrt{\left( \sum_{i=0}^{n-1} X_i^2 - \frac{1}{n} \left( \sum_{i=0}^{n-1} X_i \right)^2 \right) \left( \sum_{i=0}^{n-1} \sin^2(a_i) - \frac{1}{n} \left( \sum_{i=0}^{n-1} \sin(a_i) \right)^2 \right)}},$$

$$r_{cs} = \frac{\sum_{i=0}^{n-1} \cos(a_i) \sin(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} \sin(a_i) \sum_{i=0}^{n-1} \cos(a_i)}{\sqrt{\left( \sum_{i=0}^{n-1} \sin^2(a_i) - \frac{1}{n} \left( \sum_{i=0}^{n-1} \sin(a_i) \right)^2 \right) \left( \sum_{i=0}^{n-1} \cos^2(a_i) - \frac{1}{n} \left( \sum_{i=0}^{n-1} \cos(a_i) \right)^2 \right)}}.$$

## StatsCircularMeans

**StatsCircularMeans** [*flags*] *srcWave*

The StatsCircularMeans operation calculates the mean of a number of circular means, returning the mean angle (grand mean), the length of the mean vector, and optionally confidence interval around the mean angle. Output is to the history area and to the W\_CircularMeans wave in the current data folder.

### Flags

- /ALPH=val* Sets the significance level (default 0.05).
- /CI* Calculates the confidence interval (labeled CI\_t1 and CI\_t2) around the mean angle.
- /NSOA* Performs nonparametric second order analysis according to Moore's version of Rayleigh's test where  $H_0$  corresponds to uniform distribution around the circle. Moore's test ranks entries by the lengths of the mean radii (second column of the input) from smallest (rank 1) to largest (rank  $n$ ) and then computes the statistic:

$$R' = \sqrt{\frac{\left(\frac{1}{n} \sum_{i=0}^{n-1} (i+1) \cos(a_i)\right)^2 + \left(\frac{1}{n} \sum_{i=0}^{n-1} (i+1) \sin(a_i)\right)^2}{n}},$$

where  $a_i$  are the mean angle entries (from column 1) corresponding to vector length rank  $(i+1)$ . The critical value is obtained from Moore's distribution  
**StatsInvMooreCDF**.

- /PSOA* Perform parametric second order analysis where  $H_0$  corresponds to no mean population direction. It assumes that the second order quantities are from a bivariate normal distribution. If this is not the case, use */NSOA* above. The test statistic is:

$$F = \frac{k(k-2)}{2} \left[ \frac{\bar{X}^2 S_{y^2} - 2\bar{X}\bar{Y}S_{xy} + \bar{Y}^2 S_{x^2}}{S_{x^2} S_{y^2} - S_{xy}^2} \right]$$

where

$$\bar{X} = \frac{1}{n} \sum_{i=0}^{n-1} X_i = \frac{1}{n} \sum_{i=0}^{n-1} r_i \cos(a_i),$$

$$\bar{Y} = \frac{1}{n} \sum_{i=0}^{n-1} Y_i = \frac{1}{n} \sum_{i=0}^{n-1} r_i \sin(a_i),$$

$$S_{x^2} = \sum_{i=0}^{n-1} X_i^2 - \frac{1}{n} \left( \sum_{i=0}^{n-1} X_i \right)^2,$$

$$S_{y^2} = \sum_{i=0}^{n-1} Y_i^2 - \frac{1}{n} \left( \sum_{i=0}^{n-1} Y_i \right)^2,$$

$$S_{xy} = \sum_{i=0}^{n-1} X_i Y_i - \frac{1}{n} \sum_{i=0}^{n-1} X_i \sum_{i=0}^{n-1} Y_i.$$

Here  $n$  is the number of means in *srcWave* and the critical value is computed from the F distribution, equivalent to executing:

Print StatsInvFCDF(1-alpha, 2, n-2)

- /Q* No results printed in the history area.

## StatsCircularMoments

---

|                   |                                                                                                                                                                                                             |

### Details

The `srcWave` input to `StatsCircularMeans` must be a single or double precision two column wave containing in each row a mean angle (radians) and the length of a mean radius (the first column contains mean angles and the second column contains mean vector lengths). `srcWave` must not contain any NaNs or INFs. The confidence interval calculation follows the procedure outlined by Batschelet.

`V_flag` will be set to -1 for any error and to zero otherwise.

## StatsCircularMoments

**StatsCircularMoments** [*flags*] *srcWave*

The `StatsCircularMoments` operation computes circular statistical moments and optionally performs angular uniformity tests for the data in `srcWave`. The extent of the calculation is determined by the requested moment. The default results are stored in the `W_CircularStats` wave in the current data folder and are optionally displayed in a table. Additional results are listed under the corresponding flags.

### Flags

|                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <code>/ALPH=<i>alpha</i></code>          | Sets an <i>alpha</i> value for computing confidence intervals (default is 0.05).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>/AXD=<i>p</i></code>               | Designates the input as p-axial data. For example, if the input represents undirected lines then <i>p</i> =2 and the operation multiplies the angles by a factor <i>p</i> (after shifting <code>/ORGN</code> and accounting for <code>/CYCL</code> ). It does not back-transform the mean or median axis.                                                                                                                                                                                                                                                                                                                                                |
| <code>/CYCL=<i>cycle</i></code>          | Specifies the length of the data cycle. You do not need to do so if you are using one of the built-in modes, but this is still a useful option, as for setting the length of a particular month when using <code>/MODE=5</code> .                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>/GRPD={<i>start, delta</i>}</code> | Computes circular statistics for grouped data. In this case <code>srcWave</code> contains frequencies or the number of events that belong to a particular angle group. There are as many groups as there are elements in <code>srcWave</code> . The first group is centered at <i>start</i> radians and each consecutive group is centered <i>delta</i> radians away. You must set both the <i>start</i> and <i>delta</i> to sensible values. <code>srcWave</code> may contain NaNs but it is an error if all values are NaN. The only other flags that work in combination with this flag are <code>/Q</code> , <code>/T</code> , and <code>/Z</code> . |
| <code>/KUPR[=<i>k</i>]</code>            | Tests the uniformity of a circular distribution of ungrouped data using the Kuiper statistic. The data are converted into a set $\{x_i\}$ by normalizing the input angles to the range $[0,1]$ , ranking the results then using the two quantities $D_+$ and $D_-$ to compute the Kuiper statistic. Use <i>k</i> =0 for Fisher's version:                                                                                                                                                                                                                                                                                                                |

$$V = (D_+ + D_-) \left( \sqrt{n} + 0.155 + 0.24/\sqrt{n} \right),$$

Use  $k=1$ , added in Igor Pro 8.00, for the more common definition of the Kuiper statistic:

$$V = (D_+ + D_-).$$

Here

$$D_+ = \text{Max of: } \frac{1}{n} - x_0, \frac{2}{n} - x_1, \dots, 1 - x_{n-1},$$

$$D_- = \text{Max of: } x_0, x_{1-\frac{1}{n}}, \dots, x_{n-1-\frac{n-1}{n}},$$

and  $n$  is the number of valid points in *srcWave*. You can find the results in the wave *W\_CircularStats* under row label "Kuiper V" and "Kuiper CDF(V)". See Fisher and Press *et al.* for more information.

| <i>/LOS</i>                  | Computes Linear Order Statistics by sorting the angle values from small to large, dividing each angle by $2\pi$ and shifting the origin so that the output range is $[0,1]$ . The results are stored in the wave <i>W_LinearOrderStats</i> in the current data folder. The X scaling of the wave is set so that the offset and the delta are $1/(n+1)$ where $n$ is the number of non-NaN points in the input.                                                                                                                                                                                                                                                                                                                                                                 |             |                        |   |                               |   |                                 |   |                              |   |                                 |   |                                       |   |                                        |   |                                       |   |                                      |   |                                       |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|------------------------|---|-------------------------------|---|---------------------------------|---|------------------------------|---|---------------------------------|---|---------------------------------------|---|----------------------------------------|---|---------------------------------------|---|--------------------------------------|---|---------------------------------------|
| <i>/M=moment</i>             | Computes specified moments. By default, it computes the second order moments as well as skewness, kurtosis, median, and mean deviation. Use <i>/M=1</i> for the first moment. For higher moments, both the specified moment and all the default quantities are computed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |             |                        |   |                               |   |                                 |   |                              |   |                                 |   |                                       |   |                                        |   |                                       |   |                                      |   |                                       |
| <i>/MODE=mode</i>            | Handles special types of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |             |                        |   |                               |   |                                 |   |                              |   |                                 |   |                                       |   |                                        |   |                                       |   |                                      |   |                                       |

| <i>/ORGN=origin</i>          | Specifies the origin of the data (the value corresponding to an angle of zero degrees). For example, if you are using Igor date format and you want the origin to be the first second in year YYYY, use <i>/ORGN=(date2secs(YYYY, 1, 1))</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |             |                        |   |                               |   |                                 |   |                              |   |                                 |   |                                       |   |                                        |   |                                       |   |                                      |   |                                       |
| <i>/Q</i>                    | No results printed in the history area.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |             |                        |   |                               |   |                                 |   |                              |   |                                 |   |                                       |   |                                        |   |                                       |   |                                      |   |                                       |
| <i>/RAYL[=meanDirection]</i> | Performs the Rayleigh test for uniformity. If the "alternative" mean direction is specified (in radians), the test computes<br>$r0Bar = rBar \cos(tBar - meanDirection)$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |             |                        |   |                               |   |                                 |   |                              |   |                                 |   |                                       |   |                                        |   |                                       |   |                                      |   |                                       |

and then computes the significance probability of  $r0Bar$ . The null hypothesis  $H_0$  corresponds to uniformity. It is rejected when  $r0Bar$  is too large. If the mean direction is not specified then  $r0Bar$  is  $rBar$  which is always calculated as part of the first moments so the operation only computes the relevant significance probability (P-Value). The critical values for both cases are computed according to Durand and Greenwood.

`/SAW` Saves the translated angle data in the wave `W_AngleWave` in the current data folder.

`/T=k` Displays results in a table.  $k$  specifies the table behavior when it is closed.

$k=0$ : Normal with dialog (default).

$k=1$ : Kills with no dialog.

$k=2$ : Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists, but does not display the output wave from the current data folder, the table is renamed and a new table is created.

`/Z` Ignores errors. `V_flag` will be set to -1 for any error and to zero otherwise.

### Details

`StatsCircularMoments` is equivalent to `WaveStats` but it applies to circular data, which are distributed on the perimeter of a circle representing some period or cycle. If your data are not described by one of the built-in modes, you can specify the value of the origin (`/ORGN`), which is mapped to zero degrees and the size of a cycle or period.

When you use Igor date formats with the built-in modes for dates, the default origin is set to zero. The default cycle in the case of Mode 4 is 366. This is done in order to handle both leap and nonleap years. Similarly, Mode 5 uses a cycle of 31 days. Note that the internal conversion from Igor date to (year, month, day) is independent of the cycle specification and is therefore not affected by this choice. You should use the `/CYCL` flag if you use one of these modes with a fixed size of year or month.

The parameters listed below are computed and displayed (see row labels) in the table. Here  $N$  is the number of valid (non-NaN) angles  $\{\theta_i\}$

$$C = \sum_{i=1}^n \cos \theta_i$$

$$S = \sum_{i=1}^n \sin \theta_i$$

$$R = \sqrt{C^2 + S^2}$$

$$cBar = \bar{C} = C/n$$

$$sBar = \bar{S} = S/n$$

$$rBar = \bar{R} = R/n$$

$$tBar = \bar{\theta} = \begin{cases} \text{atan}(S/C) & S > 0, C > 0 \\ \text{atan}(S/C) + \pi & C < 0 \\ \text{atan}(S/C) + 2\pi & S < 0, C > 0 \end{cases}$$

$$V = 1 - \bar{R}$$

$$v = \sqrt{-2 \log(1 - V)}$$

median is the value which minimizes

$$d(\theta) = \pi - \frac{1}{n} \sum_{i=1}^n \left| \pi - |\theta_i - \bar{\theta}| \right|$$

mean deviation = The minimum of the last equation when  $\theta \rightarrow$  median.

Higher order moments are denoted with the moment number such that  $t_{3\bar{}}$  is the uncentered third moment of the angle while primed quantities are relative to mean direction  $t_{\bar{}}$ . Using this notation

$$\widehat{\rho}_2 = \frac{1}{n} \sum_{i=1}^n \cos 2(\theta_i - \bar{\theta})$$

$$\text{circular dispersion} = \frac{1 - \widehat{\rho}_2}{2\bar{R}^2}$$

$$\text{skewness} = \frac{\widehat{\rho}_2 \sin(\hat{\mu}'_2 - 2\bar{\theta})}{(1 - \bar{R})^{3/2}}$$

$$\text{kurtosis} = \frac{\widehat{\rho}_2 \cos(\hat{\mu}'_2 - 2\bar{\theta}) - \bar{R}^4}{(1 - \bar{R})^2}$$

where

$$\hat{\mu}'_p = \begin{cases} \text{atan}(S_p/C_p) & S_p > 0, C_p > 0 \\ \text{atan}(S_p/C_p) + \pi & C_p < 0 \\ \text{atan}(S_p/C_p) + 2\pi & S_p < 0, C_p > 0 \end{cases}$$

and

$$C_p = \frac{1}{n} \sum_{i=1}^n \cos p\theta_i, \quad S_p = \frac{1}{n} \sum_{i=1}^n \sin p\theta_i.$$

## StatsCircularTwoSampleTest

**StatsCircularTwoSampleTest** [*flags*] *waveA*, *waveB*

The StatsCircularTwoSampleTest operation performs second order analysis of angles. Using the appropriate flags you can choose between parametric or nonparametric, unordered or paired tests. The input consists of two waves that contain one or two columns. The first column contains angle data (mean angles) expressed in radians and an optional second column that contains associated vector lengths. The waves must be either single or double precision. Results are stored in the W\_StatsCircularTwoSamples wave in the current data folder and optionally displayed in a table. Some of the tests may have additional outputs.

### Flags

|                    |                                                                                                                                                                                                             |

| /T= <i>k</i>       | Displays results in a table. <i>k</i> specifies the table behavior when it is closed.<br><i>k</i> =0: Normal with dialog (default).<br><i>k</i> =1: Kills with no dialog.<br><i>k</i> =2: Disables killing. |
| /Z                 | Ignores any errors.                                                                                                                                                                                         |

### Details

The nonparametric paired-sample test (/NPR) is Moore's test for paired angles applied in second order analysis. The input can consist of one or two column waves. When both waves contain a single column the operation proceeds as if all the vector length were identically 1. The Moore statistic ( $H_0 \rightarrow$  pair equality) is computed and compared to the critical value from the Moore distribution (see **StatsInvMooreCDF**).

The nonparametric second-order two-sample test (/NSOA) consists of pre-processing where the grand mean is subtracted from the two inputs followed by application of Watson's  $U^2$  test (**StatsWatsonUSquaredTest**) with  $H_0$  implying that the two samples came from the same population. The results of this test are stored in the wave W\_WatsonUtest.

The parametric paired-sample test (/PPR) is due to Hotelling. In this test the input should consist of both angular and vector length data. The test statistic is compared with a critical value from the F distribution (**StatsInvFCDF**).

The parametric second order two-sample test (/PSOA) is an extension of Hotelling one-sample test to second order analysis where an F-like statistic is computed corresponding to  $H_0$  of equal mean angles.

## StatsCMSSDCDF

### StatsCMSSDCDF (C, n)

The StatsCMSSDCDF function returns the cumulative distribution function of the C distribution (mean square successive difference), which is

$$f(C, n) = \frac{\Gamma(2m + 2)}{a2^{2m+1} [\Gamma(m + 1)]^2} \left(1 - \frac{C^2}{a^2}\right)^m,$$

where

$$a^2 = \frac{(n^2 + 2n - 12)(n - 2)}{(n^3 - 13n + 24)},$$

$$m = \frac{(n^4 - n^3 - 13n^2 + 37n - 60)}{2(n^3 - 13n + 24)}.$$

The distribution ( $C > 0$ ) can then be expressed as

$$F(C, n) = \frac{\Gamma(2m + 2)}{a2^{2m+1} [\Gamma(m + 1)]^2} C {}_2F_1\left(\frac{1}{2}, -m, \frac{3}{2}, \frac{C^2}{a^2}\right),$$

where  ${}_2F_1$  is the hypergeometric function **hyperG2F1**.

## StatsCochranTest

### StatsCochranTest [flags] [wave1, wave2, ... wave100]

The StatsCochranTest operation performs Cochran's (Q) test on a randomized block or repeated measures dichotomous data. Output is to the M\_CochranTestResults wave in the current data folder or optionally to a table.

### Flags

|             |                                                                                                                                                                              |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /ALPH = val | Sets the significance level (default val=0.05).                                                                                                                              |
| /Q          | No results printed in the history area.                                                                                                                                      |
| /T=k        | Displays results in a table. k specifies the table behavior when it is closed.<br>k=0: Normal with dialog (default).<br>k=1: Kills with no dialog.<br>k=2: Disables killing. |

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists but it does not display the output wave from the current data folder, the table is renamed and a new table is created.

/WSTR=waveListString

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.

## StatsContingencyTable

---

`/Z` Ignores errors. `V_flag` will be set to -1 for any error and to zero otherwise.

### Details

`StatsCochranTest` computes Cochran's statistic and compares it to a critical value from a Chi-squared distribution, which depends only of the significance level and the number of groups (columns). The null hypothesis for the test is that all columns represent the same proportion of the effect represented by a non-zero data.

The Chi-square distribution is appropriate when there are at least 4 columns and at least 24 total data points.

Dichotomous data are presumed to consist of two values 0 and 1, thus `StatsCochranTest` distinguishes only between zero and any nonzero value, which is considered to be 1; it does not allow NaNs or INFs. Input waves can be a single 2D wave or a list of 1D numeric waves, which can also be specified in a string list with `/WSTR`. In the standard terminology, data rows represent blocks and data columns represent groups. `H0` corresponds to the assumption that all groups have the same proportion of 1's.

With the `/T` flag, it displays the results in a table that contains the number of rows, the number of columns, the Cochran statistic, the critical value, and the conclusion (1 to accept `H0` and 0 to reject it).

`V_flag` will be set to -1 for any error and to zero otherwise.

Chapter III-12, **Statistics** for a function and operation overview; **StatsFriedmanTest**.

## StatsContingencyTable

**StatsContingencyTable** [*flags*] **srcWave**

The `StatsContingencyTable` operation performs contingency table analysis on 2D and 3D tables. Output is to the `W_ContingencyTableResults` wave in the current data folder or optionally to a table or the history area.

### Flags

`/ALPH = val` Sets the significance level (default `val=0.05`).

`/COR = mode` Sets the correction type for 2x2 tables. By default there is no correction. Use `mode=1` for Yates and `mode=2` for Haber correction.

`/FEXT={row, col}` Computes Fisher's Exact P-value with 2x2 contingency tables. `row` and `col` are zero-based indices of the table entry where it computes the probability of getting the results in the table or more extreme values. Without the `/Q` flag, it prints the probabilities of each individual table in the history.

Given the contingency table:

|        | Succeeded | Failed |
|--------|-----------|--------|
| Group1 | 11        | 8      |
| Group2 | 4         | 9      |

Example 1: When you use `/FEXT={0, 0}` the P-value represents the sum of the probabilities of the first group having in the Succeeded column 11 or more extreme values, i.e., 12, 13, 14, and 15. In each case the remaining table elements are adjusted so that row and column sums remain constant.

Example 2: When you needed to evaluate the sum of the probabilities of Group2 having 4 counts or less in the Succeeded column, then the appropriate flag is `/FEXT={1, 1}`, which effectively computes the equivalent of having 9, 10, 11, 12, and 13 Failed counts. In each case it computes the upper, the lower, and the two-tail probabilities.

`/HTRG` Tests for heterogeneity between tables stored as layers of 3D wave.

`/LLIK` Computes log likelihood statistic.

`/Q` No results printed in the history area.

`/T=k` Displays results in a table. *k* specifies the table behavior when it is closed.

*k*=0: Normal with dialog (default).

*k*=1: Kills with no dialog.

*k*=2: Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists but it does not display the output wave from the current data folder, the table is renamed and a new table is created.

`/Z` Ignores errors. `V_flag` will be set to -1 for any error and to zero otherwise.

### Details

`StatsContingencyTable` supports 2D waves representing single contingency tables or 3D waves representing multiple 2D tables (where each table is a layer) or a single 3D table. Each entry in the wave must contain a frequency value and must be a positive number; it does not support 0's, NaNs, or INFs. In the special case of 2x2 tables, use the `/COR` flag to compute the statistic using either the Yates or Haber corrections. Except for the heterogeneity option you can also compute the log likelihood statistic. In all the tests,  $H_0$  corresponds to independence between the tested variables.

For 3D tables `StatsContingencyTable` provides Chi-squared, degrees of freedom, the critical value, and optionally the log likelihood G statistic (`/LLIK` flag) for each of the following cases:

- Mutual independence by testing if all three variables are independent of each other.
- Partial dependence (rows) by testing if rows independent of columns and layers.
- Partial dependence (columns) by testing if columns independent of rows and layers.
- Partial dependence (layers) by testing if layers independent of rows and columns.

In each case you should compare the statistic with the critical value and reject  $H_0$  if the statistic exceeds or equals the critical value.

You should examine the table entries to determine if the Chi-square statistic is appropriate (if the frequency is smaller than 6 for `/ALPH=0.05` you should consider computing the Fisher exact test).

`V_flag` will be set to -1 for any error and to zero otherwise.

## StatsCorrelation

`StatsCorrelation(waveA [, waveB])`

The `StatsCorrelation` function computes Pearson's correlation coefficient between two real valued arrays of data of the same length. Pearson *r* is give by:

$$r = \frac{\sum_{i=0}^{n-1} (\text{waveA}[i] - A)(\text{waveB}[i] - B)}{\sqrt{\sum_{i=0}^{n-1} (\text{waveA}[i] - A)^2 \sum_{i=0}^{n-1} (\text{waveB}[i] - B)^2}}$$

Here *A* is the average of the elements in *waveA*, *B* is the average of the elements of *waveB* and the sum is over all wave elements.

### Details

If you use both *waveA* and *waveB* then the two waves must have the same number of points but they could be of different number type. If you use only the *waveA* parameter then *waveA* must be a 2D wave. In this case `StatsCorrelation` will return 0 and create a 2D wave `M_Pearson` where the (*i,j*) element is Pearson's *r* corresponding to columns *i* and *j*.

Fisher's *z* transformation converts Person's *r* above to a normally distributed variable *z*:

## StatsDExpCDF

---

$$z = \frac{1}{2} \ln \left( \frac{1+r}{1-r} \right),$$

with a standard error

$$\sigma_z = \frac{1}{\sqrt{n-3}}.$$

You can convert between the two representations using the following functions:

```
Function pearsonToFisher(inr)
 Variable inr
 return 0.5*(ln(1+inr)-ln(1-inr))
End

Function fisherToPearson(inz)
 Variable inz
 return tanh(inz)
End
```

**See Also**

**Correlate**, **StatsLinearCorrelationTest**, and **StatsCircularCorrelationTest**.

## StatsDExpCDF

**StatsDExpCDF** (*x*, *m*, *s*)

The StatsDExpCDF function returns the double-exponential cumulative distribution function

$$F(x; \mu, \sigma) = \begin{cases} \exp\left(\frac{x-\mu}{\sigma}\right) & \text{when } x < \mu \\ 1 - \frac{1}{2} \exp\left(-\left|\frac{x-\mu}{\sigma}\right|\right) & \text{when } x \geq \mu \end{cases}$$

for  $\sigma > 0$ . It returns NaN when  $\sigma = 0$ .

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsDExpPDF** and **StatsInvDExpCDF**.

## StatsDExpPDF

**StatsDExpPdf** (*x*, *m*, *s*)

The StatsDExpPdf function returns the double-exponential probability distribution function

$$f(x; \mu, \sigma) = \frac{1}{2\sigma} \exp\left[-\left|\frac{x-\mu}{\sigma}\right|\right],$$

where  $\mu$  is the location parameter and  $\sigma > 0$  is the scale parameter. Use  $\mu = 0$  and  $\sigma = 1$  for the standard form of the double exponential distribution. It returns NaN when  $\sigma = 0$ .

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsDExpCDF** and **StatsInvDExpCDF**.

## StatsDIPTest

**StatsDIPTest** [/Z] *srcWave*

The StatsDIPTest operation performs Hartigan test for unimodality.

**Flags**

/Z            Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

**Details**

The input to the operation *srcWave* is any real numeric wave. Outputs are: V\_Value contains the dip statistic; V\_min is the lower end of the modal interval; and V\_max is the higher end of the modal interval. Percentage points or critical values for the dip statistic can be obtained from simulations using an identical sample size as in this example:

```
Function getCriticalValue(sampleSize,alpha)
Variable sampleSize,alpha

 Make/O/N=(sampleSize) dataWave
 Make/O/N=100000 dipResults
 Variable i
 for(i=0;i<100000;i+=1)
 dataWave=enoise(100)
 StatsDipTest dataWave
 dipResults[i]=V_Value
 endfor
 Histogram/P/B=4 dipResults // Compute the PDF.
 Wave W_Histogram
 Integrate/METH=1 W_Histogram/D=W_INT // Compute the CDF.
 Findlevel/Q W_int,(1-alpha) // Find the critical value.
 return V_LevelX
End
```

**See Also**

Chapter III-12, **Statistics** for a function and operation overview.

**StatsDunnettTest**

**StatsDunnettTest** [*flags*] [*wave1, wave2,... wave100*]

The StatsDunnettTest operation performs the Dunnett test by comparing multiple groups to a control group. Output is to the M\_DunnettTestResults wave in the current data folder or optionally to a table. StatsDunnettTest usually follows StatsANOVA1Test.

**Flags**

/ALPH = *val*            Sets the significance level (default *val*=0.05).

/CIDX=*cIndex*           Specifies the (zero based) index of the input wave corresponding to the control group. The default is zero (the first wave corresponds to the control group).

/Q                        No results printed in the history area.

/SWN                      Creates a text wave, T\_DunnettDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column.

/T=*k*                     Displays results in a table. *k* specifies the table behavior when it is closed.

*k*=0:            Normal with dialog (default).

*k*=1:            Kills with no dialog.

*k*=2:            Disables killing.

## StatsErlangCDF

| <code>/WSTR=<i>waveListString</i></code> | Specifies a string containing a semicolon-separated list of waves that contain sample data. Use <i>waveListString</i> instead of listing each wave after the flags.                                                                                   |
| <code>/Z</code>                          | Ignores errors. <code>V_flag</code> will be set to -1 for any error and to zero otherwise.                                                                                                                                                            |

### Details

StatsDunnettTest inputs are two or more 1D numeric waves (one wave for each group of samples). The input waves may contain different number of points, but they must contain two or more valid entries per wave.

For output to a table (using `/T`), each labelled row represents the results of the test for comparing the means of one group to the control group, and rows are ordered so that all comparisons are computed sequentially starting with the group having the smallest mean. The contents of the labeled columns are:

|        |                                                                |
|--------|----------------------------------------------------------------|
| First  | The difference between the group means                         |
| Second | SE (which is computed for possibly unequal number of points)   |
| Third  | The q statistic for the pair which may be positive or negative |
| Fourth | The critical q' value                                          |
| Fifth  | 0 if the conclusion is to reject $H_0$ or 1 to accept $H_0$    |
| Sixth  | The P-value                                                    |

---

`V_flag` will be set to -1 for any error and to zero otherwise.

## StatsErlangCDF

**StatsErlangCDF**(*x*, *b*, *c*)

The StatsErlangCDF function returns the Erlang cumulative distribution function

$$F(x; b, c) = 1 - \frac{\Gamma\left(c, \frac{x}{b}\right)}{\Gamma(c)}.$$

where  $b > 0$  (also as  $\lambda = 1/b$ ) is the scale parameter,  $c > 0$  the shape parameter,  $\Gamma(x)$  the **gamma** function, and  $\Gamma(a, x)$  the incomplete gamma function **gammaInc**.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsErlangPDF**.

## StatsErlangPDF

**StatsErlangPDF**(*x*, *b*, *c*)

The StatsErlangPDF function returns the Erlang probability distribution function

$$f(x; b, c) = \frac{\left(\frac{x}{b}\right)^{c-1} \exp\left(-\frac{x}{b}\right)}{b(c-1)!}.$$

where  $b > 0$  (also as  $\lambda = 1/b$ ) is the scale parameter and  $c > 0$  the shape parameter.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsErlangCDF**.

## StatsErrorPDF

**StatsErrorPDF**( $x$ ,  $a$ ,  $b$ ,  $c$ )

The StatsErrorPDF function returns the error probability distribution function or the exponential power distribution

$$f(x; a, b, c) = \frac{\exp\left[-\frac{1}{2}\left(\frac{|x-a|}{b}\right)^{\frac{2}{c}}\right]}{b2^{\frac{c}{2}+1}\Gamma\left(1+\frac{c}{2}\right)}.$$

where  $a$  is the location parameter,  $b > 0$  is the scale parameter,  $c > 0$  is the shape parameter, and  $\Gamma(x)$  is the **gamma** function.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview.

## StatsEValueCDF

**StatsEValueCDF**( $x$ ,  $\mu$ ,  $\sigma$ )

The StatsEValueCDF function returns the extreme-value (type I, Gumbel) cumulative distribution function

$$F(x; \mu, \sigma) = 1 - \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right),$$

where  $\sigma > 0$ . This is also known as the “minimum” form or distribution of the smallest extreme. To obtain the distribution of the largest extreme reverse the sign of  $\sigma$ .

#### See Also

Chapter III-12, **Statistics** for a function and operation overview.

**StatsEValuePDF**, **StatsInvEValueCDF**, **StatsGEVCDF**, **StatsGEVPDF**

## StatsEValuePDF

**StatsEValuePDF**( $x$ ,  $\mu$ ,  $\sigma$ )

The StatsEValuePDF function returns the extreme-value (type I, Gumbel) probability distribution function

$$F(x; \mu, \sigma) = 1 - \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right),$$

where  $\sigma > 0$ . This is also known as the “minimum” form or the distribution of the smallest extreme. To obtain the distribution of the largest extreme reverse the sign of  $\sigma$ .

#### See Also

Chapter III-12, **Statistics** for a function and operation overview.

## StatsExpCDF

---

**StatsEValueCDF**, **StatsInvEValueCDF**, **StatsGEVCDF**, **StatsGEVPDF**

## StatsExpCDF

**StatsExpCDF**( $x$ ,  $\mu$ ,  $\sigma$ )

The StatsExpCDF function returns the exponential cumulative distribution function

$$F(x; \mu, \sigma) = 1 - \exp\left(-\frac{x - \mu}{\sigma}\right),$$

where  $x \geq \mu$  and  $\sigma > 0$ . It returns NaN for  $\sigma = 0$ .

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsExpPDF** and **StatsInvExpCDF**.

## StatsExpPDF

**StatsExpPDF**( $x$ ,  $\mu$ ,  $\sigma$ )

The StatsExpPDF function returns the exponential probability distribution function

$$f(x; \mu, \sigma) = \frac{1}{\sigma} \exp\left(-\frac{x - \mu}{\sigma}\right),$$

where  $\mu$  is the location parameter and  $\sigma > 0$  is the scale parameter. Use  $\mu=0$  and  $\sigma=1$  for the standard form of the exponential distribution. It returns NaN for  $\sigma=0$ .

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsExpCDF** and **StatsInvExpCDF**.

## StatsFCDF

**StatsFCDF**( $x$ ,  $n1$ ,  $n2$ )

The StatsFCDF function returns the cumulative distribution function for the F distribution with shape parameters  $n1$  and  $n2$

$$F(x; n_1, n_2) = 1 - \text{Betainc}\left(\frac{n_2}{2}, \frac{n_1}{2}, \frac{n_2}{n_2 + n_1 x}\right),$$

where *Betainc* is the incomplete beta function.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsFPDF** and **StatsInvFCDF**.

## StatsFPDF

**StatsFPDF**( $x$ ,  $n1$ ,  $n2$ )

The StatsFPDF function returns the probability distribution function for the F distribution with shape parameters  $n1$  and  $n2$

$$f(x; n_1, n_2) = \frac{\Gamma\left(\frac{n_1 + n_2}{2}\right) \left(\frac{n_1}{n_2}\right)^{\frac{n_1}{2}} x^{\frac{n_1}{2} - 1}}{\Gamma\left(\frac{n_1}{2}\right) \Gamma\left(\frac{n_2}{2}\right) \left(1 + \frac{n_1 x}{n_2}\right)^{\frac{n_1 + n_2}{2}}}.$$

Chapter III-12, **Statistics** for a function and operation overview; **StatsFCDF** and **StatsInvFCDF**.

**StatsFriedmanCDF**

**StatsFriedmanCDF**(*x*, *n*, *m*, *method*, *useTable*)

The StatsFriedmanCDF function returns the cumulative probability distribution of the Friedman distribution with *m* rows and *n* columns. The exact Friedman distribution is computationally intensive, taking on the order of  $(n!)^m$  iterations. You may be able to use a range of precomputed exact values by passing a nonzero value for *useTable*, which will use *method* only if the value is not in the table. For large *m*, consider using the Chi-squared or the Monte-Carlo approximations. To abort execution, press the **User Abort Key Combinations**.

| <i>method</i> | What It Does                                         |
|---------------|------------------------------------------------------|
| 0             | Exact computation.                                   |
| 1             | Chi-square approximation.                            |
| 2             | Monte-Carlo approximation.                           |
| 3             | Use built-table only and return NaN if not in table. |

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsInvFriedmanCDF** and **StatsFriedmanTest**.

**StatsFriedmanTest**

**StatsFriedmanTest** [*flags*] [*wave1*, *wave2*,... *wave100*]

The StatsFriedmanTest operation performs Friedman's test on a randomized block of data. It is a nonparametric analysis of data contained in either individual 1D waves or in a single 2D wave. Output is to the M\_FriedmanTestResults wave in the current data folder or optionally to a table.

**Flags**

|                             |                                                                                                                                                                                                             |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/ALPH = val</i>          | Sets the significance level (default <i>val</i> =0.05).                                                                                                                                                     |
| <i>/Q</i>                   | No results printed in the history area.                                                                                                                                                                     |
| <i>/RW</i>                  | Saves the ranking wave M_FriedmanRanks, which contains the rank values corresponding to each input datum.                                                                                                   |
| <i>/T=k</i>                 | Displays results in a table. <i>k</i> specifies the table behavior when it is closed.<br><i>k</i> =0: Normal with dialog (default).<br><i>k</i> =1: Kills with no dialog.<br><i>k</i> =2: Disables killing. |
|                             | The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results.                                                                         |
| <i>/WSTR=waveListString</i> | Specifies a string containing a semicolon-separated list of waves that contain sample data. Use <i>waveListString</i> instead of listing each wave after the flags.                                         |
| <i>/Z</i>                   | Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.                                                                                                                               |

**Details**

The Friedman test ranks the input data on a row-by-row basis, sums the ranks for each column, and computes the Friedman statistic, which is proportional to the sum of the squares of the ranks.

Input waves can be a single 2D wave or a list of 1D numeric waves, which can also be specified in a string list with */WSTR*. All 1D waves must have the same number of points. A 2D wave must not contain any NaNs.

## StatsFTest

---

The critical value for the Friedman distribution is fairly difficult to compute when the number of rows and columns is large because it requires a number of permutations on the order of  $(\text{numColumns!})^{\text{numRows}}$ . A certain range of these critical values are supported by precomputed tables. When the exact critical value is not available you can use one of the two approximations that are always computed: the Chi-squared approximation or the Iman and Davenport approximation, which converts the Friedman statistic is converted to a new value  $F$  then compares it with critical values from the F distribution using weighted degrees of freedom.

With the `/T` flag, it displays the results in a table that contains the number of rows, the number of columns, the Friedman statistic, the exact critical value (if available), the Chi-squared approximation, the Iman and Davenport approximation, and the conclusion (1 to accept  $H_0$  and 0 to reject it).

`V_flag` will be set to -1 for any error and to zero otherwise.

## StatsFTest

**StatsFTest** [*flags*] *wave1*, *wave2*

The StatsFTest operation performs the F-test on the two distributions in *wave1* and *wave2*, which can be any real numeric type, must contain at least two data points each, and can have an arbitrary number of dimensions. Output is to the `W_StatsFTest` wave in the current data folder or optionally to a table.

### Flags

|                          |                                                                                                                                                                                                                                                                                        |

### Details

The F statistic is the ratio of the variance of *wave1* to the variance of *wave2*. We assume the waves have equal wave variances and that  $H_0$  is  $\sigma_1 = \sigma_2$ . For the upper one-tail test we reject  $H_0$  if  $F$  is greater than the upper critical value or if  $F$  is smaller than the lower critical value in the lower one-tail test. In the two-tailed test we reject  $H_0$  if  $F$  is either greater than the upper critical value or smaller than the lower critical value. The critical values are computed by numerically solving for the argument at which the cumulative distribution function (CDF) equals the appropriate values for the tests. The CDF is given by

$$F(x, n_1, n_2) = 1 - \text{betai}\left(\frac{n_2}{2}, \frac{n_1}{2}, \frac{n_2}{n_2 + n_1 x}\right),$$

where the degrees of freedom  $n_1$  and  $n_2$  equal the number of valid (non-NaN) points in each wave -1, and *betai* is the incomplete beta function. To get the critical value for the upper one-tail test we solve  $F(x)=1-$

alpha. For the lower one-tail test we solve  $F(x)=\alpha$ . In the two-tailed test the lower critical value is a solution for  $F(x)=\alpha/2$  and the upper critical value is a solution for  $F(x)=1-\alpha/2$ .

The F-test requires that the two samples are from normally distributed populations.

## StatsGammaCDF

**StatsGammaCDF**( $x$ ,  $\mu$ ,  $\sigma$ ,  $\gamma$ )

The StatsGammaCDF function returns the gamma cumulative distribution function

$$F(x; \mu, \sigma, \gamma) = \frac{\Gamma_{inc}\left(\gamma, \frac{x - \mu}{\sigma}\right)}{\Gamma(\gamma)}. \quad \begin{array}{l} x \geq \mu \\ \sigma, \gamma > 0 \end{array}$$

where  $\Gamma$  is the gamma function and  $\Gamma_{inc}$  is the incomplete gamma function **gammaInc**.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGammaPDF** and **StatsInvGammaCDF**.

## StatsGammaPDF

**StatsGammaPDF**( $x$ ,  $\mu$ ,  $\sigma$ ,  $\gamma$ )

The StatsGammaPDF function returns the gamma probability distribution function

$$f(x; \mu, \sigma, \gamma) = \frac{\left(\frac{x - \mu}{\sigma}\right)^{\gamma-1} \exp\left(-\frac{x - \mu}{\sigma}\right)}{\sigma \Gamma(\gamma)}. \quad \begin{array}{l} x \geq \mu \\ \sigma, \gamma > 0 \end{array}$$

where  $\mu$  is the location parameter,  $\sigma$  is the scale parameter,  $\gamma$  is the shape parameter, and  $\Gamma$  is the gamma function.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGammaCDF** and **StatsInvGammaCDF**.

## StatsGeometricCDF

**StatsGeometricCDF**( $x$ ,  $p$ )

The StatsGeometricCDF function returns the geometric cumulative distribution function

$$F(x, p) = 1 - (1 - p)^{x+1}.$$

where  $p$  is the probability of success in a single trial and  $x$  is the number of trials for  $x \geq 0$ .

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsGeometricPDF** and **StatsInvGeometricCDF**.

## StatsGeometricPDF

**StatsGeometricPDF**( $x$ ,  $p$ )

The StatsGeometricPDF function returns the geometric probability distribution function

$$f(x, p) = p(1 - p)^x,$$

## StatsHodgesAjneTest

---

where the  $p$  is the probability of success in a single trial and  $x$  is the number of trials  $x \geq 0$ .

## StatsHodgesAjneTest

**StatsHodgesAjneTest** [*flags*] *srcWave*

The StatsHodgesAjneTest operation performs the Hodges-Ajne nonparametric test for uniform distribution around a circle. Output is to the *W\_HodgesAjne* wave in the current data folder or optionally to a table.

### Flags

|                      |                                                                                                                                                                                                                     |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/ALPH = val</i>   | Sets the significance level (default <i>val</i> =0.05).                                                                                                                                                             |
| <i>/Q</i>            | No results printed in the history area.                                                                                                                                                                             |
| <i>/SA=specAngle</i> | Uses the Batschelet modification of the Hodges-Ajne test to test for uniformity against the alternative of concentration around the specified angle. <i>specAngle</i> must be expressed in radians modulus $2\pi$ . |
| <i>/T=k</i>          | Displays results in a table. <i>k</i> specifies the table behavior when it is closed.<br><i>k</i> =0: Normal with dialog (default).<br><i>k</i> =1: Kills with no dialog.<br><i>k</i> =2: Disables killing.         |

### Details

The input *srcWave* must contain angles in radians, can be any number of dimensions, can be single or double precision, and should not contain NaNs or INFs.

StatsHodgesAjneTest performs the standard Hodges-Ajne test, which simply tests for uniformity against the hypothesis that the population is not uniformly distributed around the circle. This test finds a diameter that divides the circle into two halves such that one contains the least number of data  $m$ , the test statistic.

Use */SA* to perform the modified (Batschelet) test, which tests against the alternative that the population is concentrated somehow about the specified angle. The modified test counts the number of points  $m'$  in 90-degree neighborhoods around the specified angle. The test statistic is given by  $C=n-m'$  where  $n$  is the number of points in the wave. The critical value is computed from the binomial probability density.

In both cases  $H_0$  is rejected if the statistic is smaller than the critical value.

*V\_flag* will be set to -1 for any error and to zero otherwise.

## StatsGEVCDF

**StatsGEVCDF**(*x*,  $\mu$ ,  $\sigma$ ,  $\xi$ )

The StatsGEVCDF function returns the generalized extreme value cumulative distribution function.

$$F(x, \mu, \sigma, \xi) = \exp \left\{ - \left[ 1 + \xi \left( \frac{x - \mu}{\sigma} \right)^{-1/\xi} \right] \right\},$$

where

$$1 + \xi \left( \frac{x - \mu}{\sigma} \right) > 0,$$

and  $\sigma > 0$ .

## StatsGEVPDF

**StatsGEVPDF**(*x*, *μ*, *σ*, *ξ*)

The StatsGEVPDF function returns the generalized extreme value probability distribution function.

$$f(x, \mu, \sigma, \xi) = \frac{1}{\sigma} \left[ 1 + \xi \left( \frac{x - \mu}{\sigma} \right) \right]^{(-1/\xi)-1} \exp \left\{ - \left[ 1 + \xi \left( \frac{x - \mu}{\sigma} \right)^{-1/\xi} \right] \right\},$$

where

$$1 + \xi \left( \frac{x - \mu}{\sigma} \right) > 0,$$

and  $\sigma > 0$ .

## StatsHyperGCDF

**StatsHyperGCDF**(*x*, *m*, *n*, *k*)

The StatsHyperGCDF function returns the hypergeometric cumulative distribution function, which is the probability of getting *x* marked items when drawing (without replacement) *k* items out of a population of *m* items when *n* out of the *m* are marked.

**Details**

The hypergeometric distribution is

$$F(x; m, n, k) = \sum_{L=0}^x \frac{\binom{n}{L} \binom{m-L}{k-L}}{\binom{m}{k}},$$

where  $\binom{a}{b}$  is the **binomial** function. All parameters must be positive integers and must have  $m > n$  and  $x < k$ ; otherwise it returns NaN.

## StatsHyperGPDF

---

### References

Klotz, J.H., *Computational Approach to Statistics*.

## StatsHyperGPDF

**StatsHyperGPDF**(*x*, *m*, *n*, *k*)

The StatsHyperGPDF function returns the hypergeometric probability distribution function, which is the probability of getting *x* marked items when drawing without replacement *k* items out of a population of *m* items where *n* out of the *m* are marked.

### Details

The hypergeometric distribution is

$$f(x; m, n, k) = \frac{\binom{n}{x} \binom{m-n}{k-x}}{\binom{m}{k}},$$

where  $\binom{a}{b}$  is the **binomial** function. All parameters must be positive integers and must have  $m > n$  and  $x < k$ .

Chapter III-12, **Statistics** for a function and operation overview; **StatsHyperGCDF**.

## StatsInvBetaCDF

**StatsInvBetaCDF**(*cdf*, *p*, *q* [, *a*, *b*])

The StatsInvBetaCDF function returns the inverse of the beta cumulative distribution function. There is no closed form expression for the inverse beta CDF; it is evaluated numerically.

The defaults (*a*=0 and *b*=1) correspond to the standard beta distribution.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsBetaCDF** and **StatsBetaPDF**.

## StatsInvBinomialCDF

**StatsInvBinomialCDF**(*cdf*, *p*, *N*)

The StatsInvBinomialCDF function returns the inverse of the binomial cumulative distribution function. The inverse function returns the value at which the binomial CDF with probability *p* and total elements *N*, has the value 0.95. There is no closed form expression for the inverse binomial CDF; it is evaluated numerically.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsBinomialCDF** and **StatsBinomialPDF**.

## StatsInvCauchyCDF

**StatsInvCauchyCDF**(*cdf*,  $\mu$ ,  $\sigma$ )

The StatsInvCauchyCDF function returns the inverse of the Cauchy-Lorentz cumulative distribution function

$$x = \mu + \sigma \tan \left[ \pi \left( cdf - \frac{1}{2} \right) \right].$$

It returns NaN for  $cdf < 0$  or  $cdf > 1$ .

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsCauchyCDF** and **StatsCauchyPDF**.

## StatsInvChiCDF

**StatsInvChiCDF**(*x*, *n*)

The StatsInvChiCDF function returns the inverse of the chi-squared distribution of  $x$  and shape parameter  $n$ . The inverse of the distribution is also known as the percent point function.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsChiCDF** and **StatsChiPDF**.

## StatsInvCMSSDCDF

**StatsInvCMSSDCDF**(*cdf*, *n*)

The StatsInvCMSSDCDF function returns the critical values of the C distribution (mean square successive difference distribution), which is given by

$$f(C, n) = \frac{\Gamma(2m + 2)}{a2^{2m+1} [\Gamma(m + 1)]^2} \left( 1 - \frac{C^2}{a^2} \right)^m,$$

where

$$a^2 = \frac{(n^2 + 2n - 12)(n - 2)}{(n^3 - 13n + 24)},$$

$$m = \frac{(n^4 - n^3 - 13n^2 + 37n - 60)}{2(n^3 - 13n + 24)}.$$

Critical values are computed from the integral of the probability distribution function.

Chapter III-12, **Statistics** for a function and operation overview; **StatsCMSSDCDF** and **StatsSRTTest**.

## StatsInvDExpCDF

**StatsInvDExpCDF**(*cdf*,  $\mu$ ,  $\sigma$ )

The StatsInvDExpCDF function returns the inverse of the double-exponential cumulative distribution function

$$x = \begin{cases} \mu + \sigma \ln(2cdf) & \text{when } cdf < 0.5 \\ \mu - \sigma \ln[2(1 - cdf)] & \text{when } cdf \geq 0.5 \end{cases}$$

It returns NaN for  $cdf < 0$  or  $cdf > 1$ .

## StatsInvEValueCDF

---

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsDExpCDF** and **StatsDExpPDF**.

## StatsInvEValueCDF

**StatsInvEValueCDF**(*cdf*,  $\mu$ ,  $\sigma$ )

The StatsInvEValueCDF function returns the inverse of the extreme-value (type I, Gumbel) cumulative distribution function

$$x = \mu - \sigma \ln(1 - cdf)$$

where  $\sigma > 0$ . It returns NaN for  $cdf < 0$  or  $cdf > 1$ . This inverse applies to the “minimum” form of the distribution. Reverse the sign of  $\sigma$  to obtain the inverse distribution of the maximum form.

### See Also

Chapter III-12, **Statistics** for a function and operation overview.

**StatsEValueCDF**, **StatsEValuePDF**, **StatsGEVCDF**, **StatsGEVPDF**

## StatsInvExpCDF

**StatsInvExpCDF**(*cdf*,  $\mu$ ,  $\sigma$ )

The StatsInvExpCDF function returns the inverse of the exponential cumulative distribution function

$$x = \mu - \sigma \ln(1 - cdf).$$

It returns NaN for  $cdf < 0$  or  $cdf > 1$ .

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsExpCDF** and **StatsExpPDF**.

## StatsInvFCDF

**StatsInvFCDF**(*x*, *n1*, *n2*)

The StatsInvFCDF function returns the inverse of the F distribution cumulative distribution function for *x* and shape parameters *n1* and *n2*. The inverse is also known as the percent point function.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsFCDF** and **StatsFPDF**.

## StatsInvFriedmanCDF

**StatsInvFriedmanCDF**(*cdf*, *n*, *m*, *method*, *useTable*)

The StatsInvFriedmanCDF function returns the inverse of the Friedman distribution cumulative distribution function of *cdf* with *m* rows and *n* columns. Use this typically to compute the critical values of the distribution

```
Print StatsInvFriedmanCDF(1-alpha,n,m,0,1)
```

where alpha is the significance level of the associated test.

The complexity of the computation of Friedman CDF is on the order of  $(n!)^m$ . For nonzero values of *useTable*, searches are limited to the built-in table for distribution values. If *n* and *m* are not in the table the calculation may still proceed according to the *method*.

| <i>method</i> | What It Does                                              |
|---------------|-----------------------------------------------------------|
| 0             | Exact computation(slow, not recommended).                 |
| 1             | Chi-square approximation.                                 |
| 2             | Monte-Carlo approximation (slow).                         |
| 3             | Use built-in table only and return a NaN if not in table. |

For large  $m$  and  $n$ , consider using the Chi-squared or the Iman and Davenport approximations. To abort execution, press the **User Abort Key Combinations**.

**Note:** Table values are different from computed values for both methods. Table values use more conservative criteria than computed values. Table values are more consistent with published values because the Friedman distribution is a highly irregular function with multiple steps of arbitrary sizes. The standard for published tables provides the X value of the next vertical transition to the one on which the specified P is found.

Precomputed tables use these values:

| $n$ | $m$                                                |
|-----|----------------------------------------------------|
| 3   | 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16 |
| 4   | 2, 3, 4, 5, 6, 7, 8, 9                             |
| 5   | 2, 3, 4, 5, 6                                      |
| 6   | 2, 3, 4, 5                                         |
| 7   | 2, 3, 4                                            |
| 8   | 2, 3                                               |
| 9   | 2, 3                                               |

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsLogNormalCDF** and **StatsLogNormalPDF** functions.

## StatsInvMaxwellCDF

**StatsInvMaxwellCDF**(cdf, k)

The StatsInvMaxwellCDF function returns the evaluated numerically inverse of the Maxwell cumulative distribution function. There is no closed form expression.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsMaxwellCDF** and **StatsMaxwellPDF** functions.

## StatsInvMooreCDF

**StatsInvMooreCDF**(cdf, N)

The StatsInvMooreCDF function returns the inverse cumulative distribution function for Moore's  $R^*$ , which is used as a critical value in nonparametric version of the Rayleigh test for uniform distribution around the circle. It supports the range  $3 \leq N \leq 120$  and does not change appreciably for  $N > 120$ .

The inverse distribution is computed from polynomial approximations derived from simulations and should be accurate to approximately three significant digits.

## StatsInvNBinomialCDF

**StatsInvNBinomialCDF**(cdf, k, p)

The StatsInvNBinomialCDF function returns the numerically evaluated inverse of the negative binomial cumulative distribution function. There is no closed form expression.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNBinomialCDF** and **StatsNBinomialPDF** functions.

## StatsInvNCChiCDF

**StatsInvNCChiCDF**(cdf, n, d)

The StatsInvNCChiCDF function returns the inverse of the noncentral chi-squared cumulative distribution function. It is computationally intensive because the inverse is computed numerically and involves multiple evaluations of the noncentral distribution, which is evaluated from a series expansion.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNCChiCDF**, **StatsNCChiPDF**, **StatsChiCDF**, and **StatsChiPDF** functions.

## StatsInvNCFCDF

**StatsInvNCFCDF**(cdf, n1, n2, d)

The StatsInvNCFCDF function returns the numerically evaluated inverse of the cumulative distribution function of the noncentral F distribution. *n1* and *n2* are the shape parameters and *d* is the noncentrality measure. There is no closed form expression for the inverse.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNCFCDF** and **StatsNCFPDF** functions.

## StatsInvNormalCDF

**StatsInvNormalCDF**(cdf, m, s)

The StatsInvNormalCDF function returns the numerically computed inverse of the normal cumulative distribution function. There is no closed form expression.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNormalCDF** and **StatsNormalPDF** functions.

## StatsInvParetoCDF

**StatsInvParetoCDF**(cdf, a, c)

The StatsInvParetoCDF function returns the inverse of the Pareto cumulative distribution function

$$x = \frac{a}{(1 - cdf)^{(1/c)}}$$

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsParetoCDF** and **StatsParetoPDF** functions.

## StatsInvPoissonCDF

**StatsInvPoissonCDF**(cdf, λ)

The StatsInvPoissonCDF function returns the numerically evaluated inverse of the Poisson cumulative distribution function. There is no closed form expression for the inverse Poisson distribution.

## StatsInvPowerCDF

---

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPoissonCDF** and **StatsPoissonPDF** functions.

## StatsInvPowerCDF

**StatsInvPowerCDF**(*cdf*, *b*, *c*)

The **StatsInvPowerCDF** function returns the inverse of the Power Function cumulative distribution function

$$x = b / cdf^{(1/c)}.$$

where the scale parameter *b* and the shape parameter *c* satisfy  $b, c > 0$ .

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPowerCDF**, **StatsPowerPDF** and **StatsPowerNoise** functions.

## StatsInvQCDF

**StatsInvQCDF**(*cdf*, *r*, *c*, *df*)

The **StatsInvQCDF** function returns the critical value of the Q cumulative distribution function for *r* the number of groups, *c* the number of treatments, and *df* the error degrees of freedom ( $df=r*c*(n-1)$  with sample size *n*).

### Details

The Q distribution is the maximum of several Studentized range statistics. For a simple Tukey test, use  $r=1$ .

### Examples

The critical value for a Tukey test comparing 5 treatments with 6 samples and 0.05 significance is:

```
Print StatsInvQCDF(1-0.05,1,5,5*(6-1))
```

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsTukeyTest** function.

## StatsInvQpCDF

**StatsInvQpCDF**(*ng*, *nt*, *df*, *alpha*, *side*, *sSizeWave*)

The **StatsInvQpCDF** function returns the critical value of the Q' cumulative distribution function for *ng* the number of groups, *nt* the number of treatments, and *df* the error degrees of freedom. *side*=1 for upper-tail or *side*=2 for two-tailed critical values.

*sSizeWave* is an integer wave of *ng* columns and *nt* rows specifying the number of samples in each treatment. If *sSizeWave* is a null wave (" ") **StatsInvQpCDF** computes the number of samples from  $df=ng*nt*(n-1)$  with *n* truncated to an integer.

### Details

**StatsInvQpCDF** is a modified Q distribution typically used with Dunnett's test, which compares the various means with the mean of the control group or treatment.

**StatsInvQpCDF** differs from other **StatsInvXXX** functions in that you do not specify a *cdf* value for the inverse (usually  $1-\alpha$  for the critical value). Here *alpha* selects one- or two-tailed critical values.

It is computationally intensive, taking longer to execute for smaller *alpha* values.

### Examples

The critical value for a Dunnett test comparing 4 treatments with 4 samples and (upper tail) 0.05 significance is:

```
// n=4 because 12=1*4*(4-1).
Print StatsInvQpCDF(1,4,12,0.05,1," ")
2.28734
```

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsDunnettTest** and **StatsInvQCDF** functions.

## StatsInvRayleighCDF

**StatsInvRayleighCDF**(cdf [, s [, m]])

The **StatsInvRayleighCDF** function returns the inverse of the Rayleigh cumulative distribution function given by

$$x = \mu + \sigma \sqrt{-2 \ln(1 - cdf)},$$

with defaults  $s=1$  and  $m=0$ . It returns NaN for  $s \leq 0$  and zero for  $x \leq m$ .

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRayleighCDF** and **StatsRayleighPDF** functions.

## StatsInvRectangularCDF

**StatsInvRectangularCDF**(cdf, a, b)

The **StatsInvRectangularCDF** function returns the inverse of the rectangular (uniform) cumulative distribution function

$$x = a + cdf(b - a), \quad a < b.$$

where  $a < b$ .

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRectangularCDF** and **StatsRectangularPDF** functions.

## StatsInvSpearmanCDF

**StatsInvSpearmanCDF**(cdf, N)

The **StatsInvSpearmanCDF** function returns the inverse cumulative distribution function for Spearman's  $r$ , which is used as a critical value in rank correlation tests.

The inverse distribution is computed by finding the value of  $r$  for which it attains the  $cdf$  value. The result is usually lower than in published tables, which are more conservative when the first derivative of the distribution is discontinuous.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRankCorrelationTest**, **StatsSpearmanRhoCDF**, and **StatsKendallTauTest** functions.

## StatsInvStudentCDF

**StatsInvStudentCDF**(cdf, n)

The **StatsInvStudentCDF** function returns the numerically evaluated inverse of Student cumulative distribution function. There is no closed form expression.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsStudentCDF** and **StatsStudentPDF** functions.

## StatsInvTopDownCDF

**StatsInvTopDownCDF**(cdf, N)

The **StatsInvTopDownCDF** function returns the inverse cumulative distribution function for the top-down distribution. For  $3 \leq N \leq 7$  it uses a lookup table CDF and returns the next higher value of  $r$  for which the distribution value is larger than  $cdf$ . For  $8 \leq N \leq 50$  it returns the nearest value for which the built-in distribution returns  $cdf$ . For  $N > 50$  it returns the scaled normal approximation.

Tabulated values are from Iman and Conover who pick as the critical value the very first transition of the distribution following the specified  $cdf$  value. These tabulated values tend to be slightly higher than calculated values for  $7 < N < 15$ .

## StatsInvTriangularCDF

---

### References

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRankCorrelationTest** and **StatsTopDownCDF** functions.

## StatsInvTriangularCDF

**StatsInvTriangularCDF**(cdf, a, b, c)

The StatsInvTriangularCDF function returns the inverse of the triangular cumulative distribution function

$$x = \begin{cases} a + \sqrt{cdf(b-a)(c-a)} & 0 \leq cdf \leq \frac{c-a}{b-a} \\ b - \sqrt{(1-cdf)(b-a)(b-c)} & \frac{c-a}{b-a} \leq cdf \leq 1 \end{cases}$$

where  $a < c < b$ .

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsTriangularCDF** and **StatsTriangularPDF** functions.

## StatsInvUSquaredCDF

**StatsInvUSquaredCDF**(cdf, n, m, method, useTable)

The StatsInvUSquaredCDF function returns the inverse of Watson's  $U^2$  cumulative distribution function integer sample sizes  $n$  and  $m$ . Use a nonzero value for *useTable* to search a built-in table of values. If  $n$  and  $m$  cannot be found in the table, it will proceed according to *method*:

| <i>method</i> | What It Does                                              |
|---------------|-----------------------------------------------------------|
| 0             | Exact computation using Burr algorithm (could be slow).   |
| 1             | Tiku approximation using chi-squared.                     |
| 2             | Use built-in table only and return a NaN if not in table. |

For large  $n$  and  $m$ , consider using the Tiku approximation. To abort execution, press the **User Abort Key Combinations**. Because  $n$  and  $m$  are interchangeable,  $n$  should always be the smaller value. For  $n > 8$  the upper limit in the table matched the maximum that can be computed using the Burr algorithm. There is no point in using method 0 with  $m$  values exceeding these limits.

The inverse is obtained from precomputed tables of Watson's  $U^2$  (see **StatsUSquaredCDF**).

**Note:** Table values are different from computed values. These values use more conservative criteria than computed values. Table values are more consistent with published values because the  $U^2$  distribution is a highly irregular function with multiple steps of arbitrary sizes. The standard for published tables provides the  $X$  value of the next vertical transition to the one on which the specified  $P$  is found. See **StatsInvFriedmanCDF**.

| /Z                 | Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.                                                                                                                               |

### Details

StatsJBTest computes the Jarque-Bera statistic

$$JB = \frac{n}{6} \left( S^2 + \frac{K^2}{4} \right),$$

where *S* is the skewness, *K* is the kurtosis, and *n* is the number of points in the input wave. We can express *S* and *K* terms of the *j*th moment of the distribution for *n* samples  $X_i$

$$\mu_j = \frac{1}{n} \sum_{i=1}^n (X_i - \bar{X})^j$$

as

$$S = \frac{\mu_3}{(\mu_2)^{3/2}},$$

and

$$K = \frac{\mu_4}{(\mu_2)^2} - 3.$$

The Jarque-Bera statistic is asymptotically distributed as a Chi-squared with two degrees of freedom. For values of  $n$  in the range [7,2000] the operation provides critical values obtained from Monte-Carlo simulations. For further details or if you would like to run your own simulation to obtain critical values for other values of  $n$ , use the JarqueBeraSimulation example experiment.

StatsJBTest reports the number of finite data points, skewness, kurtosis, Jarque-Bera statistic, asymptotic critical value, and the critical value obtained from Monte-Carlo calculations as appropriate; it ignores NaNs and INFs.

## StatsKDE

**StatsKDE** [*flags*] *srcWave*

StatsKDE can be used to estimate a PDF from original data distribution. Unlike histograms, this method produces a smooth result as it constructs the PDF from a normalized superposition of kernel functions.

The StatsKDE operation was added in Igor Pro 7.00.

#### Flags

### Details

StatsKDE estimates the PDF of a distribution of values using a smoothing kernel and a bandwidth parameter which affects the degree of smoothing.

Theory suggests that the Epanechnikov kernel is the most efficient but many expressions for the optimal bandwidth are derived for the Gaussian kernel. If `srcWave` contains  $N$  points and the requested output (`/S` flag) has  $M$  points then the computational complexity is  $O(NM)$ . For large problems it may be beneficial to use the Gaussian kernel via the `FastGaussTransform` operation.

## StatsKendallTauTest

**StatsKendallTauTest** [*flags*] *wave1* [, *wave2*]

The StatsKendallTauTest operation performs the nonparametric Mann-Kendall test, which computes a correlation coefficient  $\tau$  (similar to Spearman's correlation) from the relative order of the ranks of the data. Output is to the `W_StatsKendallTauTest` wave in the current data folder.

### Flags

|                   |                                                                                                                                                                                                                       |

| <code>/Z</code>   | Ignores errors. <code>V_flag</code> will be set to -1 for any error and to zero otherwise.                                                                                                                            |

### Details

Inputs may be a pair of XY (1D) waves of any real numeric type or a single 1D wave, which is equivalent to using a pair of XY waves where the X wave is monotonically increasing function of the point number. StatsKendallTauTest ignores wave scaling.

Kendall's  $\tau$  is 1 for a monotonically increasing input and -1 for monotonically decreasing input. The significance of the test is computed from the normal approximation

$$\text{Var}(\tau) = \frac{4n + 10}{9n(n - 1)},$$

where  $n$  is the number of data points in each wave. The significance is expressed as a P-value for the null hypothesis of no correlation.

**References**

Kendall, M.G., *Rank Correlation Methods*, 3rd ed., Griffin, London, 1962.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; **StatsRankCorrelationTest**.

For small values of  $n$  you can compute the exact probability using the procedure WM\_KendallSProbability().

**StatsKSTest**

**StatsKSTest** [*flags*] *srcWave* [, *distWave*]

The StatsKSTest operation performs the Kolmogorov-Smirnov (KS) goodness-of-fit test for two continuous distributions. The first distribution is *srcWave* and the second distribution can be expressed either as the optional wave *distWave* or as a user function with /CDFF. Output is to the W\_KSResults wave in the current data folder.

**Flags**

- /ALPH = *val*                Sets the significance level (default *val*=0.05).
- /CDFF=*func*                Specifies a user function expressing the cumulative distribution function. See Details.
- /Q                            No results printed in the history area.
- /T=*k*                        Displays results in a table. *k* specifies the table behavior when it is closed.
  - k*=0:            Normal with dialog (default).
  - k*=1:            Kills with no dialog.
  - k*=2:            Disables killing.
- /Z                            Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

**Details**

The Kolmogorov-Smirnov (KS) goodness-of-fit test applies only to continuous distributions and cases where the compared distribution (expressed as a user function) is completely specified without estimating parameters from the data. It compares the cumulative distribution function (CDF) of two distributions and sets the test statistic D to the largest difference between the CDFs. Because CDFs are in the range [0,1], D is also bound by this range.

When specifying the distributions with two waves, StatsKSTest first sorts the data in the waves and then computes the CDFs and D. You can also specify one of the distributions with a user function. For example, the following function tests if the data in *srcWave* is normally distributed with zero mean and stdv=5:

```
Function GetUserCDF(inX) : CDFFunc
 Variable inX
 return StatsNormalCDF(inX,0,5)
End
```

The “: CDFFunc” designation, which requires Igor7 or later, tells Igor to make the function accessible from the Kolmogorov-Smirnov Test dialog.

Outputs are the number of elements, the KS statistic D, and the critical value. When both distributions are specified by waves, the number of elements is the weighted value (n1\*n2)/(n1+n2).

**References**

Critical values are based on:

Birnbaum, Z. W., and Fred H. Tingey, One-sided confidence contours for probability distribution functions, *The Annals of Mathematical Statistics*, 22, 592–596, 1951.

A statistically more powerful modification of the classic KS test can be found in:

Khamis, H.J., The two-stage delta-corrected Kolmogorov-Smirnov test, *Journal of Applied Statistics*, 27, 439-450, 2000.

StatsKSTest implements the original KS test. The difficulty in implementing the modified tests for all the cases defined by Stephens is in obtaining the critical values which have to be derived by time consuming Monte-Carlo simulations.

Critiques can be found in:

D'Agostino, R.B., and M. Stephens, eds., *Goodness-Of-Fit Techniques*, Marcel Dekker, New York, 1986.

NIST/SEMATECH, Kolmogorov-Smirnov Goodness-of-Fit Test, in *NIST/SEMATECH e-Handbook of Statistical Methods*,

## StatsKuiperCDF

### StatsKuiperCDF (V)

The StatsKuiperCDF function returns the Kuiper cumulative distribution function

$$F(V) = 1 - 2 \sum_{j=1}^{\infty} (4j^2 V^2 - 1) \exp(-2j^2 V^2).$$

Accuracy is on the order of 1e-15. It returns 0 for values of  $V < 0.4$  or 1 for  $V > 3.1$ .

## StatsKWTest

### StatsKWTest [flags] [wave1, wave2, ... wave100]

The StatsKWTest operation performs the nonparametric Kruskal-Wallis test which tests variances using the ranks of the data. Output is to the W\_KWTestResults wave in the current data folder.

#### Flags

|             |                                                                                                                                                                                                                                                                                                  |      |                               |      |                       |      |                   |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------------------------------|------|-----------------------|------|-------------------|
| /ALPH = val | Sets the significance level (default val=0.05).                                                                                                                                                                                                                                                  |      |                               |      |                       |      |                   |
| /E          | Computes the exact P-value using the Klotz and Teng algorithm, which may require long computation times for large data sets. You can stop the calculation by pressing the <b>User Abort Key Combinations</b> after which all remaining results remain valid and the exact P-value is set to NaN. |      |                               |      |                       |      |                   |
| /Q          | No results printed in the history area.                                                                                                                                                                                                                                                          |      |                               |      |                       |      |                   |
| /T=k        | Displays results in a table. k specifies the table behavior when it is closed. <table> <tr> <td>k=0:</td> <td>Normal with dialog (default).</td> </tr> <tr> <td>k=1:</td> <td>Kills with no dialog.</td> </tr> <tr> <td>k=2:</td> <td>Disables killing.</td> </tr> </table>                      | k=0: | Normal with dialog (default). | k=1: | Kills with no dialog. | k=2: | Disables killing. |
| k=0:        | Normal with dialog (default).                                                                                                                                                                                                                                                                    |      |                               |      |                       |      |                   |
| k=1:        | Kills with no dialog.                                                                                                                                                                                                                                                                            |      |                               |      |                       |      |                   |
| k=2:        | Disables killing.                                                                                                                                                                                                                                                                                |      |                               |      |                       |      |                   |

/WSTR=waveListString

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.

## StatsLinearCorrelationTest

---

/Z                      Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

### Details

Inputs are two or more 1D numerical waves (one for each group of samples). Use NaNs for missing data or use waves with different number of points.

StatsKWTest always computes the critical values using both the Chi-squared and Wallace approximations. If appropriate (small enough data set) you can also use /E to obtain the exact P value. When the calculation involves many waves or many data points the calculation of the exact critical value can be very lengthy. All the results are saved in the wave W\_KWTestResults in the current data folder and are optionally displayed in a table (/T). The wave contains the following information:

| Row | Data                                                |
|-----|-----------------------------------------------------|
| 0   | Number of groups                                    |
| 1   | Number of valid data points (excludes NaNs)         |
| 2   | Alpha                                               |
| 3   | Kruskal-Wallis Statistic H                          |
| 4   | Chi-squared approximation for the critical value Hc |
| 5   | Chi-squared approximation for the P value           |
| 6   | Wallace approximation for the critical value Hc     |
| 7   | Wallace approximation for the P value               |
| 8   | Exact P value (requires /E)                         |

H<sub>0</sub> for the Kruskal-Wallis test is that all input waves are the same. If the test fails and the input consisted of more than two waves, there is no indication for possible agreement between some of the waves. See **StatsNPMCTest** for further analysis.

V\_flag will be set to -1 for any error and to zero otherwise.

## StatsLinearCorrelationTest

**StatsLinearCorrelationTest** [*flags*] *waveA*, *waveB*

The StatsLinearCorrelationTest operation performs correlation tests on *waveA* and *waveB*, which must be real valued numeric waves and must have the same number of points. Output is to the W\_StatsLinearCorrelationTest wave in the current data folder or optionally to a table.

### Flags

/ALPH = *val*            Sets the significance level (default *val*=0.05).  
/CI                        Computes confidence intervals for the correlation coefficient.  
/Q                         No results printed in the history area.  
/RHO=*rhoValue*        Tests hypothesis that the correlation has a nonzero value  $|r| \leq 1$ .

|      |                                                                                                                                                                                         |

| /Z   | Ignores errors.                                                                                                                                                                         |

**Details**

The linear correlation tests start by computing the linear correlation coefficient for the  $n$  elements of both waves:

$$r = \frac{\sum_{i=1}^n X_i Y_i - \frac{1}{n} \sum_{i=1}^n X_i \sum_{i=1}^n Y_i}{\sqrt{\left( \sum_{i=1}^n X_i^2 - \frac{1}{n} \left( \sum_{i=1}^n X_i \right)^2 \right) \left( \sum_{i=1}^n Y_i^2 - \frac{1}{n} \left( \sum_{i=1}^n Y_i \right)^2 \right)}}$$

Next it computes the standard error of the correlation coefficient

$$sr = \sqrt{\frac{1-r^2}{n-2}}$$

The basic test is for hypothesis  $H_0$ : the correlation coefficient is zero, in which case  $t$  and  $F$  statistics are applicable. It computes the statistics:

$$t = r / sr$$

and

$$F = \frac{1+|r|}{1-|r|},$$

and then the critical values for one and two tailed hypotheses (designated by  $t_{c1}$ ,  $t_{c2}$ ,  $F_{c1}$ , and  $F_{c2}$  respectively). Critical value for  $r$  are computed using

$$rc_i = \sqrt{\frac{t_c^2}{t_c^2 + n}}$$

where  $i$  takes the values 1 or 2 for one and two tailed hypotheses. Finally, it computes the power of the test at the alpha significance level for both one and two tails (Power1 and Power2).

If you use /RHO it uses the Fisher transformation to compute

$$\text{FisherZ} = \frac{1}{2} \ln \left( \frac{1+r}{1-r} \right)$$

$$\text{zeta} = \frac{1}{2} \ln \left( \frac{1+\rho}{1-\rho} \right)$$

the standard error approximation

$$\sigma_Z = \sqrt{\frac{1}{n-3}},$$

$$Z_{\text{statistic}} = \frac{\text{FisherZ} - z_{\text{eta}}}{\sigma_Z},$$

and the critical values from the normal distribution  $Z_{ci}$ .

The confidence intervals are calculated differently depending on the hypothesis for the value of the correlation coefficient. If /RHO is not used the confidence intervals are computed using the critical value  $F_{c2}$ , otherwise they are computed using the critical  $Z_{c2}$  and  $\sigma_Z$ .

## StatsLinearRegression

**StatsLinearRegression** [*flags*] [*wave0, wave1,...*]

The StatsLinearRegression operation performs regression analysis on the input wave(s). Output is to the W\_StatsLinearRegression wave in the current data folder or optionally to a table. Additionally, the M\_DunnettMCElevations, M\_TukeyMCSlopes, and M\_TukeyMCElevations waves may be created as specified.

### Flags

- /ALPH = val*                Sets the significance level (default *val*=0.05).
- /B=beta0*                   Tests the hypothesis that the slope  $b = \text{beta0}$  (default is 0). The results are expressed by the t-statistic, which can be compared with the tc value for the two-tailed test. Get the critical value for a one-tailed test using `StatsStudentCDF(1-alpha, N-2)`. It does not work with /MYVW.
- /BCIW*                      Computes two confidence interval waves for the high side and the low side of the confidence interval. The new waves are named with `_CH` and `_CL` suffixes respectively appended to the Y wave name and are created in the current data folder. For multiple runs a numeric suffix will also be appended to the names.
- /BPIW[=mAdditional]*        Computes prediction interval waves for the high side and the low side of the confidence interval on a single additional measurement (default). Use *mAdditional* to specify additional measurements. The new waves are named with `_PH` and `_PL` suffixes respectively appended to the Y wave name and are created in the current data folder. For multiple runs a numeric suffix will also be appended to the names.
- /DET=controlIndex*        Performs Dunnett's multicomparison test for the elevations. The test requires more than two Y waves for regression, the test for the slopes should not reject the equal slope hypothesis, and the test for the elevations should reject the equal elevation hypothesis. *controlIndex* is the zero-based index of the Y wave representing the control (X waves do not count in the index specification). The test compares the elevation of every Y wave with the specified control.
- Output is to the M\_DunnettMCElevations wave in the current data folder or optionally to a table. For every Y wave and control Y wave combination, the results include SE, q, q' (shown as qp), and the conclusion with 1 to accept the hypothesis of equal elevations or 0 to reject it. Use /TAIL to determine the critical value and the sense of the test. If you use /TUK you will also get the Tukey test for the set of elevations.

*/MYVW={xWave, yWave}*

Specifies that the input consists of multiple Y values for each X value. It ignores all other inputs and the results are appropriate only for multiple Y values at each X point.

*yWave* is a 2D wave of values arranged in columns. Use NaNs for padding where rows do not have the same number of entries as others. It will use the X scaling of *yWave* when *xWave* is null, */MYVW={\*, yWave}*.

It first tests the hypothesis ( $H_0$ ) that the population regression is linear in an analysis of variance calculation. It generates results 1-7 (see Details) as well as: Among Groups SS, Among Groups DF, Within Groups SS, Within Groups DF, Deviations from Linearity SS, Deviations from Linearity DF, F statistic defined by the ratio of Deviation from Linearity MS to Within Groups MS, and the critical value  $F_c$ .

Next, it tests the hypothesis that the slope  $\beta=0$ . If the original  $H_0$  was accepted, the new F statistic= $\text{regressionMS}/\text{residualMS}$ . Otherwise the with the critical  $F=\text{regressionMS}/\text{WithinGroupsMS}$  with a corresponding critical value. Finally, it reports the values of the coefficient of determination  $r^2$  and the standard error of the estimate  $S_{YX}$ .

*/PAIR* Specifies that the input waves are XY pairs, where each pair must be an X wave followed by a Y wave.

*/Q* No results printed in the history area.

*/RTO* Reflects the regression through the origin.

*/T=k* Displays results in a table. *k* specifies the table behavior when it is closed.

*k=0:* Normal with dialog (default).

*k=1:* Kills with no dialog.

*k=2:* Disables killing.

*/TAIL=tCode* Sets the sense of the test when applying Dunnett's test (see */DET*). *tCode* is 1 or 2 for a one-tail critical value and 4 for a two-tail critical value.

*/TUK* Performs a Tukey-type test on multiple regressions on two or more Y waves. There are two possible Tukey-type tests: The first is performed if the hypothesis of equal slopes is rejected. It compares all combinations of two Y waves to identify if some of the waves have equal slopes. Output is to the *M\_TukeyMCSlopes* wave in the current data folder or optionally to a table. For every Y wave pair, the results include the difference between slopes (absolute value), *q*, the critical value  $q_c$ , and the conclusion set to 1 for accepting the equality of the pair of slopes or 0 for rejecting the hypothesis.

The second Tukey-type test is performed if all the slopes are the same but the elevations are not. The test (see */DET*) compares all possible pairs of elevations to determine which satisfy the hypothesis of equality. Output is to the *M\_TukeyMCElevations* wave in the current data folder.

*/WSTR=waveListString*

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.

*/Z* Ignores errors.

## Details

Inputs may consist of Y waves or XY wave pairs. If X data are not used, the X values are inferred from the Y wave scaling. For multiple waves where only some have pairs, use the */PAIR* flag and enter \* in each place where the X values should be computed.

For each input StatsLinearRegression calculates:

1. Least squares regression line  $y=a+b*x$ .
2. Mean value of X:  $x\text{Bar}$ .
3. Mean value of Y:  $y\text{Bar}$ .
4. Sum of the squares  $(x_i-x\text{Bar})^2$ .
5. Sum of the squares  $(y_i-y\text{Bar})^2$ .
6. Sum of the product  $(x_iy_i-xy\text{Bar})$ .
7. Standard error of the estimate  $s_{xy}^2 = \frac{\sum(y_i - \hat{y}_i)^2}{n-2}$ .
8. F statistic for the hypothesis  $\beta=0$ .
9. Critical F value  $F_c$ .
10. Coefficient of determination  $r^2$ .
11. Standard error of the regression coefficient  $S_b$ .
12. t-statistic for the hypothesis  $\beta=\beta_0$ , NaN if /B is not specified.
13. Critical value  $t_c$  for the t-statistic above (used to calculate L1 and L2).
14. Lower confidence interval boundary (L1) for the regression coefficient.
15. Upper confidence interval boundary (L2) for the regression coefficient.

For two Y waves with the same slope, it computes a common slope (bc) and then tests the equality of the elevations (a). In both cases it computes a t-statistic and compares it with a critical value. If the elevations are also the same then it computes the common elevation (ac) and the pooled means of X and Y in (xp) and (yp).

For more than two Y waves it computes:

$$A_c = \sum_{j=1}^W A_j; \quad A_j \equiv \sum x_i^2 = \sum_{i=0}^{n_j-1} X_i^2 - \frac{1}{n_j} \left( \sum_{i=0}^{n_j-1} X_i \right)^2$$

$$B_c = \sum_{j=1}^W B_j; \quad B_j \equiv \sum xy = \sum_{i=0}^{n_j-1} XY - \frac{1}{n_j} \left( \sum_{i=0}^{n_j-1} X_i \right) \left( \sum_{i=0}^{n_j-1} Y_i \right)$$

$$C_c = \sum_{j=1}^W C_j; \quad C_j \equiv \sum y^2 = \sum_{i=0}^{n_j-1} Y_i^2 - \frac{1}{n_j} \left( \sum_{i=0}^{n_j-1} Y_i \right)^2$$

$$SSp = \sum_{j=1}^W C_j - \frac{B_j^2}{A_j}$$

$$SSc = Cc - \frac{B_c^2}{A_c}$$

$$SSt = \sum_{j=1}^W \sum_{i=0}^{n_j} Y_{ji}^2 - \frac{1}{N} \left( \sum_{j=1}^W \sum_{i=0}^{n_j} Y_{ji} \right)^2 - \frac{\left( \sum_{j=1}^W \sum_{i=0}^{n_j} X_{ji} Y_{ji} - \frac{1}{N} \left( \sum_{j=1}^W \sum_{i=0}^{n_j} X_{ji} \right) \left( \sum_{j=1}^W \sum_{i=0}^{n_j} Y_{ji} \right) \right)^2}{\sum_{j=1}^W \sum_{i=0}^{n_j} X_{ji}^2 - \frac{1}{N} \left( \sum_{j=1}^W \sum_{i=0}^{n_j} X_{ji} \right)^2}$$

$$DFp = \sum_{j=1}^W (n_j - 2)$$

$$DFt = \sum_{j=1}^W n_j - 2$$

Here  $W$  is the number of Y-waves and  $N = \sum_{j=1}^W n_j$  is the total number of data points in all Y-waves.

The test statistic  $F$  for equality of slopes is given by:

$$F = \left( \frac{SSc - SSp}{numWaves - 1} \right) / \frac{SSp}{DFp}.$$

$F_c$  is the corresponding critical value.

Output is to the W\_LinearRegressionMC wave in the current data folder.

V\_flag is set to -1 for any error and to zero otherwise.

S\_waveNames is set to a semicolon-separated list of the names of the waves created by the operation.

**StatsLogNormalCDF**( $x$ ,  $\sigma$  [,  $\theta$ ,  $\mu$ ])

The StatsLogNormalCDF function returns the lognormal cumulative distribution function

$$F(x; \sigma, \theta, \mu) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x \frac{1}{t-\theta} \exp\left\{-\left[\ln\left(\frac{t-\theta}{\mu}\right)\right]^2 / 2\sigma^2\right\} dt,$$

for  $x \geq \theta$  and  $\sigma, \mu > 0$ . The standard lognormal distribution is for  $\theta=0$  and  $\mu=1$ , which are the optional parameter defaults.

## StatsLogNormalPDF

**StatsLogNormalPDF**( $x$ ,  $\sigma$  [,  $\theta$ ,  $\mu$ ])

The StatsLogNormalPDF function returns the lognormal probability distribution function

$$f(x; \sigma, \theta, \mu) = \frac{1}{\sigma\sqrt{2\pi}} \frac{1}{x-\theta} \exp\left\{-\left[\ln\left(\frac{x-\theta}{\mu}\right)\right]^2 / 2\sigma^2\right\},$$

for  $x \geq \theta$  and  $\sigma, \mu > 0$ , where  $\theta$  is the location parameter,  $\mu$  is the scale parameter and,  $\sigma$  is the shape parameter. The standard lognormal distribution is for  $\theta=0$  and  $\mu=1$ , which are the optional parameter defaults.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsLogNormalCDF** and **StatsInvLogNormalCDF** functions.

## StatsMaxwellCDF

**StatsMaxwellCDF**( $x$ ,  $k$ )

The StatsMaxwellCDF function returns the Maxwell cumulative distribution function

$$F(x; k) = \text{gammp}\left(\frac{3}{2}, \frac{kx^2}{2}\right), \quad x > 0.$$

where **gammp** is the regularized incomplete gamma function.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsMaxwellPDF** and **StatsInvMaxwellCDF** functions.

## StatsMaxwellPDF

**StatsMaxwellPDF**( $x$ ,  $k$ )

The StatsMaxwellPDF function returns Maxwell's probability distribution function

$$f(x; k) = \sqrt{\frac{2}{\pi}} k^{3/2} x^2 \exp\left(-\frac{kx^2}{2}\right), \quad x > 0.$$

The Maxwell distribution describes, for example, the speed distribution of molecules in an ideal gas.

Chapter III-12, **Statistics** for a function and operation overview; the **StatsMaxwellCDF** and **StatsInvMaxwellCDF** functions.

## StatsMedian

### StatsMedian(*waveName*)

The StatsMedian function returns the median value of a numeric wave *waveName*, which must not contain NaNs.

#### Example

```
Make/N=5 sample1={1,2,3,4,5}
Print StatsMedian(sample1)
3
Make/N=6 sample2={1,2,3,4,5,6}
Print StatsMedian(sample2)
3.5
```

**median**, **WaveStats**, **StatsQuantiles**

## StatsMooreCDF

### StatsMooreCDF(*x*, *N*)

The StatsMooreCDF function returns the cumulative distribution function for Moore's  $R^*$ , which is used in a nonparametric version of the Rayleigh test for uniform distribution around the circle. It supports the range  $3 \leq N \leq 120$  and does not change appreciably for  $N > 120$ .

The distribution is computed from polynomial approximations derived from simulations and should be accurate to approximately three significant digits.

## StatsMultiCorrelationTest

### StatsMultiCorrelationTest [*flags*] *corrWave*, *sizeWave*

The StatsMultiCorrelationTest operation performs various tests on multiple correlation coefficients. Inputs are two 1D waves: *corrWave*, containing correlation coefficients, and *sizeWave*, containing the size (number of elements) of the corresponding samples. Although you can do all the tests at the same time, it rarely makes sense to do so.

#### Flags

*/ALPH* = *val*      Sets the significance level (default *val*=0.05).

*/CON*={*controlRow*,*tails*}

Performs a multiple comparison test using the *controlRow* element of *corrWave* as a control. It is one- or two-tailed test according to the *tails* parameter. Output is to the *M\_ControlCorrTestResults* wave in the current data folder.

## StatsMultiCorrelationTest

---

`/CONT=cWave` Performs a multiple contrasts test on the correlation coefficients. The contrasts wave, `cWave`, contains the contrast factor,  $c_i$ , entry for each of the  $n$  correlation coefficients  $r_i$  in `corrWave`, and satisfying the condition that the sum of the entries in `cWave` is zero.  $H_0$  corresponds to

$$\sum_{i=0}^{n-1} c_i r_i = 0.$$

The test statistic  $S$  is

$$S = \frac{1}{\sqrt{\frac{c_i^2}{n_i - 3}} \left| \sum_{i=0}^{n-1} c_i z_i \right|},$$

where  $z_i$  is the Fisher z transform of the correlation coefficient  $r_i$ :

$$z_i = \frac{1}{2} \ln \left( \frac{1 + r_i}{1 - r_i} \right).$$

It produces the SE value, the contrast statistic  $S$ , and the critical value, which are labeled `ContrastSE`, `ContrastS`, and `Contrast_Critical`, respectively, in the `W_StatsMultiCorrelationTest` wave.

`/Q` No results printed in the history area.

`/T=k` Displays results in a table.  $k$  specifies the table behavior when it is closed.  
 $k=0$ : Normal with dialog (default).  
 $k=1$ : Kills with no dialog.  
 $k=2$ : Disables killing.

`/TUK` Performs a Tukey-type multi comparison testing between the correlation coefficients by comparing every possible combination of pairs of correlation coefficients, computing the difference in their z-transforms, the SE, and the  $q$  statistic:

$$q = \frac{|z_j - z_i|}{\sqrt{\frac{1}{2} \left( \frac{1}{n_i - 3} + \frac{1}{n_j - 3} \right)}}.$$

The critical value is computed from the  $q$  CDF (**StatsInvQCDF**) with degrees of freedom `numWaves` and infinity. Output is to the `M_TukeyCorrTestResults` wave in the current data folder or optionally to a table.

`/Z` Ignores errors. `V_flag` will be set to -1 for any error and to zero otherwise.

### Details

Without any flags, `StatsMultiCorrelationTest` computes  $\chi^2$  for the correlation coefficients and compares it with the critical value.

$$\chi^2 = \sum_{i=0}^{n-1} z_i^2 (n_i - 3) - \frac{\left( \sum_{i=0}^{n-1} z_i (n_i - 3) \right)^2}{\sum_{i=0}^{n-1} (n_i - 3)},$$

where  $z_i$  is the Fisher's  $z$  transform of the correlation coefficients and  $n_i$  is the corresponding sample size. It computes the common correlation coefficient  $r_w$  and its transform  $z_w$ .

$$z_w = \frac{\sum_{i=0}^{n-1} z_i (n_i - 3)}{\sum_{i=0}^{n-1} (n_i - 3)}$$

These values are calculated even when not appropriate, such as when  $\chi^2$  exceeds the critical value and  $H_0$  (all samples came from populations of identical correlation coefficients) is rejected.

The operation also computes ChiSquaredP (due to S.R. Paul), a different variant of  $\chi^2$  that is corrected for bias and should be compared with the same critical value. Output is to the W\_StatsMultiCorrelationTest wave in the current data folder or optionally to a table.

## StatsNBinomialCDF

**StatsNBinomialCDF**( $x$ ,  $k$ ,  $p$ )

The StatsNBinomialCDF function returns the negative binomial cumulative distribution function

$$F(x; k, p) = \text{Betai}(k, x + 1; p),$$

where **betai** is the regularized incomplete beta function.

#### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNBinomialPDF** and **StatsInvNBinomialCDF** functions.

## StatsNBinomialPDF

**StatsNBinomialPDF**( $x$ ,  $k$ ,  $p$ )

The StatsNBinomialPDF function returns the negative binomial probability distribution function

$$f(x; k, p) = \binom{x + k - 1}{k - 1} p^k (1 - p)^x, \quad x = 0, 1, 2, \dots$$

where  $\binom{a}{b}$  is the **binomial** function.

The binomial distribution expresses the probability of the  $k$ th success in the  $x+k$  trial for two mutually exclusive results (success and failure) and  $p$  the probability of success in a single trial.

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNBinomialCDF** and **StatsInvNBinomialCDF** functions.

## StatsNCChiCDF

**StatsNCChiCDF**(*x*, *n*, *d*)

The StatsNCChiCDF function returns the noncentral chi-squared cumulative distribution function

$$F(x; n, d) = \sum_{i=1}^{\infty} \exp(d/2) \frac{(d/2)^i}{i!} F_c(x; n + 2i),$$

where  $n > 0$  corresponds to degrees of freedom,  $d \geq 0$  is the noncentrality parameter, and  $F_c$  is the central chi-squared distribution.

## StatsNCChiPDF

**StatsNCChiPDF**(*x*, *n*, *d*)

The StatsNCChiPDF function returns the noncentral chi-squared probability distribution function

$$f(x; n, d) = \frac{\sqrt{d} \exp\left(-\frac{x+d}{2}\right) x^{(n-1)/2}}{2(dx)^{n/4}} I_{n/2-1}(\sqrt{dx}).$$

where  $n > 0$  is the degrees of freedom,  $d \geq 0$  is the noncentrality parameter, and  $I_k(x)$  is the modified Bessel function of the first kind, **bessI**.

## StatsNCFPDF

**StatsNCFPDF**(*x*, *n1*, *n2*, *d*)

The StatsNCFPDF function returns the probability distribution function of the noncentral F distribution

$$f(x; n_1, n_2, d) = \frac{\exp(-d/2)}{B\left(\frac{n_1}{2}, \frac{n_2}{2}\right)} x^{n_1/2-1} (xn_1 + n_2)^{-(n_1+n_2)/2} n_1^{n_1/2} n_2^{n_2/2} {}_1F_1\left(\frac{n_1+n_2}{2}, \frac{n_1}{2}, \frac{xdn_1}{2(xn_1+n_2)}\right),$$

where  $B()$  is the **beta** function and  ${}_1F_1()$  is the hypergeometric function **hyperG1F1**.

## StatsNormalCDF

**StatsNormalCDF**( $x$ ,  $m$ ,  $s$ )

The StatsNormalCDF function returns the normal cumulative distribution function

$$F(x, \mu, \sigma) = \frac{1}{2} + \frac{1}{2} \operatorname{erf}\left(\frac{x-\mu}{\sigma\sqrt{2}}\right),$$

## StatsNormalPDF

---

where *erf* is the error function.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **erf**, **StatsNormalPDF** and **StatsInvNormalCDF** functions.

## StatsNormalPDF

**StatsNormalPDF**(*x*, *m*, *s*)

The StatsNormalPDF function returns the normal probability distribution function

$$f(x, \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right).$$

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsNormalCDF** and **StatsInvNormalCDF** functions.

## StatsNPMCTest

**StatsNPMCTest** [*flags*] [*wave1*, *wave2*,... *wave100*]

The StatsNPMCTest operation performs a number of nonparametric multiple comparison tests. Output waves are saved in the current data folder according to the test(s) performed. Some tests are only appropriate when you have the same number of samples in all groups. StatsNPMCTest usually follows **StatsANOVA1Test** or **StatsKWTest**.

### Flags

*/ALPH = val* Sets the significance level (default *val*=0.05).

*/CIDX=controlIndex* Performs nonparametric multiple comparisons on a control group specified by the zero-based *controlIndex* wave in the input list. Output is to the M\_NPCCRResults wave in the current data folder or optionally to a table. The output column contents are: the first contains the difference between the rank sums of the control and each of the other waves; the second contains the standard error (SE); the third contains the statistic  $q_i$ , defined as the ratio of the difference in rank sums to SE; the fourth contains the critical value which also depends on the tails specification (see */TAIL*); and the fifth contains the conclusion with 0 to reject  $H_0$  and 1 to accept it. One version of this test applies when all inputs contain the same number of samples. When that is not the case, it uses the Dunn-Hollander-Wolfe approach to compute an appropriate SE and to handle possible ties.

*/CONW=cWave* Performs a nonparametric multiple contrasts tests. *cWave* has one point for each input wave. The *cWave* value is 1 to include the corresponding (zero based) input wave in the first group, 2 to include the wave in the second group, or zero to exclude the wave.

The contrast is defined as the difference between the normalized sum of the ranks of the first group and that of the second group. If *cWave*={0,1,1,2}, then the contrast is computed as

$$\text{contrast: } \frac{1}{3}[R_{n1} + R_{n2} + R_{n3}] - R_{n4}.$$

where  $R_{ni}$  is the normalized rank sum of the samples from the corresponding input wave. Note the significance of allowing zeros in the contrast wave because the actual ranking is performed on the pool of all the samples.

Output is to the M\_NPMConResults wave in the current data folder or optionally to a table. The output column contents are: the first is the contrast value; the second is the standard error (SE); the third is the statistic S, which is the ratio of the absolute value of the contrast to SE; the fourth is the critical value (from  $\chi^2$  the approximation); and the fifth is the conclusion with 0 to reject  $H_0$  and 1 indicating acceptance.

This test supports input waves with different number of samples and can also handle tied ranks. Note that the contrast wave used here is structured differently than for **StatsMultiCorrelationTest**.

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /DHW     | Performs the Dunn-Holland-Wolfe test, which supports unequal number of samples and accounts for ties in the rank sums. Output is to the M_NPMCDHWResults wave in the current data folder or optionally to a table. The output column contents are: the first contains the difference between the means of the rank sums (rank sums divided by the number of samples in the group), the second contains the standard error (SE), the third contains the DHW statistic Q, the fourth contains the critical value, and the fifth contains the conclusion (0 to reject $H_0$ and 1 to accept).                                                                                                                            |
| /Q       | No results printed in the history area.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| /SWN     | Creates a text wave containing wave names corresponding to each row of the comparison table. Depending on your choice of tests, the following wave names are created:<br>/CIDX test: T_NPCCResultsDescriptors<br>/DHW test: T_NPMCDHWDescriptors<br>/SNK test: T_NPMCSNKResultsDescriptors<br>/TUK test: T_NPMCTukeyDescriptors                                                                                                                                                                                                                                                                                                                                                                                       |
| /T=k     | Displays results in a table. $k$ specifies the table behavior when it is closed.<br>$k=0$ : Normal with dialog (default).<br>$k=1$ : Kills with no dialog.<br>$k=2$ : Disables killing.<br><br>The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results.                                                                                                                                                                                                                                                                                                                                                                                    |
| /TAIL=tc | Specifies $H_0$ with /CIDX.<br>$tc=1$ : One tailed test ( $\mu_c \leq \mu_a$ ).<br>$tc=2$ : One tailed test ( $\mu_c \geq \mu_a$ ).<br>$tc=4$ : Default; two tailed test ( $\mu_c = \mu_a$ ).<br><br>Code combinations are not allowed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| /SNK     | Performs a nonparametric variation on the Student-Newman-Keuls test where the standard error SE is a function of $p$ (the rank difference). This test requires equal numbers of samples in all groups; use /DHW for unequal sizes.<br><br>Output is to the M_NPMCSNKResults wave in the current data folder. The output column contents are: the first contains the difference between rank sums, the second contains the standard error (SE), the third contains the $p$ value (rank difference), the fourth the statistic, the fifth contains the critical value, and the sixth contains the conclusion (0 to reject $H_0$ and 1 to accept). This test is more sensitive to differences than the Tukey test (/TUK). |

- /TUK** Perform a Tukey-type (Nemenyi) multiple comparison test using the difference between the rank sums. This is the default that is performed if you do not specify any of the test flags. This test requires equal numbers of points in all waves; use /DHW for unequal sizes.
- Output is to the M\_NPMCTukeyResults wave in the current data folder. The output column contents are: the first contains the difference between the rank sums, the second contains the SE values, the third contains the statistic  $q$ , the fourth contains the critical value for this specific alpha and the number of groups; and the last contains a conclusion flag with 0 indicating a rejection of  $H_0$  and 1 indicating acceptance.  $H_0$  postulates that the paired means are the same.
- /WSTR=waveListString** Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.
- /Z** Ignores errors.

### Details

Inputs to StatsNPMCTest are two or more 1D numerical waves (one wave for each group of samples) containing two or more valid entries. The waves must have the same number of points for the use /SNK and /TUK tests, otherwise, for waves of differing lengths you must use the Dunn-Hollander-Wolfe test (/DHW).

V\_flag will be set to zero for no execution errors. Individual tests may fail if, for example, there are different number of samples in the input waves for a test that requires an equal number of points. StatsNPMCTest skips failed tests and V\_flag will be a binary combination identifying the failed test(s):

- V\_flag & 1 Tukey method failed (/TUK).  
V\_flag & 2 Student-Newman-Keuls failed (/SNK).

V\_flag will be set to -1 for any other errors.

## StatsNPNominalSRTest

**StatsNPNominalSRTest** [*flags*] [*srcWave*]

The StatsNPNominalSRTest operation performs a nonparametric serial randomness test for nominal data consisting of two types. The null hypothesis is that the data are randomly distributed. Output is to the W\_StatsNPSRTest wave in the current data folder.

### Flags

- /ALPH = val** Sets the significance level (default *val*=0.05).
- /Q** No results printed in the history area.
- /P={*m,n,u*}** Provides a summary of the data instead of providing the nominal series. *m* is the number of elements of the first type, *n* is the number of elements of the second type, and *u* is the number of runs or contiguous sequences of each type. Do not use *srcWave* with /P.
- /T=*k*** Displays results in a table. *k* specifies the table behavior when it is closed.
- k*=0: Normal with dialog (default).
  - k*=1: Kills with no dialog.
  - k*=2: Disables killing.
- /Z** Ignores errors.

**Details**

The input wave to `StatsNPNominalSRTest` is specified with `srcWave` or `/P`. The wave must contain exactly two values. If `srcWave` is a text wave, then each type can be designated by a letter or by a short string (less than 200 bytes). If `srcWave` is numeric, you should avoid the usual floating point waves, which can give rise to internal representations of more than two distinct values. Output to `W_StatsNPSRTest` includes the total number of points ( $N$ ), the number of occurrences ( $m$ ) of the first variable, the number of occurrences ( $n$ ) of the second variable, and the number of runs ( $u$ ). When both  $m$  and  $n$  are less than 300, it computes the P value (probability  $P(u' < u)$ ) and the critical values using the Swed and Eisenhart algorithm. When  $m$  or  $n$  are larger than 300, it computes the mean and standard deviation of an equivalent normal distribution with the corresponding critical value.

**StatsParetoCDF**

**StatsParetoCDF**( $x$ ,  $a$ ,  $c$ )

The `StatsParetoCDF` function returns the Pareto cumulative distribution function

$$F(x; a, c) = 1 - \left(\frac{a}{x}\right)^c.$$

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsParetoPDF** and **StatsInvParetoCDF** functions.

**StatsParetoPDF**

**StatsParetoPDF**( $x$ ,  $a$ ,  $c$ )

The `StatsParetoPDF` function returns the Pareto probability distribution function

$$f(x; a, c) = \frac{c}{x} \left(\frac{a}{x}\right)^c, \quad \begin{array}{l} a, c > 0 \\ x \geq a. \end{array}$$

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsParetoCDF** and **StatsInvParetoCDF** functions.

**StatsPermute**

**StatsPermute**( $waveA$ ,  $waveB$ ,  $dir$ )

The `StatsPermute` function permutes elements in `waveA` based on the lexicographic order of `waveB` and the direction `dir`. It returns 1 if a permutation is possible and returns 0 otherwise. Use `dir=1` for the next permutation and `dir=-1` for a previous permutation.

**Details**

Both `waveA` and `waveB` must be numeric. The lexicographic order of elements in the index wave is set so that permutations start with the index wave `waveB` in ascending order and end in descending order. Elements of `waveA` are permuted in place according to the order of the indices in `waveB` which are clipped (after permutation) to the valid range of entries in `waveA`. `waveB` is also permuted in place in order to allow you to obtain sequential permutations. If `waveA` consists of real numbers you can permute them using the lexicographic value of the entries directly. To do so pass "\$ " for `waveB`. Whenever it returns 0, neither `waveA` and `waveB` are changed.

## StatsPoissonCDF

---

### Examples

```
Function AllPermutations(num)
 Variable num

 Variable i,nf=factorial(num)
 Make/O/N=(num) wave0=p+1,waveA,waveB=p

 Print wave0
 for(i=0;i<nf;i+=1)
 waveA=wave0
 if(statsPermute(waveA,waveB,1)==0)
 break
 endif
 print waveA
 endfor
end
```

Executing AllPermutations(3) prints:

```
wave0[0] = {1,2,3}
waveA[0] = {1,3,2}
waveA[0] = {2,1,3}
waveA[0] = {2,3,1}
waveA[0] = {3,1,2}
waveA[0] = {3,2,1}
```

## StatsPoissonCDF

**StatsPoissonCDF**(*x*, *λ*)

The StatsPoissonCDF function returns the Poisson cumulative distribution function

$$F(x; \lambda) = \sum_{i=0}^x \frac{\exp(-\lambda) \lambda^i}{i!}, \quad x = 0, 1, 2, \dots$$

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPoissonPDF** and **StatsInvPoissonCDF** functions.

## StatsPoissonPDF

**StatsPoissonPDF**(*x*, *λ*)

The StatsPoissonPDF function returns the Poisson probability distribution function

$$f(x; \lambda) = \frac{\exp(-\lambda) \lambda^x}{x!}, \quad x = 0, 1, 2, \dots$$

where  $\lambda$  is the shape parameter.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPoissonCDF** and **StatsInvPoissonCDF** functions.

## StatsPowerCDF

**StatsPowerCDF**(*x*, *b*, *c*)

The StatsPowerCDF function returns the Power Function cumulative distribution function

$$F(x; b, c) = \left(\frac{x}{b}\right)^c$$

where the scale parameter *b* and the shape parameter *c* satisfy  $b, c > 0$  and  $b \geq x \geq 0$ .

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPowerPDF**, **StatsInvPowerCDF** and **StatsPowerNoise** functions.

**StatsPowerNoise****StatsPowerNoise**(*b*, *c*)

The StatsPowerNoise function returns a pseudorandom value from the power distribution function with probability distribution:

$$f(x; b, c) = \frac{c}{x} \left( \frac{x}{b} \right)^c.$$

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use SetRandomSeed. The algorithm uses the Mersenne Twister random number generator.

**See Also**

The **SetRandomSeed** operation.

The **StatsPowerPDF**, **StatsInvPowerCDF** and **StatsInvPowerCDF** functions.

**Noise Functions** on page III-390.

Chapter III-12, **Statistics** for a function and operation overview.

**StatsPowerPDF****StatsPowerPDF**(*x*, *b*, *c*)

The StatsPowerPDF function returns the Power Function probability distribution function

$$f(x, b, c) = \frac{|c|}{x} \left( \frac{x}{b} \right)^c,$$

where *b* is a scale parameter and *c* is a shape parameter.

For *b*, *c* > 0, *x* is drawn from *b* >= *x* >= 0.

For *b* > 0, *c* < 0, *x* is drawn from *x* > *b*.

For *b* < 0, *c* > 0, *x* is drawn from -*b* <= *x* <= 0.

For *b* < 0, *c* < 0, *x* is drawn from *x* < -*b*.

Note that for -1 < *c* < 0 the average diverges and the magnitude of a mean calculated from *N* samples will increase indefinitely with *N*.

**See Also**

Chapter III-12, **Statistics** for a function and operation overview; the **StatsPowerCDF**, **StatsInvPowerCDF** and **StatsPowerNoise** functions.

**StatsQCDF****StatsQCDF**(*q*, *r*, *c*, *df*)

The StatsQCDF function returns the value of the Q cumulative distribution function for *r* the number of groups, *c* the number of treatments, and *df* the error degrees of freedom (*f* = *rc*(*n*-1) with sample size *n*).

**Details**

The Q distribution is the maximum of several Studentized range statistics. For a simple Tukey test, use *r*=1.

Copenhaver, M.D., and B.S. Holland, Multiple comparisons of simple effects in the two-way analysis of variance with fixed effects, *Journal of Statistical Computation and Simulation*, 30, 1-15, 1988.

## StatsQpCDF

---

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsTukeyTest** function.

## StatsQpCDF

**StatsQpCDF**(*q*, *nr*, *nt*, *dt*, *side*, *sSizeWave*)

The StatsQpCDF function returns the Q' cumulative distribution function associated with Dunnett's test.

Here *nr* is the number of groups (should be set to 1), *nt* is the number of treatments, *df* is the error degrees of freedom.

Set *side*=1 for upper-tail or *side*=2 for two-tailed CDF.

*sSizeWave* is an integer wave of *nt* rows specifying the number of samples in each treatment.

### Details

StatsQpCDF is a modified Q distribution typically used with Dunnett's test, which compares the various means with the mean of the control group or treatment

## StatsQuantiles

**StatsQuantiles** [*flags*] *srcWave*

The StatsQuantiles operation computes quantiles and elementary univariate statistics for a set of data in *srcWave*.

### Flags

|                     |                                                                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /ALL                | Invokes all flags except /Q, /QM, and /Z.                                                                                                                                                                                  |
| /BOX                | Computes parameters necessary to construct a box plot.                                                                                                                                                                     |
| /iNaN               | Ignores NaNs, which are sorted to the end of the array by default.                                                                                                                                                         |
| /IW                 | Creates an index wave W_QuantilesIndex. W_QuantilesIndex[i] corresponds to the position of <i>srcWave</i> [i] when sorted from minimum to maximum.                                                                         |
| /Q                  | No information printed in the history area.                                                                                                                                                                                |
| /QM= <i>qMethod</i> | Specifies the method for computing quartiles. <i>qMethod</i> has one of these values:<br>0: Tukey (default).<br>1: Minitab.<br>2: Moore and McCabe.<br>3: Mendenhall and Sincich.<br><br>See Details for more information. |
| /QW                 | Creates a single precision wave W_QuantileValues containing the quantile value corresponding to each entry in <i>srcWave</i> .                                                                                             |
| /STBL               | Uses a stable sort, which may require significant computation time for multiple entries with the same value.                                                                                                               |

|                         |                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/T=k</code>       | Displays the result wave <code>W_StatsQuantiles</code> in a table and specifies window behavior when the user attempts to close the table.<br><code>k=0:</code> Normal with dialog (default).<br><code>k=1:</code> Kills with no dialog.<br><code>k=2:</code> Disables killing.<br><br>If you use <code>/K=2</code> you can still kill the window using the <b>KillWindow</b> operation. |
| <code>/TM</code>        | Computes the tri-mean: $0.25*(V\_Q25+2*median+V\_Q75)$ .                                                                                                                                                                                                                                                                                                                                 |
| <code>/TRIM=tVal</code> | Computes the trimmed mean which is the mean value of the entries between the quantiles <code>tVal</code> (in %) and $100-tVal$ . By default <code>tVal=25</code> and the trimmed mean corresponds to the midmean.                                                                                                                                                                        |
| <code>/Z</code>         | Ignores any errors.                                                                                                                                                                                                                                                                                                                                                                      |

### Details

StatsQuantiles produces quick five-number summaries or more detailed results for univariate data. Values are returned in the wave `W_StatsQuantiles` and in the variables:

|                       |                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>V_min</code>    | Minimum value.                                                                                                                                                                                                                                                                                                                                                         |
| <code>V_max</code>    | Maximum value.                                                                                                                                                                                                                                                                                                                                                         |
| <code>V_Median</code> | Median value.                                                                                                                                                                                                                                                                                                                                                          |
| <code>V_Q25</code>    | Lower quartile.                                                                                                                                                                                                                                                                                                                                                        |
| <code>V_Q75</code>    | Upper quartile.                                                                                                                                                                                                                                                                                                                                                        |
| <code>V_IQR</code>    | Inter-quartile range $V\_Q75-VQ25$ , which is also known as the H-spread.                                                                                                                                                                                                                                                                                              |
| <code>V_MAD</code>    | Median absolute deviation.                                                                                                                                                                                                                                                                                                                                             |
| <code>V_mode</code>   | The most frequent value.<br><br>If there is a tie and several values have the highest frequency then the lowest value among them is returned as the mode.<br><br>If all values in <code>srcWave</code> are unique or if the number of points in <code>srcWave</code> is less than 3, <code>V_mode</code> is set to NaN.<br><br>This output was added in Igor Pro 7.00. |

Entries in the wave `W_StatsQuantiles` depend on your choice of flags. Each row has a row label explicitly defining its value. If you use the `/ALL` flag, `W_StatsQuantiles` will contain the following row labels:

|                                      |                              |
|--------------------------------------|------------------------------|
| <code>minValue</code>                | <code>lowerInnerFence</code> |
| <code>maxValue</code>                | <code>lowerOuterFence</code> |
| <code>Median</code>                  | <code>upperInnerFence</code> |
| <code>Q25</code>                     | <code>upperOuterFence</code> |
| <code>Q75</code>                     | <code>triMean</code>         |
| <code>IQR</code>                     | <code>trimmedMean</code>     |
| <code>MedianAbsoluteDeviation</code> |                              |

Otherwise, `W_StatsQuantiles` will contain the first five entries and any additionally requested value. You should always access values using the dimension labels (see **Dimension Labels** on page II-93).

There is frequently some confusion in comparing statistical results computed by different programs because each may use a different definition of quartiles. You can specify the method of computing the quartiles as you prefer with the `/QM` flag. If you neglect to choose a method, StatsQuantiles uses Tukey's method, which computes quartiles (also called hinges) as the lower and upper median values between the

## StatsRankCorrelationTest

---

median of the data and the edges of the array. The Moore and McCabe method is similar to Tukey's method except you do not include the median itself in computing the quartiles. Mendenhall and Sincich compute the quartiles using 1/4 and 3/4 of (numDataPoints+1) and round to the nearest integer (if the fraction part is exactly 0.5 they round up for the lower quartile and down for the upper quartile). Minitab uses the same expressions but instead of rounding it uses linear interpolation.

StatsQuantiles uses a stable index sorting routine so that

```
IndexSort W_QuantilesIndex,srcWave
```

is a monotonically increasing wave.

## StatsRankCorrelationTest

**StatsRankCorrelationTest** [*flags*] *waveA*, *waveB*

The StatsRankCorrelationTest operation performs Spearman's rank correlation test on *waveA* and *waveB*, 1D waves containing the same number of points. Output is to the W\_StatsRankCorrelationTest wave in the current data folder.

### Details

StatsRankCorrelationTest ranks *waveA* and *waveB* and then computes the sum of the squared differences of ranks for all rows. Ties are assigned an average rank and the corrected Spearman rank correlation coefficient is computed with ties. It reports the sum of the squared ranks (sumDi2), the sums of the ties coefficients (sumTx and sumTy respectively), the Spearman rank correlation coefficient (in the range [-1,1]), and the critical value.  $H_0$  corresponds to zero correlation against the alternative of nonzero correlation. The critical value is usually lower than the one in published tables. When the first derivative of the CDF is discontinuous, tables tend to use a more conservative value by choosing the next transition of the CDF as the critical value. StatsRankCorrelationTest is not as powerful as **StatsLinearCorrelationTest**.

## StatsRayleighCDF

**StatsRayleighCDF**(*x* [, *s* [, *m*]])

The StatsRayleighCDF function returns the Rayleigh cumulative distribution function

$$F(x; \sigma, \mu) = 1 - \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right), \quad \sigma > 0, x > \mu.$$

with defaults *s*=1 and *m*=0. It returns NaN for *s* ≤ 0 and zero for *x* ≤ *m*.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRayleighPDF** and **StatsInvRayleighCDF** functions.

## StatsRayleighPDF

**StatsRayleighPDF**(*x* [, *s* [, *m*]])

The StatsRayleighPDF function returns the Rayleigh probability distribution function

$$f(x; \sigma, \mu) = \frac{x - \mu}{\sigma^2} \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right), \quad \sigma > 0, x > \mu.$$

with defaults *s*=1 and *m*=0. It returns NaN for *s* ≤ 0 and zero for *x* ≤ *m*.

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRayleighCDF** and **StatsInvRayleighCDF** functions.

## StatsRectangularCDF

**StatsRectangularCDF**(*x*, *a*, *b*)

The StatsRectangularCDF function returns the rectangular (uniform) cumulative distribution function

$$F(x, a, b) = \begin{cases} 0 & x \leq a \\ \frac{x - a}{b - a} & a \leq x \leq b \\ 1 & x \geq b \end{cases}$$

where *a* < *b*.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; the **StatsRectangularPDF** and **StatsInvRectangularCDF** functions.

## StatsRectangularPDF

**StatsRectangularPDF**(*x*, *a*, *b*)

The StatsRectangularPDF function returns the rectangular (uniform) probability distribution function

$$f(x; a, b) = \begin{cases} \frac{1}{b - a} & a \leq x \leq b \\ 0 & \text{otherwise} \end{cases}$$

where  $a < b$ .

## StatsResample

**StatsResample** /N=*numPoints* [*flags*] *srcWave*

The StatsResample operation resamples *srcWave* by drawing (with replacement) *numPoints* values from *srcWave* and storing them in the wave W\_Resampled or M\_Resampled if /MC is used. You can iterate the process and compute various statistics on the data samples.

### Flags

*/ITER=n* Repeats the resampling for *n* iterations, which is useful only when combined with */WS* or */SQ*.

The */ITER* flag is ignored by the Jack-Knife analysis (*/JCKN*).

*/JCKN=ufunc* Performs Jack-Knife analysis. Here *ufunc* is a user function of the format:

```
Function ufunc(inWave)
 wave inWave
 ... compute some statistic for inWave
 return someValue
End
```

The results are stored in the wave W\_JackKnifeStats in the current data folder. Use

Edit W\_JackKnifeStats.ld

to display the wave with dimension labels.

In the Jack-Knife method the operation runs *N* iterations where *N* is the number of points in *srcWave*. In each iteration the operation calls the user-defined function *ufunc(inWave)* passing it an internal wave which contains (*N*-1) samples from *srcWave*. The function computes some user-defined statistic, say "Z", and stores it in *inWave*. At the end of iterations the operation uses the Z values in *inWave* to compute various Jack-Knife estimates. The standard estimator is defined as:

$$Z = ufunc(srcWave).$$

The Jack-Knife estimator is simply:

$$\hat{z} = \frac{1}{n} \sum_{i=1}^n z_i.$$

The Jack-Knife t-estimator is slightly less biased. It is given by:

$$t = nZ - (n - 1)\hat{z},$$

The estimate of the standard error is given by:

$$\hat{\sigma}_{\hat{z}} = \sqrt{\frac{n-1}{n} \sum_{i=1}^n (z_i - \hat{z})^2}.$$

The Jack-Knife analysis ignores the */N* and */ITER* flags. The number of points and the number of iterations are determined by the number of points in *srcWave*.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/K</code>           | Kills <code>W_Resampled</code> after passing it to <code>WaveStats</code> . When <code>/ITER</code> is used, <code>W_Resampled</code> is not saved.                                                                                                                                                                                                                                                       |
| <code>/MC</code>          | Use <code>/MC</code> when you want to sample random (complete) rows from a multi-column 2D <code>srcWave</code> . The combination of <code>/N=n</code> with <code>/MC</code> results in the wave <code>M_Resampled</code> in the current data folder. <code>M_Resampled</code> will have <code>n</code> rows, the same number of columns and the same data type as <code>srcWave</code> .                 |
| <code>/N=numPoints</code> | Specifies the number of points sampled from <code>srcWave</code> .<br>The <code>/N</code> flag is ignored by the Jack-Knife analysis ( <code>/JCKN</code> ).                                                                                                                                                                                                                                              |

### Details

StatsResample can perform Bootstrap Analysis, permutations tests, and Monte-Carlo simulations. It draws the specified number of data points (with replacement) from `srcWave` and places them in a destination wave `W_Resampled`.

Specify `/WS` or `/SQ` to use the `WaveStats` or `StatsQuantiles` operations, respectively, to compute results directly from the data. StatsResample normally creates the wave `W_Resampled` and, optionally, the `M_WaveStats` and `W_StatsQuantiles` waves. Both options also create various `V_` variables described below. If you use more than one iteration, StatsResample creates instead the waves `M_WaveStatsSamples` and `M_StatsQuantilesSamples` for the results.

`M_WaveStatsSamples` (with `/WS`) contains a column for each iteration. Each column is equivalent to the contents of `M_WaveStats` for that iteration. You can use the command

```
Edit M_WaveStatsSamples.ld
```

to display the results in a table using row labels, and, for example, to display a graph of the rms of the samples as a function of iteration number execute:

```
Display M_WaveStatsSamples[5] []
```

`M_StatsQuantilesSamples` (with `/SQ`) contains a column for each iteration. Each column consists of the contents of `W_StatsQuantiles` for the corresponding data. Here again you can execute the command

```
Edit M_StatsQuantilesSamples.ld
```

to display the wave in a table using row labels. To display a graph of the median as a function of iteration execute:

```
Display M_statsQuantilesSamples[2] []
```

### Output Variables

StatsResample creates the following variables: `V_Median`, `V_Q25`, `V_Q75`, `V_IQR`, `V_min`, `V_max`, `V_numNaNs`, `V_numINFs`, `V_avg`, `V_sdev`, `V_rms`, `V_adev`, `V_skew`, `V_kurt`, and `V_Sum`.

These variables are valid only if you use either `/SQ` or `/WS`, but not both, and only if you do not use `/ITER`. Unused variables are set to NaN.

## StatsSample

---

If you use /SQ the operation sets V\_Median, V\_Q25, V\_Q75, V\_IQR, V\_min, and V\_max.

If you use /WS the operation sets V\_min, V\_max, V\_numNaNs, V\_numINFs, V\_avg, V\_sdev, V\_rms, V\_adev, V\_skew, V\_kurt, and V\_Sum.

### See Also

## StatsSample

**StatsSample** /N=*numPoints* [*flags*] *srcWave*

StatsSample creates a random, non-repeating sample from *srcWave*.

It samples *srcWave* by drawing without replacement *numPoints* values from *srcWave* and storing them in the output wave W\_Sampled or M\_Sampled if /MC or /MR are used.

The /N flag is required.

### Flags

|                      |                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /ACMB                | Creates a wave containing all unique combinations of <i>numPoints</i> values from <i>srcWave</i> . It is assumed that <i>srcWave</i> is a 1D numeric wave containing more than <i>numPoints</i> elements. The results are stored in the wave M_Combinations in the current data folder. Each row in the result wave corresponds to a unique combination of samples.<br>Added in Igor Pro 7.00. |
| /CMPL                | Stores all data elements from <i>srcWave</i> that were excluded from the random sample in the wave W_CompWave or M_CompWave in the current data folder. /CMPL was added in Igor Pro 8.00.                                                                                                                                                                                                      |
| /N= <i>numPoints</i> | Specifies the number of points sampled from <i>srcWave</i> . When combined with /MC, <i>numPoints</i> is the number of sampled rows and when combined with /MR, it is the number of sampled columns.                                                                                                                                                                                           |
| /MC                  | Use /MC (multi-column) to randomly sample full rows from <i>srcWave</i> , i.e., the output consists of all columns of each selected row. /MC and /MR are mutually exclusive flags.                                                                                                                                                                                                             |
| /MR                  | Use /MR (multi-row) to randomly sample full columns from <i>srcWave</i> , i.e., the output consists of all rows of each of the selected columns. /MC and /MR are mutually exclusive flags.                                                                                                                                                                                                     |
| /Z                   | Ignores errors.                                                                                                                                                                                                                                                                                                                                                                                |

### Details

If you omit /MC and /MR, the output is a 1D wave named W\_Sampled where the samples are chosen from *srcWave* without regard to its dimensionality.

If you use either /MC or /MR the output is a 2D wave named M\_Sampled which will have either the same number of columns (/MC) as *srcWave* or the same number of rows (/MR) as *srcWave*.

## StatsRunsCDF

**StatsRunsCDF**(*n*, *r*)

The StatsRunsCDF function returns the cumulative distribution function for the up and down runs distribution for total number of runs *r* in a random linear arrangement of *n* unequal elements. There is no closed form expression. It is computed numerically from the recursion of the probability density

$$f(r,n) = \frac{rf(r,n-1) + 2f(r-1,n-1) + (n-r)f(r-2,n-1)}{n},$$

with the initial condition

$$f(1,n) = \frac{2}{n!}.$$

Chapter III-12, **Statistics** for a function and operation overview; the **StatsSRTTest** function.

## StatsScheffeTest

**StatsScheffeTest** [*flags*] [*wave1*, *wave2*, ... *wave100*]

The StatsScheffeTest operation performs Scheffe's test for the equality of the means. It supports two basic modes: the default tests all possible combinations of pairs of waves; the second tests a single combination where the precise form of  $H_0$  is determined by the coefficients of a contrast wave (see /CONT). Output is to the M\_ScheffeTestResults wave in the current data folder.

### Flags

/ALPH=*val* Sets the significance level (default 0.05).

/CONW=*cWave* Performs a multiple contrasts test. *cWave* has one point for each input wave. The *cWave* value is 1 to include the corresponding (zero based) input wave in the first group, 2 to include the wave in the second group, or zero to exclude the wave.

The contrast is defined as the difference between the normalized sum of the ranks of the first group and that of the second group. If  $cWave=\{0,1,1,2\}$ , then the contrast hypothesis  $H_0$  corresponds to:

$$\frac{\bar{X}_1 + \bar{X}_2 + \bar{X}_3}{3} - \bar{X}_4 = 0.$$

For each pair of waves ( $i, j$ ) with  $i \neq j$ , it computes

$$SE_{ij} = \sqrt{s^2 \left( \frac{1}{n_j} + \frac{1}{n_i} \right)}, \quad s^2 = \sum_{i=1}^W \sum_{j=0}^{n_j-1} X_j^2 - \sum_{i=1}^W \frac{\left( \sum_{j=0}^{n_j-1} X_j \right)^2}{n_j},$$

the statistic

$$S = \frac{\left| \sum_{i=0}^{n-1} c_i \bar{X}_i \right|}{SE},$$

## StatsShapiroWilkTest

---

the critical value, and a result field which is set to 1 if  $H_0$  should be accepted or 0 if it should be rejected.  $W$  is the total number of waves,  $n_i$  and  $\bar{X}_i$  are respectively the number of data points and the average of wave  $i$ .

|                              |                                                                                                                                                                                          |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /Q                           | No results printed in the history area.                                                                                                                                                  |
| /SWN                         | Creates a text wave, T_ScheffeDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column. |
| /T=k                         | Displays results in a table. $k$ specifies the table behavior when it is closed.<br>$k=0$ : Normal with dialog (default).<br>$k=1$ : Kills with no dialog.<br>$k=2$ : Disables killing.  |
|                              | The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.                                                     |
| /WSTR= <i>waveListString</i> | Specifies a string containing a semicolon-separated list of waves that contain sample data. Use <i>waveListString</i> instead of listing each wave after the flags.                      |
| /Z                           | Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.                                                                                                            |

### Details

The default of StatsScheffeTest (also known as the S test) tests the hypotheses of equality of means for each possible pair of samples. It is not as powerful as Tukey's test (**StatsTukeyTest**) and is more useful for hypotheses formulated as multiple contrasts (see /CONT).

Zar, J.H., *Biostatistical Analysis*, 4th ed., 929 pp., Prentice Hall, Englewood Cliffs, New Jersey, 1999.

### See Also

Chapter III-12, **Statistics** for a function and operation overview; **StatsANOVA1Test**, **StatsDunnettTest** and **StatsTukeyTest**.

## StatsShapiroWilkTest

**StatsShapiroWilkTest** [*flags*] *srcWave*

The StatsShapiroWilkTest computes Shapiro-Wilk statistic  $W$  and its associated P-value and stores them in V\_statistic and V\_prob respectively.

### Flags

|    |                                         |
|----|-----------------------------------------|
| /Q | No results printed in the history area. |
| /Z | Ignores errors.                         |

### Details

The Shapiro-Wilk tests the null hypothesis that the population is normally distributed. If the P-value is less than the selected alpha then the null hypothesis, normality, is rejected.

The test is valid only for waves containing 3 to 5000 data points. The operation ignores any NaNs or INFs in *srcWave*.

### Example

```
// Test normally distributed data
Make/O/N=(200) ggg=gnoise(5)
StatsShapiroWilkTest ggg
W=0.995697 p=0.846139 // p>alpha so accept normality
```

```
// Test uniform distribution
Make/O/N=(200) eee=enoise(5)
StatsShapiroWilkTest eee
W=0.959616 p=1.7979e-05 // p<alpha so reject normality
```

## StatsSignTest

**StatsSignTest** [*flags*] *wave1*, *wave2*

The StatsSignTest operation performs the sign test for paired-sample data contained in *wave1* and *wave2*.

### Flags

*/ALPH=val* Sets the significance level (default 0.05).

*/Q* No results printed in the history area.

*/T=k* Displays results in a table. *k* specifies the table behavior when it is closed.

*k=0:* Normal with dialog (default).

*k=1:* Kills with no dialog.

*k=2:* Disables killing.

*/Z* Ignores errors. *V\_flag* will be set to -1 for any error and to zero otherwise.

### Details

The input waves must be the equal length, real numeric waves and must not contain any NaNs or INFs. Results are saved in the wave *W\_SignTest* and are optionally displayed in a table. StatsSignTest computes the differences in each pair and counts the total number of entries with positive and negative differences, and tests the results using a binomial distribution. When the number of data pairs exceeds 1024 it uses a normal approximation to the binomials for calculating the probabilities and the power of the test.

## StatsSpearmanRhoCDF

**StatsSpearmanRhoCDF** (*r*, *N*)

The StatsSpearmanRhoCDF function returns the cumulative distribution function for Spearman's *r*, which is used in rank correlation test. It is valid for  $N > 1$  and  $-1 \leq r \leq 1$ . The distribution is mostly computed using the Edgeworth series expansion.

## StatsSRTest

**StatsSRTest** [*flags*] *srcWave*

The StatsSRTest operation performs a parametric or nonparametric serial randomness test on *srcWave*, which must contain finite numerical data. The null hypothesis of the test is that the data are randomly distributed. Output is to the *W\_StatsSRTest* wave in the current data folder.

**Flags**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /ALPH = <i>val</i> | Sets the significance level (default <i>val</i> =0.05).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| /GCD               | Tests the output of a random number generator (RNG). <i>srcWave</i> consists of values between 0 and $2^{32}$ (converted to unsigned 32-bit integers). GCD computes the gcd for consecutive pairs of data in <i>srcWave</i> . The number of steps in the GCD and the distribution of the GCD's are compared with ideal distributions and corresponding P values are reported. This test is part of Marsaglia's Die-Hard battery of tests. P-values close to either 0 or 1 indicate a nonideal RNG. You should use the reported minimum and maximum values to check that the input is indeed in the proper range. Typically <i>srcWave</i> consists of at least $1e6$ entries. |
| /NAPR              | Use the normal approximation even when the number of points is below 150.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| /NP                | Performs a nonparametric serial randomness test by counting the numbers of runs up and down and computing the probability that such a value is obtained by chance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| /P                 | Performs a parametric serial randomness test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| /Q                 | No results printed in the history area.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Details**

The parametric test for serial randomness is according to Young. *C* is given by

$$C = 1 - \frac{\sum_{i=0}^{n-2} (X_i - X_{i+1})^2}{2 \sum_{i=0}^{n-1} (X_i - \bar{X})^2},$$

where  $\bar{X}$  is the mean and *n* is the number of points in *srcWave*. The critical value is obtained from mean square successive difference distribution **StatsInvCMSSDCDF**. For more than 150 points, StatsSRTest uses the normal approximation and provides the critical values from the normal distribution. For samples from a normal distribution, *C* is symmetrically distributed about 0 with positive values indicating positive correlation between successive entries and negative values corresponding to negative correlation.

The nonparametric test consists of counting the number of runs that are successive positive or successive negative differences between sequential data. If two sequential data are the same it computes two numbers of runs by considering the two possibilities where the equality is replaced with either a positive or a negative difference. The results of the operation include the number of runs up and down, the number of unchanged values (the number of places with no difference between consecutive entries), the size of the longest run and its associated probability, the number of converted equalities, and the probability that the number of runs is less than or equal to the reported number (**StatsRunsCDF**). When equalities are encountered the operation computes the probabilities that the computed number of runs or less can be found in an equivalent random sequence.

Converted equalities are those with the same sign on both sides so that when we replace the equality by the opposite sign we increase the number of runs. The equalities that are not converted are found between two different signs and therefore regardless of the sign that we give them they do not affect the total number of runs. We implicitly assume that the data does not contain more than one sequential equalities.

The longest run is determined without taking into account equalities or their conversions. The probability of the longest run is computed from Equation 6 of Olmstead, which is accurate within 0.001 when the

number of runs is 5 or more. This probability applies to either positive or negative differences and should be divided by two if a specific sign is selected.

## StatsStudentCDF

**StatsStudentCDF**(*t*, *n*)

The StatsStudentCDF function returns the Student (uniform) cumulative distribution function

$$F(t,n) = \begin{cases} \frac{1}{2} \left\{ 1 + I\left(\frac{n}{2}, \frac{1}{2}; 1\right) - I\left(\frac{n}{2}, \frac{1}{2}; \frac{n}{n+t^2}\right) \right\} & t > 0 \\ \frac{1}{2} \left\{ 1 + I\left(\frac{n}{2}, \frac{1}{2}; \frac{n}{n+t^2}\right) - I\left(\frac{n}{2}, \frac{1}{2}; 1\right) \right\} & t < 0 \\ \frac{1}{2} & t = 0 \end{cases}$$

where  $n > 0$  is degrees of freedom and  $I$  is the incomplete beta function **betai**.

## StatsStudentPDF

**StatsStudentPDF**(*t*, *n*)

The StatsStudentPDF function returns the Student (uniform) probability distribution function

$$f(t,n) = \frac{\left(\frac{n}{n+t^2}\right)^{(n+1)/2}}{\sqrt{n} B\left(\frac{n}{2}, \frac{1}{2}\right)}$$

where  $n > 0$  is degrees of freedom and  $B()$  is the **beta** function.

## StatsTopDownCDF

**StatsTopDownCDF**(*r*, *N*)

The StatsTopDownCDF function returns the cumulative distribution function for the top-down correlation coefficient. It is computationally intensive because it must evaluate many permutations [ $O((n!)^2)$ ]. It exactly calculates the distribution for  $3 \leq N \leq 7$ ; outside this range it uses Monte-Carlo estimation for  $8 \leq N \leq 50$  and asymptotic Normal approximation for  $N > 50$ . The Monte-Carlo estimate uses 1e6 random permutations fitted with two 9-order polynomials for the range [-1,0] and [0,1]. The results are within 0.2% of exact values where known.

## StatsTriangularCDF

**StatsTriangularCDF**(*x*, *a*, *b*, *c*)

The StatsTriangularCDF function returns the triangular cumulative distribution function

$$F(x; a, b, c) = \begin{cases} 0 & x \leq a \\ \frac{(x-a)^2}{(b-a)(c-a)} & a < x \leq c \\ 1 - \frac{(b-x)^2}{(b-a)(b-c)} & c < x < b \\ 1 & x \geq b \end{cases}$$

where  $a < c < b$ .

Chapter III-12, **Statistics** for a function and operation overview; the **StatsTriangularPDF** and **StatsInvTriangularCDF** functions.

## StatsTriangularPDF

**StatsTriangularPDF**(*x*, *a*, *b*, *c*)

The StatsTriangularPDF function returns the triangular probability distribution function

$$f(x; a, b, c) = \begin{cases} \frac{2(x-a)}{(b-a)(c-a)} & a \leq x < c \\ \frac{2(b-x)}{(b-a)(b-c)} & c < x \leq b \\ 0 & \text{Otherwise} \end{cases}$$

where  $a < c < b$ .

## StatsTrimmedMean

**StatsTrimmedMean**(*waveName*, *trimValue*)

The StatsTrimmedMean function returns the mean of the wave *waveName* after removing *trimValue* fraction of the values from both tails of the distribution. *trimValue* is a number in the range [0, 0.5]. *waveName* can be any real numeric type.

Chapter III-12, **Statistics** for a function and operation overview; **StatsQuantiles** and **mean**.

## StatsTTest

**StatsTTest** [*flags*] *wave1* [, *wave2*]

The StatsTTest operation performs two kinds of T-tests: the first compares the mean of a distribution with a specified mean value (/MEAN) and the second compares the means of the two distributions contained in *wave1* and *wave2*, which must contain at least two data points, can be any real numeric type, and can have an arbitrary number of dimensions. Output is to the W\_StatsTTest wave in the current data folder or optionally to a table.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /ALPH = <i>val</i>  | Sets the significance level (default <i>val</i> =0.05).                                                                                                                                                                                                                                                                                                                                                                 |
| /CI                 | Computes the confidence intervals for the mean(s).                                                                                                                                                                                                                                                                                                                                                                      |
| /DFM= <i>m</i>      | Specifies method for calculating the degrees of freedom.<br><i>m</i> =0: Default; computes equivalent degrees of freedom accounting for possibly different variances.<br><i>m</i> =1: Computes equivalent degrees of freedom but truncates to a smaller integer.<br><i>m</i> =2: Computes degrees of freedom by $DF=n_1+n_2-2$ , where <i>n</i> is the sum of points in the wave. Appropriate when variances are equal. |
| /MEAN= <i>meanV</i> | Compares <i>meanV</i> with the mean of the distribution in <i>wave1</i> . Outputs are the number of points in the wave, the degrees of freedom (accounting for any NaNs), the average, standard deviation ( $\sigma$ ),                                                                                                                                                                                                 |

$$s_{\bar{X}} = \frac{\sigma}{\sqrt{DF + 1}},$$

the statistic

$$t = \frac{\bar{X} - meanV}{s_{\bar{X}}}$$

and the critical value, which depends on /TAIL.

|       |                                                                                                                                                                                                                                    |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /PAIR | Specifies that the input waves are pairs and computes the difference of each pair of data to get the average difference $\bar{d}$ and the standard error of the difference $S_{\bar{d}}$ . The t statistic is the ratio of the two |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

$$t = \frac{\bar{d}}{S_{\bar{d}}}.$$

In this case  $H_0$  is that the difference  $\bar{d}$  is zero.

This mode does not support /CI and /DFM.

|    |                                         |
|----|-----------------------------------------|
| /Q | No results printed in the history area. |
|----|-----------------------------------------|

- /T=k*                      Displays results in a table. *k* specifies the table behavior when it is closed.  
*k=0*:                      Normal with dialog (default).  
*k=1*:                      Kills with no dialog.  
*k=2*:                      Disables killing.
- The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
- /TAIL=tailCode*        Specifies  $H_0$ .  
*tailCode=1*:              One tailed test ( $\mu_1 \leq \mu_2$ ).  
*tailCode=2*:              One tailed test ( $\mu_1 \geq \mu_2$ ).  
*tailCode=4*:              Default; two tailed test ( $\mu_1 = \mu_2$ ).
- When performing paired tests using */PAIR*:  
*tailCode=1*:              One tailed test ( $\mu_d \leq 0$ ).  
*tailCode=2*:              One tailed test ( $\mu_d \geq 0$ ).  
*tailCode=4*:              Default; two tailed test ( $\mu_d = 0$ ).
- Here  $\mu_d$  is the mean of the difference population.
- /Z*                              Ignores errors. *V\_flag* will be set to -1 for any error and to zero otherwise.

**Details**

When comparing the mean of a single distribution with a hypothesized mean value, you should use */MEAN* and only one wave (*wave1*). If you use two waves StatsTTest performs the T-test for the means of the corresponding distributions (which is incompatible with */MEAN*).

When comparing the means of two distributions, the default t-statistic is computed from Welch's approximate t:

$$t' = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}},$$

where  $s_i^2$  are variances,  $n_i$  the number of samples, and  $\bar{x}_i$  the averages of the respective waves. This expression is appropriate when the number of points and the variances of the two waves are different. If you want to compute the t-statistic using pooled variance you can use the */AEVR* flag. In this case the pooled variance is given by

$$s_p^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2},$$

and the t-statistic is

$$t = \frac{\bar{x}_1 - \bar{x}_2}{s_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}.$$

The different test are:

| $H_0$           | Rejection Condition        |
|-----------------|----------------------------|
| $\mu_1 = \mu_2$ | $ t  \geq Tc(\alpha, \nu)$ |
| $\mu_1 > \mu_2$ | $t \leq Tc(\alpha, \nu)$   |
| $\mu_1 < \mu_2$ | $t \geq Tc(\alpha, \nu)$   |

$Tc$  is the critical value and  $\nu$  is the effective number of degrees of freedom (see /DFM flag). When accounting for possibly unequal variances,  $\nu$  is given by

$$\nu = \frac{\left( \frac{s_1^2}{n_1} + \frac{s_2^2}{n_2} \right)^2}{\frac{\left( \frac{s_1^2}{n_1} \right)^2}{n_1 - 1} + \frac{\left( \frac{s_2^2}{n_2} \right)^2}{n_2 - 1}}$$

The critical values ( $Tc$ ) are computed by numerically by solving for the argument at which the cumulative distribution function (CDF) equals the appropriate values for the tests. The CDF is given by

$$F(x) = \begin{cases} \frac{1}{2} \text{betai} \left( \frac{\nu}{2}, \frac{1}{2}, \frac{\nu}{\nu + x^2} \right) & x < 0 \\ 1 - \frac{1}{2} \text{betai} \left( \frac{\nu}{2}, \frac{1}{2}, \frac{\nu}{\nu + x^2} \right) & x \geq 0. \end{cases}$$

To get the critical value for the upper one-tail test we solve  $F(x)=1-\alpha$ . For the lower one-tail test we solve for  $x$  the equation  $F(x)=\alpha$ . In the two-tailed test the lower critical value is a solution for  $F(x)=\alpha/2$  and the upper critical value is a solution for  $F(x)=1-\alpha/2$ .

The T-test assumes both samples are randomly taken from normal population distributions.

## StatsTukeyTest

**StatsTukeyTest** [*flags*] [*wave1*, *wave2*,... *wave100*]

The StatsTukeyTest operation performs multiple comparison Tukey (HSD) test and optionally the Newman-Keuls test. Output is to the M\_TukeyTestResults wave in the current data folder. StatsTukeyTest usually follows **StatsANOVA1Test**.

#### Flags

|                    |                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /ALPH = <i>val</i> | Sets the significance level (default <i>val</i> =0.05).                                                                                                                                |
| /NK                | Computes the Newman-Keuls test.                                                                                                                                                        |
| /Q                 | No results printed in the history area.                                                                                                                                                |
| /SWN               | Creates a text wave, T_TukeyDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column. |

## StatsUSquaredCDF

---

*/T=k* Displays results in a table. *k* specifies the table behavior when it is closed.

*k=0*: Normal with dialog (default).

*k=1*: Kills with no dialog.

*k=2*: Disables killing.

*/WSTR=waveListString*

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.

*/Z* Ignores errors.

### Details

Inputs to StatsTukeyTest are two or more 1D numeric waves (one wave for each group of samples) containing any numbers of points but with at least two or more valid entries.

The contents of the M\_TukeyTestResults columns are: the first contains the difference between the group means  $\bar{X}_i - \bar{X}_j$ , the second contains SE (supports unequal number of points), the third contains the q statistic for the pair, and the fourth contains the critical q value, the fifth contains the conclusion with 0 to reject  $H_0$  ( $\mu_i = \mu_j$ ) or 1 to accept  $H_0$ , with */NK*, the sixth contains the *p* values

$$p = \text{rank}[\bar{X}_i] - \text{rank}[\bar{X}_j] + 1,$$

the seventh contains the critical values, and the eighth contains the Newman-Keuls conclusion (with 0 to reject and 1 to accept  $H_0$ ). The order of the rows is such that all possible comparisons are computed sequentially starting with the comparison of the group having the largest mean with the group having the smallest mean.

V\_flag will be set to -1 for any error and to zero otherwise.

## StatsUSquaredCDF

**StatsUSquaredCDF**(*u2*, *n*, *m*, *method*, *useTable*)

The StatsUSquaredCDF function returns the cumulative distribution function for Watson's  $U^2$  with parameters *u2* ( $U^2$  statistic) and integer sample sizes *n* and *m*. The calculation is computationally intensive, on the order of binomial(*n+m*, *m*). Use a nonzero value for *useTable* to search a built-in table of values. If *n* and *m* cannot be found in the table, it will proceed according to *method*:

| <i>method</i> | What It Does                                              |
|---------------|-----------------------------------------------------------|
| 0             | Exact computation using Burr algorithm (could be slow).   |
| 1             | Tiku approximation using chi-squared.                     |
| 2             | Use built-in table only and return a NaN if not in table. |

For large *n* and *m*, consider using the Tiku approximation. To abort execution, press the **User Abort Key Combinations**.

Precomputed tables, using the algorithm described by Burr, contain these values:

| <i>n</i> | <i>m</i> |
|----------|----------|
| 4        | 4-30     |
| 5        | 5-30     |
| 6        | 6-30     |
| 7        | 7-30     |

| <i>n</i> | <i>m</i> |
|----------|----------|
| 8        | 8-26     |
| 9        | 9-22     |
| 10       | 10-18    |
| 11       | 11-16    |
| 12       | 12-14    |
| 13       | 13       |

Because *n* and *m* are interchangeable, *n* should always be the smaller value. For *n*>8 the upper limit in the table matched the maximum that can be computed using the Burr algorithm. There is no point in using method 0 with *m* values exceeding these limits.

## StatsVariancesTest

**StatsVariancesTest** [*flags*] [*wave1*, *wave2*,... *wave100*]

The StatsVariancesTest operation performs Bartlett's or Levene's test to determine if wave variances are equal. Output is to the W\_StatsVariancesTest wave in the current data folder or optionally to a table.

### Flags

/ALPH=*val* Sets the significance level (default *val*=0.05).

/METH=*m* Specifies the test type.

*m*=0: Bartlett test (default).

*m*=1: Levene's test using the mean.

*m*=2: Modified Levene's test using the median.

*m*=3: Modified Levene's test using the 10% trimmed mean.

/Q No results printed in the history area.

/T=*k* Displays results in a table. *k* specifies the table behavior when it is closed.

*k*=0: Normal with dialog (default).

*k*=1: Kills with no dialog.

*k*=2: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/WSTR=*waveListString*

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.

/Z Ignores errors. V\_flag will be set to -1 for any error and to zero otherwise.

### Details

All tests define the null hypothesis by

$$H_0 : \quad \sigma_1^2 = \sigma_2^2 = \dots = \sigma_k^2,$$

against the alternative

$$H_a : \quad \sigma_i^2 \neq \sigma_j^2 \text{ for at least one } i \neq j.$$

Bartlett's test computes:

$$T = \frac{(n-k)\ln(\sigma_w^2) - \sum_{i=1}^k (n_i - 1)\ln(\sigma_i^2)}{1 + \frac{1}{3(k-1)} \left[ \sum_{i=1}^k \frac{1}{n_i - 1} - \frac{1}{N - k} \right]}.$$

Here  $\sigma_i^2$  is the variance of the  $i$ th wave,  $N$  is the sum of the points of all the waves,  $n_i$  is the number of points in wave  $i$ , and  $k$  is the number of waves. The weighted variance is given by

$$\sigma_w^2 = \sum_{i=1}^k \frac{(n_i - 1)\sigma_i^2}{N - k}.$$

$H_0$  is rejected if  $T$  is greater than the critical value taken from the  $\chi^2$  distribution computed by solving for  $x$ :

$$1 - \alpha = 1 - \text{gammap}\left(\frac{k-1}{2}, \frac{x}{2}\right).$$

Levene's test computes:

$$W = \frac{(N-k) \sum_{i=1}^k n_i (\bar{Z}_i - \bar{Z})^2}{(k-1) \sum_{i=1}^k \sum_{j=1}^k (Z_{ij} - \bar{Z}_i)^2},$$

where

$$Z_{ij} = |Y_{ij} - \bar{Y}_i|,$$

$$\bar{Z}_i = \frac{1}{n_i} \sum_{j=1}^k Z_{ij},$$

$$\bar{Z} = \frac{1}{N} \sum_{i=1}^k \sum_{j=1}^k Z_{ij}.$$

$\bar{Y}_i$  depends on /METH.

$H_0$  is rejected if  $W$  is greater than the critical value from the F distribution computed by solving for  $x$ :

$$1 - \alpha = 1 - \text{betai}\left(\frac{v_2}{2}, \frac{v_1}{2}, \frac{v_2}{v_2 + v_1 x}\right).$$

## StatsWatsonUSquaredTest

**StatsWatsonUSquaredTest** [*flags*] *srcWave1*, *srcWave2*

The StatsWatsonUSquaredTest operation performs Watson's nonparametric two-sample  $U^2$  test for samples of circular data. Output is to the *W\_WatsonUtest* wave in the current data folder or optionally to a table.

### Flags

*/ALPH = val*      Sets the significance level (default *val*=0.05).

*/Q*                No results printed in the history area.

*/T=k*              Displays results in a table. *k* specifies the table behavior when it is closed.

*k=0:*            Normal with dialog (default).

*k=1:*            Kills with no dialog.

*k=2:*            Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

*/Z*                Ignores errors.

**Details**

The input waves, *srcWave1* and *srcWave2*, each must contain at least two angles in radians (mod  $2\pi$ ), can have any number of dimensions, and can be single or double precision. They must not contain any NaNs or INFs.

The Watson  $U^2$   $H_0$  postulates that the two samples came from the same population against the different populations alternative. In the calculation, StatsWatsonUSquaredTest ranks the two inputs, accounts for possible ties, computes the test statistic  $U^2$ , and compares it with the critical value. Because of the difficulty of computing the critical values, it always computes first the approximation due to Tiku and if possible it computes the exact critical value using the method outlined by Burr. You can evaluate the  $U^2$  CDF to get more information about the critical region.

V\_flag will be set to -1 for any error and to zero otherwise.

**References**

We have found that this method leads to slightly different results depending on the compiler and the system on which it is implemented:

**StatsWatsonWilliamsTest**

**StatsWatsonWilliamsTest** [*flags*] [*srcWave1*, *srcWave2*, *srcWave3*,...]

The StatsWatsonWilliamsTest operation performs the Watson-Williams test for two or more sample means. Output is to the W\_WatsonWilliams wave in the current data folder or optionally to a table.

**Flags**

/ALPH = *val*            Sets the significance level (default *val*=0.05).

/Q                        No results printed in the history area.

/T=*k*                     Displays results in a table. *k* specifies the table behavior when it is closed.

*k*=0:                     Normal with dialog (default).

*k*=1:                     Kills with no dialog.

*k*=2:                     Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/WSTR=*waveListString*

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.

/Z                        Ignores errors.

**Details**

The StatsWatsonWilliamsTest must have at least two input waves, which contain angles in radians, can be single or double precision, and can be of any dimensionality; the waves must not contain any NaNs or INFs.

The Watson-Williams  $H_0$  postulates the equality of the means from all samples against the simple inequality alternative. The test computes the sums of the sines and cosines from which it obtains a weighted *r* value (*rw*). According to Mardia, you should use different statistics depending on the size of *rw*: for  $rw > 0.95$  use the simple F statistic, but for  $0.95 > rw > 0.7$  you should use the F-statistic with the K correction factor. Otherwise you should use the t-statistic. StatsWatsonWilliamsTest computes both the (corrected) F-statistic and the t-statistic as well as their corresponding critical values.

V\_flag will be set to -1 for any error and to zero otherwise.

## StatsWheelerWatsonTest

**StatsWheelerWatsonTest** [*flags*] [*srcWave1*, *srcWave2*, *srcWave3*,...]

The StatsWheelerWatsonTest operation performs the nonparametric Wheeler-Watson test for two or more samples. Output is to the W\_WheelerWatson wave in the current data folder or optionally to a table.

### Flags

|                    |                                                                                       |
|--------------------|---------------------------------------------------------------------------------------|
| /ALPH = <i>val</i> | Sets the significance level (default <i>val</i> =0.05).                               |
| /Q                 | No results printed in the history area.                                               |
| /T= <i>k</i>       | Displays results in a table. <i>k</i> specifies the table behavior when it is closed. |
|                    | Displays results in a table. <i>k</i> specifies the table behavior when it is closed. |
| <i>k</i> =0:       | Normal with dialog (default).                                                         |
| <i>k</i> =1:       | Kills with no dialog.                                                                 |
| <i>k</i> =2:       | Disables killing.                                                                     |

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

*/WSTR=waveListString*

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use *waveListString* instead of listing each wave after the flags.

*/Z* Ignores errors.

### Details

The StatsWatsonWilliamsTest must have at least two input waves, which contain angles in radians (mod  $2\pi$ ), can be single or double precision, and can be of any dimensionality; the waves must not contain any NaNs or INFs.

The Wheeler-Watson  $H_0$  postulates that the samples came from the same population. The extension of the test to more than two samples is due to Mardia. The Wheeler-Watson test is not valid for data with ties, in which case you should use Watson's  $U^2$  test.

*V\_flag* will be set to -1 for any error and to zero otherwise.

## StatsWilcoxonRankTest

**StatsWilcoxonRankTest** [*flags*] *waveA*, *waveB*

The StatsWilcoxonRankTest operation performs the nonparametric Wilcoxon-Mann-Whitney two-sample rank test or the Wilcoxon Signed Rank test (for paired data) on *waveA* and *waveB*. Output is to the *W\_WilcoxonTest* wave in the current data folder or optionally to a table.

*waveA* and *waveB* must not contain NaNs or INFs.

### Flags

*/ALPH = val* Sets the significance level (default *val*=0.05).

*/APRX=m* Sets the approximation method. It computes an exact critical value by default.  
*m*=1: Standard normal approximation with ties (Zar P. 151).  
*m*=2: Improved normal approximation (Zar P. 152).

Approximations may be appropriate for large sample sizes when computation may take a long time.

*/Q* No results printed in the history area.

*/T=k* Displays results in a table. *k* specifies the table behavior when it is closed.  
*k*=0: Normal with dialog (default).  
*k*=1: Kills with no dialog.  
*k*=2: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

*/TAIL=tail* *tail* is a bitwise parameter that specifies the tails tested.  
 Bit 0: Lower tail.  
 Bit 1: Upper tail (default).  
 Bit 2: Two tail.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

You can perform any combination of tests by adding their corresponding tail values (/TAIL=7 tests all tail possibilities). Note that H0 changes according to the selected tail.

|       |                                                                                                                                                                                                                                                                                                                                            |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /WSRT | Performs the Wilcoxon Signed Rank Test for paired data. The test computes statistics $T_p$ and $T_m$ , lower-tail, upper-tail, and two-tail P-values. If the number of samples is less than 200 it computes exact P-values, otherwise they are computed using the normal approximation. Do not use /ALPH, /APRX, and /TAIL with this flag. |
| /Z    | Ignores errors.                                                                                                                                                                                                                                                                                                                            |

### Details

The Wilcoxon-Mann-Whitney test combines the two samples and ranks them to compute the statistic  $U$ . If  $waveA$  has  $m$  points and  $waveB$  has  $n$  points, then  $U$  is given by

$$U = mn + \frac{m(m+1)}{2} - R_1,$$

with the corresponding statistic  $U'$  given by

$$U' = nm + \frac{n(n+1)}{2} - R_2.$$

where  $R_i$  is the ranks of data in the  $i$ th wave (ranked in ascending order).

The distribution of  $U$  is difficult to compute, requiring the number of possible permutations of  $m$  elements of  $waveA$  and  $n$  elements of  $waveB$  that give rise to  $U$  values that do not exceed the one computed. The distribution is computed according to the algorithm developed by Klotz. With increasing sample size one can avoid the time consuming distribution computation and use a normal approximation instead. Klotz recommends this approximation for  $N=m+n \sim 100$ .

Use /APRX=2 for the best approximation. The two approximations are discussed by Zar.

The Wilcoxon Signed Rank Test, or Wilcoxon Paired-Sample Test, ranks the difference between pairs of values and computes the sums of the positive ranks ( $T_p$ ) and the negative ranks ( $T_m$ ). It calculates  $T_p$  and  $T_m$  and P-values for all tail combinations. The P-values are:

P\_lower\_tail     $P(W_p \leq T_p)$

P\_upper\_tail     $P(W_p \geq T_p)$

P\_two\_tail       $2 * \text{Min}(P\_lower\_tail, P\_upper\_tail)$

$W_p$  is the generic symbol for the sum of positive ranks for the given number of pairs.

$V\_flag$  will be set to -1 for any error and to zero otherwise.

In both Wilcoxon-Mann-Whitney two-sample rank test and the Wilcoxon Signed Rank test  $H_0$  is that the data in the two input waves are statistically the same.

## StatsWRCorrelationTest

**StatsWRCorrelationTest** [*flags*] *waveA*, *waveB*

The StatsWRCorrelationTest operation performs a Weighted Rank Correlation test on *waveA* and *waveB*, which contain the ranks of sequential factors. The waves are 1-based, integer ranks of factors in the range 1-2<sup>31</sup>.

StatsWRCorrelationTest computes a top-down correlation coefficient using Savage sums as well as the critical and P-values. Output is to the W\_StatsWRCorrelationTest wave in the current data folder or optionally to a table.

### Flags

|                    |                                                                                                                                                                                                                                                                                                                                                         |

### Details

The StatsWRCorrelationTest input waves must be one-dimensional and have the same length. The waves are 1-based, integer ranks of factors corresponding to the point number. Ranks may have ties in which case you should repeat the rank value. For example, if the second and third entries have the same rank you should enter {1,2,2,4}.  $H_0$  stipulates that the same factors are most important in both groups represented by *waveA* and *waveB*.

The top-down correlation is the sum of the product of Savage sums for each row:

$$r_{TD} = \frac{\sum_{i=1}^n S_{iA} S_{iB} - n}{n - S_1},$$

where  $n$  is the number of rows and the Savage sum  $S_i$  is

$$S_i = \sum_{j=i}^n \frac{1}{j},$$

and  $S_{iA}$  corresponds to the  $S_j$  value of the rank of the data in row ( $i-1$ ) of *waveA*.

## STFT

**STFT [flags] srcWave**

The STFT operation computes the Short-Time Fourier Transform of *srcWave*. STFT was added in Igor Pro 8.00.

Output is stored in the wave M\_STFT in the current data folder or in a wave specified by the /DEST flag.

**Flags**

- /DB=dbMode*      *dbMode* determines if output is scaled in decibels:  
 0:      No dB scaling (default)  
 1:      Scale the output to standard dB using  $20 \cdot \log(\text{wave})$   
 2:      Compute dBFS (dB relative to full scale where 0 is the maximum value)
- /DEST=destWave*      Specifies the output wave created by the FFT operation.  
 It is an error to attempt specify the same wave as both *srcWave* and *destWave*.  
 The default output wave name M\_STFT is used if you omit /DEST.  
 When used in a function, the STFT operation by default creates a real wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-71 for details.
- /HOPS=hopSize*      Specifies the offset in points between centers of consecutive source segments. By default this value is 1 and the transform is computed for segments that are offset by a single points from each other.
- /OUT=mode*      Sets the output wave format.  
*mode=1*:      Complex output (default)  
*mode=2*:      Real output  
*mode=3*:      Magnitude  
*mode=4*:      Magnitude square  
*mode=5*:      Phase  
*mode=6*:      Scaled magnitude  
*mode=7*:      Scaled magnitude squared
- The scaled quantities apply to transforms of real valued inputs where the output is normally folded in the first dimension (because of symmetry). The scaling applies a factor of 2 to the squared magnitude of all components except the DC. The scaled transforms should be used whenever Parseval's relation is expected to hold.
- /PAD=newSize*      Converts each segment of *srcWave* into a padded array of length *newSize*. The padded array contains the original data at the center of the array with zeros elements on both sides.
- /RP=[startPoint, endPoint]*      Specifies the range of *srcWave* from which data are sampled in point numbers. *startPoint* is the first point at which segments are centered. Wave data from points preceding *startPoint* are used as needed for the left parts of beginning segments.
- /RX=(startX, endX)*      Specifies the range of *srcWave* from which data are sampled in X values. The operation expects  $startX < endX$ . *startX* corresponds to the first point at which segments are centered. Data from points preceding *startX* are used as necessary to fill left parts of the beginning segments.
- /SEGS=segSize*      Sets the length of the segment sampled from *srcWave* in points. The segment is optionally padded to a larger dimension (see /PAD) and multiplied by a window function prior to FFT. The default segment size is 128 when the number of points in *srcWave* is greater than 128. Otherwise it is set to one less than the number of points in the *srcWave*. The operation requires that *segSize* is at least 32 points.

*/WINF=windowKind*

Premultiplies a data segment with the selected window function. The default window is Hanning. See **Window Functions** on page V-223 for details.

*/Z*

Ignores errors. *V\_flag* is set to -1 for any error and to zero otherwise.

### Details

The Short-Time Fourier Transform is a time-frequency representation for a 1D array. The squared magnitude of the transform is known as the "spectrogram" for time series or "sonogram" in the case of sound input. The operation comprises the following steps:

1. Sampling the data.

A segment of size specified by */SEGS* is sampled from *srcWave* centered about the first point in the wave or as specified by */RX* or */RP* flags. When the first point is at the beginning of the wave the centering implies that the first half of the segment is set to zero. If the first point is somewhere else the operation uses as many points as are available in the wave and sets the rest to zero. End effects are mitigated by scaling the result by a factor that accounts for the actual number of source data used in the segment. Subsequent segments are each centered at *hopSize* points from the previous center.

2. Apply windowing.

The selected segment is multiplied by the specified window function.

3. Apply padding.

If padding is specified the windowed data are centered onto a zero padded array. Padding may be used to simulate longer arrays for improved spectral resolution.

4. Compute the FFT.

Initial complex transform may be further processed according to the */OUT* flag.

## StopMSTimer

### StopMSTimer(*timerRefNum*)

The StopMSTimer function frees up the timer associated with the *timerRefNum* and returns the number of elapsed microseconds since StartMSTimer was called for this timer.

### Parameters

*timerRefNum* is the value returned by StartMSTimer or the special values -1 or -2. If *timerRefNum* is not valid then StopMSTimer returns 0.

On Windows, passing -1 returns the clock frequency of the timer and. On Macintosh, it returns NaN.

Passing -2 returns the time in microseconds since the computer was started.

### Details

If you want to make sure that all timers are free, call StopMSTimer ten times with *timerRefNum* equal to 0 through 9. It is OK to stop a timer that you never started.

The function result may exclude the time the system has spent in sleep states. As of this writing this applies to Macintosh only, but this behavior may change in the future since it is determined by the operating system.

### Examples

How long does an empty loop take on your computer?

```
Function TestMSTimer()
 Variable timerRefNum
 Variable microSeconds
 Variable n
```

## str2num

---

```
timerRefNum = StartMSTimer
if (timerRefNum == -1)
 Abort "All timers are in use"
endif
n=10000
do
 n -= 1
while (n > 0)
microSeconds = StopMSTimer(timerRefNum)
Print microSeconds/10000, "microseconds per iteration"
End
```

### See Also

**StartMSTimer**, **ticks**, **DateTime**

## str2num

**str2num**(*str*)

The **str2num** function returns a number represented by the string expression *str*.

### Details

**str2num** returns NaN if *str* does not contain the text for a number.

**str2num** skips leading spaces and tabs and then reads up to the first non-numeric character.

### See Also

The **char2num**, **num2char** and **num2str** functions.

The **sscanf** operation for more complex parsing jobs.

## StrConstant

**StrConstant** *ksName*="literal string"

The **StrConstant** declaration defines the string *literal string* under the name *ksName* for use by other code, such as in a switch construct.

### See Also

The **Constant** keyword for numeric types, **Constants** on page IV-50, and **Switch Statements** on page IV-43.

## String

**String** [/G] *strName* [/N=*name*] [=*strExpr*] [, *strName* [/N=*name*] [=*strExpr*] ...]

The **String** operation creates string variables and gives them the specified names.

### Flags

- /G** Creates a global string. Overwrites any existing string with the same name.
- /N=*name*** Specifies a local name for the global string variable. **/N** was added in Igor Pro 8.00 and is available in user-defined functions only. See **SVAR Creation** below for details.

### Details

The string variable is initialized when it is created if you supply the *=strExpr* initializer. However, when **String** is used to declare a function parameter, it is an error to attempt to initialize it.

You can create more than one string variable at a time by separating the names and optional initializers with commas.

If used in a procedure, the new string is local to that procedure unless the **/G** flag is used. If used on the command line, **String** is equivalent to **String/G**.

*strName* can optionally include a data folder path.

### SVAR Creation

In a user-defined function, you need a local SVAR reference to access a global string variable. If you use a simple name rather than a path, Igor automatically creates an SVAR:

```
String/G sVar1 // Creates an SVAR named sVar1
```

If you use a path or a \$ expression, Igor does not create an automatic SVAR reference. You can explicitly create SVARs like this:

```
String/G root:sVar2
SVAR sVar2 = root:sVar2 // Creates an SVAR named sVar2

String path = "root:sVar3"
String/G $path
SVAR sVar3 = $path // Creates an SVAR named sVar3
```

In Igor Pro 8.00 and later, you can explicitly create an SVAR reference in a user-defined function using the /N flag, like this:

```
String/G sVar4/N=sVar4 // Creates an SVAR named sVar4
String/G root:sVar5/N=sVar5 // Creates an SVAR named sVar5
String path = "root:sVar6"
String/G $path/N=sVar6 // Creates an SVAR named sVar6
```

The name used for the SVAR does not need to be the same as the name of the global variable:

```
String/G sVar7/N=sv7 // Creates an SVAR named sv7
String/G root:sVar8/N=sv8 // Creates an SVAR named sv8
String path = "root:sVar9"
String/G $path/N=sv9 // Creates an SVAR named sv9
```

## StringByKey

**StringByKey**(*keyStr*, *kwListStr* [, *keySepStr* [, *listSepStr* [, *matchCase*]])

The StringByKey function returns a substring extracted from *kwListStr* based on the specified key contained in *keyStr*. *kwListStr* should contain keyword-value pairs such as "KEY=value1, KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for *keySepStr* and *listSepStr*.

Use StringByKey to extract a string value from a string containing a "key1:value1;key2: value2;" style list such as those returned by functions like **AxisInfo** or **TraceInfo**.

If the key is not found or if any of the arguments is "" then a zero-length string is returned.

*keySepStr*, *listSepStr*, and *matchCase* are optional; their defaults are ":", ";", and 0 respectively.

### Details

*kwListStr* is searched for an instance of the key string bound by *listSepStr* on the left and a *keySepStr* on the right. The text up to the next *listSepStr* is returned.

*kwListStr* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *keySepStr* and *listSepStr* are always case-sensitive. Searches for *keyStr* in *kwListStr* are usually case-insensitive. Setting the optional *matchCase* parameter to 1 makes the comparisons case sensitive.

In Igor6, only the first byte of *keySepStr* and *listSepStr* was used. In Igor7 and later, all bytes are used.

If *listSepStr* is specified, then *keySepStr* must also be specified. If *matchCase* is specified, *keySepStr* and *listSepStr* must be specified.

### Examples

```
Print StringByKey("BKEY", "AKEY:hello;BKEY:nok-nok") // prints "nok-nok"
Print StringByKey("KY", "KX=1;ky=hello", "=") // prints "hello"
Print StringByKey("KY", "KX:1,KY:joe", ":", ",") // prints "joe"
Print StringByKey("kz", "KZ:1st,kz:2nd", ":", ",") // prints "1st"
Print StringByKey("kz", "KZ:1st,kz:2nd", ":", ",", 1) // prints "2nd"
```

### See Also

The **NumberByKey**, **RemoveByKey**, **ReplaceNumberByKey**, **ReplaceStringByKey**, **ItemsInList**, **AxisInfo**, **IgorInfo**, **SetWindow**, and **TraceInfo** functions.

### StringCRC

**StringCRC** (*inCRC*, *str*)

The StringCRC function returns a 32-bit cyclic redundancy check value of bytes in *str* starting with *inCRC*.

Pass 0 for *inCRC* the first time you call StringCRC for a particular stream of bytes as represented by the string data.

Pass the last-returned value from StringCRC for *inCRC* if you are creating a CRC value for a given stream of bytes through multiple calls to StringCRC.

#### Details

Polynomial used is:

$$x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$$

See `crc32.c` in the public domain source code for `zlib` for more information.

#### See Also

Hash, WaveHash, WaveCRC

### StringFromList

**StringFromList** (*index*, *listStr* [, *listSepStr*] [, *offset*])

The StringFromList function returns the *index*th substring extracted from *listStr* starting *offset* bytes into *listStr*. *listStr* should contain items separated by *listSepStr* which typically is ";".

Use StringFromList to extract an item from a string such as those returned by functions like **TraceNameList** and **AnnotationList**.

#### Parameters

*index* is the zero-based index of the list item that you want to get. If *index* < 0, or *index* ≥ the number of items in list, or if *listStr* or *listSepStr* is "", then a zero-length string is returned.

*listStr* contains a series of text items separated by *listSepStr*. The trailing separator is optional though recommended. For example, these are both valid lists:

```
"First;Second;"
"First;Second"
```

*listSepStr* is optional. If omitted it defaults to ";". Prior to Igor Pro 7.00, only the first byte of *listSepStr* was used. Now all bytes are used.

*offset* is optional and requires Igor Pro 7.00 or later. If omitted it defaults to 0. The search begins *offset* bytes into *listStr*. When iterating through lists containing large numbers of items, using the *offset* parameter provides dramatically faster execution.

#### Details

For optimal performance, especially with lists larger than 100 items, provide the *separatorStr* and *offset* parameters as shown in the DemoStringFromList example below. When using this technique, the *index* parameter must be 0 and the *offset* parameter controls which list item is returned.

#### Examples

```
Print StringFromList(0, "wave0;wave1;") // Prints "wave0"
Print StringFromList(2, "wave0;wave1;") // Prints ""
Print StringFromList(1, "wave0;;wave2") // Prints ""
```

```
// Iterate quickly over a list using the offset parameter
Function DemoQuickStringFromList(list)
 String list // A semicolon-separated string list

 String separator = ";"
 Variable separatorLen = strlen(separator)
 Variable numItems = ItemsInList(list)

 Variable offset = 0
 Variable i
 for(i=0; i<numItems; i+=1)
 // When using offset, the index parameter is always 0
 String item = StringFromList(0, list, separator, offset)
```

```

 // Do something with item
 offset += strlen(item) + separatorLen
 endfor
End

```

## StringList

**StringList**(*matchStr*, *separatorStr* [, *dfr* ])

The **StringList** function returns a string containing a list of global string variables selected based on the *matchStr* parameter. The string variables listed are all in the current data folder or the data folder specified by *dfr*.

**Details**

For a string variable name to appear in the output string, it must match *matchStr*. *separatorStr* is appended to each string variable name as the output string is generated.

The name of each string variable is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

|           |                                                     |
|-----------|-----------------------------------------------------|
| "*"       | Matches all string variable names                   |
| "xyz"     | Matches name xyz only                               |
| "*xyz"    | Matches names which end with xyz                    |
| "xyz*"    | Matches names which begin with xyz                  |
| "*xyz*"   | Matches names which contain xyz                     |
| "abc*xyz" | Matches names which begin with abc and end with xyz |

The returned list contains names only, without data folder paths. Thus, they are not suitable for accessing string variables outside the current or specified data folder.

*matchStr* may begin with the ! character to return items that do not match the rest of *matchStr*. For example:

|         |                                                         |
|---------|---------------------------------------------------------|
| "!*xyz" | Matches variable names which <i>do not</i> end with xyz |
|---------|---------------------------------------------------------|

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

*dfr* is an optional data folder reference: a data folder name, an absolute or relative data folder path, or a reference returned by, for example, **GetDataFolderDFR**. The *dfr* parameter requires Igor Pro 9.00 or later.

**Examples**

|                                      |                                                                                                |
|--------------------------------------|------------------------------------------------------------------------------------------------|
| <code>StringList ("*", ";")</code>   | Returns a list of all string variables in the current data folder.                             |
| <code>StringList ("S_*", ";")</code> | Returns a list of all string variables in the current data folder whose names begin with "S_". |

**See Also**

**VariableList**, **WaveList**, **DataFolderList**

### StringMatch

**StringMatch**(*string*, *matchStr*)

The StringMatch function tests *string* for a match to *matchStr*. You may include asterisks in *matchStr* as a wildcard character.

StringMatch returns 1 to indicate a match, 0 for no match or NaN if it ran out of memory.

#### Details

*matchStr* is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

|           |                                                                                   |
|-----------|-----------------------------------------------------------------------------------|
| "*"       | Matches any string.                                                               |
| "xyz"     | Matches the string "xyz" only.                                                    |
| "*xyz"    | Matches strings ending with "xyz", for instance "abcxyz".                         |
| "xyz*"    | Matches strings beginning with xyz, for instance "xyzpqr".                        |
| "*xyz*"   | Matches strings containing xyz, for instance "abcxyzpqr".                         |
| "abc*xyz" | Matches strings beginning with abc and ending with xyz, for instance "abcpxrxyz". |

If *matchStr* begins with the ! character, a match is indicated if *string* does *not* match *matchStr*. For example:

|         |                                                   |
|---------|---------------------------------------------------|
| "!*xyz" | Matches strings which <i>do not</i> end with xyz. |
|---------|---------------------------------------------------|

The ! character is considered to be a normal character if it appears anywhere else.

Note that matching is case-insensitive, so "xyz" also matches "XYZ" or "Xyz".

Also note that it is impossible to match an asterisk in *string*: use **GrepString** instead.

Among other uses, the StringMatch function can be used to build your own versions of the **WaveList** function, using **NameOfWave** and stringmatch to qualify names of waves found by **WaveRefIndexedDFR**.

#### See Also

The **GrepString**, **CmpStr**, **strsearch**, **Demo**, **ListMatch**, and **ReplaceString** functions and the **sscanf** operation.

### strlen

**strlen**(*str*)

The strlen function returns the number of bytes in the string expression *str*.

strlen returns NaN if the *str* is NULL. A local string variable or a string field in a structure that has never been set is NULL. NULL is not the same as zero length. Use **numtype** to test if the result from strlen is NaN.

#### Examples

```
String zeroLength = ""
String neverSet
Print strlen(zeroLength), strlen(neverSet)

// Test if a string is null
Variable len = strlen(neverSet) // NaN if neverSet is null
if (numtype(len) == 2) // strlen returned NaN?
 Print "neverSet is null"
endif
```

#### See Also

**Characters Versus Bytes** on page III-485, **Character-by-Character Operations** on page IV-173

### strsearch

**strsearch**(*str*, *findThisStr*, *start* [, *options*])

The strsearch function returns the byte position of the string expression *findThisStr* in the string expression *str*.

**Details**

strsearch performs a case-sensitive search.

strsearch returns -1 if *findThisStr* does not occur in *str*.

The search starts from the byte position in *str* specified by *start*; 0 references the start of *str*.

strsearch clips *start* to one less than the length of *str* in bytes, so it is useful to use `Inf` for *start* when searching backwards to ensure that the search is from the end of *str*.

*options* is an optional bitwise parameter specifying the search options:

- 1: Search backwards from *start*.
- 2: Ignore case.
- 3: Search backwards and ignore case.

**Examples**

```
String str="This is a test isn't it?"
Print strsearch(str,"test",0) // prints 10
Print strsearch(str,"TEST",0) // prints -1
Print strsearch(UpperStr(str),"TEST",0) // prints 10
Print strsearch(str,"TEST",0,2) // prints 10
Print strsearch(str,"is",0) // prints 2
Print strsearch(str,"is",3) // prints 5
Print strsearch(str,"is",Inf,1) // prints 15
```

**See Also**

**sscanf**, **FindListItem**, **ReplaceString**, **Character-by-Character Operations**

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

**strswitch-case-endswitch**

```
strswitch(<string expression>
 case <literal><constant>:
 <code>
 [break]
 [default:
 <code>]
endswitch
```

A strswitch-case-endswitch statement evaluates a string expression and compares the result to the case labels using a case-insensitive comparison. If a case label matches *string expression*, then execution proceeds with *code* following the matching case label. When none of the cases match, execution will continue at the default label, if it is present, or otherwise the strswitch will be exited with no action taken. Note that although the break statement is optional, in almost all case statements it will be required for the strswitch to work correctly.

**See Also**

**Switch Statements** on page IV-43, **default** and **break** for more usage details.

**STRUCT**

```
STRUCT structureName localName
```

STRUCT is a reference that creates a local reference to a Structure accessed in a user-defined function. When a Structure is passed to a user function, it can only be passed by reference, so in the declaration within the function you must use *&localStructName* to define the function input parameter.

**See Also**

**Structures in Functions** on page IV-98 for further information.

See the **Structure** keyword for creating a Structure definition.

### StructFill

**StructFill** [ */AC=createFlags* */SDFR=dfr* ] *structVar*

StructFill is a programmer-convenience operation that initializes NVAR, SVAR and WAVE fields in a structure. At run time, it scans through the fields in the specified structure and attempts to set all null NVAR, SVAR and WAVE fields by looking up corresponding same-named globals in the current data folder or in the specified data folder.

StructFill was added in Igor Pro 8.00.

#### Parameters

*structVar* is the name of a STRUCT variable.

#### Flags

- /AC=createFlags*      Enables auto-creation of globals.  
Bit 0 enables creation of numeric and string global variables which are set to 0 and "" respectively. Variables are auto-created only if they do not already exist.  
Bit 1 enables creation of waves which are created with zero points. Waves are auto-created only if they do not already exist.
- /SDFR=dfr*            Specifies a data folder. If you omit */SDFR*, the current data folder used.  
See **The /SDFR Flag** on page IV-79 for details.

#### Output Variables

StructFill sets the following output variables:

- V\_Flag                The number of NVAR, SVAR and WAVE fields that were successfully initialized.  
V\_Error               The number of NVAR, SVAR and WAVE fields that could not be initialized.

If auto-creation is off, a field can not be initialized if the corresponding global variable, string variable, or wave does not exist. If auto-creation is on, a field can not be initialized if there was an error creating the global variable or wave.

When using auto-creation, errors are not reported other than via V\_Error.

If you unexpectedly get non-zero for V\_Error, you can print the structure to see which fields were left null.

#### See Also

**Structures in Functions** on page IV-98

### StructGet

**StructGet** [*/B=b*] *structVar*, *waveStruct* [ [*colNum*] ]

**StructGet** /S [*/B=b*] *structVar*, *strStruct*

The StructGet operation reads binary numeric data from a specified column of a wave or from a string variable and copies the data into the designated structure variable. The source wave or string will have been filled beforehand by **StructPut**.

#### Parameters

*structVar* is the name of an existing structure that is to be filled with new data values.

*waveStruct* is the name of a wave containing binary numeric data that will be used to fill *structVar*. Use the optional *colNum* parameter to specify a column from the structure wave. The contents of *waveStruct* are created beforehand using StructPut.

*strStruct* is the name of a string variable containing binary numeric data. The contents of *strStruct* are created beforehand using StructPut.

**Flags**

|                   |                                                                                                                                                                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/B=b</code> | Sets the byte ordering for reading of structure data.<br><i>b=0</i> : Reads in native byte order.<br><i>b=1</i> : Reads bytes in reversed order.<br><i>b=2</i> : Default; reads data in big-endian, high-byte-first order (Motorola).<br><i>b=3</i> : Reads data in little-endian, low-byte-first order (Intel). |
| <code>/S</code>   | Reads binary data from a string variable, which was set previously with StructPut.                                                                                                                                                                                                                               |

**Details**

The data that are stored in *waveStruct* and *strStruct* are in binary format so you can not directly view a meaningful representation of their contents by printing them or viewing the wave in a table. To view the contents of *waveStruct* or *strStruct* you must use StructGet to export them back into a structure and then retrieve the members.

If *colNum* is out of bounds it will be clipped to valid values and an error reported. If the row dimension does not match the structure size, as much data as possible will be copied to the structure.

By default, data are read in big-endian, high-byte order (Motorola). This allows data written on one platform to be read on the other.

**See Also**

The **StructPut** operation for writing structure data to waves or strings.

**StructPut**

```
StructPut [/B=b] structVar, waveStruct [[colNum]]
```

```
StructPut /S [/B=b] structVar, strStruct
```

The StructPut operation copies the binary numeric data in a structure variable to a specified column in a wave or to a string variable. The data in the wave or string can be read out into another structure using **StructGet**.

**Parameters**

*structVar* is the name of a structure from which data will be exported.

*waveStruct* is the name of an existing wave to which data will be exported. Use the optional *colNum* parameter to specify a column in *waveStruct* to contain the data. The first column of *waveStruct* will be filled if *colNum* is omitted.

*strStruct* is the name of an existing string variable to which data will be exported.

**Flags**

|                   |                                                                                                                                                                                                                                                                                                                      |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/B=b</code> | Sets the byte ordering for writing of structure data.<br><i>b=0</i> : Writes in native byte order.<br><i>b=1</i> : Writes bytes in reversed order.<br><i>b=2</i> : Default; writes data in big-endian, high-byte-first order (Motorola).<br><i>b=3</i> : Writes data in little-endian, low-byte-first order (Intel). |
| <code>/S</code>   | Writes binary data to a string variable.                                                                                                                                                                                                                                                                             |

**Details**

The structure fields to be exported must contain only numeric data in either integer, floating point, or double precision format. If the structure contains any objects such as String, NVAR, WAVE, etc., then only the numeric data at the end of the structure is copied. If there is no suitable data at the end, an error is generated at compile time. Prior to Igor Pro 8, the presence of any illegal field would result in an error.

If needed, StructPut will redimension *waveStruct* to unsigned byte format, will set the number of rows to equal the size of the structure, and set the column dimension large enough to accommodate the size specified by *colNum*. You can think of *waveStruct* as a one-dimensional array of structure contents indexed by *colNum* although the wave is actually two-dimensional with each column containing a copy of a separate structure.

## Structure

---

By default, data are written in big-endian, high-byte order (Motorola). This allows data written on one platform to be read on the other.

After you have exported the structure data to *waveStruct* or *strStruct* they will contain binary data that you cannot inspect directly. To view the contents of *waveStruct* or *strStruct*, you must use the original structure or use `StructGet` to export them into another structure.

The `StructGet` operation for reading structure data from waves or strings.

## Structure

**Structure** *structureName*

*memType memName [arraySize] [, memName [arraySize]]*

...

**EndStructure**

The `Structure` keyword introduces a structure definition in a user function. Within the body of the structure you declare the member type (*memType*) and the corresponding member name(s) (*memName*). Each *memName* may be declared with an optional array size.

### Details

Structure member types (*memType*) can be any of the following Igor objects: Variable, String, WAVE, NVAR, SVAR, DFREF, FUNCREF, or STRUCT.

Igor structures also support additional member types, as given in the next table, for compatibility with C programming structures and disk files.

| Igor Member Type | C Equivalent        | Size    | Note                            |
|------------------|---------------------|---------|---------------------------------|
| char             | signed 8-bit int    | 1 byte  |                                 |
| uchar            | unsigned 8-bit int  | 1 byte  |                                 |
| int16            | signed 16-bit int   | 2 bytes |                                 |
| uint16           | unsigned 16-bit int | 2 bytes |                                 |
| int32            | signed 32-bit int   | 4 bytes |                                 |
| uint32           | unsigned 32-bit int | 4 bytes |                                 |
| int64            | signed 64-bit int   | 8 bytes | Requires Igor Pro 7.00 or later |
| uint64           | unsigned 64-bit int | 8 bytes | Requires Igor Pro 7.00 or later |
| float            | float               | 4 bytes |                                 |
| double           | double              | 8 bytes |                                 |

The Variable and double types are identical although Variable can be also specified as complex (using the /C flag).

Each structure member may have an optional *arraySize* specification, which gives the number of elements contained by the structure member. The array size is an integer number from 1 to 400 except for members of type STRUCT for which the upper limit is 100.

### See Also

**Structures in Functions** on page IV-98 for further information.

See the `STRUCT` declaration for creating a local reference to a Structure.

## StrVarOrDefault

**StrVarOrDefault**(*pathStr*, *defStrVal*)

The StrVarOrDefault function checks to see if *pathStr* points to a string variable and if so, it returns its value. If the string variable does not exist, returns *defStrVal* instead.

### Details

StrVarOrDefault initializes input values of macros so they can remember their state without needing global variables to be defined first. Numeric variables use the corresponding numeric function, **NumVarOrDefault**.

### Examples

```
Macro foo(nval,sval)
 Variable nval=NumVarOrDefault("root:Packages:mypack:nvalSav",2)
 String sval=StrVarOrDefault("root:Packages:mypack:svalSav","Hi")

 DFREF dfsav= GetDataFolderDFR()
 NewDataFolder/O/S root:Packages
 NewDataFolder/O/S mypack
 Variable/G nvalSav= nval
 String/G svalSav= sval
 SetDataFolder dfsav
End
```

## StudentA

**StudentA**(*t*, *DegFree*)

**Note:** This function is deprecated. New code should use the more accurate **StatsStudentCDF**.

The StudentA function returns the area from  $-t$  to  $t$  under the Student's T distribution having *DegFree* degrees of freedom. That is, it returns the probability that a random sample from Student's T is between  $-t$  and  $t$ .

Note that this is the *bi-tail* result. That is, it gives the area from  $-t$  to  $t$ , rather than the cumulative area from  $-\infty$  to  $t$ . It is this latter number that is commonly tabulated- StudentA returns the probability  $1-\alpha$  where the area from  $-\infty$  to  $t$  is the probability  $1-\alpha/2$ .

StudentA tests whether a normally-distributed statistic is significantly different from a certain value. You could use it to test whether an intercept from a line fit is significantly different from zero:

```
Make/O/N=20 Data=0.5*x+2+gnoise(1) // line with Gaussian noise
Display Data
CurveFit line Data /D
Print "Prob = ", StudentA(W_coef[0]/W_sigma[0], V_npnts-2)
```

Because the noise is random, the results will differ slightly each time this is tried. When we did it, the result was:

```
Prob = 0.999898
```

which indicates that the intercept of the line fit was different from zero with 99.99 per cent probability.

### See Also

**StatsStudentCDF**, **StatsStudentPDF**, **StatsInvStudentCDF**

## StudentT

**StudentT**(*Prob*, *DegFree*)

**Note:** This function is deprecated. New code should use the more accurate **StatsInvStudentCDF**.

The StudentT function returns the  $t$  value corresponding to an area *Prob* under the Student's T distribution from  $-t$  to  $t$  for *DegFree* degrees of freedom.

Note that this is a *bi-tail* result, which is what is usually desired. Tabulated values of the Student's T distribution are commonly the one-sided result.

StudentT calculates confidence intervals from standard deviations for normally-distributed statistics. For instance, you can use it to calculate a confidence interval for the coefficients from a curve fit:

```
Make/O/N=20 Data=0.5*x+2+gnoise(1) // line with Gaussian noise
Display Data
```

## Submenu

---

```
CurveFit line Data /D
print "intercept = ", W_coef[0], "±", W_sigma[0]*StudentT(0.95, V_npnts-2)
print "slope = ", W_coef[1], "±", W_sigma[1]*StudentT(0.95, V_npnts-2)
```

### See Also

**StatsStudentCDF, StatsStudentPDF, StatsInvStudentCDF**

## Submenu

**Submenu** *menuNameStr*

The Submenu keyword introduces a submenu definition. It is used inside a Menu definition. See Chapter IV-5, **User-Defined Menus** for further information.

## sum

**sum**(*waveName* [, *x1*, *x2*])

The sum function returns the sum of the wave elements for points from  $x=x1$  to  $x=x2$ .

### Details

The X scaling of the wave is used only to locate the points nearest to  $x=x1$  and  $x=x2$ . To use point indexing, replace  $x1$  with `pnt2x(waveName, pointNumber1)`, and a similar expression for  $x2$ .

If  $x1$  and  $x2$  are not specified, they default to  $-\infty$  and  $+\infty$ , respectively.

If the points nearest to  $x1$  or  $x2$  are not within the point range of 0 to `numpts(waveName)-1`, sum limits them to the nearest of point 0 or point `numpts(waveName)-1`.

If any values in the point range are NaN, sum returns NaN.

### Examples

```
Make/O/N=100 data; SetScale/I x 0, Pi, data
data=sin(x)
Print sum(data, 0, Pi) // the entire point range, and no more
Print sum(data) // same as -infinity to +infinity
Print sum(data, Inf, -Inf) // +infinity to -infinity
```

The following is printed to the history area:

```
Print sum(data, 0, Pi) // the entire point range, and no more
63.0201
Print sum(data) // same as -infinity to +infinity
63.0201
Print sum(data, Inf, -Inf) // +infinity to -infinity
63.0201
```

### See Also

**mean, area, SumSeries, SumDimension**

## SumDimension

**SumDimension** [*flags*] *srcWave*

The SumDimension operation sums values in *srcWave* along the specified dimension.

The SumDimension operation was added in Igor Pro 7.00.

### Flags

*/D=dimension*      Specifies a zero-based dimension number.

*dimension=0:*      Rows

*dimension=1:*      Columns

*dimension=2:*      Layers

*dimension=3:*      Chunks

If you omit */D* the operation sums the highest dimension in the wave.

|                             |                                                                                                                                                                                                                                                                                              |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/DEST=destWave</code> | Specifies the output wave created by the operation. If <i>destWave</i> already exists it is overwritten by the new results.<br>If you omit <code>/DEST</code> the operation saves the data in <code>W_SumDimension</code> if the output wave is 1D or <code>M_SumDimension</code> otherwise. |
| <code>/Y=type</code>        | Specifies the data type of the output wave. See <b>WaveType</b> for the supported values of type.<br>If you omit <code>/Y</code> , the output wave is double precision.<br>Pass -1 for <code>type</code> to force the output wave to have the same data type as <i>srcWave</i> .             |

### Details

The operation sums one dimension of an N dimensional wave producing an output wave with N-1 dimensions except if *srcWave* is 1D wave in which case `SumDimension` produces a single point 1D output wave. For example, given a 4D wave of dimensions `dim0 x dim1 x dim2 x dim3` and the command:

```
SumDimension/D=1/DEST=wout wave4d
creates a wave wout that satisfies
```

$$wout[i][k][l] = \sum_{j=0}^{dim1-1} wave4d[i][j][k][l],$$

and `wout` has dimensions `dim0 x dim2 x dim3`.

If any values in *srcWave* are NaN, the corresponding sum element will be NaN.

## SumSeries

**SumSeries** [*flags*] *keyword=value*

The `SumSeries` operation computes the sum of the results returned from a user-defined function for input values between two specified index limits.

`SumSeries` was added in Igor Pro 7.00.

### Flags

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/CCNT=nc</code> | When summing with one or two infinite limits you can use this flag to specify the minimum number of calls to the summand function which, when added to the sum, produce a change that is less than the tolerance. By default <code>nc=10</code> .<br><br>If you are summing a well-behaved monotonic series it is sufficient to set <code>nc=1</code> . In some pathological cases it is useful to check that the sum remains effectively unchanged even after many terms are added to the series. |
| <code>/INAN</code>    | Ignore NaNs returned from the user function. In the case of a complex valued summand, a NaN in either the real or imaginary components excludes the contribution of the term to the sum.                                                                                                                                                                                                                                                                                                           |
| <code>/Q</code>       | Quiet mode; do not print in the history.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>/Z[=z]</code>   | <code>/Z</code> or <code>/Z=1</code> prevents reporting any errors. If the operation encounters an error it sets <code>V_Flag</code> to the error code.                                                                                                                                                                                                                                                                                                                                            |

### Keywords

|                            |                                                                                                           |
|----------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>lowerLimit=n1</code> | Specifies the starting index at which the summand is evaluated. <i>n1</i> must be either an integer -INF. |
|----------------------------|-----------------------------------------------------------------------------------------------------------|

|                                     |                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>series=<i>userFunc</i></code> | Specifies the name of the user function that returns the summand (i.e., a single term in the sum that corresponds to the input index). See <b>The SumSeries Summand Function</b> below for details.                                                                                                                  |
| <code>upperLimit=<i>n2</i></code>   | Specifies the last value at which the summand is evaluated. <i>n2</i> must be either an integer INF.                                                                                                                                                                                                                 |
| <code>tolerance=<i>tol</i></code>   | Specifies a tolerance value used when one or both of the limits are infinite. By default, the tolerance value is 1e-10. <i>tol</i> must be finite. If both limits are finite this keyword is ignored.                                                                                                                |
| <code>paramWave=<i>pw</i></code>    | <p><i>pw</i> is a single-precision or double-precision wave that is passed to the summand function. This is useful if you need to provide the summand function external/global data.</p> <p>If you omit the <code>paramWave</code> keyword then the summand function receives a null wave as the parameter wave.</p> |

### The SumSeries Summand Function

You specify the summand function using the `series` keyword. The form of the user-defined summand function is:

```
Function summandReal(inW,index)
 Wave inW
 Variable index
 ... compute something
 return result
End
```

The index changes by 1 for each successive call to the summand.

You can also define a complex summand function:

```
Function/C summandComplex(inW,index)
 Wave inW
 Variable index
 ... compute something
 Variable/C result
 return result
End
```

### Details

The SumSeries operation is primarily intended for use with one or two infinite limits. If both limits are finite the operation performs the straightforward sum by calling the summand function once for every index from `lowerLimit` to `upperLimit`, inclusive.

If one limit is infinite the sum is evaluated by starting from the finite limit and proceeding in the direction of the infinite limit index until convergence is reached. Convergence in this context is defined as multiple (*nc*) consecutive calls to the summand which do not change the value of the sum by more than the tolerance value. By default *nc*=10 but you can change it using the `/CCNT` flag.

When both limits are infinite the operation first computes the sum for indices 0 to INF and then the sum from -1 to -INF. The two calculations are independent and require that the same convergence condition is met independently in each case. When the summand function is complex the convergence condition must hold for the real and imaginary components independently.

The operation does not perform any test on the summand function to estimate its rate of convergence. If you provide a non-converging summand function the operation can run indefinitely. You can abort it by pressing the **User Abort Key Combinations** or by clicking the Abort button.

The result of the sum is stored in `V_resultR` and, if the summand function returns a complex result, `V_resultI`.

If the calculation completes without error `V_Flag` is set to 0. Otherwise it contains an error code.

### Examples

A simple test case is the geometric series for powers of 1/2. The sum of  $x^i$  for  $i=0$  to  $i=INF$  where  $0 < x < 1$  is given by  $1/(1-x)$ . For  $x=1/2$ , this sum is 2.

```

Function s1(paramWave, index)
 Wave/Z paramWave // Not used
 Variable index

 return 0.5^index
End

// Execute:
SumSeries series=s1,lowerLimit=0,upperLimit=INF
Print V_resultR

```

In the next example we use the series expansion of cosine and sine to evaluate  $\exp(i\pi)$ .

```

Function/C s2(paramWave, index)
 Wave/Z paramWave // Not used
 Variable index

 Variable n2=2*index
 Variable xx=pi^n2
 Variable sn=(-1)^index
 Variable fn=Factorial(n2)
 return cmplx(sn*xx/fn,sn*xx*pi/(fn*(n2+1)))
End

// Execute:
SumSeries series=s2,lowerLimit=0,upperLimit=INF
Print V_resultR,V_resultI

```

In the next example we sum 18 terms in the series for  $\exp(x)$  using a parameter wave to pass the value of  $x$ .

```

Function fex(paramWave, index)
 Wave/Z paramWave // Contains x value at which to evaluate exp(x)
 Variable index

 Variable xx = paramWave[0]
 if (index == 0)
 return 1
 endif
 return (xx^index) / factorial(index)
End

// Execute:
Make/D/O exponent = {-1} // The value of x at which to evaluate exp(x)
SumSeries series=fex, lowerLimit=0, upperLimit=17, paramWave=exponent
Print/D V_resultR - exp(-1) // Compare with built-in exp function

```

## SVAR

**SVAR** [/Z] [/SDFR=*dfr*] *localName* [= *pathToStr*] [, *localName1* [= *pathToStr1*]]...

SVAR is a declaration that creates a local reference to a global string variable accessed in a user-defined function.

The SVAR reference is required when you access a global string variable in a function. At compile time, the SVAR statement specifies a local name referencing a global string variable. At runtime, it makes the connection between the local name and the actual global variable. For this connection to be made, the global string variable must exist when the SVAR statement is executed.

When *localName* is the same as the global string variable name and you want to reference a global variable in the current data folder, you can omit *pathToStr*.

*pathToStr* can be a full literal path (e.g., root:FolderA:var0), a partial literal path (e.g., :FolderA:var0) or \$ followed by string variable containing a computed path (see **Converting a String into a Reference Using \$** on page IV-61).

You can also use a data folder reference or the /SDFR flag to specify the location of the string variable if it is not in the current data folder. See **Data Folder References** on page IV-78 and **The /SDFR Flag** on page IV-79 for details.

If the global variable may not exist at runtime, use the /Z flag and call **SVAR\_Exists** before accessing the variable. The /Z flag prevents Igor from flagging a missing global variable as an error and dropping into the Igor debugger. For example:

## SVAR\_Exists

---

```
SVAR/Z nv=<pathToPossiblyMissingStringVariable>
if(SVAR_Exists(sv))
 <do something with sv>
endif
```

Note that to create a global string variable, you use the **String/G** operation.

### Flags

`/SDFR=dfr` Specifies the source data folder. See **The /SDFR Flag** on page IV-79 for details.

`/Z` An SVAR reference to a null string variable does not cause an error or a debugger break.

### See Also

**SVAR\_Exists** function.

**Accessing Global Variables and Waves** on page IV-64.

**Converting a String into a Reference Using \$** on page IV-61.

## SVAR\_Exists

### SVAR\_Exists(name)

The **SVAR\_Exists** function returns 1 if the specified SVAR reference is valid or 0 if not. It can be used only in user-defined functions.

For example, in a user function you can test if a global string variable exists like this:

```
SVAR /Z str1 = gStr1 // /Z prevents debugger from flagging bad SVAR
if (!SVAR_Exists(str1)) // No such global string variable?
 String/G gStr1 = "" // Create and initialize it
endif
```

**WaveExists**, **NVAR\_Exists**, and **Accessing Global Variables and Waves** on page IV-64.

## switch-case-endswitch

```
switch(<numeric expression>
 case <literal><constant>:
 <code>
 [break]
 [default:
 <code>]
endswitch
```

A switch-case-endswitch statement evaluates the numeric expression and rounds the result to the nearest integer. If a case label matches *numerical expression*, then execution proceeds with *code* following the matching case label. When no cases match, execution continues at the default label, if present, or otherwise the switch exits with no action taken. Although the break statement is optional, in almost all case statements it is required for the switch to work correctly.

Literal numbers used as case labels are required by the compiler to be integers. Numeric constants used as case labels are rounded by the compiler to the nearest integers.

### See Also

**Switch Statements** on page IV-43, **default** and **break** for more usage details.

## t

### t

The **t** function returns the T value for the current chunk of the destination wave when used in a multidimensional wave assignment statement. T is the scaled chunk index while **s** is the chunk index itself.

### Details

Unlike **x**, outside of a wave assignment statement, **t** does not act like a normal variable.

**See Also**

**Waveform Arithmetic and Assignments** on page II-74.

For other dimensions, the **p**, **q**, **r**, and **s** functions.

For scaled dimension indices, the **x**, **y**, and **z** functions.

**TabControl**

**TabControl** [/Z] *ctrlName* [**keyword** = **value** [, **keyword** = **value** ...]]

The TabControl operation creates tab panels for controls.

For information about the state or status of the control, use the **ControlInfo** operation.

**Parameters**

*ctrlName* is the name of the TabControl to be created or changed.

The following keyword=value parameters are supported:

|                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>align</b> = <i>alignment</i>                        | Sets the alignment mode of the control. The alignment mode controls the interpretation of the <i>leftOrRight</i> parameter to the <b>pos</b> keyword. The <b>align</b> keyword was added in Igor Pro 8.00.<br><br>If <i>alignment</i> =0 (default), <i>leftOrRight</i> specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.<br><br>If <i>alignment</i> =1, <i>leftOrRight</i> specifies the position of the right end of the control and the right end position remains fixed if the control size is changed. |
| <b>appearance</b> ={ <i>kind</i> [, <i>platform</i> ]} | Sets the appearance of the control. <i>platform</i> is optional. Both parameters are names, not strings.<br><br><i>kind</i> can be one of <b>default</b> , <b>native</b> , or <b>os9</b> .<br><br><i>platform</i> can be one of <b>Mac</b> , <b>Win</b> , or <b>All</b> .<br><br>See <b>DefaultGUIControls Default Fonts and Sizes</b> for how enclosed controls are affected by native TabControl appearance.<br><br>See <b>Button</b> for more appearance details.                                                                                                                   |
| <b>disable</b> = <i>d</i>                              | Sets user editability of the control.<br><br><i>d</i> =0: Normal.<br><i>d</i> =1: Hide.<br><i>d</i> =2: Draw in gray state; disable control action.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>fColor</b> =( <i>r,g,b[,a]</i> )                    | Sets the initial color of the tab labels. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> . Use of transparency is discouraged. The default is opaque black.<br><br>To further change the color of the tab labels text, use escape sequences in the text specified by the <b>tabLabel</b> keyword.                                                                                                                                                                                                                          |
| <b>focusRing</b> = <i>fr</i>                           | Enables or disables the drawing of a rectangle indicating keyboard focus:<br><br><i>fr</i> =0: Focus rectangle will not be drawn.<br><i>fr</i> =1: Focus rectangle will be drawn (default).<br><br>On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.                                                                                                                                                                                                                 |
| <b>font</b> = " <i>fontName</i> "                      | Sets the font used for tabs, e.g., <b>font</b> ="Helvetica".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>fsize</b> = <i>s</i>                                | Sets the font size for tabs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## TabControl

---

|                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fstyle=<i>fs</i></code>                      | <p><i>fs</i> is a bitwise parameter with each bit controlling one aspect of the font style as follows:</p> <ul style="list-style-type: none"><li>Bit 0: Bold</li><li>Bit 1: Italic</li><li>Bit 2: Underline</li><li>Bit 4: Strikethrough</li></ul> <p>See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings.</p>                                                                                      |
| <code>help={<i>helpStr</i>}</code>                 | <p>Sets the help for the control.</p> <p><i>helpStr</i> is limited to 1970 bytes (255 in Igor Pro 8 and before).</p> <p>You can insert a line break by putting “\r” in a quoted string.</p>                                                                                                                                                                                                                                    |
| <code>labelBack=(<i>r,g,b[,a]</i>) or 0</code>     | <p>Sets fill color for current tab and the interior. <i>r</i>, <i>g</i>, <i>b</i>, and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b>.</p> <p>If not set, then interior is transparent and the current tab is filled with the window background, though this style is platform-dependent.</p> <p>If you use an opaque fill color, drawing objects will not be seen because they will be covered up.</p> |
| <code>noproc</code>                                | <p>Specifies that no function is to run when clicking a tab.</p>                                                                                                                                                                                                                                                                                                                                                               |
| <code>pos={<i>leftOrRight,top</i>}</code>          | <p>Sets the position in <b>Control Panel Units</b> of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.</p>                                                                                                                                                                                            |
| <code>pos+={<i>dx,dy</i>}</code>                   | <p>Offsets the position of the control in <b>Control Panel Units</b>.</p>                                                                                                                                                                                                                                                                                                                                                      |
| <code>proc=<i>procName</i></code>                  | <p>Specifies the function to run when the tab is pressed. Your function must hide and show other controls as desired. /Z No error reporting.

### Tab Control Action Procedure

The action procedure for a TabControl takes a predefined `WMTabControlAction` structure as a parameter to the function:

```
Function ActionProcName(TC_Struct) : TabControl
 STRUCT WMTabControlAction &TC_Struct
 ...
 return 0
End
```

The “: TabControl” designation tells Igor to include this procedure in the Procedure pop-up menu in the Tab Control dialog.

See **WMTabControlAction** for details on the WMTabControlAction structure.

Although the return value is not currently used, action procedures should always return zero.

When clicking a TabControl with the selector arrow, click in the title region. The control is not selected if you click in the body. This is to make it easier to select controls in the body rather than the TabControl itself.

### Example

Designing a TabControl with all the accompanying interior controls can be somewhat difficult. Here is a suggested technique:

First, create and set the size and label for one tab. Then create the various controls for this first tab. Before starting on the second tab, create the TabControl’s procedure so that it can be used to hide the first set of controls. Then add the second tab, click it to run your procedure and start adding controls for this new tab. When done, update your procedure so the new controls are hidden when you start on the third tab.

Here is an example:

1. Create a panel and a TabControl:

```
NewPanel /W={150,50,478,250}
ShowTools
TabControl MyTabControl, pos={29,38}, size={241,142}, tabLabel(0)="First Tab", value=0
```

2. Add a few controls to the interior of the TabControl:

```
Button button0, pos={52,72}, size={80,20}, title="First"
CheckBox check0, pos={52,105}, size={102,15}, title="Check first", value=0
```

3. Write an action procedure:

```
Function TabActionProc(tc) : TabControl
 STRUCT WMTabControlAction& tc

 switch(tc.eventCode)
 case 2: // Mouse up
 Button button0, disable=(tc.tab!=0)
 CheckBox check0, disable=(tc.tab!=0)
 break
 endswitch
End
```

4. Set the action procedure and add a new tab:

```
TabControl MyTabControl, proc=TabActionProc, tabLabel(1)="Second Tab"
```

5. Click the second tab, which hides the first tab’s controls, and then add new controls like this:

```
Button button1, pos={58,73}, size={80,20}, title="Second"
CheckBox check1, pos={60,105}, size={114,15}, title="Check second", value= 0
```

6. Finally, change the action procedure by adding these lines at the end:

```
Button button1, disable=(tc.tab!=1)
CheckBox check1, disable=(tc.tab!=1)
```

### TabControl

#### TabControl

TabControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined tab control. See **Procedure Subtypes** on page IV-204 for details. See **TabControl** for details on creating a tab control.

### Table

#### Table

Table is a procedure subtype keyword that identifies a macro as being a table recreation macro. It is automatically used when Igor creates a window recreation macro for a table. See **Procedure Subtypes** on page IV-204 and **Killing and Recreating a Table** on page II-229 for details.

### TableStyle

#### TableStyle

TableStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Table dialog and in the Table Macros menu. See **Table Style Macros** on page II-260 for details.

### TableInfo

#### TableInfo(*winNameStr*, *itemIndex*)

The TableInfo function returns a string containing a semicolon-separated list of keywords and values that describe a column in a table or overall properties of the table. The main purpose of TableInfo is to allow an advanced Igor programmer to write a procedure which formats or arranges a table or which manipulates the table selection.

#### Parameters

*winNameStr* is the name of an existing table window or "" to refer to the top table.

*itemIndex* is one of the following:

| <i>itemIndex</i> Value | Returns                                                                                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -2                     | Information about the table as a whole.                                                                                                                                       |
| -1                     | Information about the Point column                                                                                                                                            |
| ≥0                     | Information about a column other than the Point column. 0 refers to the first column after the Point column, 1 refers to the second column after the Point column, and so on. |

TableInfo returns "" in the following situations:

- *winNameStr* is "" and there are no table windows.
- *winNameStr* is a name but there are no table windows with that name.
- *itemIndex* not -2 and is out of range for an existing column.

#### Details

If *itemIndex* is -2, the returned string describes the table as a whole and contains the following keywords, with a semicolon after each keyword-value pair.

| Keyword   | Information Following Keyword                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------|
| TABLENAME | The name of the table.                                                                                                    |
| HOST      | The host specification of the table's host window if it is a subwindow or "" if it is a top-level table window.           |
| ROWS      | Number of used rows in the table.                                                                                         |
| COLUMNS   | Number of used columns in the table including the Point column.                                                           |
| SELECTION | A description of the table selection as you would specify it when invoking the ModifyTable operation's selection keyword. |

| Keyword    | Information Following Keyword                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FIRSTCELL  | An identification of the first visible data cell in the top/left corner of the table in row-column format. The first data cell is at location 0, 0.                                                                                                                                                                                                                                                                                                           |
| LASTCELL   | An identification of the last visible data cell in the bottom/right corner of the table in row-column format.                                                                                                                                                                                                                                                                                                                                                 |
| TARGETCELL | An identification of the target (highlighted) data cell in row-column format.                                                                                                                                                                                                                                                                                                                                                                                 |
| ENTERING   | 1 if an entry has been started in the entry line, 0 if not.                                                                                                                                                                                                                                                                                                                                                                                                   |
| ENTRYTEXT  | The text displayed in the entry line. If the user is editing the text in the entry line, this is the text as edited so far. If the user is not editing, it is the value of the first selected cell, as text.<br><br>The ENTRYTEXT keyword is the last keyword-value pair in the returned string. It is not terminated with a trailing ";" character unless the entry line text itself ends with ";".<br><br>The ENTRYTEXT keyword was added in Igor Pro 9.00. |

If *itemIndex* is -1 up to but not including the number of used columns to the right of the Point column, the returned string describes the specified column and contains the following keywords, with a semicolon after each keyword-value pair.

| Keyword    | Information Following Keyword                                                                                                                                                                                                                                                                                                                              |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TABLERNAME | The name of the table.                                                                                                                                                                                                                                                                                                                                     |
| HOST       | The host specification of the table's host window if it is a subwindow or "" if it is a top-level table window.                                                                                                                                                                                                                                            |
| COLUMNNAME | Name of the column as you would specify it to the Edit operation if you were creating a table showing just the column of interest.                                                                                                                                                                                                                         |
| TYPE       | Column's type which will be one of the following: Unused, Point, Index, Label, Data, RealData, ImagData. "Index" identifies a index column such as the X values of a wave. "Label" identifies a column of dimension labels. "Data" identifies a data column of a scalar wave. RealData and ImagData identify a real or imaginary column of a complex wave. |
| INDEX      | Column's position. -1 refers to the Point column, 0 to the first data column, and so on.                                                                                                                                                                                                                                                                   |
| DATATYPE   | Numeric data type of the wave or zero for text waves. See WaveType for a definition of data type codes.                                                                                                                                                                                                                                                    |
| WAVE       | A full data folder path to the wave displayed in the column or "" for the Point column.                                                                                                                                                                                                                                                                    |
| COLUMNS    | The total number of columns in the table from the wave for the column for which you are getting information. This can be used to skip over all of the columns of a multidimensional wave.                                                                                                                                                                  |
| HDIM       | The wave dimension displayed horizontally as you move from one column to the next. 0 means rows, 1 means columns, 2 means layers, 3 means chunks.                                                                                                                                                                                                          |
| VDIM       | The wave dimension displayed vertically in the column. 0 means rows, 1 means columns, 2 means layers, 3 means chunks.                                                                                                                                                                                                                                      |
| TITLE      | As specified for the ModifyTable operation's title keyword.                                                                                                                                                                                                                                                                                                |
| WIDTH      | Column's width in points.                                                                                                                                                                                                                                                                                                                                  |
| FORMAT     | As specified for the ModifyTable operation's format keyword.                                                                                                                                                                                                                                                                                               |
| DIGITS     | As specified for the ModifyTable operation's digits keyword.                                                                                                                                                                                                                                                                                               |

---

### Examples

This example makes the table's target cell advance by one position within the range of selected cells each time it is called. To try it, create a table, select a range of cells and then run the function using the Macros menu.

```
Menu "Macros"
 "Test/1", /Q, AdvanceTargetCell("")
End

Function AdvanceTargetCell(tableName)
 String tableName // Name of table or "" for top table.

 String info = TableInfo(tableName, -2)
 if (strlen(info) == 0)
 return -1 // No such table
 endif

 String selectionInfo
 selectionInfo = StringByKey("SELECTION", info)

 Variable fRow, fCol, lRow, lCol, tRow, tCol
 sscanf selectionInfo, "%d,%d,%d,%d,%d,%d", fRow, fCol, lRow, lCol, tRow, tCol

 tCol += 1
 if (tCol > lCol)
 tCol = fCol
 tRow += 1
 if (tRow > lRow)
 tRow = fRow
 endif
 endif

 ModifyTable selection=(-1,-1, -1, -1, tRow, tCol)
End
```

## Tag

**Tag** [*flags*] [*taggedObjectName*, *xAttach* [, *textStr*]]

The Tag operation puts a tag on the target or named graph window or subwindow. A tag is an annotation that is attached to a particular point on a trace, image, waterfall plot, or axis in a graph.

The Tag operation can be invoked in several ways as illustrated by these examples:

```
// Make a wave and a graph
Make wave0 = sin(x/8); Display wave0

// Tag command with all optional parameters included
Tag/N=tag0 wave0, 0, "Point 0 on wave0" // Add a tag to a trace

// Tag command with all optional parameters omitted
Tag/C/N=tag0/F=0 // Change frame using /F flag
```

```
// Tag command with optional text parameter omitted
Tag/C/N=tag0 wave0, 50 // Change the tagged point
```

*taggedObjectName* and *xAttach* can be omitted only when changing an existing tag using Tag/C/N=<tag name>. *textStr* can be included only if *taggedObjectName* and *xAttach* are included.

**Parameters**

*taggedObjectName* is a trace, image or axis name which identifies the object to which the tag is to be attached. The name can be optionally followed by the # character and an instance number to distinguish multiple trace or image instances of the same wave. An axis name can be one of the standard axis names (bottom, top, left, or right) or a user-defined free axis name.

The *taggedObjectName* parameter is a name so, if you have a string variable containing the name, you must precede the string variable name with the \$ operator.

*xAttach* identifies the point on the trace, image, or axis, to which the tag is to be attached. See *xAttach Parameter* below for details.

*textStr* is the text that is to appear in the tag.

**xAttach Parameter**

*xAttach* identifies the point on the trace, image, or axis, to which the tag is to be attached.

For a trace tag, *xAttach* is the X wave scaling value of the attachment point.

For an image tag, *xAttach* is the X index in terms of the image wave's X scaling of the wave element to be tagged treating the wave as if it were 1D.

For a horizontal axis tag, *xAttach* is the X axis value of the point on the axis to which the tag is to be attached. Specifying NaN for *xAttach* centers the tag on the axis.

For a vertical axis tag, *xAttach* is the Y axis value of the point on the axis to which the tag is to be attached. Specifying NaN for *xAttach* centers the tag on the axis.

**Flags**

|                      |                                                                                              |
|----------------------|----------------------------------------------------------------------------------------------|
| <i>/A=anchorCode</i> | Specifies position of tag anchor point. <i>anchorCode</i> is a literal, <i>not</i> a string. |
| LT                   | left top                                                                                     |
| LC                   | left center                                                                                  |
| LB                   | left bottom                                                                                  |
| MT                   | middle top                                                                                   |
| MC                   | middle center (default)                                                                      |
| MB                   | middle bottom                                                                                |
| RT                   | right top                                                                                    |
| RC                   | right center                                                                                 |
| RB                   | right bottom                                                                                 |

The anchor point is on the tag itself. Any line or arrow drawn from the tag to the wave starts at the tag's anchor point. The anchor point also determines the precise spot on the tag which represents its position.

|               |                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/AO=a0</i> | Sets the text's auto-orientation mode. A non-zero <i>a0</i> value overrides the <i>/O</i> value.<br><i>/AO</i> is for trace tags only. Setting <i>/AO</i> for any other kind of annotation has no effect.<br>An auto-oriented tag's text rotates whenever it is redrawn, usually when the underlying data changes, the graph is resized, or when the tag is attached to a new point. |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                             |                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             | The values for <i>ao</i> are:                                                                                                                                                                                                                                                                                                                                                                               |
|                             | <i>ao</i> =0: No auto-orientation. Use the /O value (default).                                                                                                                                                                                                                                                                                                                                              |
|                             | <i>ao</i> =1: Tangent to the trace line at the attachment point.                                                                                                                                                                                                                                                                                                                                            |
|                             | <i>ao</i> =2: Tangent to the trace line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal.                                                                                                                                                                                                                                                                                     |
|                             | <i>ao</i> =3: Perpendicular to the trace line.                                                                                                                                                                                                                                                                                                                                                              |
|                             | <i>ao</i> =4: Perpendicular to the trace line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal.                                                                                                                                                                                                                                                                               |
| <i>/AXS[=isAxisTag]</i>     | Specifies that <i>taggedObjectName</i> is to be interpreted as an axis name. This is useful when the axis name is the same as one of the graph's trace or image instance names. <i>/AXS</i> is the same as <i>/AXS=1</i> . The <i>/AXS</i> flag was added in Igor Pro 9.00.                                                                                                                                 |
| <i>/B=(r,g,b[,a])</i>       | Sets color of the tag's background. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> .                                                                                                                                                                                                                                                            |
| <i>/B=b</i>                 | Controls the tag background.<br><i>b</i> =0: Opaque background.<br><i>b</i> =1: Transparent background.<br><i>b</i> =2: Same background as the graph plot area background.<br><i>b</i> =3: Same background as the window background.                                                                                                                                                                        |
| <i>/C</i>                   | Changes the existing tag.                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>/F=frame</i>             | Controls the tag frame.<br><i>frame</i> =0: No frame.<br><i>frame</i> =1: Underline frame.<br><i>frame</i> =2: Box frame.                                                                                                                                                                                                                                                                                   |
| <i>/G=(r,g,b[,a])</i>       | Sets color of the text in the tag. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> .                                                                                                                                                                                                                                                             |
| <i>/H=legendSymbolWidth</i> | <i>legendSymbolWidth</i> sets width of the legend symbol (the sample line or marker) in points. Use 0 for the default, automatic width.                                                                                                                                                                                                                                                                     |
| <i>/I=i</i>                 | Controls the tag visibility.<br><i>i</i> =1: Tag will be invisible if it is "off screen". "Off screen" means that its attachment point or any part of the tag's text is off screen. This is esthetically pleasing but gives you nothing to grab if you want to drag the tag back on screen.<br><i>i</i> =0: Tag will always be visible. If it is "off screen", it appears at the extreme edge of the graph. |
| <i>/IMG[=isAxisTag]</i>     | Specifies that <i>taggedObjectName</i> is to be interpreted as an image instance name. This is useful when the image instance name is the same as one of the graph's trace instance names or one of the axis names. <i>/IMG</i> is the same as <i>/IMG=1</i> . The <i>/IMG</i> flag was added in Igor Pro 9.00.                                                                                             |
| <i>/K</i>                   | Kills existing tag.                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>/L=line</i>              | Controls the line attaching the tag to the tagged point.<br><i>line</i> =0: No line from tag to attachment point.<br><i>line</i> =1: Line connecting tag to attachment point.<br><i>line</i> =2: Line with arrow pointing from tag to attachment point.<br><i>line</i> =3: Line with arrow pointing from attachment point to tag.<br><i>line</i> =4: Line with arrows at both ends.                         |

---

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/LS=</i> <i>linespace</i> | Specifies a tweak to the normal line spacing where <i>linespace</i> is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>/M[=sameSize]</i>         | <p><i>/M</i> or <i>/M=1</i> specifies that legend markers should be the same size as the marker in the graph.</p> <p><i>/M=0</i> turns same-size mode off so that the size of the marker in the legend is based on text size.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>/N=name</i>               | Specifies name of the tag to create or change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>/O=rot</i>                | <p>Sets the text's rotation. <i>rot</i> is in (integer) degrees, counterclockwise and must be a number from -360 to 360.</p> <p>0 is normal horizontal left-to-right text, 90 is vertical bottom-to-top text.</p> <p>If the tag is attached to a trace (not an image or axis), any non-zero <i>/AO</i> value will overwrite this rotation value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>/P=tipOffset</i>          | Sets the offset from the tip of a tag's line or arrow to the point on the wave that it is tagging. <i>tipOffset</i> is a positive number from 0 to 200 in points. If <i>tipOffset=0</i> (default), it automatically chooses an appropriate offset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>/Q[=contourInstance]</i>  | <p>Associates a tag with a particular contour level trace in a graph recreation macro. Of interest mainly to hard-core programmers.</p> <p>When "<i>=contourInstance</i>" is present, <i>/Q</i> associates the tag with the contour wave. Igor will feel free to change or delete the tag, as appropriate, when it recalculates the contour (because you changed the contour data or appearance, the graph size or the axis range). <i>contourInstance</i> is a contour instance name, such as <i>zWave</i> or <i>zWave#1</i> if you have the same wave contoured twice in the graph.</p> <p><i>/Q</i> by itself, with "<i>=contourInstance</i>" not present, disassociates the tag from the contour wave. Igor will no longer modify or delete the tag (unless the contour level to which it is attached is deleted). If you manually tweak a contour label, using the Modify Annotation dialog, Igor uses this flag.</p> |
| <i>/R=newName</i>            | Renames the tag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>/S=style</i>              | <p>Controls the tag frame style.</p> <p><i>style=0</i>: Single frame.</p> <p><i>style=1</i>: Double frame.</p> <p><i>style=2</i>: Triple frame.</p> <p><i>style=3</i>: Shadow frame.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>/T=tabSpec</i>            | <i>tabSpec</i> is a single number in points, such as <i>/T=72</i> , for evenly spaced tabs or a list of tab stops in points such as <i>/T={ 50, 150, 225 }</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>/TL=extLineSpec</i>       | <p>Specifies extended tag line parameters similar to the <b>SetDrawEnv</b> arrow settings.</p> <p><i>extLineSpec</i> = {<i>keyword</i> = <i>value</i>,...} or zero to turn off all extended specifications.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

Valid *keyword-value* pairs are:

|                                  |                                                                                                                                             |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>len=l</code>               | Length of arrow head in points ( $l=0$ for auto).                                                                                           |
| <code>fat=f</code>               | Width to length ratio of arrow head (default is 0.5 same as $f=0$ ).                                                                        |
| <code>style=s</code>             | Sets barb side mode (see <b>SetDrawEnv</b> <code>astyle</code> for values).                                                                 |
| <code>shar =s</code>             | Sets sharpness between -1 and 1 (default is 0; blunt).                                                                                      |
| <code>frame=f</code>             | Sets frame thickness in outline mode.                                                                                                       |
| <code>lThick=l</code>            | Sets line thickness in points (default is 0.5 for $l=0$ ).                                                                                  |
| <code>lineRGB=(r,g,b[,a])</code> | Sets color for lines. $r$ , $g$ , $b$ , and $a$ specify the color and optional opacity as <b>RGBA Values</b> . The default is opaque black. |
| <code>dash=d</code>              | Specifies dash pattern number between 0 and 17 (see <b>SetDashPattern</b> for patterns).                                                    |

|                         |                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/W=winName</code> | Operates on the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |
| <code>/V=vis</code>     | Controls annotation visibility.<br><br><code>vis=0:</code> Invisible annotation; not selectable. The annotation is still listed in <b>AnnotationList</b> .<br><br><code>vis=1:</code> Visible annotation (default).                                                                                                                                            |
| <code>/X=xOffset</code> | Distance from point to tag as percentage of graph width. For axis tags, the offsets are proportional to the size of the text used for the axis labels.                                                                                                                                                                                                         |
| <code>/Y=yOffset</code> | Distance from point to tag as percentage of graph height. For axis tags, the offsets are proportional to the size of the text used for the axis labels.                                                                                                                                                                                                        |
| <code>/Z=freeze</code>  | Controls freezing of tag position.<br><br><code>freeze=1:</code> Freezes tag position (you can't move it with the mouse).<br><br><code>freeze=0:</code> Unfreezes it.                                                                                                                                                                                          |

## Details

If the `/C` flag is used, it must be the first flag in the command and must be followed immediately by the `/N=name` flag.

If the `/K` flag is used, it must be the first flag in the command and must be followed immediately by the `/N=name` flag with no further flags or parameters.

*taggedObjectName* and *xAttach* can be omitted only when changing an existing tag using `Tag/C/N=<tag name>`. *textStr* can be included only if *taggedObjectName* and *xAttach* are included. This syntax allows changes to the tag to be made through the *flags* parameters without needing to respecify the other parameters. Similarly, the tag's attachment point can be changed without needing to respecify the *textStr* parameter.

A tag can have at most 100 lines.

*textStr* can contain escape codes which affect subsequent characters in the text. An escape code is introduced by a backslash character. In a literal string, you must enter two backslashes to produce one. See **Backslashes in Annotation Escape Sequences** on page III-58 for details.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See **Annotation Escape Codes** on page III-53 for details.

"\r" inserts a carriage-return character which starts a new line of text in the annotation.

Some escape codes insert text based on the wave point or axis to which a tag is attached. See **Tag Escape Codes** on page III-55 and **Axis Label Escape Codes** on page III-57 for details.

The characters "<??>" in a tag indicate that you specified an invalid escape code or used a font that is not available.

### Examples

Following is an example of various ways in which axis tags can be used:

```
Make/O jack=sin(x/8)
SetScale x,0,14e9,"y" jack
Display jack
Label bottom "\\u#2" // turn off default axis label
ModifyGraph axOffset(bottom)=1.16667 // make room for tag (manual adustment)
Tag/N=axisTag0/F=0/A=MT/X=0.20/Y=-4.29/L=0 bottom, Nan, "\\JCTime (\\U)r2nd line"

// Now tag a few important points
Tag/N=axisTag1/F=0/A=LB/X=1.20/Y=3.00 bottom, 0, "Big Bang"
Tag/N=axisTag2/F=0/A=MB/X=0.00/Y=2.86 bottom, 8000000000, "Earth formed"
Tag/N=axisTag3/F=0/A=RB/X=-0.80/Y=4.71 bottom, 13040000000, "Dinosaurs ruled"
```

## TagVal

### TagVal (code)

TagVal is a very specialized function that is only valid when called from within the text of a tag as part of a \{} dynamic text escape sequence. It returns a number reflecting some property of the tag and helps you to display information about the tagged wave. The property is selected by the *code* parameter:

| <i>code</i> | <b>Return Value</b>                                                                                                                                                                                                                             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | Similar to \OP, returns the tag attach point number.                                                                                                                                                                                            |
| 1           | Similar to \OX, returns the X coordinate of tag attachment in the graph. When a tag is attached to an XY pair of traces, the X coordinate will most likely be different than the tag's X scaling attachment value specified in the Tag command. |
| 2           | Similar to \OY, returns the Y coordinate of tag attachment in the graph or the Y axis value in a Waterfall plot.                                                                                                                                |
| 3           | Similar to \OZ, returns the Z coordinate of tag attachment in a contour, image, or Waterfall plot.                                                                                                                                              |
| 4           | Similar to \Ox, returns the trace x offset.                                                                                                                                                                                                     |
| 5           | Similar to \Oy, returns the trace y offset.                                                                                                                                                                                                     |
| 6           | Returns the X muloffset (with the not set value 0 translated to 1).                                                                                                                                                                             |
| 7           | Returns the Y muloffset (with the not set value 0 translated to 1).                                                                                                                                                                             |

Because TagVal returns a numeric value, the result can be formatted any way you wish using the **printf** formatting codes. In contrast, the \O codes insert preformatted text, and you don't have control over the format.

TagVal is sometimes used in conjunction with the **TagWaveRef** function. For example, you might write a user-defined function that calculates a value as a function of a wave and a point number.

### Examples

```
Tag wave0, 0, "Y value is \\{\\"%g\\", TagVal(2) }"
Tag wave0, 0, "Y value is \\{\\"%g\\", TagWaveRef() [TagVal(0)] }"
Tag wave0, 0, "Y value is \\OY"
```

These examples all produce identical results.

## TagWaveRef

---

### See Also

The **Tag** operation, the **TagWaveRef** function.

For a discussion of wave references, see **Wave Reference Functions** on page IV-197.

## TagWaveRef

### TagWaveRef ( )

TagWaveRef is a very specialized function that is only valid when called from within the text of a tag as part of a `\{ }` dynamic text escape sequence. It returns a wave reference to the wave that the tag is on and helps you to display information about the tagged wave. It is often used in conjunction with the **TagVal** function. You can pass the result of TagWaveRef to any function that takes a *Wave* parameter.

### Examples

Show the name of the data folder containing the tagged wave:

```
Tag wave0, 0, "\\ON is in \\{\\"%s\", GetWavesDataFolder(TagWaveRef(), 0)}"
```

The **Tag** operation, the **TagVal** function

For a discussion of wave references, see **Wave Reference Functions** on page IV-197.

## tan

### tan (angle)

The tan function returns the tangent of *angle* which is in radians.

In complex expressions, *angle* is complex, and tan(*angle*) returns a complex value:

$$\tan(x + iy) = \frac{\sin(x + iy)}{\cos(x + iy)} = \frac{\sin(2x) + i \sinh(2y)}{\cos(2x) + \cosh(2y)}$$

### See Also

atan, atan2, sin, cos, sec, csc, cot

## tanh

### tanh (num)

The tanh function returns the hyperbolic tangent of *num*:

$$\tanh(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

In complex expressions, *num* is complex, and tanh(*num*) returns a complex value.

## Text2Bezier

**Text2Bezier** [ *flags* ] *fontNameStr*, *fstyle*, *textStr*, *xWaveName*, *yWaveName*

The Text2Bezier operation creates the data for a Bezier curve corresponding to the outline of some text using the supplied font information. The output waves are formatted to be drawn using Igor's DrawBezier operation.

### Parameters

|                    |                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>fontNameStr</i> | A string expression containing the name of a font to be used for generating outlines.                                                                                                                                                                                                                              |
| <i>fstyle</i>      | <p><i>fstyle</i> is a bitwise parameter with each bit controlling one aspect of the font style as follows::</p> <p>Bit 0:     Bold</p> <p>Bit 1:     Italic</p> <p>Bit 2:     Underline</p> <p>Bit 4:     Strikethrough</p> <p>See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings.</p> |
| <i>textStr</i>     | A string expression containing the text to be transformed into Bezier outlines.                                                                                                                                                                                                                                    |
| <i>xWaveName</i>   | Specifies X output wave to receive the Bezier curve data.                                                                                                                                                                                                                                                          |
| <i>yWaveName</i>   | Specifies Y output wave to receive the Bezier curve data.                                                                                                                                                                                                                                                          |

### Flags

|               |                                                                                                                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/FS=fs</i> | <i>fs</i> is the font size to apply while generating the outlines. Without this flag, glyphs are scaled to unit size. The scaling parameters for DrawBezier are limited to a maximum of 20, so you will probably need to use this flag if you want very large text. |
| <i>/O</i>     | Allow overwriting the output waves.                                                                                                                                                                                                                                 |

### Details

To draw the text outline, pass the output waves from Text2Bezier to the DrawBezier operation. The coordinates are such that the DrawBezier origin will be the left baseline of the text. In most cases you will want to use the SetDrawEnv operation to set the coordinate system to absolute. If you wish to fill the text with color or gradient, you will need to use the SetDrawEnv subpaths keyword.

### Output Variables

|        |                                                                 |
|--------|-----------------------------------------------------------------|
| V_Flag | 0 for success, 1 for general failure, 2 for extraction failure. |
|--------|-----------------------------------------------------------------|

### Examples

```
// Extract text to Bezier data
Text2Bezier/O/FS=20 "Helvetica", 0, "Text2Bezier", textx, texty

// Draw outline in a graph window with no fill
Display /W=(100,100,700,450)
SetDrawLayer UserFront
SetDrawEnv fillpat=0,xcoord= abs,ycoord= abs// fillpat=0 specifies no fill
DrawBezier 100,100,1,1,textx,texty

// Draw outline three times larger and filled with a gradient shading
// subpaths=1 draws the entire Bezier as a series of subpaths for correct filling
SetDrawEnv xcoord= abs,ycoord= abs,subpaths= 1,
 gradient= {0, 0, 0, 1, 0, (65535,65535,0), (65535,0,0)}
DrawBezier 100,150,3,3,textx,texty
```

### See Also

## TextBox

**TextBox** [*flags*] [*textStr*]

The TextBox operation puts a textbox on the target or named graph window. A textbox is an annotation that is not associated with any particular trace.

### Parameters

*textStr* is the text that is to appear in the textbox. It is optional.

## TextBox

---

### Flags

*/A=anchorCode* Specifies position of textbox anchor point.

| <i>anchorCode</i> | Position      | <i>anchorCode</i> | Position     |
|-------------------|---------------|-------------------|--------------|
| LT                | left top      | RT                | right top    |
| LC                | left center   | RC                | right center |
| LB                | left bottom   | RB                | right bottom |
| MT                | middle top    |                   |              |
| MC                | middle center |                   |              |
| MB                | middle bottom |                   |              |

*anchorCode* is a literal, *not* a string.

For interior textboxes, the anchor point is on the rectangular edge of the plot area of the graph window (where the left, bottom, right, and top axes are drawn).

For exterior textboxes, the anchor point is on the rectangular edge of the entire graph window.

*/B=(r,g,b[,a])* Sets the color of the textbox background. *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**.

*/B=b*

Controls the textbox background.

*b=0*: Opaque background.

*b=1*: Transparent background.

*b=2*: Same background as the graph plot area background.

*b=3*: Same background as the window background.

*/C*

Changes existing textbox.

*/D={thickMult [, shadowThick [, haloThick]]}*

*thickMult* multiplies the normal frame thickness of a text-box. The thickness may be set using just */D=thickMult*.

*shadowThick*, if present, overrides Igor's normal shadow thickness. It is in units of fractional points.

*haloThick* governs the annotation's halo thickness (a surrounding band of the annotation's background color), which can be -1 to 10 points wide.

The default *haloThick* value is -1, which preserves the behavior of previous versions of Igor where the halo of all annotations was set by the global variable root:V\_TBBufZone. Any negative value of *haloThick* (-0.5, for example) will be overridden by V\_TBBufZone if it exists, otherwise the absolute value of *haloThick* will be used. A zero or positive value overrides V\_TBBufZone.

Any of the parameters may be missing. To set *haloThick* to 0 without changing other parameters, use */D={ , , 0 }*.

*/E[=exterior]*

*/E* or */E=1* forces textbox (or legend) to be exterior to graph (provided *anchorCode* is not MC) and pushes the graph margins away from the anchor edge(s). */E=2* also forces exterior mode but does not push the margins.

*/E=0* returns it to the default (an "interior textbox" which can be anywhere in the graph window).

|                             |                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/F=frame</i>             | Controls the textbox frame.<br><i>frame=0</i> : No frame.<br><i>frame=1</i> : Underline frame.<br><i>frame=2</i> : Box frame.                                                                                                                                                                                                                                  |
| <i>/G=(r,g,b[,a])</i>       | Sets color of the text in the textbox. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> .                                                                                                                                                                                                            |
| <i>/H=legendSymbolWidth</i> | <i>legendSymbolWidth</i> sets width of the legend symbol (the sample line or marker) in points. Use 0 for the default, automatic width.                                                                                                                                                                                                                        |
| <i>/K</i>                   | Kills existing textbox.                                                                                                                                                                                                                                                                                                                                        |
| <i>/LS= linespace</i>       | Specifies a tweak to the normal line spacing where <i>linespace</i> is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line.                                                                                                                                         |
| <i>/M[=sameSize]</i>        | <i>/M</i> or <i>/M=1</i> specifies that legend markers should be the same size as the marker in the graph.<br><br><i>/M=0</i> turns same-size mode off so that the size of the marker in the legend is based on text size.                                                                                                                                     |
| <i>/N=name</i>              | Specifies the name of the textbox to change or create.                                                                                                                                                                                                                                                                                                         |
| <i>/O=rot</i>               | Sets the text's rotation. <i>rot</i> is in (integer) degrees, counterclockwise and must be a number from -360 to 360.<br><br>0 is normal horizontal left-to-right text, 90 is vertical bottom-to-top text.                                                                                                                                                     |
| <i>/R=newName</i>           | Renames the textbox.                                                                                                                                                                                                                                                                                                                                           |
| <i>/S=style</i>             | Controls the textbox frame style.<br><i>style=0</i> : Single frame.<br><i>style=1</i> : Double frame.<br><i>style=2</i> : Triple frame.<br><i>style=3</i> : Shadow frame.                                                                                                                                                                                      |
| <i>/T=tabSpec</i>           | <i>tabSpec</i> is a single number in points, such as <i>/T=72</i> , for evenly spaced tabs or a list of tab stops in points such as <i>/T={ 50, 150, 225 }</i> .                                                                                                                                                                                               |
| <i>/V=vis</i>               | Controls annotation visibility.<br><i>vis=0</i> : Invisible annotation; not selectable. The annotation is still listed in <b>AnnotationList</b> .<br><i>vis=1</i> : Visible annotation (default).                                                                                                                                                              |
| <i>/W=winName</i>           | Operates in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy. |
| <i>/X=xOffset</i>           | For interior textboxes <i>xOffset</i> is the distance from anchor to textbox as a percentage of the plot area width.<br><br>For exterior textboxes <i>xOffset</i> is the distance from anchor to textbox as a percentage of the graph window width. See <i>/E</i> and <i>/A</i> .                                                                              |
| <i>/Y=yOffset</i>           | <i>yOffset</i> is the distance from anchor to textbox as a percentage of the plot area height (interior textboxes) or graph window height (exterior textboxes). See <i>/E</i> and <i>/A</i> .                                                                                                                                                                  |

## TextEncoding

---

*/Z=freeze* Controls freezing of textbox position.  
*freeze=1:* Freezes textbox position (you can't move it with the mouse).  
*freeze=0:* Unfreezes it.

### Details

Use the optional */W=winName* flag to specify a specific graph or layout window. When used on the command line or in a Macro, Proc, or Window procedure, */W* must precede all other flags.

If the */C* flag is used, it must be the first flag in the command (except that it may follow an initial */W*) and must be followed immediately by the */N=name* flag.

If the */K* flag is used, it must be the first flag in the command (or follow an initial */W*) and must be followed immediately by the */N=name* flag with no further flags or parameters.

*textStr* is optional. If missing, the textbox text is unchanged. This allows changes to the textbox to be made through the flags without changing the text.

A textbox can have at most 100 lines.

*textStr* can contain escape codes which affect subsequent characters in the text. An escape code is introduced by a backslash character. In a literal string, you must enter two backslashes to produce one. See **Backslashes in Annotation Escape Sequences** on page III-58 for details.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See **Annotation Escape Codes** on page III-53 for details.

The characters "<??>" in a textbox indicate that you specified an invalid escape code or used a font that is not available.

### Examples

```
TextBox/C/N=t1/X=25/Y=50
```

moves the textbox named t1 to the location defined by X=25 and Y=50.

```
TextBox/C/N=t1 "New Text"
```

changes the text for t1.

See the **printf** operation for formatting codes used in *formatStr*.

**Programming with Annotations** on page III-52.

**Trace Names** on page II-270, **Programming With Trace Names** on page IV-87.

## TextEncoding

```
#pragma TextEncoding = "<text encoding name>"
```

**#pragma TextEncoding** is a compiler directive that tells Igor the text encoding used by a procedure file. Igor needs to know this in order to correctly interpret non-ASCII characters in the file. We recommend that you add a **TextEncoding** pragma to your procedure files.

All new procedure files should use the UTF-8 text encoding:

```
#pragma TextEncoding = "UTF-8"
```

See **Text Encoding Names and Codes** on page III-492 for a list of accepted text encoding names.

This statement must be flush against the left edge of the procedure file with no indentation. It is usually placed at or near the top of the file.

The **TextEncoding** pragma was added in Igor Pro 7.00 and is ignored by earlier versions.

See **The TextEncoding Pragma** on page IV-55 for further explanation.

## TextEncodingCode

**TextEncodingCode** (*textEncodingNameStr*)

The TextEncodingCode function returns the Igor text encoding code for the named text encoding or 0 if the text encoding is unknown.

The TextEncodingCode function was added in Igor Pro 7.00.

### Parameters

*textEncodingNameStr* is an Igor text encoding name as listed under **Text Encoding Names and Codes** on page III-492.

### Details

Igor ignores all non-alphanumeric characters in text encoding names so "Shift JIS", "ShiftJIS", "Shift\_JIS" and "Shift-JIS" are equivalent.

It also ignores leading zeros in numbers embedded in text encoding names so "ISO-8859-1" and "ISO-8859-01" are equivalent.

TextEncodingCode does a case-insensitive comparison.

### See Also

**Text Encodings** on page III-461, **Text Encoding Names and Codes** on page III-492, **TextEncodingName**

## TextEncodingName

**TextEncodingName** (*textEncoding, index*)

The TextEncodingName function returns one or more text encoding names corresponding to the specified text encoding code. The result is returned as a string value.

If *textEncoding* is not a valid Igor text encoding code or if *index* is out of range, TextEncodingName returns "Unknown".

This function is mainly useful for providing a human-readable string corresponding to a given text encoding code for display purposes. You might use it to generate some Internet-compatible text, such as an HTML page, if you need a string to specify the charset.

The TextEncodingName function was added in Igor Pro 7.00.

### Parameters

*textEncoding* is an Igor text encoding code as listed under **Text Encoding Names and Codes** on page III-492.

*index* specifies which text encoding name you want. A given text encoding can be identified by more than one name. Normally you will pass 0 to get the first text encoding name for the specified text encoding code. This is the preferred text encoding name. You can pass 1 for the second name, if any, 2 for the third, if any, and so on. You can pass -1 to get a semicolon-separated list of all text encoding names for the specified text encoding.

### Details

Internally Igor has a table of text encoding codes and the corresponding text encoding names. For a given code there may be more than one acceptable name. For example, for the code 2 (MacRoman), the names "macintosh", "MacRoman" and "x-macroman" are accepted, with "macintosh" being preferred. The TextEncodingName function returns a text encoding name from the internal table.

The preferred name is usually the name recognized by the Internet Assigned Numbers Authority (IANA) as listed at <http://www.iana.org/assignments/character-sets>.

### Examples

```
// Get the preferred name for the MacRoman text encoding (2)
String firstName = TextEncodingName(2, 0); Print firstName

// Get the second name for the MacRoman text encoding (2)
String secondName = TextEncodingName(2, 1); Print secondName

// Get a semicolon-separated list of all text encoding names for MacRoman
String names = TextEncodingName(2, -1); Print names
```

## TextFile

---

### See Also

**Text Encodings** on page III-461, **Text Encoding Names and Codes** on page III-492, **TextEncodingCode**

## TextFile

**TextFile**(*pathName*, *index* [, *creatorStr*])

**Note:** TextFile is antiquated. Use **IndexedFile** instead.

The TextFile function returns a string containing the name of the *index*th TEXT file from the folder specified by *pathName*.

On Macintosh, TextFile returns only files whose file type property is TEXT, regardless of the file's extension.

On Windows, Igor considers files with ".txt" extensions to be of type TEXT.

### Details

TextFile returns an empty string (" ") if there is no such file.

*pathName* is the name of an Igor symbolic path; it is *not* a string.

*index* starts from zero.

*creatorStr* is an optional string argument containing four ASCII characters such as "IGR0". Only files of the specified Macintosh creator code are indexed. Set *creatorStr* to "?????" to index all text files (or omit the argument altogether). This argument is ignored on Windows systems.

The order of files in a folder is determined by the operating system.

### Examples

You can use TextFile in a procedure to sequence through each TEXT file in a folder, put the name of the text file into a string variable, and use this string variable as a parameter to the **LoadWave** or **Open** operations:

```
Function/S PrintFirstLineOfTextFiles(pathName)
 String pathName // Name of an Igor symbolic path.

 Variable refNum, index
 String str, fileName
 index = 0
 do
 fileName = TextFile($pathName, index)
 if (strlen(fileName) == 0)
 break // No more files
 endif
 Open/R/P=$pathName refNum as fileName
 FReadLine refNum, str // Read first line including CR/LF
 Print fileName + ":" + str // Print file name and first line
 Close refNum
 index += 1 // Next file
 while (1)
End
```

### See Also

See the **IndexedFile** function, which is similar to TextFile but works on files of any type, and also **IndexedDir**. Also see the **LoadWave** and **Open** the operations.

## TextHistogram

**TextHistogram** [*flags*] *srcTextWave*

The TextHistogram operation computes the histogram of a text wave where the output bins represent the count of occurrences of each unique string found in *srcTextWave*.

The TextHistogram operation was added in Igor Pro 9.00.

**Flags**

|                                        |                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/CI</code>                       | Performs case-insensitive string comparison.<br>If you omit <code>/CI</code> TextHistogram performs case-sensitive comparison unless you include <code>/LOC</code> .                                                                                                                                                                      |
| <code>/DN=<i>binsCountsWave</i></code> | Specifies the numeric output wave that contains the count for each bin. If you omit <code>/DN</code> , the numeric output wave is created in the current data folder and named <code>W_TextHistogram</code> .                                                                                                                             |
| <code>/DT=<i>binsTextWave</i></code>   | Specifies the text output wave that contains the strings corresponding to each bin. If you omit <code>/DT</code> , the text output wave is created in the current data folder and named <code>T_TextHistogram</code> .                                                                                                                    |
| <code>/FREE</code>                     | Creates all output waves as a free waves.<br><code>/FREE</code> is permitted in user-defined functions only. If you use <code>/FREE</code> then all output wave parameters must be simple names, not paths or \$ expressions.<br>See <b>Free Waves</b> on page IV-90 for details on free waves.                                           |
| <code>/LOC</code>                      | Performs case-insensitive string comparison following locale-aware rules. This option results in significantly slower performance.                                                                                                                                                                                                        |
| <code>/SORT=<i>mode</i></code>         | Sets the order of the output bins.<br><i>mode</i> =0: The output waves are ordered from the bin with the largest count to the bin with the smallest count. This is the default if you omit <code>/SORT</code> .<br><i>mode</i> =1: The output waves are ordered from the bin with the longest string to the bin with the shortest string. |
| <code>/Z</code>                        | Suppress errors. You can use <code>V_Flag</code> to detect and handle errors yourself.                                                                                                                                                                                                                                                    |

**Details**

TextHistogram does case-sensitive string comparisons unless you specify `/CI` or `/LOC` in which case it does case-insensitive string comparisons.

TextHistogram scans *srcTextWave* and counts matching string entries. It treats text waves of all dimensions as if they were 1D waves.

The output of the operation consists of two waves: a text wave containing the text corresponding to each bin and a numeric wave containing the bin counts. You can specify the destination waves using the `/DT` and `/DN` flags. If you omit `/DT` the text output wave is created in the current data folder and named `T_TextHistogram`. If you omit `/DN` the numeric output wave is created in the current data folder and named `W_TextHistogram`. The output waves overwrite any previously-existing waves with the same names.

The operation creates automatic wave references for the output waves specified by `/DT` and `/DN`. See **Automatic Creation of WAVE References** on page IV-71 for details. It does not create wave references for the default output waves created if you omit `/DT` or `/DN` so you need explicit wave references.

When using case-insensitive mode the output text wave may use any one of the equivalent forms of the text represented by the bin.

**Output Variables**

TextHistogram sets the following output variable:

|                     |                                                        |
|---------------------|--------------------------------------------------------|
| <code>V_flag</code> | 0 if the operation succeeded or a non-zero error code. |
|---------------------|--------------------------------------------------------|

**See Also**

### ThreadGroupCreate

**ThreadGroupCreate** (*nt*)

The ThreadGroupCreate function creates a thread group containing *nt* threads and returns a thread ID number. Use the number of computer processors for *nt* when trying to improve computation speed using parallel threads. A background worker might use just one thread regardless of the number of processors.

**See Also**

**ThreadSafe Functions** on page IV-105 and **ThreadSafe Functions and Multitasking** on page IV-327.

### ThreadGroupGetDF

**ThreadGroupGetDF** (*tgID*, *waitms*)

**ThreadGroupGetDFR** should be used instead of ThreadGroupGetDF which causes memory leaks.

The ThreadGroupGetDF function retrieves a data folder path string from a thread group queue and removes the data folder from the queue.

When called from a preemptive thread it returns a data folder from the thread group's input queue. When called from the main thread it returns a data folder from the thread group's output queue.

*tgID* is a thread group ID returned by **ThreadGroupCreate**. You can pass 0 for *tgID* when calling ThreadGroupGetDF from a preemptive thread. You must pass a valid thread group ID when calling ThreadGroupGetDF from the main thread.

*waitms* is the maximum number of milliseconds to wait for a data folder to become available in the queue. Pass 0 to test if a data folder is available immediately. Pass INF to wait indefinitely or until a user abort.

ThreadGroupGetDF returns "" if the timeout period specified by *waitms* expires and no data folder is available in the queue.

**See Also**

**ThreadSafe Functions** on page IV-105 and **ThreadSafe Functions and Multitasking** on page IV-327.

The **ThreadGroupGetDFR** function.

### ThreadGroupGetDFR

**ThreadGroupGetDFR** (*tgID*, *waitms*)

The ThreadGroupGetDFR function retrieves a data folder reference from a thread group queue and removes the data folder from the queue. The data folder becomes a free data folder.

When called from a preemptive thread it returns a data folder from the thread group's input queue. When called from the main thread it returns a data folder from the thread group's output queue.

*tgID* is a thread group ID returned by **ThreadGroupCreate**. You can pass 0 for *tgID* when calling ThreadGroupGetDFR from a preemptive thread. You must pass a valid thread group ID when calling ThreadGroupGetDFR from the main thread.

*waitms* is the maximum number of milliseconds to wait for a data folder to become available in the queue. Pass 0 to test if a data folder is available immediately. Pass INF to wait indefinitely or until a user abort.

ThreadGroupGetDFR returns a NULL data folder reference if the timeout period specified by *waitms* expires and no data folder is available in the queue. You can test for NULL using **DataFolderRefStatus**.

**See Also**

**ThreadSafe Functions** on page IV-105, **ThreadSafe Functions and Multitasking** on page IV-327 and **Free Data Folders** on page IV-95.

### ThreadGroupPutDF

**ThreadGroupPutDF** *tgID*, *datafolder*

The ThreadGroupPutDF operation posts data to a preemptive thread group.

**Parameters**

*tgID* is thread group ID returned by **ThreadGroupCreate**, *datafolder* is the data folder you wish to send to the thread group.

*datafolder* can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

### Details

When you call it from the main thread, **ThreadGroupPutDF** removes *datafolder* from the main thread's data hierarchy and posts to the input queue of the thread group specified by *tgID*.

When you call it from a preemptive thread, use 0 for *tgID* and the data folder will be posted to the output queue of thread group to which thread belongs.

Input and output data folders may be retrieved from the queues by calling the string function **ThreadGroupGetDF** or **ThreadGroupGetDFR**.

**Warning:** Take care not to use any stale WAVE, NVAR, or SVAR variables that might contain references to objects in the data folder. Use **WAVEClear** on all WAVE reference variables that might contain references to waves that are in the data folder being posted before calling **ThreadGroupPutDF**. An error will occur if any waves in the data folder are in use or referenced in a WAVE variable.

**Warning:** Any DFREF variables that refer to the data folder (or any child thereof) must be cleared prior to executing this command. You can clear a DFREF using `df r=$ "`.

From the standpoint of the source thread, ThreadGroupPutDF is conceptually similar to KillDataFolder and, like KillDataFolder, if the current data folder is within *datafolder*, the current data folder is set to the parent of *datafolder*. You can not pass `root`: as *datafolder*.

### See Also

The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-105, and **ThreadSafe Functions and Multitasking** on page IV-327.

## ThreadGroupRelease

**ThreadGroupRelease**(*tgID* [, *beGraceful*])

The ThreadGroupRelease function releases the thread group referenced by *tgID*. *tgID* is the thread group ID returned by **ThreadGroupCreate**. Any data folders remaining in the group's input or output queues are discarded.

Specifying *tgID*=-2 kills all running threads in all thread groups.

Normally you call ThreadGroupRelease after all threads in the group have completed. In the event that threads are still running, they are aborted. An attempt is made to safely stop running threads but, if they continue to run, they are killed.

The *beGraceful* parameter, added in Igor Pro 9.00, affects thread worker functions that include catch blocks to handle aborts gracefully. If *beGraceful* is omitted or is 0, ThreadGroupRelease performs aborts in a way that interferes with such catch blocks. If *beGraceful* is 1, the catch blocks run normally. See **Aborting Threads** on page IV-334 for details.

ThreadGroupRelease returns zero if successful, -1 if an error occurred (probably invalid *tgID*), or -2 if a force quit was needed. In the latter case, you should restart Igor Pro.

### See Also

The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-105, and **ThreadSafe Functions and Multitasking** on page IV-327.

## ThreadGroupWait

**ThreadGroupWait**(*tgID*, *waitms*)

The ThreadGroupWait function returns index+1 of the first thread found still running after *waitms* milliseconds or returns zero if all are done.

*tgID* is the thread group ID returned by **ThreadGroupCreate** and *waitms* is milliseconds to wait.

If any of the threads of the group encountered a runtime error, the first such error will be reported now.

## ThreadProcessorCount

---

Use zero for *waitms* to just test or provide a large value to cause the main thread to sleep until the threads are finished. You can use INF to wait forever or until a user abort. If you know the maximum time the threads should take, you can use that value so you can print an error message or take other action if the threads don't return in time.

When ThreadGroupWait is called, Igor updates certain internal variables including variables that track whether a thread has finished and what result it returned. Therefore you must call ThreadGroupWait before calling **ThreadReturnValue**.

ThreadGroupWait updates the internal state of all threads in the group.

### Finding a Free Thread

If you pass -2 for *waitms*, ThreadGroupWait returns index+1 of the first free (not running) thread or 0 if all threads in the group are running.

This allows you to dispatch a thread anytime a free thread is available. See **Parallel Processing - Thread-at-a-Time Method** on page IV-330 for an example.

The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-105, and **ThreadSafe Functions and Multitasking** on page IV-327.

## ThreadProcessorCount

### ThreadProcessorCount

The ThreadProcessorCount function returns the number of processors in your computer. For example, on a Macintosh Core Duo, it would return 2.

## ThreadReturnValue

### ThreadReturnValue(*tgID*, *index*)

The ThreadReturnValue function returns the value that the specified thread function returned when it exited. Returns NAN if thread is still running. *tgID* is the thread group ID returned by **ThreadGroupCreate** and *index* is the thread number.

When **ThreadGroupWait** is called, Igor updates certain internal variables including variables that track whether a thread has finished and what result it returned. Therefore you must call ThreadGroupWait before calling ThreadReturnValue.

### See Also

The **ThreadGroupCreate** function, **ThreadSafe Functions** on page IV-105, and **ThreadSafe Functions and Multitasking** on page IV-327.

## ThreadSafe

### ThreadSafe Function *funcName*()

The ThreadSafe keyword declaration specifies that a user function can be used for preemptive multitasking background tasks on multiprocessor computer systems.

A ThreadSafe function is one that can operate correctly during simultaneous execution by multiple threads. Such functions are generally limited to numeric or utility functions. Functions that access windows are not ThreadSafe. To determine if an operation is ThreadSafe, use the Command Help tab of the Help Browser and choose ThreadSafe from the pop-up menu.

ThreadSafe functions can call other ThreadSafe functions but may not call non-ThreadSafe functions. Non-ThreadSafe functions can call ThreadSafe functions.

### See Also

**ThreadSafe Functions** on page IV-105 and **ThreadSafe Functions and Multitasking** on page IV-327.

## ThreadStart

### ThreadStart *tgID*, *index*, *WorkerFunc(param1, param2,...)*

The ThreadStart operation starts the specified function running in a preemptive thread.

**Parameters**

*tgID* is thread group ID returned by **ThreadGroupCreate**, *index* is the desired thread of the group to set up to execute the specified ThreadSafe *WorkerFunc*.

**Details**

The worker function starts running immediately.

The worker function must be defined as ThreadSafe and must return a real or complex numeric result.

The worker function's return value can be obtained after the function finishes by calling **ThreadReturnValue**. Igor records the fact that a thread has terminated when you call ThreadGroupWait so you must call ThreadGroupWait before calling ThreadReturnValue.

The worker function can take variable and wave parameters. It can not take pass-by-reference parameters or data folder reference parameters.

Any waves you pass to the worker are accessible to both the main thread and to your preemptive thread. Such waves are marked as being in use by a thread and Igor will refuse to perform any manipulations that could change the size of the wave.

**See Also**

The **ThreadGroupCreate** and **ThreadReturnValue** functions; **ThreadSafe Functions** on page IV-105, and **ThreadSafe Functions and Multitasking** on page IV-327.

**ticks****ticks**

The ticks function returns the number of ticks (approximately 1/60 second) elapsed since the operating system was initialized.

**See Also**

The **StopMSTimer** function.

**TickWavesFromAxis**

```
TickWavesFromAxis [/W=graphName /DEST= {textWaveName, numericWaveName} /O]
 axisName
```

The TickWavesFromAxis operation generates a pair of waves suitable for use as user tick waves (see **User Ticks from Waves** on page II-301). This allows you to programmatically determine the tick marks and tick labels that Igor would create for a given graph axis in auto mode.

TickWavesFromAxis was added in Igor Pro 8.00.

TickWavesFromAxis generates two waves: a two-column text wave containing tick labels and the names of tick types, and a numeric wave giving the positions of the ticks along the axis. By default, the information stored in the output waves reflects the automatically generated ticks based on the current axis settings but you can change this using the /AUTO flag.

By default the waves are given names derived from the graph window and axis name:

<*graphname*>\_<*axisname*>\_labels and <*graphname*>\_<*axisname*>\_values. Use /DEST to give the waves custom names.

**Parameters**

*axisName* is the name of the axis for which the tick waves are generated. This will usually be left, bottom, right or top, but may be the name of a free axis.

## Tile

---

### Flags

*/AUTO=mode* Controls the axis settings that are used when generating the output waves:  
*mode = 0* Computed manual tick settings are used.  
*mode = 1* The automatic tick settings are used (default).  
*mode = 2* Either computed manual ticks or auto ticks are used, depending on the current setting of the graph.

If you use */AUTO=0* and the graph is currently in auto mode, the results could be surprising if you haven't actually set the computed manual ticks settings.

*/AUTO* was added in Igor Pro 9.00.

*/DEST={textWaveName, numericWaveName}*

Specifies custom names for the generated waves. *textWaveName* is the name of the text wave containing the tick labels. *numericWaveName* is the name of the numeric wave containing the axis position values for the ticks. If the waves don't already exist, they are created.

You may use data folder syntax as long as the data folders already exist.

The operation may create wave references for the destination waves if called in a user-defined function. See **Automatic Creation of WAVE References** on page IV-71 for details.

*/O* Tells TickWavesFromAxis that it can overwrite existing waves.

Igor returns an error if you attempt to overwrite a numeric wave with a text wave or a text wave with a numeric wave.

*/W=winName* Specifies the graph containing the axis. This may be a subwindow path. If you omit */W*, the top graph window is used.

### Details

The TickWavesFromAxis operation depends on drawing the axis to generate the list of ticks. It causes a screen refresh, equivalent to calling **DoUpdate**, twice during its execution.

The TickWavesFromAxis operation honors your axis format settings and manual range. It works on regular numeric axes, log axes and date/time axes. At this time it does not work on category axes or axes using user ticks from waves.

## Tile

**Tile** [*flags*] [*objectName* [, *objectName*]...]

The Tile operation tiles the specified objects in the top page layout.

### Parameters

*objectName* is the name of a graph, table, picture or annotation object in the top page layout.

### Flags

*/A=(rows,cols)* Specifies number of rows/columns in which to tile objects.

*/G=grout* Specifies grout, the spacing between window tiles, in prevailing coordinates (points unless preceded by */I*, */M* or */R*).

*/I* Specifies coordinates in inches.

*/M* Specifies coordinates in centimeters.

|                                   |                                                                                                                                                                                                                                                                           |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/O=objTypes</i>                | Adds objects of type(s) specified by bitwise mask to list of objects to be tiled:<br>Bit 0: Tile graphs.<br>Bit 1: Tile tables.<br>Bit 3: Tile pictures.<br>Bit 5: Tile textboxes.<br><br>See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings. |
| <i>/R</i>                         | Specifies coordinates measured in percent of the printable page.                                                                                                                                                                                                          |
| <i>/S</i>                         | Adds selected objects to objects to be tiled.                                                                                                                                                                                                                             |
| <i>/W=(left,top,right,bottom)</i> | Specifies page layout area in which to tile objects. Coordinates are in points unless <i>/I</i> , <i>/M</i> or <i>/R</i> are specified before <i>/W</i> .                                                                                                                 |

**Details**

If */A=(rows,cols)* is not used, Tile uses an appropriate number of rows and columns. If */A=(rows,cols)* is used, objects are tiled in a grid of that many rows and columns. If *rows* or *cols* is zero, it substitutes an appropriate number for the zero parameter.

Objects to be tiled are determined by the */S* and */O=objTypes* flags and by any *objectNames*.

If no */S* or */O* flags are present and there are no *objectNames*, then all objects in the layout are tiled.

Otherwise the objects to be tiled are determined as follows:

- All objects specified by *objectNames* are tiled.
- If the */S* flag is present, the selected objects, if any, are also tiled.
- If the */O=objTypes* flag is present then any objects specified by *objTypes* are also tiled. *objTypes* is a bitwise mask, so */O=3* tiles both graphs and tables.

**See Also**

The **Stack** operation.

## TileWindows

**TileWindows** [*flags*] [*windowName* [, *windowName*]...]

The TileWindows operation tiles the specified windows on the desktop (*Macintosh*) or in the Igor frame window (*Windows*).

**Flags**

|                       |                                                                                                                  |
|-----------------------|------------------------------------------------------------------------------------------------------------------|
| <i>/A=(rows,cols)</i> | Specifies number of rows/columns in which to tile windows.                                                       |
| <i>/C</i>             | Adds the command window to the windows to be tiled.                                                              |
| <i>/G=grout</i>       | Specifies grout, the spacing between tiles, in prevailing units (points unless <i>/I</i> or <i>/M</i> are used). |
| <i>/I</i>             | Specifies coordinates in inches.                                                                                 |
| <i>/M</i>             | Specifies coordinates in centimeters.                                                                            |
| <i>/O=objTypes</i>    | Adds windows of types specified by <i>objTypes</i> to windows to be tiled.                                       |

## time

---

*objTypes* is a bitwise mask where:

|         |                    |
|---------|--------------------|
| Bit 0:  | Graphs             |
| Bit 1:  | Tables             |
| Bit 2:  | Page layouts       |
| Bit 4:  | Notebooks          |
| Bit 6:  | Control panels     |
| Bit 7:  | Procedure windows  |
| Bit 9:  | Help windows       |
| Bit 12: | XOP target windows |
| Bit 14: | Camera windows     |
| Bit 16: | Gizmo windows      |

Other bits should always be zero. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

*/P* Adds the main procedure window to the windows to be tiled.

*/R* Specifies coordinates measured as % of tiling rectangle.

*/W=(left,top,right,bottom)*

Specifies tiling rectangle on the screen. Coordinates are in points unless */L*, */M*, or */R* are specified before */W*.

### Details

The windows to be tiled are determined by the */C*, */P*, and */O=objTypes* flags and by the *windowNames*. If no */C*, */P* or */O* flags are present and there is no *windowNames* then all windows are tiled.

Otherwise the windows to be tiled are determined as follows:

- All named windows are tiled.
- If the */C* flag is present, the command window is also tiled.
- If the */P* flag is present, the procedure window is also tiled.
- If the */O=objTypes* flag is present, any windows specified by *objTypes* are also tiled.

### Examples

To tile all the procedure windows, including the main one, use:

```
TileWindows/P/O=128 // 2^7=128
```

### See Also

The **StackWindows** operation.

## time

**time** ()

The time function returns a string containing the current local time. The empty parentheses are required.

### See Also

The **date**, **date2secs** and **DateTime** functions.

## TitleBox

**TitleBox** [/Z] *ctrlName* [*keyword = value* [, *keyword = value* ...]]

The TitleBox operation creates the named title box in the target window.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*ctrlName* is the name of the TitleBox control to be created or changed.

The following keyword=value parameters are supported:

|                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| anchor= <i>hv</i>                              | <p>Specifies the anchor mode using a two letter code, <i>hv</i>. <i>h</i> may be L, M, or R for left, middle, and right. <i>v</i> may be T, C, or B for top, center and bottom. Default is LT.</p> <p>If fixedSize=1, the anchor code sets the positioning of text within the frame.</p>                                                                                                                                                                                                                                                                                                                                                                                                          |
| align= <i>alignment</i>                        | <p>Sets the alignment mode of the control. The alignment mode controls the interpretation of the <i>leftOrRight</i> parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.</p> <p>If <i>alignment</i>=0 (default), <i>leftOrRight</i> specifies the position of the left end of the control and the position of the control depends on the anchor keyword.</p> <p>If <i>alignment</i>=1, <i>leftOrRight</i> specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.</p> <p>There is a conflict between the align keyword and the anchor keyword. See <b>TitleBox Positioning</b> on page V-1037.</p> |
| appearance={ <i>kind</i> [, <i>platform</i> ]} | <p>Sets the appearance of the control. <i>platform</i> is optional. Both parameters are names, not strings.</p> <p><i>kind</i> can be one of default, native, or os9.</p> <p><i>platform</i> can be one of Mac, Win, or All.</p> <p>See <b>Button</b> and <b>DefaultGUIControls</b> for more appearance details.</p>                                                                                                                                                                                                                                                                                                                                                                              |
| disable= <i>d</i>                              | <p>Sets user editability of the control.</p> <p><i>d</i>=0: Normal.</p> <p><i>d</i>=1: Hide.</p> <p><i>d</i>=2: Draw in gray state.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| fColor=( <i>r,g,b[,a]</i> )                    | <p>Sets color of the titlebox. <i>r</i>, <i>g</i>, <i>b</i>, and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## TitleBox

---

|                                                |                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>fstyle=<i>fs</i></code>                  | <p><i>fs</i> is a bitwise parameter with each bit controlling one aspect of the font style as follows:</p> <ul style="list-style-type: none"><li>Bit 0:     Bold</li><li>Bit 1:     Italic</li><li>Bit 2:     Underline</li><li>Bit 4:     Strikethrough</li></ul> <p>See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings.</p>                          |
| <code>help={<i>helpStr</i>}</code>             | <p>Sets the help for the control.</p> <p><i>helpStr</i> is limited to 1970 bytes (255 in Igor Pro 8 and before).</p> <p>You can insert a line break by putting “\r” in a quoted string.</p>                                                                                                                                                                                        |
| <code>labelBack=(<i>r,g,b[,a]</i>)</code> or 0 | <p>Sets background color for title box. <i>r</i>, <i>g</i>, <i>b</i>, and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b>. If not set (or <code>labelBack=0</code>), then background is transparent (not erased).</p>                                                                                                                                        |
| <code>pos={<i>leftOrRight,top</i>}</code>      | <p>Sets the position in <b>Control Panel Units</b> of the top/left or top/right corner of the control at the time it is created. Unless <code>fixedSize=1</code>, a TitleBox control adjusts its size to fit the title text and the position can move in a way that depends on the anchor and align modes. See <b>TitleBox Positioning</b> on page V-1037.</p>                     |
| <code>pos+={<i>dx,dy</i>}</code>               | <p>Offsets the position of the control in <b>Control Panel Units</b>.</p>                                                                                                                                                                                                                                                                                                          |
| <code>size={<i>w,h</i>}</code>                 | <p>Sets the width and height of the control in pixels.</p> <p>If <code>fixedSize=1</code>, sets the width of the control in pixels. If <code>fixedSize=0</code>, a TitleBox control adjusts its size to the title text, resulting in confusion about what the size does. In this case, <code>size={0,0}</code> is recommended. See <b>TitleBox Positioning</b> on page V-1037.</p> |
| <code>title=<i>titleStr</i></code>             | <p>Sets the text of the title box to <i>titleStr</i>. <i>titleStr</i> is limited to 100 bytes.</p> <p>Using escape codes you can change the font, size, style, and color of the title. See <b>Annotation Escape Codes</b> on page III-53 or details.</p>                                                                                                                           |
| <code>variable=<i>svar</i></code>              | <p>Specifies an optional global string variable from which to get the TitleBox text.</p>                                                                                                                                                                                                                                                                                           |
| <code>win=<i>winName</i></code>                | <p>Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.</p> <p>When identifying a subwindow with <i>winName</i>, see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.</p>                                                                             |

### Flags

`/Z`           No error reporting.

### Details

The text can come from either the `title=titleStr` or `variable=svar` method. Whichever is used last is the current method. The maximum length of text with the `title=titleStr` method is 100 bytes while the `variable=svar` method has no limit.

Using escape codes you can change the font, size, style and color of text, and apply other effects. See **Annotation Escape Codes** on page III-53 for details.

By default, the titlebox automatically resizes itself relative to the anchor point on the rectangle that encloses the text. Therefore you can specify a size of 0,0 along with a `pos` value in order to place the anchor point at the desired position. When `fixedSize=1` is used, the titlebox does not resize itself and instead honors the values specified via the `size` keyword.

TitleBoxes can be used not only for titles but also as status or results readout areas, especially in conjunction with the `variable=svar` mode. When using a titlebox like this, you may find it useful to use `fixedSize=1` so that the titlebox doesn't change size as the text changes.

### TitleBox Positioning

For compatibility with other controls, you can use the `align=1` to maintain the position of the right end of a `TitleBox` control. This presents a conflict with the `anchor` keyword. To resolve the conflict, these rules are applied:

Applying `align=1`, which sets the alignment mode to right alignment, overrides any horizontal positioning specified using the `anchor` keyword.

Applying the `anchor` keyword resets the alignment mode to 0 and the `anchor` mode controls the horizontal position of the control.

If you specify `fixedSize=1`, only the `align` and `pos` keywords affect horizontal positioning; the `anchor` keyword has no effect.

For clarity, don't mix the `anchor` and `align` keywords unless you are using `fixedSize=1`. Use `anchor` in preference to `align` unless you are trying to keep the right ends of various types of controls aligned, especially on high-resolution displays on Windows.

### Examples

```
NewPanel /W=(94,72,459,294)
DrawLine 150,32,150,140
DrawLine 70,100,213,100 // draw crossing lines at 150,100

// illustrate a default box
TitleBox tb1,title="A title box\rwith 2 lines",pos={150,100}

// Move center to 150,100
TitleBox tb1,pos={150,100},size={0,0},anchor=MC

// Set background color and therefore opaque mode
TitleBox tb1,labelBack=(55000,55000,65000)

// Now a few frame styles. Run these one at a time
TitleBox tb1,frame= 0 // no frame
TitleBox tb1,frame= 2 // plain frame
TitleBox tb1,frame= 3 // 3D sunken
TitleBox tb1,frame= 4 // 3D raised
TitleBox tb1,frame= 5 // text well

// Now some fancy text...
TitleBox tb1,frame= 1 // back to default (3D raised)
TitleBox tb1,title= "\Z18\[020 log\B10\M|[1 + 2K(jwt) + (jwt)\S2\M]|\S-1"

// Create a string variable and hook up to the TitleBox
String s1= "text from a string variable"
TitleBox tb1,variable=s1

// Change string variable contents & note automatic update of TitleBox
s1= "something new"

// A TitleBox with right end at X=200 because the align keyword takes precedence
TitleBox tb, pos={200,40},size={0,0},align=1,anchor=MT,title="Short Title"

// A TitleBox with right end at X=200 because align by itself overrides
// any preexisting anchor
TitleBox tb, pos={200,40},size={0,0},align=1,title="Short Title"

// A TitleBox with text centered in the frame and right end at X=200,
// with frame always 75 points wide
TitleBox tb, pos={200,40},size={75,20},align=1,fixedSize=1,anchor=MT,title="Short Title"
```

## ToCommandLine

**ToCommandLine** *commandsStr*

The `ToCommandLine` operation sends command text to the command line without executing the command(s).

## ToolsGrid

---

The intended usage is for user-created panel windows with “To Cmd Line” buttons that are mimicking built-in Igor dialogs. You’ll usually want to use `Execute`, instead.

### Parameters

*commandsStr*            The text of one or more commands.

### Details

To send more than one line of commands, separate the commands with “\r” characters.

**Note:**            `ToCommandLine` does not work when typed on the command line; use it only in a Macro, Proc, or Function.

### Examples

```
Macro CmdPanel ()
 PauseUpdate; Silent 1
 NewPanel /W=(150,50,430,229)
 Button toCmdLine,pos={39,148},size={103,20},title="To Cmd Line"
 Button toCmdLine,proc=ToCmdLineButtonProc
End

Function ToCmdLineButtonProc(ctrlName) : ButtonControl
 String ctrlName

 String cmd="MyFunction(xin,yin,\"yResult\")" // line 1: generate results
 cmd += "\rDisplay yOutput vs wx as \"results\"" // line 2: display results
 ToCommandLine cmd

 return 0
End
```

## ToolsGrid

**ToolsGrid** [/W=*winName*] **keyword** = **value** [, **keyword** = **value** ...]

The `ToolsGrid` operation controls the grid you can use for laying out draw or control objects.

### Parameters

`ToolsGrid` can accept multiple *keyword = value* parameters on one line.

*snap=n*                Turns snap to grid on (*n*=1) or off (*n*=0).

*visible=n*             Turns on grid visibility (*n*=1) or hides it (*n*=0).

*grid=(xy0,dxy,ndiv)* Defines both X and Y grids where *ndiv* is the number of subdivisions between major grid lines and *xy0* and *dxy* define the origin and spacing. Units are in points.

*gridx=(x0,dx,ndiv)* Defines the X grid where *ndiv* is the number of subdivisions between major grid lines and *x0* and *dx* define the origin and spacing. Units are in points.

*gridy=(y0,dy,ndiv)* Defines the Y grid where *ndiv* is the number of subdivisions between major grid lines and *y0* and *dy* define the origin and spacing. Units are in points.

### Flags

/W=*winName*           Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Details

The default grid is 1 inch with 8 subdivisions. The grid is visible only in draw or selector mode and appears in front of the currently active draw layer.

## TraceFromPixel

**TraceFromPixel**(*xpixel*, *ypixel*, *optionsString*)

The TraceFromPixel function returns a string based on an attempt to hit test the provided X and Y coordinates. Used to determine if the mouse was clicked on a trace in a graph.

When a trace is found, TraceFromPixel returns a string containing the following KEY:value; pairs:

TRACE: *tracename*

HITPOINT: *pnt*

*tracename* will be quoted if necessary and may contain instance notation. *pnt* is the point number index into the trace's wave when the hit was detected. If a trace is not found near the coordinate point, a zero length string is returned.

### Parameters

*xpixel* and *ypixel* are the X and Y pixel coordinates.

*optionsString* can contain the following:

WINDOW: *winName*;

PREF: *traceName*;

ONLY: *traceName*;

DELTAX: *dx*; DELTAY: *dy*;

Use the WINDOW option to hit test in a graph other than the top graph. Use the ONLY option to search only for a special target trace. If the PREF option is used then the search will start with the specified trace but if no hit is detected, it will go on to the others.

When identifying a subwindow with WINDOW: *winName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The DELTAX and DELTAY values must both be specified to alter the region that Igor searches for traces. The *dx* and *dy* values are in pixels and the region searched is the rectangle from *xpixel-dx* to *xpixel+dx* and *ypixel-dy* to *ypixel+dy*.

If DELTAX or DELTAY are omitted, the search region depends on whether PREF or ONLY are specified. If either are specified then Igor first searches for the trace using *dx* = 3 and *dy* = 3. If the trace is not identified, Igor searches again using *dx* = 6 and *dy* = 6. If the trace is still not identified, Igor gives up and returns a zero-length result string.

If neither PREF nor ONLY are specified then Igor uses tries 3, 6, 12, and 24 for *dx* and *dy* until it finds a trace or gives up and returns a zero-length result string.

**Trace Names** on page II-270, **Programming With Trace Names** on page IV-87.

## TraceInfo

**TraceInfo**(*graphNameStr*, *ywavenameStr*, *instance*)

The TraceInfo function returns a string containing a semicolon-separated list of information about the trace in the named graph window or subwindow.

### Parameters

*graphNameStr* can be "" to refer to the top graph.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

*yWaveNameStr* is either the name of a wave containing data displayed as a trace in the named graph, or a trace name (wave name with "#n" appended to distinguish the nth image of the wave in the graph). You might get a trace name from the **TraceNameList** function.

If *yWaveNameStr* contains a wave name, *instance* identifies which trace of *yWaveNameStr* you want information about. *instance* is usually 0 because there is normally only one instance of a given wave

## TraceInfo

---

displayed in a graph. Set *instance* to 1 for information about the second trace of the wave named by *yWaveNameStr*, etc. If *yWaveNameStr* is "", then information is returned on the *instanceth* trace in the graph. If *yWaveNameStr* is a trace name, and *instance* is zero, the instance is extracted from *yWaveNameStr*. If *instance* is greater than zero, the wave name is extracted from *yWaveNameStr*, and information is returned concerning the *instanceth* instance of the wave.

### Details

The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

| Keyword    | Information Following Keyword                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AXISFLAGS  | Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| AXISZ      | Z value of a contour level trace or NaN if the trace is not a contour trace.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ERRORBARS  | The ErrorBars command for the trace, as it would appear in the recreation macro (without the beginning tab character).                                                                                                                                                                                                                                                                                                                                                                                                          |
| RECREATION | List of keyword commands as used by ModifyGraph command. The format of these keyword commands is:<br><i>keyword(x)=modifyParameters;</i>                                                                                                                                                                                                                                                                                                                                                                                        |
| TYPE       | The type of trace:<br>0: XY or waveform trace<br>1: Contour trace<br>2: Box plot trace<br>3: Violin plot trace<br><br>TYPE was added in Igor Pro 8.00.                                                                                                                                                                                                                                                                                                                                                                          |
| XAXIS      | X axis name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| XRANGE     | Point subrange of the trace's X data wave in "[startPoint],pendPoint : increment]" format.<br><b>Note:</b> Unlike the actual syntax of a trace subrange specification where increment is preceded by a semicolon character, here it is preceded by a colon character to preserve the notion that semicolon is what separates the keyword-value groups.<br><br>If the entire X wave is displayed (the usual case), the XRANGE value is "[*]".<br><br>If an X wave is not used to display the trace, then the XRANGE value is "". |
| XWAVE      | X wave name if any, else blank.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| XWAVEDF    | Full path to the data folder containing the X wave or blank if no X wave.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| YAXIS      | Y axis name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| YRANGE     | Point subrange of the trace's Y data wave or "[*]".                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the ";", prepend "ModifyGraph ", replace the "x" with the name of a trace ("data#1" for instance) and then **Execute** the resultant string as a command.

**Note:** The syntax of any subrange specifications in the RECREATION information are modified in the same way as for XRANGE and YRANGE. Currently only the zColor, zmrkSize, and zmrkNum keywords might have a subrange specification.

### Examples

This example shows how to extract a string value from the keyword-value list returned by TraceInfo:

```
String yAxisName= StringByKey("YAXIS", TraceInfo("", "", 0))
```

This example shows how to extract a subrange and put the semicolon back:

```
String yRange= StringByKey("YRANGE", TraceInfo("", "", 0))
Print yRange // prints "[30,40:2]"
yRange= ReplaceString(":", yRange, ";")
Print yRange // prints "[30,40;2]"
```

The next example shows the trace information for the second instance of the wave "data" (which has an instance number of 1) displayed in the top graph:

```
Make/O data=x;Display/L/T data,data // two instances of data: 0 and 1
Print TraceInfo("", "data", 1) [0,64]
Print TraceInfo("", "data", 1) [65,128]
```

Prints the following in the history area:

```
XWAVE: ;YAXIS:left;XAXIS:top;AXISFLAGS:/T;AXISZ:NaN;XWAVEDF: ;YRANG
E: [*];XRANGE: ;TYPE:0;ERRORBARS: ;RECREATION: zColor(x)=0; zColorMax
```

Following is a function that returns the marker code from the given instance of a named wave in the top graph. This example uses the convenient `GetNumFromModifyStr()` function provided by the `#include <Readback ModifyStr>` procedures, which are useful for parsing strings returned by `TraceInfo`.

```
#include <Readback ModifyStr>
Function MarkerOfWave(wv, instance)
 Wave wv
 Variable instance

 Variable marker
 String info = TraceInfo("", NameOfWave(wv), instance)

 marker = GetNumFromModifyStr(info, "marker", "", 0)
 return marker
End
```

The **Execute** operation.

## TraceNameList

**TraceNameList**(*graphNameStr*, *separatorStr*, *optionsFlag*)

The `TraceNameList` function returns a string containing a list of trace names in the graph window or subwindow identified by *graphNameStr*.

### Parameters

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The parameter *separatorStr* should contain a single ASCII character such as "," or ";" to separate the names.

### Details

The bits of *optionsFlag* have the following meanings:

| Bit Number | Bit Value | Meaning                                                        |
|------------|-----------|----------------------------------------------------------------|
| 0          | 1         | Include normal graph traces                                    |
| 1          | 2         | Include contour traces                                         |
| 2          | 4         | Omit hidden traces (the default is to list even hidden traces) |
| 3          | 8         | Include box plot traces                                        |
| 4          | 16        | Include violin plot traces                                     |

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

A trace name is defined as the name of the Y wave that defines the trace with an optional #ddd suffix that distinguishes between two or more traces that have the same wave name. It may also be a user-defined trace name. Since the trace name has to be parsed, it is quoted if necessary.

## TraceNameToWaveRef

---

Commands that take a trace name as a parameter or in a keyword can use a string containing a trace name with the \$ operator to specify traceName. For instance, to change the display mode of a wave, you might use

```
ModifyGraph mode(myWave#1)=3
```

but

```
String myTraceName="myWave#1"
ModifyGraph mode($myTraceName)=3
```

will also work.

### Examples

```
Make/O jack,'jack # 2';Display jack,jack,'jack # 2','jack # 2'
Print TraceNameList("",",",1)
Prints: jack;jack#1;'jack # 2';'jack # 2'#1;

// Generate a list of hidden traces
Make/O jack,jill,joy;Display jack,jill,joy
ModifyGraph hideTrace(joy)=1// hide joy
// (hidden + visible) - visible = hidden
String visibleTraces=TraceNameList("",",",1+4)// only visible normal traces
String allNormalTraces=TraceNameList("",",",1)// hidden + visible normal traces
String hiddenTraces= RemoveFromList(visibleTraces,allNormalTraces)
Print hiddenTraces
// Prints: joy;
```

## TraceNameToWaveRef

**TraceNameToWaveRef**(*graphNameStr*, *traceNameStr*)

The TraceNameToWaveRef function returns a wave reference to the Y wave corresponding to the given trace in the graph window or subwindow named by *graphNameStr*.

### Parameters

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The trace is identified by the string in *traceNameStr*, which could be a string determined using **TraceNameList**. Note that the same trace name can refer to different waves in different graphs.

Use **Instance Notation** (see page IV-20) to choose from traces in a graph that represent waves of the same name. For example, if *traceNameStr* is "myWave#2", it refers to the third instance of wave "myWave" in the graph ("myWave#0" or just "myWave" is the first instance).

For a discussion of wave references, see **Wave Reference Functions** on page IV-197.

For commands referencing other waves in a graph: **ImageNameList**, **ImageNameToWaveRef**, **ContourNameList**, and **ContourNameToWaveRef**.

## Triangulate3D

**Triangulate3D** [/OUT=*format*] *srcWave*

The Triangulate3D operation creates a Delaunay “triangulation” of a 3D scatter wave. The output is a list of tetrahedra that completely span the convex volume defined by *srcWave*. Triangulate3D can also generate the triangulation needed for performing 3D interpolation for the same domain. Normally *srcWave* is a triplet wave (a 2D wave of 3 columns), but can use any 2D wave that has more than 3 columns (the operation ignores all but the first 3 columns).

### Flags

|                     |                                                                                                                                                                                                                                                                                                          |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /OUT= <i>format</i> | Specifies how to save the output triangulation data.                                                                                                                                                                                                                                                     |
| <i>format</i> =1:   | Default; saves the triangulation result in the wave M_3DVertexList, which contains in each row, indices to rows in <i>srcWave</i> that describe the X, Y, Z coordinates of a single tetrahedral vertex. Each tetrahedron is described by one row in M_3DVertexList.                                      |
| <i>format</i> =2:   | Saves the triangulation result in the wave M_TetraPath, which is a triplet path wave describing the tetrahedra edges. For each tetrahedron, there are four rows (triangles) separated by row of NaNs. The total number of rows in M_TetraPath is 20 times the number of tetrahedra in the triangulation. |
| <i>format</i> =4:   | Saves a wave containing internal diagnostic information generated during the triangulation process.                                                                                                                                                                                                      |
| /VOL                | Computes the volume of the full convex hull by summing the volumes of the tetrahedra generated in the triangulation. The result is stored in the variable V_value. This flag requires Igor Pro 7.00 or later.                                                                                            |

### Details

Triangulate3D implements Watson’s algorithm for tetrahedralization of a set of points in three dimensions. It starts by creating a very large tetrahedron which inscribes all the data points followed by a sequential insertion of one datum at a time. With each new datum the algorithm finds the tetrahedron in which the datum falls. It then proceeds to subdivide the tetrahedron so that the datum becomes a vertex of new tetrahedra.

The algorithm suffers from two known problems. First, it may, due to numerical instabilities, result in tetrahedra that are too thin. You can get around this problem by introducing a slight random perturbation in the input wave. For example:

```
srcWave+=enoise(amp)
```

Here amp is chosen so that it is much smaller than the smallest cartesian distance between two input points.

The second problem has to do with memory allocations which may exhaust available memory for some pathological spatial distributions of data points. The operation reports both problems in the history area.

### Examples

```
Make/O/N=(10,3) ddd=gnoise(5) // create random 10 points in space
Triangulate3d/out=2 ddd

// now display the triangulation in Gizmo:
Window Gizmo0() : GizmoPlot
 PauseUpdate; Silent 1
 if(exists("NewGizmo")!=4)
 DoAlert 0, "Gizmo XOP must be installed"
 return
 endif
 NewGizmo/N=Gizmo0 /W=(309,44,642,373)
 ModifyGizmo startRecMacro
 ModifyGizmo scalingMode=2
 AppendToGizmo Scatter=root:ddd,name=scatter0
 ModifyGizmo ModifyObject=scatter0 property={ scatterColorType,0}
 ModifyGizmo ModifyObject=scatter0 property={ Shape,2}
 ModifyGizmo ModifyObject=scatter0 property={ size,0.2}
```

## TrimString

---

```
ModifyGizmo ModifyObject=scatter0 property={ color,0,0,0,1}
AppendToGizmo Path=root:M_TetraPath,name=path0
ModifyGizmo ModifyObject=path0 property={ pathColor,0,0,1,1}
ModifyGizmo setDisplayList=0, object=scatter0
ModifyGizmo setDisplayList=1, object=path0
ModifyGizmo autoscaling=1
ModifyGizmo compile
ModifyGizmo endRecMacro
End
```

### See Also

The **Interpolate3D** operation and the **Interp3D** function.

## TrimString

**TrimString**(*str* [, *simplifyInternalSpaces*])

The TrimString function returns a string identical to *str* except that leading and trailing whitespace characters are removed. The whitespace characters are space, tab, carriage-return and linefeed.

If the optional second parameter is non-zero, then each run of whitespace characters between words in *str* is "simplified" to a single space character.

TrimString was added in Igor Pro 7.00.

### Examples

```
Print TrimString(" spaces at ends ") // Prints "spaces at ends"
Print TrimString(" spaces at ends ", 1) // Prints "spaces at ends"
```

### See Also

**SplitWave**, **RemoveEnding**, **ReplaceString**

## trunc

**trunc** (*num*)

The trunc function returns the integer closest to *num* in the direction of zero.

The result for INF and NAN is undefined.

### See Also

The **round**, **floor**, and **ceil** functions.

## try

**try**

The try flow control keyword marks the beginning of the initial code block in a try-catch-endtry flow control construct.

### See Also

The **try-catch-endtry** flow control statement for details.

## try-catch-endtry

```
try
 <code>
catch
 <code to handle abort>
endtry
```

A try-catch-endtry flow control statement provides a means for catching and responding to abort conditions in user functions. A programmatic abort is generated when the code executes **Abort**, **AbortOnRTE** or

**AbortOnValue.** A user abort is generated when the user clicks the Abort button or presses the user abort key combination.

When code executes in the try-catch area, a programmatic abort immediately jumps to the code in the catch-endtry area rather than jumping to the end of the user function. A user abort jumps to the catch-endtry area when a flow control keyword such as for or while executes or at the end of the try code. Normal flow (no aborts) skips all code within the catch-endtry area.

### Details

During execution of code in the catch-endtry area, user aborts are suppressed. This means that, if the user attempts to abort procedure execution by pressing the **User Abort Key Combinations** or by clicking the Abort button, this will not abort the catch code itself.

When an abort occurs, information about the cause of the abort is returned via the `V_AbortCode` variable as follows:

- 4: Abort triggered by AbortOnRTE.
- 3: Abort caused by Abort operation.
- 2: Stack overflow abort.
- 1: User abort.
- >=1: Abort triggered by AbortOnValue.

### See Also

**Flow Control for Aborts** on page IV-48 and **try-catch-endtry Flow Control** on page IV-48 for further details.

The **AbortOnRTE** and **AbortOnValue** keywords, and the **Abort** operation.

## UInt64

**uint64 localName**

Declares a local unsigned 64-bit integer in a user-defined function or structure.

UInt64 is available in Igor Pro 7 and later. See **Integer Expressions** on page IV-37 for details.

### See Also

**Int, Int64**

## UniqueName

**UniqueName**(*baseName*, *objectType*, *startSuffix* [, *windowNameStr*])

The UniqueName function returns the concatenation of *baseName* and a number such that the result is not in conflict with any other object name.

*windowNameStr* is optional. If missing, it is taken to be the top graph, panel, layout, or notebook according to the value of *objectType*.

In Igor Pro 9.00 or later, you can use the **CreateDataObjectName** function as a replacement for some combination of CheckName, CleanupName, and UniqueName to create names of waves, global variables, and data folders.

### Details

*baseName* should be an unquoted name, such as you might receive from the user via a dialog or control panel.

## UniqueName

---

*objectType* is one of the following:

- 1 Wave
- 2 Reserved
- 3 Numeric variable
- 4 String variable
- 5 XOP target window
- 6 Graph window
- 7 Table window
- 8 Layout window
- 9 Control panel window
- 10 Notebook window
- 11 Data folder
- 12 Symbolic path
- 13 Picture
- 14 Annotation in the named or topmost graph or layout
- 15 Control in the named or topmost graph or panel
- 16 Notebook action character in the named or topmost notebook
- 17 Gizmo window (added in Igor Pro 9.00)

*startSuffix* is the number used as a starting point when generating the numeric suffix that makes the name unique. Normally you should pass zero for *startSuffix*. If you know that names of the form *base0* through *baseN* are in use, you can make *UniqueName* run a bit faster by passing *N+1* as the *startSuffix*.

The *windowNameStr* argument is used only with object types 14, 15, and 16. The returned name is unique only to the window (other windows might have objects with the same name). If a named window is given but does not exist, *UniqueName* returns *baseName startSuffix*. *windowNameStr* is ignored for other object types.

### The Main Namespace

Waves, numeric variables, string variables, built-in and external functions, built-in and external operations, user-defined functions, macros and reserved keywords exist in the main namespace. The names of each of those objects must be unique in that namespace.

### Window Namespace

Values of *objectType* from 5 through 10 refer to the window namespace.

The expression

```
CheckName("<name>", x) // where x is 5, 6, 7, 8, 9 or 10
```

returns 0 if the specified name is syntactically legal and unique in the window namespace.

That does not guarantee that the name is allowed as a window name because the *DoWindow/C* operation, which changes a window's name, requires that the name also not conflict with objects in the main namespace. Consequently, to determine if a name is allowed as a window name, use this:

```
// Window names must be unique in both the window and main namespaces
Variable nameOK = CheckName("<name>", 6) == 0 && CheckName("<name>", 1) == 0
```

### Window Macro Names

Window macro names are treated different from other main namespace names. *DoWindow/C* allows you to change the name of a window to the name of an existing window macro but not to any other name in the main namespace. Also this expression:

```
CheckName("<name>", x) // where x is 1, 3, 4 (main namespace)
```

returns 0 even if the specified name is used as a window macro name.

### UniqueName Thread Safety

As of Igor Pro 8.00, you can call *UniqueName* from an Igor preemptive thread but only if *objectType* is 1 (wave), 3 (global numeric variable), 4, (global string variable), 11 (data folder), or 12 (symbolic path). For any other value of *objectType*, *UniqueName* returns a runtime error.

### Examples

```
String uniqueWaveName = UniqueName(baseWaveName, 1, 0)
String uniqueControlName = UniqueName("ctrl", 15, 0, "Panel0")
```

### See Also

**Object Names** on page III-503, **Programming with Liberal Names** on page IV-168,  
**CreateDataObjectName**, **CheckName**, **CleanupName**

## UnPadString

**UnPadString**(*str*, *padValue*)

The UnPadString function undoes the action of PadString. It returns a string identical to *str* except that trailing bytes of *padValue* are removed.

### See Also

**PadString**

## UnsetEnvironmentVariable

**UnsetEnvironmentVariable**(*varName*)

The UnsetEnvironmentVariable function deletes the variable named *varName* from the environment of Igor's process, if it exists

The function returns 0 if it succeeds or a nonzero value if it fails.

The UnsetEnvironmentVariable function was added in Igor Pro 7.00.

### Parameters

*varName*                    The name of an environment variable which does not need to actually exist. It must not be an empty string and may not contain an equals sign (=).

### Details

The environment of Igor's process is composed of a set of key=value pairs that are known as environment variables.

The environment of Igor's process is composed of a set of key=value pairs that are known as environment variables. Any child process created by calling ExecuteScriptText inherits the environment variables of Igor's process.

UnsetEnvironmentVariable changes the environment variables present in Igor's process and any future process created by ExecuteScriptText but does not affect any other processes already created.

On Windows, environment variable names are case-insensitive. On other platforms, they are case-sensitive.

### Examples

```
Variable result
result = SetEnvironmentVariable("SOME_VARIABLE", "15") // Sets the variable
result = UnsetEnvironmentVariable("SOME_VARIABLE") // Unsets the variable
```

### See Also

**GetEnvironmentVariable**, **SetEnvironmentVariable**

## Unwrap

**Unwrap** *modulus*, *waveName* [, *waveName*]...

The Unwrap operation scans through each named wave trying to undo the effect of a modulus operation.

### Parameters

*modulus* is the value applied to the named waves through the **mod** function as if the command:

```
waveName = mod(waveName, modulus)
```

had been executed. It is this calculation which Unwrap attempts to undo.

## UnzipFile

---

### Details

The unwrap operation works with 1D waves only. See **ImageUnwrapPhase** for phase unwrapping in two dimensions.

### Examples

If you perform an FFT on a wave, the result is a complex wave in rectangular coordinates. You can create a real wave that contains the phase of the result of the FFT with the command:

```
wave2 = imag(r2polar(wave1))
```

However, the rectangular to polar conversion leaves the phase information modulo  $2\pi$ . You can restore the phase information with the command:

```
Unwrap 2*pi, wave2
```

Because the first point of a wave that has been FFTed has no phase information, in this example you would *precede* the Unwrap command with the command:

```
wave2[0] = wave2[1]
```

### See Also

The **ImageUnwrapPhase** operation and **mod** function.

## UnzipFile

```
UnzipFile [/O[=mode] /PASS=passwordStr /PIN=inputPathName /POUT=outputPathName /Z[=z]] inputFileStr, outputFolderStr
```

The UnzipFile operation unzips a file and saves the contents of the file in the specified output directory.

**Warning:** If you specify /O=2 for an output directory that already exists, all previous contents of the directory are deleted.

The UnzipFile operation was added in Igor Pro 9.00.

### Input File Parameter

*inputFileStr* specifies the zip file to unzip. The file name extension is not important but the file must be a zip file.

*inputFileStr* can be a full path to the file, in which case /PIN=*inputPathName* is not needed, a partial path relative to the directory associated with *inputPathName*, or the name of a file in the folder associated with *inputPathName*.

If you use a full or partial path for *inputFileStr*, see **Path Separators** on page III-453 for details on forming the path.

### Output Folder Parameter

*outputFolderStr* specifies the directory into which the contents of the zip file will be extracted.

*outputFolderStr* can be a full path to the directory, in which case /POUT=*outputPathName* is not needed, a partial path relative to the directory associated with *outputPathName*, or an empty string in which case the directory specified by /POUT=*outputPathName* is used for the output directory.

If *outputFolderStr* is an empty string, the /POUT flag specifies the output directory.

If *outputFolderStr* is not an empty string, it must end with a directory name and not a path separator such as colon or backslash.

If you use a full or partial path for *outputFolderStr*, see **Path Separators** on page III-453 for details on forming the path.

If the output directory does not exist, it is created automatically.

## Flags

- `/O[=mode]` Controls whether the contents of the output directory are overwritten.
- `mode=0:` Does not overwrite. If the output directory exists and is not empty, the operation generates an error. This is the default behavior if you omit `/O`.
  - `mode=1:` Merges the contents of the zip file with the existing contents of the output directory. Any existing file with the same name as a file within the zip file is overwritten.  
  
Unlike `/O=2`, the contents of the output directory and any subdirectories are not deleted. If the output directory already contains files whose names do not conflict with files in the zip file, those files remain untouched.  
  
`/O=1` is the same as `/O`.
  - `mode=2:` Deletes all contents of the output directory before extracting the contents of the zip file. Use this option if you want the contents of the output directory to exactly reflect the contents of the zip file.  
  
**Warning:** If you specify `/O=2` for an output directory that already exists, all previous contents of the directory are deleted.
- `/PASS=passwordStr`  
  
Specifies the password for a password-protected zip file. Only the older ZipCrypto "encryption" algorithm is supported, not the newer and much more secure AES-256 algorithm.
- `/PIN=inputPathName`  
  
Contributes to the specification of the input zip file to be extracted. `inputPathName` is the name of an existing symbolic path. See *Input File Parameter* above for details.
- `/POUT=outputPathName`  
  
`/` Contributes to the specification of the output directory into which the zip file's contents will be extracted. `outputPathName` is the name of an existing symbolic path. See *Output Folder Parameter* above for details.
- `/Z[=z]` Suppress error generation.
- `/Z=0:` Do not suppress errors. If an error occurs, Igor aborts procedure execution. This is the default behavior if you omit `/Z`.
  - `/Z=1:` Suppress errors. Errors do not abort procedure execution. Check the `V_Flag` output variable to see if an error occurred.
- `/Z` alone has the same effect as `/Z=1`.

## Output Variables

UnzipFile sets the following output variables:

- `V_flag` `V_flag` is set to zero if the operation succeeds or to a non-zero Igor error code if it fails. You can use `V_flag` along with the `/Z` flag to handle errors and prevent them from halting procedure execution.
- `S_outputFullPath` A string containing the full path to the output directory. If the operation fails, `S_outputFullPath` is set to "".

## Limitations

File and directory names within a zip file that contain non-ASCII characters may not have the correct names after unzipping.

The created and modified timestamps of a file are reconstructed with limited range and precision. Some zip files store these timestamps in an alternative format that allows for greater precision and range, but the current unzip algorithm does not support this newer format.

## UpperStr

---

### Examples

```
// Unzip a file using full paths
String zipFileString = "C:Users:Fred:Documents:Test.zip"
String outputPathString = "C:Users:Fred:Documents:Extracted"
UnzipFile zipFileString, outputPathString
// Unzip a file using symbolic paths
String zipFileName = "Test.zip"
String outputFolderName = "" // Unzip to folder specified by /POUT
UnzipFile/PIN=home/POUT=home zipFileName, outputFolderName
```

## UpperStr

### UpperStr (*str*)

The UpperStr function returns a string expression in which all lower-case ASCII characters in *str* are converted to upper-case.

### See Also

The LowerStr function.

## URLDecode

### URLDecode (*inputStr*)

The URLDecode function returns a percent-decoded copy of the percent-encoded string *inputStr*. It is unlikely that you will need to use this function; it is provided for completeness.

For an explanation of percent-encoding, see **Percent Encoding** on page IV-266.

### Example

```
String theURL = "http://google.com?key1=35%25%20larger"
theURL = URLDecode(theURL)
Print theURL
http://google.com?key1=35% larger
```

### See Also

URLEncode, URLRequest, URLs on page IV-265.

## URLEncode

### URLEncode (*inputStr*)

The URLEncode function returns a percent-encoded copy of *inputStr*.

Percent-encoding is useful when encoding the query part of a URL or when the URL contains special characters that might otherwise be misinterpreted by a web server. For an explanation of percent-encoding, see **Percent Encoding** on page IV-266.

### Example

```
String baseURL = "http://google.com"
String key1 = "key1"
String value1 = URLEncode("35% larger")
String theURL = ""
sprintf theURL, "%s?%s=%s", baseURL, key1, value1
Print theURL
http://google.com?key1=35%25%20larger
```

### See Also

URLDecode, URLRequest, URLs on page IV-265.

## URLRequest

### URLRequest [ flags ] url=urlStr [method=methodName, headers=headersStr]

The URLRequest operation connects to a URL using the specified method and optionally stores the response from the server. *urlStr* can point to a remote server or to a local file. The server's response is stored in the S\_serverResponse output variable or in a file if you use the /FILE flag.

The URLRequest operation was added in Igor Pro 7.00.

**Keywords**

The `url=urlStr` keyword is required. All others are optional.

`url=urlStr` A string containing the URL to retrieve. See **URLs** on page IV-265 for details.

`method=methodName` Specifies which method to use for the request. The get method is used by default. This table shows the valid methods for each supported scheme. Not all servers support all of the listed methods.

| Scheme      | Supported Methods            |
|-------------|------------------------------|
| http, https | get, post, put, head, delete |
| ftp         | get, put                     |
| file        | get, put                     |

Because *methodName* is a name, not a string, you must not enclose it in quotes.

Before using the post method, you should read **The HTTP POST Method** on page V-1055 so that you know how to use the optional headers parameter.

If you use the head method, URLRequest sets the `S_serverResponse` output variable to "" because only the headers are retrieved. As with other methods, the headers are stored in the `S_headers` output variable.

`headers=headersStr` Specifies a string containing additional or replacement headers to use with the request. This parameter is ignored unless the scheme is http or https.

The headers parameter is provided primarily for use with the post method when making HTTP requests and is ignored for schemes other than http/https. The header consists of a colon-separated key:value pair (though see the next paragraph for an exception). Pairs must be separated by a carriage return (\r) character.

Certain standard headers (such as Content-Type and User-Agent) may automatically be set when making the request. You can override those default values by using this keyword and setting a different value. If you add a header with no content, as in "Accept:" (there is no data on the right side of the colon), the internally used header is disabled. To actually add a header with no content, use the form "MyHeader;" (note the trailing semicolon).

Any headers specified with this keyword are sent only to the http server, not to the proxy server, if one is in use.

See **The HTTP POST Method** on page V-1055 for a detailed explanation and examples.

**Flags**

`/AUTH={username, password }`

Uses the specified *username* and *password* string parameters for authentication. Values provided here override any username and/or password provided as part of the URL. To specify a username but not a password, pass "" for the *password* parameter.

**Note:** See **Safe Handling of Passwords** on page IV-268 for more information on how to use URLRequest to prevent authentication information, such as passwords, from being accidentally revealed.

- /DFIL=dataFileNameStr* Specifies a file name to use as a source of data. Typically this flag is used only with the put or post methods, but it is accepted with all methods. Unless *dataFileNameStr* is a full path, the */P* flag must also be used. When using the post or put methods, one and only one of the */DFIL* or */DSTR* flags must be used.
- When you use */DFIL* and the method is anything other than put, the "Content-Type: application/x-www-form-urlencoded" header is automatically added. If necessary, you can override this behavior using the headers keyword. See **The HTTP POST Method** on page V-1055 for more information.
- /DSTR=dataStr* Specifies the string to use as a source of data. Typically you use this flag only with the put or post methods, but it is accepted with all methods. When using the post or put methods, one and only one of the */DFIL* or */DSTR* flags must be used.
- When */DSTR* is used and the method is anything other than put, the "Content-Type: application/x-www-form-urlencoded" header is automatically added. If necessary, you can override this behavior using the headers keyword. See **The HTTP POST Method** on page V-1055 for more information.
- /FILE=destFileNameStr* If present, URLRequest saves the server's response in a file instead of in the *S\_serverResponse* output variable.
- URLRequest ignores */FILE* if you include the */IGN* flag and the *ignoreResponse* parameter is not 0.
- destFileNameStr* can be a full path to the file, in which case */P=pathName* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If the file already exists, URLRequest returns an error unless you include the */O* flag.
- If you include */O* and the file already exists, the existing file is overwritten. This happens even in the event of an empty response or transfer error.
- You should consider using the */FILE* flag when you are expecting the server to return a large amount of data, such as when downloading a file.
- /IGN[=ignoreResponse]* Ignore and do not store the server's response to the request. */IGN* alone has the same effect as */IGN=1*.
- If *ignore* is turned on, URLRequest sets the *S\_serverResponse* output variable to "", regardless of whether the server responded to the request or not. If you include the */FILE* flag, URLRequest does not create the output file and sets *S\_fileName* is set to "".
- This flag is useful only when your goal is to establish a connection with a server and the server's response is not important. All error message codes and strings are still set when *ignore* is on.
- /IGN=0*: Same as no */IGN*.
- /IGN=1*: Ignore server response completely. *S\_headers* is set to "".
- /IGN=2*: Ignore server response but capture the headers of the response. *S\_serverResponse* is set to "" but *S\_headers* will contain the headers.
- /NRED=maxNumRedirects* Specifies the maximum number of redirects that are allowed. A redirect means that when a certain URL is requested, the server responds telling the client to try a different URL. Most web browsers automatically follow server redirects, up to a certain limit. For security purposes, it is sometimes useful to prevent redirects from being followed at all.
- maxNumRedirects* is a number between -1 and 1000. To allow infinite redirection, set *maxNumRedirects* to -1. If you omit the */NRED* flag, a moderate value (currently 20, but subject to change in the future) is used.

`/O` Specifies that the file is to be overwritten when you use the `/FILE` flag and the output file already exists. If you omit `/O` and the file exists, URLRequest returns an error.

`/P=pathName` Specifies the folder to use for the output file, specified by the `/FILE` flag, and/or the source data file, specified by the `/DFIL` flag. `pathName` is the name of an existing Igor symbolic path.

The `/P` flag affects both the `/FILE` and `/DFIL` flags. If you use both flags and want to use different directories, you must provide a full path for one or both of the `/FILE` and `/DFIL` flag parameters.

If the `/P` flag is used without one or both of the `/FILE` and `/DFIL` flags, it is ignored.

`/PROX[={proxyURLStr, proxyUserNameStr, proxyPassStr, proxyOptions}]`

**NOTE: This flag is experimental and has not been extensively tested. The behavior of this flag may change in the future, or it may be eliminated entirely.**

Designates a proxy server to be used when making the connection.

`proxyURLStr` is either the host name or IP address of the proxy server, or a full URL. If a full URL is used, the scheme specifies which kind of proxy is used. Typically the scheme for a proxy server should be either `http` or `socks5`. If no scheme is provided, `http` is assumed. See [URLs](#) on page IV-265 for more information.

If the proxy server does not require authentication, or if the username and password for the proxy server are specified in `proxyURLStr`, the optional `proxyUserNameStr` and `proxyPassStr` parameters do not need to be provided. The following two examples do the same thing:

```
/PROX={"http://proxy.example.com:800"}
```

```
/PROX={"http://proxy.example.com:800", "", ""}
```

As with other URLs, you can also provide the username and password as part of the URL itself. The following two examples do the same thing:

```
/PROX={"http://proxy.example.com:800", "user", "pass"}
```

```
/PROX={"http://user:pass@proxy.example.com:800"}
```

`proxyOptions` is optional and for future use. It is currently ignored. If provided, you must set it to 0.

If you use the `/PROX` flag without any parameters, Igor attempts to get proxy information from the operating system's proxy configuration information. If Igor cannot get any proxy server information from the system, no proxy server is used.

See [Safe Handling of Passwords](#) on page IV-268 for more information on how to use URLRequest to prevent authentication information, such as passwords, from being accidentally revealed.

`/TIME=timeoutSeconds` Forces the operation to time out after `timeoutSeconds` seconds if it has not completed by that time. If this flag is not provided, URLRequest runs until the server has finished sending and receiving data. For simple requests a value of a few seconds is appropriate. However, because uploading and/or downloading large amounts of data may take a long time, if `timeoutSeconds` is too small the request might be prematurely terminated. If you omit the `/TIME` flag, or if `timeoutSeconds = 0`, there is no timeout.

Regardless of whether or not you include `/TIME`, you can abort the operation by pressing the **User Abort Key Combinations**.

## URLRequest

---

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/V=diagnosticMode</i> | This flag is useful only when your goal is to establish a connection with a server and the server's response is not important. All error message codes Controls diagnostic messages printed in the history area of the command window.<br><i>/V=0:</i> Do not print any diagnostic messages. This is the default if you omit <i>/V</i> .<br><i>/V=1:</i> Prints an error message if a run time error occurs.<br><i>/V=2:</i> Prints full debugging information. |
| <i>/Z[=z]</i>            | Suppress error generation. Use this if you want to handle errors yourself.<br><i>/Z=0:</i> Do not suppress errors. This is the default if <i>/Z</i> is omitted.<br><i>/Z=1:</i> Any errors generated by Igor do not stop execution. If there is an error the error code is stored in <i>V_Flag</i> .<br><br><i>/Z</i> alone has the same effect as <i>/Z=1</i> .                                                                                                |

### Output Variables

URLRequest sets the following output variables:

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>V_flag</i>           | <i>V_flag</i> is zero if the operation succeeds without an error or a non-zero Igor error code if it fails.<br><br>Note that "succeeds without an error" does not necessarily mean that the operation performed as you intended. For example, if you attempt to connect to a server that requires a username and password for authentication but you do not provide this information, <i>V_flag</i> is likely to be 0, indicating no error. You need to inspect the value of <i>V_responseCode</i> to ensure that it is what you expect.                                                                                                                                                                       |
| <i>V_responseCode</i>   | Contains the status code provided by the server.<br><i>V_responseCode</i> is valid only if <i>V_flag</i> is 0, meaning that no error occurred. If <i>V_flag</i> is nonzero, an error occurred and <i>V_responseCode</i> will be 0.<br><br>Different schemes use different sets of status codes.<br><br>A list of http/https status codes and their definitions can be found at:<br><a href="http://www.w3.org/Protocols/rfc2616/rfc2616-sec10.html">http://www.w3.org/Protocols/rfc2616/rfc2616-sec10.html</a><br><br>A list of FTP status codes can be found at:<br><a href="https://en.wikipedia.org/wiki/List_of_FTP_server_return_codes">https://en.wikipedia.org/wiki/List_of_FTP_server_return_codes</a> |
| <i>S_serverResponse</i> | Contains the server's response to the request.<br><i>S_serverResponse</i> is set to "" if you use the <i>/FILE</i> flag or the <i>/IGN=1</i> or <i>/IGN=2</i> flags.<br><br>We recommend that you use the <i>/FILE</i> flag when you expect the size of the server response to be large, such as when downloading a large file.                                                                                                                                                                                                                                                                                                                                                                                |
| <i>S_headers</i>        | Contains a list of all of the headers received as part of the response. Header names are separated from their value by a colon and pairs are separated by a carriage return followed by a line feed ( <code>\r\n</code> ). For schemes other than http and https, <i>S_headers</i> is set to "".                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>S_fileName</i>       | Contains the full Igor-style path to the output file if the <i>/FILE</i> flag was used. If there was an error saving to the specified file, or another kind of error, or if the <i>/FILE</i> flag was not used, <i>S_fileName</i> is set to "".                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

### Basic Examples

```
// Retrieve the contents of the WaveMetrics home page.
// Output is stored in S_serverResponse
URLRequest url="http://www.wavemetrics.com"

// Download the Windows Igor6 installer and save it as a file on the desktop.
```

```

NewPath/O Desktop, SpecialDirPath("Desktop", 0, 0, 0)
String theURL = "http://www.wavemetrics.net/Downloads/Win/setupIgor6.exe"
URLRequest/FILE="setupIgor6.exe"/P=Desktop url=theURL

// Download a file to the desktop from an FTP server.
NewPath/O Desktop, SpecialDirPath("Desktop", 0, 0, 0)
String theURL = "ftp://ftp.wavemetrics.com/test/test.htm"
URLRequest/O/FILE="test.htm"/P=Desktop url=theURL

// Upload the same file to the FTP server.
theURL = "ftp://user:pass@ftp.wavemetrics.com/test.htm"
URLRequest/DFIL="test.htm"/P=Desktop method=put, url=theURL

```

### Using the File Scheme

URLRequest supports the file scheme in URLs. You must provide the full path to the file as a native Windows-style or UNIX-style path, depending on which platform the code is running.

You must specify the schema as "file:///". Note that you must use three front slash characters (/) between the colon and the full file path (for most URLs you would only use two slashes).

```

URLRequest url="file:///C:\\Data\\Trial1\\control.ibw" // Works on Windows only
URLRequest url="file:///Users/bob/Data/Trial1/control.ibw" // Works on Macintosh only
URLRequest url="file:///C:\\Data\\Trial1\\control.ibw" // Doesn't work
URLRequest url="file:///Users/bob/Data/Trial1/control.ibw" // Doesn't work

```

The following example shows how to convert a full Igor file path to a native path suitable for use as a file URL:

```

String nativeFilePath
#ifdef WINDOWS
 String igorFilePath = "C:Documents:myFile.txt"
 nativeFilePath = ParseFilePath(5, igorFilePath, "*", 0, 0)
#endif
#ifdef MACINTOSH
 String igorFilePath = "MacintoshHD:Documents:myFile.txt"
 nativeFilePath = ParseFilePath(5, igorFilePath, "/", 0, 0)
 // Remove the leading "/" from nativeFilePath. Otherwise,
 // when we prepend "file:://" below, we'd end up with four
 // slashes, which isn't allowed.
 nativeFilePath = nativeFilePath[1, INF]
#endif
URLRequest url="file:://" + nativeFilePath

```

### The HTTP POST Method

Like the HTTP GET method, the HTTP POST method can be used to transmit information to a web server. When using the GET method, all information must be contained within the URL itself. As an example, making a GET request to the URL <<http://www.google.com/search?q=Igor+Pro+WaveMetrics>> searches Google using the keywords "Igor", "Pro", and "WaveMetrics".

Unlike the GET method, the POST method allows the client to send information to the server that is not contained within the URL itself. This is necessary in many situations, such as when uploading a file or transferring a large amount of data. In addition, because the data contained in POST requests is typically not stored in the log files of web servers, it is more appropriate for sending data that is secure, such as login credentials and form submissions which might contain sensitive information.

When using the POST method, the client must encode its data using one of several methods and must tell the server what type of data is being sent and how it is encoded. The client does this by setting the Content-Type header that is part of the request. The most commonly used content type is "application/x-www-form-urlencoded". Unless you provide your own Content-Type header using the optional headers parameter, URLRequest will set this header for you. This is true regardless of which data source (/DSTR for string or /DFIL for file) you use for the POST.

Here is a simple example that uses the POST method with URL encoded data (the default Content-Type).

```

String theURL = "http://www.example.com/process.php"
String nameData = URLEncode("name") + "=" + URLEncode("Dan P. Ikes, Jr.")
String address = "650 E. Chicago Ave."
String addressData = URLEncode("address") + "=" + URLEncode(address)
String postData = nameData + "&" + addressData
URLRequest/DSTR=postData method=post, url=theURL

```

There are two things to note in this example.

## URLRequest

---

First, both the key name and value string are passed through **URLEncode** so that any special characters can be percent-encoded.

Second, keys and values are separated by an equal sign ("=") and key/value pairs are separated by an ampersand("&"). These characters are not passed through URLEncode because doing so would cause them to lose their meaning as special characters.

For more information on using the application/x-www-form-urlencoded content type, see <http://www.w3.org/TR/html401/interact/forms.html#h-17.13.4.1>

It is also possible to transmit more complicated data using the POST method, such as simulating a form that contains regular text fields as well as a file upload field. To do so you must set the Content-Type header using the headers parameter. You must also build your post data using a multi-part header. Here is an example:

```
String theURL = "http://www.example.com/process.php"
String postData = ""
// Note: The boundary is arbitrary. It needs to be
// unique enough that it is not contained within any
// of the actual data being transmitted in the post.
String boundary = "AaBbCcDd0987"

// name
postData += "--" + boundary + "\r\n" // beginning of this part
postData += "Content-Disposition: form-data; name=\"name\"\r\n"
postData += "\r\n"
postData += "Dan P. Ikes, Jr.\r\n"

// address
postData += "--" + boundary + "\r\n"
postData += "Content-Disposition: form-data; name=\"address\"\r\n"
postData += "\r\n"
postData += "650 E. Chicago Ave.\r\n"

// file
// Open the file we plan to send and store the binary
// contents of the file in a string.
Variable refNum
Open/R/Z/P=Igor refNum as "ReadMe.ihf"
FStatus refNum
Variable fileSize = V_logEOF
String fileContents = ""
fileContents = PadString(fileContents, fileSize, 0)
FBinRead refNum, fileContents
Close refNum
postData += "--" + boundary + "\r\n"
postData += "Content-Disposition: form-data; name=\"file\"; filename=\"ReadMe.ihf\"\r\n"
postData += "Content-Type: application/octet-stream\r\n"
postData += "Content-Transfer-Encoding: binary\r\n"
postData += "\r\n"
postData += fileContents + "\r\n"

postData += "--" + boundary + "--\r\n" // end of this part

String headers
headers = "Content-Type: multipart/form-data; boundary=" + boundary
URLRequest/DSTR=postData method=post, url=theURL, headers=headers
```

For more information on using the multipart/form-data content type, see <http://www.w3.org/TR/html401/interact/forms.html#h-17.13.4.2>

### Handling JSON Data

JSON (JavaScript Object Notation) is a lightweight data-interchange format that is commonly used when interacting with websites - see <https://www.json.org/json-en.html>. For full read and write JSON support in Igor Pro, we recommend using the JSON XOP, developed by byte physics. You can download it from <https://docs.byte-physics.de/json-xop>.

## ValDisplay

**ValDisplay** [/Z] *ctrlName* [**keyword = value** [, **keyword = value** ...]]

The ValDisplay operation creates or modifies the named control that displays a numeric value in the target window. The appearance of the control varies; see the **Examples** section.

For information about the state or status of the control, use the **ControlInfo** operation.

### Parameters

*ctrlName* is the name of the ValDisplay control to be created or changed.

The following keyword=value parameters are supported:

- align=alignment** Sets the alignment mode of the control. The alignment mode controls the interpretation of the *leftOrRight* parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.
- If *alignment=0* (default), *leftOrRight* specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.
- If *alignment=1*, *leftOrRight* specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.
- appearance={kind [, platform]}**
- Sets the appearance of the control. *platform* is optional. Both parameters are names, not strings.
- kind* can be one of *default*, *native*, or *os9*.
- platform* can be one of *Mac*, *Win*, or *All*.
- See **Button** and **DefaultGUIControls** for more appearance details.
- barBackColor=(r,g,b[,a])** Sets the background color under the bar (if any). *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**.
- barBackColor=0** Sets the background color under the bar to the default color, the standard document background color used on the current operating system, which is usually white.
- barmisc={lts, valwidth}** Sets the “limits text size” and the size of the type showing the bar limits. If *lts* is zero, the bar limits are not displayed. Otherwise, *lts* must be between 5 and 100.
- valwidth* is the “value readout width”. It claims the amount of horizontal space for the numeric part of the display.
- If *valwidth* equals or exceeds the control width available to it, the numeric readout uses all the room, and prevents display of any bar.
- If *valwidth* is zero, there is no numeric readout, and only the bar is displayed.
- valwidth* can range from zero to 4000, and it defaults to 1000 (which usually leaves no room for the display bar).
- bodyWidth=width** Specifies an explicit size for the body (nontitle) portion of a ValDisplay control. By default (*bodyWidth=0*), the body portion is the amount left over from the specified control width after providing space for the current text of the title portion. If the font, font size, or text of the title changes, then the body portion may grow or shrink. If you supply a *bodyWidth>0*, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.

|                                                                |                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>disable=<i>d</i></code>                                  | Sets user editability of the control.<br><code>d=0:</code> Normal.<br><code>d=1:</code> Hide.<br><code>d=2:</code> Disable user input.<br>Does not change control appearance because it is read-only.<br><code>d=3:</code> Hide and disable the control.<br>This is useful to disable a control that is also hidden because it is in a hidden tab. |
| <code>fColor=(<i>r,g,b[,a]</i>)</code>                         | Sets the initial color of the title. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> . The default is opaque black.<br>To further change the color of the title text, use escape sequences as described for <code>title=<i>titleStr</i></code> .                                        |
| <code>font="<i>fontName</i>"</code>                            | Sets the font used to display the value of the variable, e.g.,<br><code>font="Helvetica"</code>                                                                                                                                                                                                                                                    |
| <code>format=<i>formatStr</i></code>                           | Sets the numeric format of the displayed value. The default format is "%g". For a description of <i>formatStr</i> , see the <b>printf</b> operation.                                                                                                                                                                                               |
| <code>frame=<i>f</i></code>                                    | Sets frame style:<br><code>f=0:</code> Value is unframed.<br><code>f=1:</code> Default; value is framed (same as <code>f=3</code> ).<br><code>f=2:</code> Simple box.<br><code>f=3:</code> 3D sunken frame.<br><code>f=4:</code> 3D raised frame.<br><code>f=5:</code> Text well.                                                                  |
| <code>fsize=<i>s</i></code>                                    | Sets the size of the type used to display the value in the numeric readout. The default is 12 points.                                                                                                                                                                                                                                              |
| <code>fstyle=<i>fs</i></code>                                  | <i>fs</i> is a bitwise parameter with each bit controlling one aspect of the font style as follows:<br>Bit 0: Bold<br>Bit 1: Italic<br>Bit 2: Underline<br>Bit 4: Strikethrough<br>See <b>Setting Bit Parameters</b> on page IV-12 for details about bit settings.                                                                                 |
| <code>help={<i>helpStr</i>}</code>                             | Sets the help for the control.<br><i>helpStr</i> is limited to 1970 bytes (255 in Igor Pro 8 and before).<br>You can insert a line break by putting "\r" in a quoted string.                                                                                                                                                                       |
| <code>highColor=(<i>r,g,b[,a]</i>)</code>                      | Specifies the bar color when the value is greater than <i>base</i> in the limits keyword. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> .                                                                                                                                             |
| <code>labelBack=(<i>r,g,b[,a]</i>)</code> or<br><code>0</code> | Specifies the background fill color for labels. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> . The default is 0, which uses the window's background color.                                                                                                                           |
| <code>limits={<i>low,high,base</i>}</code>                     | Controls how the value is translated into a graphical representation when the display includes a bar (described fully in <b>Details</b> ). Defaults are {0,0,0}, which aren't too useful.                                                                                                                                                          |
| <code>limitsColor=(<i>r,g,b[,a]</i>)</code>                    | Sets the color of the limits text, if any. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> .                                                                                                                                                                                            |
| <code>limitsBackColor=(<i>r,g,b[,a]</i>)</code>                |                                                                                                                                                                                                                                                                                                                                                    |

---

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                     | Sets the background color under the limits text. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| limitsBackColor=0                   | Sets the background color under the limits text to the default color, the standard document background color used on the current operating system, which is usually white.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| lowColor=( <i>r,g,b[,a]</i> )       | Specifies the bar color when the value is less than <i>base</i> in the limits keyword. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| mode= <i>m</i>                      | Specifies the type of LED display to use, if any.<br><i>m</i> =0: Bar mode (default).<br><i>m</i> =1: Oval LED.<br><i>m</i> =2: Rectangular LED.<br><i>m</i> =3: Bar mode with no fractional part.<br><i>m</i> =4: Candy-stripe effect for the bar area to support indefinite-style progress windows. The value is taken to be the phase of the candy stripe. When using value= <i>_NUM:n</i> , <i>n</i> is taken as an increment value so you would normally just use 1. Uses the native platform appearance if the high and low colors are left as default. Note native formats may not fill vertical space. See <b>Progress Windows</b> on page IV-156 for an example. |
| pos={ <i>leftOrRight,top</i> }      | Sets the position in <b>Control Panel Units</b> of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| pos+={ <i>dx,dy</i> }               | Offsets the position of the display in <b>Control Panel Units</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| rename= <i>newName</i>              | Gives the ValDisplay control a new name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| size={ <i>width,height</i> }        | Sets width and height of display in <b>Control Panel Units</b> . <i>width</i> can range from 10 to 200 units, <i>height</i> from 5 to 200 units. Default width is 50, default height is determined by the numeric readout font size.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| title= <i>titleStr</i>              | Sets title of display to the specified string expression. The title appears to the left of the display. If this title is too long, it won't leave enough room to display the bar or even the numeric readout! Defaults to "" (no title).<br><br>Using escape codes you can change the font, size, style, and color of the title. See <b>Annotation Escape Codes</b> on page III-53 or details.                                                                                                                                                                                                                                                                            |
| value= <i>valExpr</i>               | Displays the numeric expression <i>valExpr</i> . It is <i>not</i> a string.<br><br>As of version 6.1, you can use the syntax <i>_NUM:num</i> to specify a numeric value without using a dependency.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| valueColor=( <i>r,g,b[,a]</i> )     | Sets the color of the value readout text, if any. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| valueBackColor=( <i>r,g,b[,a]</i> ) | Sets the background color under the value readout text. <i>r</i> , <i>g</i> , <i>b</i> , and <i>a</i> specify the color and optional opacity as <b>RGBA Values</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| valueBackColor=0                    | Sets the background color under the value readout text to the default color, the standard document background color used on the current operating system, which is usually white.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| win= <i>winName</i>                 | Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.<br><br>When identifying a subwindow with <i>winName</i> , see <b>Subwindow Syntax</b> on page III-92 for details on forming the window hierarchy.                                                                                                                                                                                                                                                                                                                                                                          |

## ValDisplay

`zeroColor=(r,g,b[,a])` Governs the LED color (in LED mode only). *r*, *g*, *b*, and *a* specify the color and optional opacity as **RGBA Values**. Used in conjunction with the `limits` keyword such that `zeroColor` determines one endpoint color when `base` is between *low* and *high*, or LED color when the value is less than *low*.

### Flags

`/Z` No error reporting.

### Details

The target window must be a graph or panel.

The appearance of the ValDisplay control depends primarily on the *width* and *valwidth* parameters and the width of the title. Space for the individual elements is allocated from left to right, with the title receiving first priority. If the control width hasn't all been used by the title, then the value display gets either *valwidth* **Control Panel Units** of room, or what is left. If the control width hasn't been used up, the bar is displayed in the remaining control width:

If you use the `bodyWidth` keyword, the value readout width and bar width occupy the body width. The total control width is then `bodyWidth+title width`, and the width from the `size` keyword is ignored.

The limits values *low*, *high*, and *base* and the value of *valExpr* control how the bar, if any, is drawn. The bar is drawn from a starting position corresponding to the *base* value to an ending position determined by the value of *valExpr*, *low* and *high*. *low* corresponds to the left side of the bar, and *high* corresponds to the right. The position that corresponds to the *base* value is linearly interpolated between *low* and *high*.

For example, with *low*= -10, *high*=10, and *base*= 0, a *valExpr* value of 5 will draw from the center of the bar area (0 is centered between -10 and 10) to the right, halfway from the center to the right of the bar area (5 is halfway from 0 to 10):

The *valExpr* must be executable at any time. The expression is stored and executed when the ValDisplay needs to be updated. However, execution will occur outside the routine that creates the ValDisplay, so you must not use local variables in the expression.

*valExpr* may be enclosed in quotes and preceded with a # character (see **When Dependencies are Updated** on page IV-231) to defer evaluation of the validity of the numeric expression, which may be needed if the expression references as-yet-nonexistent global variables or user-defined functions:

```
ValDisplay valdisp0 value=notAVar*2 // "unknown name or symbol" error
ValDisplay valdisp0 value=#"notAVar*2" // still not valid, no error
Variable notAVar=3 // now valid; ValDisplay works
```

In a ValDisplay, the `# " "` syntax permits use of a string expression. Normally, the `#` prefix signifies that the following text must be a literal quoted string. String expressions are evaluated at runtime to obtain the final expression for the ValDisplay. In other words, there is a level of indirection.

### Examples

Here is a sampling of the various types of ValDisplay controls available:

You can use a ValDisplay to replace the bar mode with a solid color fill designed to look like an LED. Use the mode keyword with `mode=1` to create an oval LED or `mode=2` to create a rectangular LED. You can specify different frames with the rectangular LED but only a simple frame is available for the oval mode. Use `mode=0` to revert to bar mode.

The color and brightness of the LED depends on the value that the ValDisplay is monitoring combined with the `limits={low, high, base}` setting, the two color settings used in bar mode along with a third color (`zeroColor`) that is used only in LED mode. When the value is between *low* and *high*, the color is a linear combination of endpoint colors. If *base* is between *low* and *high*, the endpoint colors are the low color and the zero color, or the zero color and the high color. For values outside the limits, the appropriate limiting color is chosen.

If *base* is less than the *low*, the endpoint colors are the low color and the high color. In this case, if the value is less than *low* the LED takes on the zero color.

You should use the `bodyWidth` setting in conjunction with LED mode to keep the LED from dramatically changing size or disappearing when the title is changed or if your experiment is moved to a different platform (Macintosh vs PC).

Try the ValDisplay Demo example experiment to see these different modes in action. Choose File→Example Experiments→Feature Demos→ValDisplay Demo.

### Variable

**Variable** [*flags*] *varName* [/N=*name*] [=numExpr] [, *varName* [/N=*name*] [=numExpr] ]...

The Variable operation creates real or complex variables and gives them the specified name.

#### Flags

- /C Declares a complex variable.
- /D Obsolete, included only for backward compatibility (see **Details**).
- /G Creates a variable with global scope and overwrites any existing variable.
- /N=*name* Specifies a local name for the global string variable. /N was added in Igor Pro 8.00 and is available in user-defined functions only. See **NVAR Creation** below for details.

#### Details

The variable is initialized when it is created if you supply the initial value. However, when Variable is used to declare a function parameter, it is an error to attempt to initialize it.

You can create more than one variable at a time by separating the names and optional initializers for multiple variables with a comma.

Numeric variables are double precision. In ancient times, variables could be single or double precision and the /D flag meant double precision. The /D flag is allowed for backward compatibility but is no longer needed and should not be used in new code.

If used in a macro or function the new variable is local to that macro or function unless the /G flag is used. If used on the command line, the new variable is global.

*varName* can include a data folder path.

#### NVAR Creation

In a user-defined function, you need a local NVAR reference to access a global string variable. If you use a simple name rather than a path, Igor automatically creates an NVAR:

```
Variable/G nVar1 // Creates an NVAR named nVar1
```

If you use a path or a \$ expression, Igor does not create an automatic NVAR reference. You can explicitly create NVARs like this:

```
Variable/G root:nVar2
NVAR nVar2 = root:nVar2 // Creates an NVAR named nVar2
```

```
String path = "root:nVar3"
Variable/G $path
NVAR nVar3 = $path // Creates an NVAR named nVar3
```

In Igor Pro 8.00 and later, you can explicitly create an NVAR reference in a user-defined function using the /N flag, like this:

```
Variable/G nVar4/N=nVar4 // Creates an NVAR named nVar4
Variable/G root:nVar5/N=nVar5 // Creates an NVAR named nVar5
String path = "root:nVar6"
Variable/G $path/N=nVar6 // Creates an NVAR named nVar6
```

The name used for the NVAR does not need to be the same as the name of the global variable:

```
Variable/G nVar7/N=nv7 // Creates an NVAR named nv7
Variable/G root:nVar8/N=nv8 // Creates an NVAR named nv8
String path = "root:nVar9"
Variable/G $path/N=nv9 // Creates an NVAR named nv9
```

#### Examples

To initialize a complex variable, use the **cmplx** function. For example:

```
Variable/C cv1 = cmplx(1,2)
```

This sets the real part of cv1 to 1 and the imaginary part to 2.

## Variance

**Variance**(*inWave* [, *x1*, *x2* ] )

Returns the variance of the real-valued *inWave*. The function ignores NaN and INF values in *inWave*.

### Parameters

*inWave* is expected to be a real-valued numeric wave. If *inWave* is a complex or text wave, Variance returns NaN.

*x1* and *x2* specify a range in *inWave* over which the variance is to be calculated. They are used only to locate the points nearest to  $x=x1$  and  $x=x2$ . The variance is then calculated over that range of points. The order of *x1* and *x2* is immaterial.

If omitted, *x1* and *x2* default to  $-\infty$  and  $+\infty$  respectively and the variance is calculated for the entire wave.

### Details

The variance is defined by

$$\text{var} = \frac{\sum_{i=1}^n (x_i - \bar{x})^2}{n - 1}$$

where

$$\bar{x} = \frac{\sum_{i=1}^n X_i}{n}.$$

### Examples

```
Make/O/N=5 test = p
SetScale/P x, 0, .1, test

// Print variance of entire wave
Print Variance(test)

// Print variance from x=0 to x=.2
Print Variance(test, 0, .2)

// Print variance for points 1 through 3
Variable x1=pnt2x(test, 1)
Variable x2=pnt2x(test, 3)
Print Variance(test, x1, x2)
```

## VariableList

**VariableList**(*matchStr*, *separatorStr*, *variableTypeCode* [, *dfr* ])

The VariableList function returns a string containing a list of the names of global variables selected based on the *matchStr* and *variableTypeCode* parameters. The variables listed are all in the current data folder or the data folder specified by *dfr*.

### Details

For a variable name to appear in the output string, it must match *matchStr* and also must fit the requirements of *variableTypeCode*. *separatorStr* is appended to each variable name as the output string is generated.

The name of each variable is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

"\*"                      Matches all variable names.

|           |                                                               |
|-----------|---------------------------------------------------------------|
| "xyz"     | Matches variable name xyz only.                               |
| "*xyz"    | Matches variable names which end with xyz.                    |
| "xyz*"    | Matches variable names which begin with xyz.                  |
| "*xyz*"   | Matches variable names which contain xyz.                     |
| "abc*xyz" | Matches variable names which begin with abc and end with xyz. |

*matchStr* may begin with the ! character to return items that do not match the rest of *matchStr*. For example:

|         |                                                          |
|---------|----------------------------------------------------------|
| "!*xyz" | Matches variable names which <i>do not</i> end with xyz. |
|---------|----------------------------------------------------------|

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

*variableTypeCode* is used to further qualify the variable. The variable name goes into the output string only if it passes the match test and its type is compatible with *variableTypeCode*. *variableTypeCode* is any one of:

- 2: System variables (K0, K1 . . .)
- 4: Scalar variables
- 5: Complex variables

*dfr* is an optional data folder reference: a data folder name, an absolute or relative data folder path, or a reference returned by, for example, **GetDataFolderDFR**.

**Examples**

|                                                      |                                                                                   |
|------------------------------------------------------|-----------------------------------------------------------------------------------|
| <code>VariableList ("*", ";", 4)</code>              | Returns a list of all scalar variables.                                           |
| <code>VariableList ("!V_*", ";", 5)</code>           | Returns a list of all complex variables except those whose names begin with "V_". |
| <code>VariableList ("*", ";", 4, root:MyData)</code> | Returns a list of all scalar variables in the root:MyData data folder.            |

**See Also**

See the **StringList** and **WaveList** functions.

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

**VCSR**

**vcsr** (*cursorName* [, *graphNameStr*])

The **vcsr** function returns the Y (vertical) value of the point which the specified cursor (A through J) is attached to in the top (or named) graph.

**Parameters**

*cursorName* identifies the cursor, which can be cursor A through J.

*graphNameStr* specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Details**

The result is computed from the coordinate system of the graph's Y axis. The Y axis used is the one used to display the wave on which the cursor is placed.

## VoigtFunc

```
VoigtFunc (X, Y)
```

The VoigtFunc function computes the Voigt function using an approximation that has, as described by the author, "accuracy is typically at at least 13 significant digits".

VoigtFunc returns values from a normalized Voigt peak centered at  $X=0$  for the given value of  $X$ . The  $X$  input is a normalized distance from the peak center:

$$X = \sqrt{\ln(2)} \frac{V - V_0}{\gamma_g}$$

where  $\gamma_g$  is the Gaussian component half-width, and  $V - V_0$  is the distance from the peak center.

The parameter  $Y$  is the shape parameter: when  $Y$  is zero, the peak is pure Gaussian. When  $Y$  approaches infinity, the shape becomes pure Lorentzian. When  $Y$  is  $\sqrt{\ln(2)}$ , the mix is half-and-half.

VoigtFunc was added in Igor Pro 7.00. The approximation used to compute it was changed Igor 8.00 for greater accuracy.

### Details

The VoigtFunc function returns values from a normalized peak that can be used as the basis for user-defined fitting functions. The function is used as the basis for the built-in Voigt fitting function and the **VoigtPeak** function.

### VoigtFunc Curve Fitting Example

Here is an example of a user-defined fitting function built on VoigtFunc:

```
Constant sqrtln2=0.832554611157698 // sqrt(ln(2))
Constant sqrtln2pi=0.469718639349826 // sqrt(ln(2)/pi)

Function MyVoigtFit(w,xx) : FitFunc
 Wave w
 Variable xx

 //CurveFitDialog/ These comments were created by the Curve Fitting dialog.
 //CurveFitDialog/ Equation:
 //CurveFitDialog/ Variable ratio = sqrtln2/gw
 //CurveFitDialog/ Variable xprime = ratio*(xx-x0)
 //CurveFitDialog/ Variable voigtY = ratio*shape
 //CurveFitDialog/ f(xx) = y0 + area*sqrtln2pi*VoigtFunc(xprime, voigtY)
 //CurveFitDialog/ End of Equation
 //CurveFitDialog/ Independent Variables 1
 //CurveFitDialog/ xx
 //CurveFitDialog/ Coefficients 5
 //CurveFitDialog/ w[0] = y0
 //CurveFitDialog/ w[1] = area
 //CurveFitDialog/ w[2] = x0
 //CurveFitDialog/ w[3] = gw (FWHM)
 //CurveFitDialog/ w[4] = shape (Lw/Gw)

 Variable voigtX = 2*sqrtln2*(xx-w[2])/w[3]
 Variable voigtY = sqrtln2*w[4]
 return w[0] + (w[1]/w[3])*2*sqrtln2pi*VoigtFunc(voigtX, voigtY)
End
```

## VoigtPeak

---

Parameter `w[0]` sets the vertical offset, `w[1]` sets the peak area, `w[2]` sets the location of the peak, `w[3]` gives the Gaussian component's full width at half max and `w[4]` is the ratio of the Lorentzian width to the Gaussian width.

After the fit, assuming you used a coefficient wave named `voigtCoefs`, you can calculate the width of the full Voigt peak as follows:

```
Variable/G w1 = voigtCoefs[4]*voigtCoefs[3]
Variable/G wg = voigtCoefs[3]
Variable wv = w1/2 + sqrt(w1^2/4 + wg^2)
```

### References

The code used to compute the `VoigtFunc` was written by Steven G. Johnson of MIT. You can learn more about it at <http://ab-initio.mit.edu/Faddeeva>.

## VoigtPeak

### **VoigtPeak**(*w*, *x*)

The `VoigtPeak` function returns a value from a Voigt peak shape defined by coefficients in wave *w* at location *x*. It was added in Igor Pro 8.00.

The Voigt peak shape is defined as a convolution of a Gaussian and a Lorentzian peak. We use an approximation that is described by the author as having "accuracy typically at least 13 significant digits". This function is equivalent to the built-in Voigt fitting function. See **Built-in Curve Fitting Functions** on page III-206.

The coefficients are:

- `w[0]`: Vertical offset.
- `w[1]`: Peak area.
- `w[2]`: Peak center location.
- `w[3]`: Gaussian component width expressed as Full Width at Half Max (FWHM).
- `w[4]`: Ratio of Lorentzian component width to the Gaussian component width. For `w[4]=0`, the peak shape is purely Gaussian, as `w[4] → ∞`, the peak shape become purely Lorentzian. A value of 1 results in Gaussian and Lorentzian components of equal width.

## WAVE

```
WAVE [/C] [/T] [/WAVE] [/DF] [/Z] [/ZZ] [/SDFR=dfr] localName [=pathToWave] [,
localName1 [=pathToWave1]]...
```

`WAVE` is a declaration that identifies the nature of a user-defined function parameter or creates a local reference to a wave accessed in the body of a user-defined function.

The optional parameter `/SDFR` flag and `pathToWave` parameter are used only in the body of a function, not in a parameter declaration.

The `WAVE` declaration is required when you use a wave in an assignment statement in a function. At compile time, the `WAVE` statement specifies that the local name references a wave. At runtime, it makes the connection between the local name and the actual wave. For this connection to be made, the wave must exist when the `WAVE` statement is executed.

The `WAVE` declaration is also required if you use a wave name as a parameter to an operation or function if `rtGlobals=3` is in effect which is the usual case.

When *localName* is the same as the global wave name and you want to reference a wave in the current data folder, you can omit the *pathToWave*.

*pathToWave* can be a full literal path (e.g., root:FolderA:wave0), a partial literal path (e.g., :FolderA:wave0) or \$ followed by string variable containing a computed path (see **Converting a String into a Reference Using \$** on page IV-61).

You can also use a data folder reference or the /SDFR flag to specify the location of the wave if it is not in the current data folder. See **Data Folder References** on page IV-78 and **The /SDFR Flag** on page IV-79 for details.

If the wave may not exist at runtime, use the /Z flag and call **WaveExists** before accessing the wave. The /Z flag prevents Igor from flagging a missing wave as an error and dropping into the debugger. For example:

```
WAVE/Z wv=<pathToPossiblyMissingWave>
if(WaveExists(wv))
 <do something with wv>
endif
```

In Igor Pro 9.00 and later, you can avoid the runtime lookup of *localName* in the current data folder by including the /ZZ flag. For example:

```
Function CallingRoutine()
 WAVE/ZZ w
 PassByRefRoutine(w)
 Print w
End

Function PassByRefRoutine(WAVE& wr)
 WAVE wr = NewFreeWave(2,2)
End
```

Without the /ZZ flag, at runtime Igor would attempt to find a wave named *w* in the current data folder. This is unnecessary in this case since *PassByRefRoutine* sets the *w* variable.

### Flags

|                   |                                                                                        |
|-------------------|----------------------------------------------------------------------------------------|
| /C                | Complex wave                                                                           |
| /T                | Text wave                                                                              |
| /WAVE             | Wave reference wave                                                                    |
| /DF               | Data folder reference wave                                                             |
| /SDFR= <i>dfr</i> | Specifies the source data folder. See <b>The /SDFR Flag</b> on page IV-79 for details. |
| /Z                | Ignores wave reference checking failures                                               |
| /ZZ               | Ignores wave reference checking failures and prevents wave lookup                      |

## WAVEClear

**WAVEClear** *localName* [, *localName1* ...]

The WAVEClear operation clears out a wave reference variable. WAVEClear is equivalent to `WAVE/Z localName= $"`.

### Details

Use WAVEClear to avoid unexpected results from certain operations such as **Duplicate** or **Concatenate**, which will reuse the contents of a WAVE reference variable and may not generate the wave in the desired data folder or with the desired name.

## WaveCRC

---

WAVEClear ensures that memory is deallocated after waves are killed as in this example:

```
Function foo()
 Make wave1
 FunctionThatKillsWave1()
 WAVEClear wave1
 AnotherFunction()
End
```

Although memory used for `wave1` will be deallocated when `foo` returns, that memory will not be automatically released while the function executes because the `WAVE` variable still contains a reference to the wave. In this example, `WAVEClear` deallocates that memory before `AnotherFunction` executes.

You can also use `WAVEClear` before passing a data folder to preemptive threads using **ThreadGroupPutDF**.

## WaveCRC

**WaveCRC**(*inCRC*, *waveName* [, *checkHeader*])

The `WaveCRC` function returns a 32-bit cyclic redundancy check value of the bytes in the named wave starting with *inCRC*.

Pass 0 for *inCRC* the first time you call `WaveCRC` for a particular stream of bytes as represented by the wave data.

Pass the last-returned value from `WaveCRC` for *inCRC* if you are creating a CRC value for a given stream of bytes through multiple calls to `WaveCRC`.

*waveName* may be a numeric or text wave.

The optional *checkHeader* parameter determines how much of the wave is checked:

| <i>checkHeader</i> | What It Does                           |
|--------------------|----------------------------------------|
| 0                  | Check only the wave data (default).    |
| 1                  | Check only the internal binary header. |
| 2                  | Check both.                            |

### Details

Polynomial used is:

$$x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$$

See `crc32.c` in the public domain source code for `zlib` for more information.

### See Also

**StringCRC**, **Hash**, **WaveHash**, **WaveModCount**

## WaveDims

**WaveDims**(*wave*)

The `WaveDims` function returns the number of dimensions used by *wave*.

Returns zero if wave reference is null. See **WaveExists** for a discussion of null wave references.

Also returns zero if wave has zero rows. A matrix will return 2.

## WaveExists

**WaveExists**(*wave*)

The `WaveExists` function returns one if wave reference is valid or zero if the wave reference is null. For example if, in a user function, you have:

```
Wave w= $"no such wave"
```

then `WaveExists(w)` will return zero.

`WaveExists` should be used in functions only. In macros, use the `exists` function instead.

#### See Also

`exists`, `NVAR_Exists`, `SVAR_Exists`, and [Accessing Global Variables and Waves](#) on page IV-64.

## WaveHash

### **WaveHash**(*wave*, *method*)

The `WaveHash` function returns a cryptographic hash of the bytes of the wave's data using the specified method. All contents of the wave's header are ignored.

#### Parameters

*wave* may reference a numeric or text wave.

*method* is a number indicating the hash algorithm to use:

- |   |                 |
|---|-----------------|
| 1 | SHA-256 (SHA-2) |
| 2 | MD4             |
| 3 | MD5             |
| 4 | SHA-1           |
| 5 | SHA-224 (SHA-2) |
| 6 | SHA-384 (SHA-2) |
| 7 | SHA-512 (SHA-2) |

#### See Also

`WaveModCount`, `WaveCRC`, `StringCRC`, `Hash`

## WaveInfo

### **WaveInfo**(*waveName*, 0)

The `WaveInfo` function returns a string containing a semicolon-separated list of information about the named wave.

The second parameter is reserved for future use and must be zero.

#### Details

The result string contains a list of keyword-value pairs. Each pair consists of a keyword, a colon, the value text, and a semicolon.

Here are the keywords:

| Keyword   | Information Following Keyword                                                                                                                                                                                                                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DUNITS    | The wave's data units.                                                                                                                                                                                                                                                                                                                                |
| FULLSCALE | Three numbers indicating whether the wave has any data full scale information, and the min and max data full scale values. The format of the FULLSCALE description is:<br><code>FULLSCALE:validFS,minFS,maxFS;</code><br><i>validFS</i> is 1 if <i>minFS</i> and <i>maxFS</i> have been set via a <code>SetScale d</code> command; otherwise it is 0. |
| LOCK      | Reads back the value set by <code>SetWaveLock</code> .                                                                                                                                                                                                                                                                                                |
| MODIFIED  | 1 if the wave has been modified since the experiment was last saved, else 0.                                                                                                                                                                                                                                                                          |
| MODTIME   | The date and time that the wave was last modified in seconds since January 1, 1904.                                                                                                                                                                                                                                                                   |

## WaveList

---

| Keyword     | Information Following Keyword                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| SIZEINBYTES | <p>The total size of the wave in bytes. This includes the wave's header, data, note, dimension labels, and unit strings. This keyword was added in Igor Pro 7.00.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| XUNITS      | <p>The wave's X units.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

---

Always pass 0 as the second input parameter. In future versions of Igor, this parameter may request other kinds of information to be returned.

A null wave reference returns a zero-length string. This might be encountered, for instance, when using **WaveRefIndexedDFR** in a loop to act on all waves in a data folder, and the loop has incremented beyond the highest valid index.

### Examples

```
Make/O wave1;SetScale x,0,1,"dyn",wave1;SetScale y,3,20,"v",wave1
String info = WaveInfo(wave1,0)
Print NumberByKey("NUMTYPE", info) // Prints 2
Print StringByKey("DUNITS", info) // Prints "v"
```

### See Also

The functions and operations listed under "About Waves" categories in the Command Help tab of the Igor Help Browser; among them are **CreationDate**, **ModDate**, **WaveModCount**, **WaveType**, **note**, and **numpts**.

**NumberByKey** and **StringByKey** functions for parsing the returned keyword list.

WaveInfo lacks information about multidimensional waves. Individual functions are provided to return dimension-related information: **DimDelta**, **DimOffset**, **DimSize**, **WaveUnits**, and **GetDimLabel**.

## WaveList

**WaveList**(*matchStr*, *separatorStr*, *optionsStr* [, *dfr* ])

The **WaveList** function returns a string containing a list of wave names selected from the current data folder or the data folder specified by *dfr* based on *matchStr* and *optionsStr* parameters. The *dfr* parameter requires Igor Pro 9.00 or later.

See **Details** for information on listing waves in graphs, and for references to newer, data folder-aware functions.

## Details

For a wave name to appear in the output string, it must match *matchStr* and also must fit the requirements of *optionsStr* and it must be in the current data folder. *separatorStr* is appended to each wave name as the output string is generated.

The name of each wave is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything.

For example:

|           |                                                                                              |
|-----------|----------------------------------------------------------------------------------------------|
| "*"       | Matches all wave names in current data folder.                                               |
| "xyz"     | Matches wave name xyz only, if xyz is in the current data folder.                            |
| "*xyz"    | Matches wave names which end with xyz and are in the current data folder.                    |
| "xyz*"    | Matches wave names which begin with xyz and are in the current data folder.                  |
| "*xyz*"   | Matches wave names which contain xyz and are in the current data folder.                     |
| "abc*xyz" | Matches wave names which begin with abc and end with xyz and are in the current data folder. |

*matchStr* may begin with the ! character to return items that do not match the rest of *matchStr*. For example:

|         |                                               |
|---------|-----------------------------------------------|
| "!*xyz" | Matches wave names which do not end with xyz. |
|---------|-----------------------------------------------|

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

*optionsStr* is used to further qualify the wave.

Use "" to accept all waves in the current data folder that are permitted by *matchStr*.

Set *optionsStr* to one or more of the following comma-separated keyword-value pairs:

| <i>optionsStr</i>          | Selection Criteria                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| "BYTE:0" or "BYTE:1"       | Waves that are not 8-bit integer (if 0) or only waves that are 8-bit integer (if 1).                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| "CMPLX:0" or "CMPLX:1"     | Waves that are not complex (if 0) or only waves that are complex (if 1).                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| "DIMS:numberOfDims"        | All waves in current data folder that have <i>numberOfDims</i> dimensions. This is the number of dimensions reported by <b>WaveDims</b> .<br>Use "DIMS:0" for all waves having no points ( <code>numpts(w) == 0</code> ).<br>Use "DIMS:1" for graph traces (or one of the X, Y, and Z waves of a contour plot).<br>Use "DIMS:2" for false color and indexed color images (see <b>Indexed Color Details</b> on page II-388).<br>Use "DIMS:3" for direct color images (see <b>Direct Color Details</b> on page II-389). |
| "DF:0" or "DF:1"           | Consider waves that are not data folder reference waves (if 0) or only waves that are data folder reference waves (if 1). You can create waves that contain data folder references using the <b>Make /DF</b> flag.                                                                                                                                                                                                                                                                                                    |
| "DP:0" or "DP:1"           | Waves that are not double precision floating point (if 0) or only waves that are double precision floating point (if 1).                                                                                                                                                                                                                                                                                                                                                                                              |
| "INT64:0" or "INT64:1"     | Consider waves that are not 64-bit integer (if 0) or only waves that are 64-bit integer (if 1). 64-bit integer waves are supported in Igor7 and later.                                                                                                                                                                                                                                                                                                                                                                |
| "INTEGER:0" or "INTEGER:1" | Waves that are not 32-bit integer (if 0) or only waves that are 32-bit integer (if 1).                                                                                                                                                                                                                                                                                                                                                                                                                                |
| "MAXCHUNKS:max"            | Waves having no more than <i>max</i> chunks.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## WaveList

---

| <i>optionsStr</i>                     | Selection Criteria                                                                                                                                                                               |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| "MAXCOLS : <i>max</i> "               | Waves having no more than <i>max</i> columns.                                                                                                                                                    |
| "MAXLAYERS : <i>max</i> "             | Waves having no more than <i>max</i> layers.                                                                                                                                                     |
| "MAXROWS : <i>max</i> "               | Waves having no more than <i>max</i> rows.                                                                                                                                                       |
| "MINCHUNKS : <i>min</i> "             | Waves having at least <i>min</i> chunks.                                                                                                                                                         |
| "MINCOLS : <i>min</i> "               | Waves having at least <i>min</i> columns.                                                                                                                                                        |
| "MINLAYERS : <i>min</i> "             | Waves having at least <i>min</i> layers.                                                                                                                                                         |
| "MINROWS : <i>min</i> "               | Waves having at least <i>min</i> rows.                                                                                                                                                           |
| "SP : 0 " or "SP : 1 "                | Waves that are not single precision floating point (if 0) or only waves that are single precision floating point (if 1).                                                                         |
| "TEXT : 0 " or "TEXT : 1 "            | Waves that are not text (if 0) or only waves that are text (if 1).                                                                                                                               |

| "WAVE : 0 " or "WAVE : 1 "            | Consider waves that do not contain wave references (if 0) or only waves that contain wave references (if 1). You can create waves that contain wave references using the <b>Make</b> /WAVE flag. |
| "WIN : "                              | All waves in the current or specified data folder that are displayed in the top graph or table. The WIN option is not threadsafe.                                                                |
| "WIN : <i>windowName</i> "            | All waves in the current or specified data folder that are displayed in the named table or graph window or subwindow. The WIN option is not threadsafe.                                          |
| "WORD : 0 " or "WORD : 1 "            | Waves that are not 16-bit integer (if 0) or only waves that are 16-bit integer (if 1).                                                                                                           |

---

You can specify more than one option by separating the options with a comma. See the **Examples**.

**Note:** Even when *optionsStr* is used to list waves used in a graph or table, the waves must be in the current data folder.

**Note:** In addition to waves displayed as normal graph traces, WaveList will list matrix waves used with **AppendImage** or NewImage and the X, Y, and Z waves used with **AppendXYZContour**.

**Note:** Individual contour traces are not listed because they have no corresponding waves. See **Contour Traces** on page II-358.

There are several functions that are more useful for listing waves in graphs and tables.

WaveList with WIN : *windowName* gives only the names of the waves in the graph or table and does not include the data folder for each wave. If you need to know what data folder the waves are in, use **WaveRefIndexed** to get the wave itself and then if needed use **GetWavesDataFolder** to get the path.

When identifying a subwindow with WIN : *windowName*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

To list the actual waves used in a graph, or to distinguish two or more instances of the same named wave in a graph, use **TraceNameList**. This function can be used in conjunction with **TraceNameToWaveRef**, and **XWaveRefFromTrace**.

Use **ContourNameList** to list contour plots in a given window and **ContourNameToWaveRef** to access the waves used to generate the contour plot.

To list the contour traces (that is, the contour lines themselves) use **TraceNameList** with the appropriate option.

Use **ImageNameList** to list images in a given window and **ImageNameToWaveRef** to access the waves used to generate the images.

## Processing Lists of Waves

Contrary to what you might expect, you can *not* use the output of WaveList directly with operations that have a list of waves as their parameters. See **Processing Lists of Waves** on page IV-198 for ways of dealing with this.

### Examples

```
// Returns a list of all waves in the current data folder.
WaveList ("*", ";", "")

// Returns a list of all waves in the current data folder and displayed in the top table or graph.
WaveList ("*", ";", "WIN:")

// Returns a list of waves in the current data folder whose names
// end in "_bkg" and which are displayed in Graph0 as 1D traces.
WaveList ("*_bkg", ";", "WIN:Graph0")

// Returns a list of waves in the current data folder whose names do not
// end in "X" and which are displayed in Graph0 as 1D traces or as one
// of the X, Y, and Z waves of an AppendXYZContour plot.
WaveList ("!*X", ";", "WIN:Graph0,DIMS:1")

// Returns a list of waves in the root:Packages:MyPackage data folder
WaveList ("*", ";", "", root:Packages:MyPackage)
```

## WaveMax

**WaveMax**(*waveName* [, *x1*, *x2*])

The WaveMax function returns the maximum value in the wave for points between  $x=x1$  to  $x=x2$ , inclusive.

### Details

If  $x1$  and  $x2$  are not specified, they default to  $-\infty$  and  $+\infty$ , respectively.

The X scaling of the wave is used only to locate the points nearest to  $x=x1$  and  $x=x2$ . To use point indexing, replace  $x1$  with `pnt2x(waveName, pointNumber1)`, and a similar expression for  $x2$ .

If the points nearest to  $x1$  or  $x2$  are not within the point range of 0 to `numpts(waveName)-1`, WaveMax limits them to the nearest of point 0 or point `numpts(waveName)-1`.

### See Also

**WaveMin**, **WaveMinAndMax**, **WaveStats**

## WaveMeanStdv

**WaveMeanStdv** *srcWave binSizeWave*

The WaveMeanStdv operation calculates the standard deviation of the means for the specified bin distribution saving the result in the wave `W_MeanStdv`.

For each entry in *binSizeWave*, *srcWave* is divided into the specified number of bins. Values in each bin are averaged and then the mean and standard deviation of the averages (among all bins) are calculated. The value of the standard deviation of the bin averages divided by the mean is then stored in `W_MeanStdv` corresponding to the bin size entry in *binSizeWave*.

All entries in *binSizeWave* must be positive integers.

### Details

When the number of points in *srcWave* does not divide evenly into the bin size entry from *binSizeWave*, the last bin will have a smaller number of data points. In order not to skew the results the values corresponding to the last bin will be dropped. If your data set is small compared to the bin size you might want to pad *srcWave* with additional values (e.g., duplicate values from the beginning of the wave).

This operation does not support NaNs. If you get a NaN as an entry in the output wave then there is either a NaN in *srcWave* or something is wrong with the calculation for that entry.

### WaveMin

**WaveMin**(*waveName* [, *x1*, *x2*])

The WaveMin function returns the minimum value in the wave for points between  $x=x1$  to  $x=x2$ , inclusive.

#### Details

If *x1* and *x2* are not specified, they default to -inf and +inf, respectively.

The X scaling of the wave is used only to locate the points nearest to  $x=x1$  and  $x=x2$ . To use point indexing, replace *x1* with `pnt2x(waveName, pointNumber1)`, and a similar expression for *x2*.

If the points nearest to *x1* or *x2* are not within the point range of 0 to `numpts(waveName)-1`, WaveMin limits them to the nearest of point 0 or point `numpts(waveName)-1`.

#### See Also

**WaveMax**, **WaveMinAndMax**, **WaveStats**

### WaveMinAndMax

**WaveMinAndMax**(*wave* [, *x1*, *x2*])

The WaveMinAndMax function returns the minimum and maximum values in the wave for points between  $x=x1$  to  $x=x2$ , inclusive.

WaveMinAndMax must be called from a function, not from the command line, because it uses multiple return syntax as shown in the example below.

WaveMinAndMax was added in Igor Pro 9.00.

#### Details

If *x1* and *x2* are not omitted, they default to -inf and +inf.

The X scaling of the wave is used only to locate the points nearest to  $x=x1$  and  $x=x2$ . To use point indexing, replace *x1* with `"pnt2x(wave,pointNumber1)"`, and a similar expression for *x2*. The resulting point numbers are clipped to the range 0..n where n is the `numpts(wave)-1`.

#### Example

```
Function DemoWaveMinAndMax()
 Make/FREE wave0 = p
 SetScale/P x, 0, 0.1, "s", wave0
 double minValue, maxValue

 [minValue, maxValue] = WaveMinAndMax(wave0)
 Printf "Entire wave: min=%g, max=%g\r", minValue, maxValue

 [minValue, maxValue] = WaveMinAndMax(wave0, 5, 10)
 Printf "From x=5 to x=10: min=%g, max=%g\r", minValue, maxValue
End
```

### WaveModCount

**WaveModCount**(*wave*)

The WaveModCount function returns a value that can be used to tell if a global wave has been changed between one call to WaveModCount and another.

WaveModCount was added in Igor Pro 8.00.

The exact value returned by WaveModCount has no significance. The only use for it is to compare the values returned by two calls to WaveModCount. If they are the different, the wave was changed in the interim.

The wave mod count for free and thread-local waves is undefined, so WaveModCount should only be used with global waves in the data hierarchy of the main thread.

A wave's mod count changes when the wave's data or properties, such as scaling, note, and dimensionality, are set. The mod count changes even if the new data or property values are the same as the old. For example, executing:

```
wave1 += 0
```

causes the mod count to change even though the data itself was not actually changed.

### Examples

```
Make/O wave1 = 5
Variable waveModCount1, waveModCount2
waveModCount1 = WaveModCount(wave1);
wave1 += 1 // Modify wave1
waveModCount2 = WaveModCount(wave1);
if (waveModCount2 != waveModCount1)
 Print "Wave has changed"
endif
```

### See Also

**WaveInfo, ModDate**

## WaveName

**WaveName**(*winNameStr*, *index*, *type*)

The WaveName function returns a string containing the name of the *index*th wave of the specified *type* in the named window or subwindow.

### Parameters

*winNameStr* can be "" to refer to the top graph or table.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Details

WaveName works on waves displayed in a graph, in a table or on the list of waves in the current data folder. If the window is a table, WaveName returns the column name (e.g., "wave0.d"), rather than the name of the wave itself (e.g., "wave0").

For most uses, we recommend that you use **WaveRefIndexed** or **WaveRefIndexedDFR** instead of WaveName. WaveName returns a string containing the wave name only, with no data folder path qualifying it. Thus, you may get erroneous results if the wave referred to in the graph has the same name as a different wave in the current data folder. Likewise, if the named wave resides in a data folder that is not the current data folder, you will not be able to refer to the named wave. Use **WaveRefIndexedDFR** instead.

*winNameStr* is a string expression containing the name of a graph or table or an empty string (""). If the string is empty and *type* is 4 then WaveName works on the list of all waves in the current data folder. If the string is empty and the type parameter is not 4 then WaveName works on the top graph or table.

*index* starts from zero.

*type* is a number from 1 to 4. When type is 4 and *winNameStr* is "", WaveName works on the list of all waves in the current data folder.

For graph windows, *type* is 1 for y waves, 2 for x waves, 3 for either y or x waves.

For table windows, *type* is 1 for data columns, 2 for index or dimension label columns, 3 for either data or index or dimension label columns.

WaveName returns an empty string ("") if there is no wave matching the parameters.

### Examples

```
WaveName("",0,4) // Returns name first wave current data folder.
WaveName("",0,1) // Returns name of first Y wave in the top graph.
WaveName("Graph0",1,2) // Returns name of second X wave in Graph0.
WaveName("Table0",1,3) // Returns name of second column in Table0.
```

### WaveRefIndexed

**WaveRefIndexed**(*winNameStr*, *index*, *type*)

The WaveRefIndexed function returns a wave reference to the *index*th wave of the specified *type* in the named window or subwindow.

To iterate through the waves in a data folder, use **WaveRefIndexedDFR** instead of WaveRefIndexed.

#### Parameters

*winNameStr* can be "" to refer to the top graph or table window or the current data folder.

When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

#### Details

WaveRefIndexed is analogous to WaveName but works better with data folders. We recommend that you use it instead of WaveName.

*winNameStr* is a string expression containing the name of a graph or table or an empty string (""). If the string is empty and *type* is 4 then WaveRefIndexed works on Igor's list of all waves in the current data folder. If the string is empty and the type parameter is not 4 then WaveRefIndexed works on the top graph or table.

*index* starts from zero.

*type* is a number from 1 to 4. When type is 4 and *winNameStr* is "", WaveRefIndexed works on the list of all waves in the current data folder.

For graph windows, *type* is 1 for y waves, 2 for x waves, 3 for either y or x waves.

For table windows, *type* is 1 for data columns, 2 for index or dimension label columns, 3 for either data or index or dimension label columns.

WaveRefIndexed returns a null reference (see **WaveExists**) if there is no wave matching the parameters.

#### Examples

```
WaveRefIndexed("", 0, 1) // Returns first Y wave in the top graph.
WaveRefIndexed("Graph0", 1, 2) // Returns second X wave in Graph0.
WaveRefIndexed("Table0", 1, 3) // wave in second column in Table0.
```

#### See Also

**WaveRefIndexedDFR**, **NameOfWave**, **GetWavesDataFolder**

For a discussion of wave references, see **Wave Reference Functions** on page IV-197.

### WaveRefIndexedDFR

**WaveRefIndexedDFR**(*dfr*, *index*)

The WaveRefIndexedDFR function returns a wave reference to the *index*th wave in the specified data folder.

#### Parameters

*dfr* is a data folder reference.

*index* is the zero-based index of the wave you want to access.

#### Details

WaveRefIndexedDFR returns a null reference (see **WaveExists**) if there is no wave corresponding to *index* in the specified data folder.

#### Example

```
// DemoWaveRefIndexedDFR can be called like this:
// DemoWaveRefIndexedDFR(root:, 0) // Work on root
// DemoWaveRefIndexedDFR(root:SubDataFolder, 0) // Work on root:SubDataFolder
// DemoWaveRefIndexedDFR(:, 0) // Work on current data folder
Function DemoWaveRefIndexedDFR(dfr, recurse)
 DFREF dfr
 Variable recurse

 Variable index = 0
 do
```

```

Wave/Z w = WaveRefIndexedDFR(dfr, index)
if (!WaveExists(w))
 break
endif
String path = GetWavesDataFolder(w, 2)
Print path
index += 1
while(1)

if (recurse)
 Variable numChildDataFolders = CountObjectsDFR(dfr, 4)
 Variable i
 for(i=0; i<numChildDataFolders; i+=1)
 String childDFName = GetIndexedObjNameDFR(dfr, 4, i)
 DFREF childDFR = dfr:$childDFName
 DemoWaveRefIndexedDFR(childDFR, 1)
 endfor
endif
End

```

**See Also****WaveRefIndexed, NameOfWave, GetWavesDataFolder**For a discussion of wave references, see **Wave Reference Functions** on page IV-197.

## WaveRefsEqual

**WaveRefsEqual(w1, w2)**

The WaveRefsEqual function returns the truth the two wave references are the same.

**See Also****Wave Reference Functions** on page IV-197

## WaveRefWaveToList

**WaveRefWaveToList(waveRefWave, option)**

The WaveRefWaveToList function returns a semicolon-separated string list containing data folder paths.

Each element of the returned string list is the full or partial path to the wave referenced by the corresponding element of *waveRefWave*. Entries in *waveRefWave* that are NULL or entries that correspond to free waves result in an empty list element.

The WaveRefWaveToList function was added in Igor Pro 7.00.

**Parameters***waveRefWave* is a wave reference wave each element of which contains a reference to an existing wave or NULL (0).*option* determines if the returned path is a full path or a partial path relative to the current data folder:*option*=0: Full path.*option*=1: Partial path relative to the current data folder.Other values of *option* are reserved for the future.**Example**

```

Function Test()
 SetDataFolder root:
 Make/O/FREE aaa
 Make/O bbb
 Make/O/WAVE/N=3 wr
 Wr[0]=aaa
 // Wr[1] is null by initialization.
 wr[2]=bbb
 Print WaveRefWaveToList(wr, 0)
End

// Executing Test() gives:
;;root:bbb;

```

## WaveStats

---

The first empty string corresponds to the free wave 'aaa' and the second empty string corresponds to the null entry in the wave reference wave.

## WaveStats

**WaveStats** [*flags*] *waveName*

The WaveStats operation computes several statistics on the named wave.

### Flags

- /ALPH=val* Sets the significance level for the confidence interval of the mean (default *val*=0.05).
- /C=method* Calculates statistics for complex waves only. Does not affect real waves. You can use *method* in various combinations to process the real, imaginary, magnitude, and phase of the wave. The result is stored in the wave M\_WaveStats (see **Details** for format). *method* is defined as follows:
- method*=0: Default; ignores the imaginary part of *waveName*. Use */W* to also store statistics in M\_WaveStats.
  - method*=1: Calculates statistics for real part of *waveName* and stores it in M\_WaveStats.
  - method*=2: Calculates statistics for imaginary part of *waveName* and stores the result in M\_WaveStats.
  - method*=4: Calculates statistics for magnitude of *waveName*, i.e.,  $\sqrt{\text{real}^2 + \text{imag}^2}$ , and stores the result in M\_WaveStats.
  - method*=8: Calculate statistics for phase of *waveName* using  $\text{atan2}(\text{imag}, \text{real})$ .
- /CCL* When computing per-column statistics using */PCST*, */CCL* tells Igor to copy the column dimension labels of the input to the corresponding columns of M\_WaveStats. */CCL* was added in Igor Pro 9.00.
- If you use a single *method* the results are stored both in M\_WaveStats and in the standard variables (e.g., V\_avg, etc.). If you specify *method* as a combination of more than one binary field then the variables reflect the results for the lowest chosen field and all results are stored in the wave M\_WaveStats.
- For example, if you use */C=12*, the variables will be set for the statistics of the magnitude and M\_WaveStats will contain columns corresponding to the magnitude and to the phase.
- In this mode V\_numInfs will always be zero.
- Note:** If you invoke this operation and M\_WaveStats already exists in the current data folder, it will be either overwritten or initialized to NaN.
- /M=moment* Calculates statistical moments. *moment* is defined as follows:
- moment*=1: Calculates only lower moments: V\_avg, V\_npnts, V\_numInfs, and V\_numNaNs. Use it if you do not need the higher moments.
  - moment*=2: Default; calculates both lower moments and higher order quantities: V\_sdev, V\_rms, V\_adev, V\_skew, and v\_kurt.
- /Q* Prevents results from being printed in history.

- /P** Causes WaveStats to set the location output variables in terms of unscaled index values instead of the default scaled index values. The location output variables are:  
`V_minRowLoc`, `V_maxRowLoc`, `V_minColLoc`, `V_maxColLoc`  
`V_minLayerLoc`, `V_maxLayerLoc`, `V_minChunkLoc`, `V_maxChunkLoc`  
 For 1D waves, `V_minRowLoc` and `V_maxRowLoc` are always unscaled.  
**/P** requires Igor Pro 8.03 or later.
- /PCST** Computes the statistics on a per-column basis for a real valued wave of two or more dimensions. The results are saved in the wave `M_WaveStats` which has the same number of columns, layers and chunks as the input wave and where the rows, designated by dimension labels, contain the standard WaveStats statistics. All the `V_` variables are set to NaN. Note that this flag is not compatible with the flags **/C**, **/R**, **/RMD**.  
 The **/PCST** flag was added in Igor Pro 7.00.
- /R=(startX,endX)** Specifies an X range of the wave to evaluate.
- /R=[startP,endP]** Specifies a point range of the wave to evaluate.  
 If you specify the range as **/R=[startP]** then the end of the range is taken as the end of the wave. If **/R** is omitted, the entire wave is evaluated.
- /RMD=[firstRow,lastRow][firstColumn,lastColumn][firstLayer,lastlayer][firstChunk,lastChunk]**  
 Designates a contiguous range of data in the source wave to which the operation is to be applied. This flag was added in Igor Pro 7.00.  
 You can include all higher dimensions by leaving off the corresponding brackets. For example:  
`/RMD= [firstRow, lastRow]`  
 includes all available columns, layers and chunks.  
 You can use empty brackets to include all of a given dimension. For example:  
`/RMD= [] [firstColumn, lastColumn]`  
 means "all rows from column A to column B".  
 You can use a `*` to specify the end of any dimension. For example:  
`/RMD= [firstRow, *]`  
 means "from firstRow through the last row".
- /W** Stores results in the wave `M_WaveStats` in addition to the various `V_` variables when **/C=0**.
- /Z** No error reporting.
- /ZSCR** Computes z scores
- $$z_i = \frac{Y_i - \bar{Y}}{\sigma},$$
- which are saved in `W_ZScores`.

### Details

WaveStats uses a two-pass algorithm to produce more accurate results than obtained by computing the binomial expansions of the third and fourth order moments.

WaveStats returns the statistics in the automatically created variables:

- `V_npnts` Number of points in range excluding points whose value is NaN or INF.  
`V_numNans` Number of NaNs.

|               |                                                                                                                                                 |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| V_numINFs     | Number of INFs.                                                                                                                                 |
| V_avg         | Average of data values.                                                                                                                         |
| V_sum         | Sum of data values.                                                                                                                             |
| V_sdev        | Standard deviation of data values,<br>$\sigma = \sqrt{\frac{\sum (Y_i - V\_avg)^2}{V\_npnts - 1}}$ <p>“Variance” is <math>V\_sdev^2</math>.</p> |
| V_sem         | Standard error of the mean $sem = \frac{\sigma}{\sqrt{V\_npnts}}$                                                                               |
| V_rms         | RMS of Y values $= \sqrt{\frac{1}{V\_npnts} \sum Y_i^2}$                                                                                        |
| V_adev        | Average deviation $= \frac{1}{V\_npnts} \sum_{i=0}^{V\_npnts-1}  Y_i - \bar{Y} $                                                                |
| V_skew        | Skewness $= \frac{1}{V\_npnts} \sum_{i=0}^{V\_npnts-1} \left( \frac{Y_i - \bar{Y}}{\sigma} \right)^3$                                           |
| V_kurt        | Kurtosis $= \left( \frac{1}{V\_npnts} \sum_{i=0}^{V\_npnts-1} \left( \frac{Y_i - \bar{Y}}{\sigma} \right)^4 \right) - 3$                        |
| V_minloc      | X location of minimum data value.                                                                                                               |
| V_min         | Minimum data value.                                                                                                                             |
| V_maxloc      | X location of maximum data value.                                                                                                               |
| V_max         | Maximum data value.                                                                                                                             |
| V_minRowLoc   | Row containing minimum data value. See /P above for further information.                                                                        |
| V_maxRowLoc   | Row containing maximum data value. See /P above for further information.                                                                        |
| V_minColLoc   | Column containing minimum data value (2D or higher waves). See /P above for further information.                                                |
| V_maxColLoc   | Column containing maximum data value (2D or higher waves). See /P above for further information.                                                |
| V_minLayerLoc | Layer containing minimum data value (3D or higher waves). See /P above for further information.                                                 |
| V_maxLayerLoc | Layer containing maximum data value (3D or higher waves). See /P above for further information.                                                 |
| V_minChunkLoc | Chunk containing minimum data value (4D waves only). See /P above for further information.                                                      |

|               |                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------|
| V_maxChunkLoc | Chunk containing maximum data value (4D waves only). See /P above for further information.             |
| V_startRow    | The unscaled index of the first row included in calculating statistics.                                |
| V_endRow      | The unscaled index of the last row included in calculating statistics.                                 |
| V_startCol    | The unscaled index of the first column included in calculating statistics. Set only when /RMD is used. |
| V_endCol      | The unscaled index of the last column included in calculating statistics. Set only when /RMD is used.  |
| V_startLayer  | The unscaled index of the first layer included in calculating statistics. Set only when /RMD is used.  |
| V_endLayer    | The unscaled index of the last layer included in calculating statistics. Set only when /RMD is used.   |
| V_startChunk  | The unscaled index of the first chunk included in calculating statistics. Set only when /RMD is used.  |
| V_endChunk    | The unscaled index of the last chunk included in calculating statistics. Set only when /RMD is used.   |

WaveStats prints the statistics in the history area unless /Q is specified. The various multidimensional min and max location variables will only print to the history area for waves having the appropriate dimensionality.

The format of the M\_WaveStats wave is:

| Row | Statistic | Row | Statistic   | Row | Statistic   | Row | Statistic  |
|-----|-----------|-----|-------------|-----|-------------|-----|------------|
| 0   | numPoints | 9   | minLoc      | 18  | maxColLoc   | 27  | startCol   |
| 1   | numNaNs   | 10  | min         | 19  | maxLayerLoc | 28  | endCol     |
| 2   | numInfs   | 11  | maxLoc      | 20  | maxChunkLoc | 29  | startLayer |
| 3   | avg       | 12  | max         | 21  | startRow    | 30  | endLayer   |
| 4   | sdev      | 13  | minRowLoc   | 22  | endRow      | 31  | startChunk |
| 5   | rms       | 14  | minColLoc   | 23  | sum         | 32  | endChunk   |
| 6   | adev      | 15  | minLayerLoc | 24  | meanL1      |     |            |
| 7   | skew      | 16  | minChunkLoc | 25  | meanL2      |     |            |
| 8   | kurt      | 17  | maxRowLoc   | 26  | sem         |     |            |

meanL1 and meanL2 are the confidence intervals for the mean

$$MeanL1 = V\_avg - t_{\alpha,v} \frac{V\_sdev}{\sqrt{V\_npnts}}, \quad \text{and} \quad MeanL2 = V\_avg + t_{\alpha,v} \frac{V\_sdev}{\sqrt{V\_npnts}}$$

where  $t_{\alpha,v}$  is the critical value of the Student T distribution for *alpha* significance and degree of freedom  $v=V\_npnts-1$ .

Use `Edit M_WaveStats.ld` to display the results in a table with dimension labels identifying each of the row statistics.

WaveStats is not entirely multidimensional aware. Even so, much of the information computed by WaveStats is useful. See **Analysis on Multidimensional Waves** on page II-95 for details.

## WaveTextEncoding

---

See the **ImageStats** operation for calculating wave statistics for specified regions of interest in 2D matrix waves.

See the **APMath** operation if you require higher precision than provided by double-precision floating point.

**WaveMax, WaveMin, WaveMinAndMax, mean, median, Variance**

## WaveTextEncoding

**WaveTextEncoding**(*wave, element, getEffectiveTextEncoding*)

The WaveTextEncoding function returns the text encoding code for the specified element of a wave. See **Wave Text Encodings** on page III-474 for background information.

This function is used to deal with text encoding issues that sometimes arise in when you load pre-Igor Pro 7 experiments. Most users will have no need to use it.

The WaveTextEncoding function was added in Igor Pro 6.30. The *getEffectiveTextEncoding* parameter was added in Igor Pro 7.00.

### Parameters

*wave* specifies the wave of interest.

*element* specifies a part of the wave, as follows:

| Value | Meaning               |
|-------|-----------------------|
| 1     | Wave name             |
| 2     | Wave units            |
| 4     | Wave note             |
| 8     | Wave dimension labels |
| 16    | Text wave content     |

*getEffectiveTextEncoding* determines if WaveTextEncoding returns a raw text encoding code or an effective text encoding code as explained below.

### Details

WaveTextEncoding returns a integer text encoding code. See **Text Encoding Names and Codes** on page III-492 for details.

As explained under **Wave Text Encodings** on page III-474, each of the wave elements has a corresponding text encoding setting. Because the notion of text encoding settings was added in Igor Pro 6.30, waves created by earlier versions have their text encoding settings set to unknown (0).

The text encoding setting stored for a given element is the "raw" text encoding. If it is unknown, then Igor applies some rules when the wave is accessed to determine an "effective" text encoding for the element being accessed. The rules are explained under **Determining the Text Encoding for a Plain Text File** on page III-469.

If *getEffectiveTextEncoding* is non-zero then WaveTextEncoding returns the effective text encoding. If *getEffectiveTextEncoding* is zero it returns the raw text encoding.

## WaveTracking

**WaveTracking** [/FREE /GLBL /LOCL] keyword

The WaveTracking operation is a debugging aid that can help you determine if your code creates waves and fails to kill them. This is especially helpful for finding free wave leaks. For background information, see **Wave Reference Counting** on page IV-205, **Free Wave Leaks** on page IV-93 and **Wave Tracking** on page IV-207.

WaveTracking was added in Igor Pro 9.00.

A fast and lightweight complement to wave tracking is **IgorInfo(16)**. For details, see **Detecting Wave Leaks** on page IV-206.

### Flags

There are three flags that tell the WaveTracking operation what category of waves an invocation of the WaveTracking operation is aimed at. You can simultaneously track or count all three categories of waves, but you must use separate invocations of the operation to control or query the tracking of each category. See **Wave Tracking** on page IV-207 for a discussion of the wave categories.

You must include one of these flags.

- /FREE Specifies that the current command applies to counting or tracking free waves.
- /GLBL Specifies that the current command applies to counting or tracking global waves (waves in the main data hierarchy starting with the root data folder).
- /LOCL Specifies that the current command applies to counting or tracking local waves (waves contained by a free data folder).

### Keywords

- counter Turns on wave tracking in counter mode for the category specified by /FREE, /GLBL, or /LOCL. Clears any existing count or tracking information for that specified category.
- tracker Turns on wave tracking in tracker mode for the category specified by /FREE, /GLBL, or /LOCL. In this mode, a list of waves of the specified category is kept. Clears any existing count or tracking information for that category.
- count Stores the count of waves in the variable V\_numWaves for the category specified by /FREE, /GLBL, or /LOCL. The count is the number of waves created and not killed since counter or tracker mode was turned on for that category.
- dump[=*n*] Prints information into the history for the category specified by /FREE, /GLBL, or /LOCL. In counter mode, it prints just the number of waves. In tracker mode, it prints a line showing the count, and a number of lines showing the name of each wave that was created but not killed since tracking began, and the wave's reference count. If waves are global or local waves, the name of the containing data folder is also printed.  
If you omit *n*, the list is limited to 10 lines. Otherwise *n* sets the maximum number of lines to print. Due to the method used for tracking, the list is in random order.
- status Stores a number for the category specified by /FREE, /GLBL, or /LOCL indicating the type of tracking or zero into the variable V\_Flag. 0 means no counting or tracking, 1 means counting, 2 means tracking.
- stop Stops wave tracking for the category specified by /FREE, /GLBL, or /LOCL and clears the count and list of waves of that category.

### Details

In counter mode, each time a wave in the specified category is created the counter is incremented. Each time a wave is killed, the counter is decremented. If you start counting after some waves have been created, and get the count after killing those waves, it is possible for the count to become negative.

In tracker mode, the count is the number of waves created and not killed since you started tracking; it cannot be negative.

Creation of waves takes approximately twice as long when tracker mode is turned on. Using counter mode has negligible effect on performance.

By default, free waves have the name `_free_`, which limits the usefulness of the tracker dump. Starting with Igor Pro 9.00, to aid wave leak investigation, both **NewFreeWave** and **Make/FREE** have options for giving names to free waves. See **Free Wave Names** on page IV-94.

## WaveTransform

---

### Output Variables

These variables are created and set by all keywords.

|            |                                                                                                                                                                                                                                          |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V_Flag     | Indicates the type of tracking currently being used. The values are:<br>0: Not tracking or counting<br>1: Counter mode<br>2: Tracker mode                                                                                                |
| V_numWaves | The number of waves of the specified category created and not killed since the last time the counter or tracker keywords were used. If no tracking is enabled, this value will be zero. Set to zero if no tracking is currently enabled. |

## WaveTransform

**WaveTransform** [*flags*] *keyword srcWave*

The WaveTransform operation transforms *srcWave* in various ways. If the /O flag is not specified then unless otherwise indicated the output is stored in the wave W\_WaveTransform, which will be of the same data type as *srcWave* and saved in the current data folder.

### Parameters

*keyword* is one of the following:

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| abs           | Calculates the absolute value of the entries in <i>srcWave</i> . It stores results in W_Abs if <i>srcWave</i> is 1D or M_Abs otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.                                                                                                                                                                                                                                                                                                                                                                                                |
| acos          | Calculates the inverse cosine of the entries in <i>srcWave</i> . It stores results in W_Acos if <i>srcWave</i> is 1D or M_Acos otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.                                                                                                                                                                                                                                                                                                                                                                                              |
| asin          | Calculates the inverse sine of the entries in <i>srcWave</i> . It stores results in W_Asin if <i>srcWave</i> is 1D or M_Asin otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.                                                                                                                                                                                                                                                                                                                                                                                                |
| atan          | Calculates the inverse tangent of the entries in <i>srcWave</i> . It stores results in W_Atan if <i>srcWave</i> is 1D or M_Atan otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.                                                                                                                                                                                                                                                                                                                                                                                             |
| cconjugate    | Calculates the complex conjugate of <i>srcWave</i> . Stores results in W_CConjugate or M_CConjugate, depending on wave dimensionality, or overwrites <i>srcWave</i> if /O is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| cos           | Calculates the cosine of the entries in <i>srcWave</i> . It stores results in W_Cos if <i>srcWave</i> is 1D or M_Cos otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. <i>srcWave</i> must be single or double precision real wave.                                                                                                                                                                                                                                                                                                                                                                                                        |
| crystalToRect | Converts triplet (three column {x,y,z}) waves from nonorthogonal crystallographic coordinates to rectangular cartesian system. The parameters provided in the /P flag are the crystallographic definition of the coordinate system given by {a, b, c, alpha, beta, gamma}. The three angles are assumed to be expressed in radians unless the /D flag is specified. The transformation sets the first component parallel to the vector a and the third component parallel to c*. The output is stored in the current data folder in the wave M_CrystalToRect which has the same data type. If the /O flag is specified, the output overwrites the original data. |
| flip          | Flips the data in <i>srcWave</i> about its center. If /O flag is used, <i>srcWave</i> is overwritten. Otherwise a new wave is created in the current data folder. The wave is named W_flipped or M_flipped according to the dimensionality of <i>srcWave</i> .                                                                                                                                                                                                                                                                                                                                                                                                   |
| index         | Fills <i>srcWave</i> as in jack=p.<br>If /P is specified then jack=p+param1.<br>The /O flag does not apply here.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| inverse       | Computes $1/srcWave[i]$ for each point in <i>srcWave</i> and stores it in W_Inverse or M_Inverse depending on the dimensionality of <i>srcWave</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| inverseIndex  | Fills <i>srcWave</i> as in <code>jack=numPnts-1-p</code> .<br>If /P is specified the <code>jack=numPnts-1-p+param1</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| magnitude     | Creates a real-valued wave that is the magnitude of <i>srcWave</i> . If you do not specify the /O flag, the output is stored in W_Magnitude or M_Magnitude depending on the dimensionality of <i>srcWave</i> ; the output precision will be the same as <i>srcWave</i> .                                                                                                                                                                                                                                                                                                                                                                                               |
| magsqr        | Creates a real-valued wave that is the magnitude squared of <i>srcWave</i> . If <i>srcWave</i> is a double precision complex wave, the output is also double precision, otherwise the output is a single precision wave. Stores the result in wave W_MagSqr or M_MagSqr, depending on the dimensionality of <i>srcWave</i> , or overwrites <i>srcWave</i> if /O is used.                                                                                                                                                                                                                                                                                               |
| max           | Calculates the maximum of a point in <i>srcWave</i> and a fixed number specified as a single parameter with the /P flag. It stores results in W_max if <i>srcWave</i> is 1D or M_max otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. See also the min keyword and the example below.                                                                                                                                                                                                                                                                                                                                                           |
| min           | Calculates the minimum of a point in <i>srcWave</i> and a fixed number specified as a single parameter with the /P flag. It stores results in W_min if <i>srcWave</i> is 1D or M_min otherwise. It will overwrite <i>srcWave</i> when used with the /O flag. See also the max keyword and the example below.                                                                                                                                                                                                                                                                                                                                                           |
| normalizeArea | Calculates the area under the curve and rescales the wave so that the area is 1. Note that waves with negative areas will be rescaled to positive values. Applies to 1D real-valued waves. It does not affect wave scaling. Stores the result in the wave W_normalizedArea or overwrites <i>srcWave</i> if /O is used.                                                                                                                                                                                                                                                                                                                                                 |
| phase         | Creates a real-valued wave containing the phase of the complex input wave. If the /O flag is not used, the output is stored in W_Phase or M_Phase depending on the dimensionality of <i>imageMatrix</i> . You can also use /P={norm} to divide the output wave by the value of <i>norm</i> .                                                                                                                                                                                                                                                                                                                                                                           |
| rectToCrystal | Converts triplet (three column {x,y,z}) waves from cartesian coordinates to nonorthogonal crystallographic coordinate system. The parameters provided in the /P flag are the crystallographic definition of the coordinate system given by {a, b, c, alpha, beta, gamma}. The three angles are assumed to be expressed in radians unless the /D flag is specified. The transformation assumes the first component parallel to the vector a and the third component parallel to $c^*$ . The output is stored in the current data folder in the wave M_RectToCrystal which has the same data type. If the /O flag is specified, the output overwrites the original data. |
| setConstant   | Sets <i>srcWave</i> points to a constant value specified by the /V flag. This keyword applies to real, numeric waves only.<br><br>You can use /R with setConstant to set a subset of a wave.<br><br>setConstant was added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| setZero       | Sets all <i>srcWave</i> points to zero. setZero was added in Igor Pro 7.00.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| sgn           | Sets the value to -1 if the entry is negative, 1 otherwise. Stores the results in W_Sgn or overwrites <i>srcWave</i> if /O is used. This operation will not work on UNSIGNED waves.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| shift         | Shifts the position of data in <i>srcWave</i> by the specified number of points.<br><br>Unlike Rotate, WaveTransform discards data points that shift outside existing wave boundaries. After the shift, vacated wave points are set to the specified <i>fillValue</i> . The shift and the <i>fillValue</i> are specified with the /P flag using the syntax: /P={numPoints, fillValue}. If you do not provide a fill value, it will be 0 for integer waves and NaN for SP and DP.                                                                                                                                                                                       |

## WaveType

---

|         |                                                                                                                                                                                                                                                                                                                                                                             |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| sin     | Calculates the sine of the entries in <i>srcWave</i> . Stores results in <i>W_Sin</i> if <i>srcWave</i> is 1D or <i>M_Sin</i> otherwise. Overwrites <i>srcWave</i> when used with the <i>/O</i> flag. <i>srcWave</i> must be a real single or double precision floating point wave.                                                                                         |
| sqrt    | Calculates the square root of the entries in <i>srcWave</i> . It stores results in <i>W_sqrt</i> if <i>srcWave</i> is 1D or <i>M_sqrt</i> otherwise. It will overwrite <i>srcWave</i> when used with the <i>/O</i> flag. <i>srcWave</i> must be single- or double-precision real wave.                                                                                      |
| tan     | Calculates the tangent of the entries in <i>srcWave</i> . The results are stored in <i>W_tan</i> if <i>srcWave</i> is 1D or <i>M_tan</i> otherwise. It will overwrite <i>srcWave</i> when used with the <i>/O</i> flag. <i>srcWave</i> must be single- or double-precision real wave.                                                                                       |
| zapINFs | Deletes elements whose value is infinity or -infinity. This is relevant for 1D single-precision and double-precision floating point waves only and does nothing for other types of 1D waves. It is not suitable for multidimensional waves and returns an error if <i>srcWave</i> is multidimensional. Use <b>MatrixOp</b> <code>replace</code> for multidimensional waves. |
| zapNaNs | Deletes elements whose value is NaN. This is relevant for 1D single-precision and double-precision floating point waves only and does nothing for other types of 1D waves. It is not suitable for multidimensional waves and returns an error if <i>srcWave</i> is multidimensional. Use <b>MatrixOp</b> <code>replaceNaNs</code> for multidimensional waves.               |

### Flags

|                                                                                        |                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/D</i>                                                                              | If present, angles in wave data are interpreted as in degrees. Otherwise they are interpreted as in radians.                                                                                                                                                                              |
| <i>/O</i>                                                                              | Overwrites input wave.                                                                                                                                                                                                                                                                    |
| <i>/P={param1...}</i>                                                                  | Specifies parameters as appropriate for the keyword that you are using. The number of parameters and their order depends on the keyword.                                                                                                                                                  |
| <i>/R=[startRow,endRow][startCol,endCol][startLayer,endLayer][startChunk,endChunk]</i> | Specifies the range of elements to set for the <code>setConstant</code> keyword.<br>You can omit parameters for dimensions that don't exist in <i>srcWave</i> . For example, if <i>srcWave</i> is 1D, specify just <i>/R=[startRow,endRow]</i> .<br><i>/R</i> was added in Igor Pro 7.00. |
| <i>/V=value</i>                                                                        | Specifies the value to use for the <code>setConstant</code> keyword. <i>/V</i> was added in Igor Pro 7.00.                                                                                                                                                                                |

### Examples

```
// Produce output values in the range [-1,1]:
WaveTransform /P={pi} phase complexWave

// Faster than myWave=myWave>1 ? 1 : myWave
WaveTransform /P={1}/O min myWave
```

## WaveType

**WaveType**(*waveName* [, *selector* ])

The **WaveType** function returns the type of data stored in the wave.

If *selector* = 1, **WaveType** returns 0 for a null wave, 1 if numeric, 2 if text, 3 if the wave holds data folder references or 4 if the wave holds wave references.

If *selector* = 2, **WaveType** returns 0 for a null wave, 1 for a normal global wave or 2 for a free wave or a wave that is stored in a free data folder.

If selector = 3, WaveType returns 0 for a null wave, 1 for a free wave (a wave that is not stored in any data folder) or 2 for a local wave (a wave that is stored in a free data folder).

If *selector* is omitted or zero, the returned value for numeric waves is a combination of bit values shown in the following table:

| Type           | Bit Number | Decimal Value | Hexadecimal Value |                              |
|----------------|------------|---------------|-------------------|------------------------------|
| complex        | 0          | 1             | 1                 |                              |
| 32-bit float   | 1          | 2             | 2                 |                              |
| 64-bit float   | 2          | 4             | 4                 |                              |
| 8-bit integer  | 3          | 8             | 8                 |                              |
| 16-bit integer | 4          | 16            | 10                |                              |
| 32-bit integer | 5          | 32            | 20                |                              |
| 64-bit integer | 7          | 128           | 80                | Requires Igor Pro 7 or later |
| unsigned       | 6          | 64            | 40                |                              |

The unsigned bit is used only with the integer types while the complex bit can be used with any numeric type. Set only one of bits 1-5 or bit 7 as they are mutually exclusive. See **Setting Bit Parameters** on page IV-12 for details about bit settings.

The returned value for non-numeric waves (text waves, wave-reference waves and data folder-reference waves) is 0.

### Examples

```
Variable waveIsComplex = WaveType(wave) & 0x01
Variable waveIs32BitFloat = WaveType(wave) & 0x02
Variable waveIs64BitFloat = WaveType(wave) & 0x04
Variable waveIs8BitInteger = WaveType(wave) & 0x08
Variable waveIs16BitInteger = WaveType(wave) & 0x10
Variable waveIs32BitInteger = WaveType(wave) & 0x20
Variable waveIs64BitInteger = WaveType(wave) & 0x80
Variable waveIsUnsigned = WaveType(wave) & 0x40
```

## WaveUnits

**WaveUnits(waveName, dimNumber)**

The WaveUnits function returns a string containing the units for the given dimension.

Use *dimNumber*=0 for rows, 1 for columns, 2 for layers, and 3 for chunks. Use -1 to get the data units. If the wave is just 1D, *dimNumber*=0 returns X units and 1 returns data units. This behavior is just like the WaveMetrics procedure WaveUnits found in the WaveMetrics Procedures folder in previous versions of Igor Pro.

**DimDelta, DimOffset, DimSize, SetScale**

## wfprintf

**wfprintf** *refNumOrStr*, *formatStr* [*flags*] *waveName* [, *waveName*]...

The **wfprintf** operation is like the **printf** operation except that it prints the contents of the named waves to a file whose file reference number is in *refNum*.

The **Save** operation also outputs wave data to a text file. Use **Save** unless you need the added flexibility provided by **wfprintf**.

### Parameters

*refNumOrStr* is a numeric expression, a string variable or an SVAR pointing to a global string variable.

If a numeric expression, then it is a file reference number returned by the **Open** operation or an expression that evaluates to 1.

If *refNumOrStr* is 1, Igor prints to the history area instead of to a file.

If *refNumOrStr* is the name of a string variable, the wave contents are "printed" to the named string variable. *refNumOrStr* can also be the name of an SVAR to print to a global string:

```
SVAR sv = root:globalString
wfprintf sv, "", wave0
```

*refNumOrStr* can not be an element of a text wave.

The value of each named wave is printed to the file according to the conversion specified in *formatStr*.

*formatStr* contains one numeric conversion specification per column. See **printf**. If *formatStr* is "", **wfprintf** uses a default format which gives tab-delimited columns.

### Flags

Note: /R must follow the *formatStr* parameter directly without an intervening comma.

/R=(startX,endX) Specifies an X range in the wave(s) to print.

/R=[startP,endP] Specifies a point range in the wave(s) to print.

### Details

As of Igor7, **wfprintf** supports 1D and 2D waves. Previously it supported 1D waves only.

The number of conversion characters in *formatStr* must exactly match the number of wave columns in all input waves. With real waves, the total number of columns is limited to 100. With complex waves, the real column and imaginary column each count as a column and the total number of columns is limited to 200.

The only conversion characters allowed are fFeEgdouxXcs (the floating point, integer and string conversion characters). You cannot use an asterisk to specify field width or precision. If any of these restrictions is intolerable, you can use **fprintf** in a loop.

With integer conversion characters d, o, u, x, and X, applied to floating point waves, **wfprintf** rounds the fractional part.

In Igor Pro 9.00 and later, there is no limit to the length of an element of a text wave parameter passed to the **wfprintf** operation. Previously text wave element contents were clipped to about 500 bytes. There is also no limit to the length of *formatStr*. Previously it was limited to 800 bytes.

### Examples

```
Function Example1()
 Make/O/N=10 wave0=sin(p*pi/10) // test numeric wave
 Make/O/N=10/T textWave= "row "+num2istr(p) // test text wave
 Variable refNum
 Open/P=home refNum as "output.txt" // open file for write
 wfprintf refNum, "%s = %g\r"/R=[0,5], textWave, wave0 // print 6 values each
 Close refNum
End
```

The resulting output.txt file contains:

```
row 0 = 0
row 1 = 0.309017
row 2 = 0.587785
```

```
row 3 = 0.809017
row 4 = 0.951057
row 5 = 1
```

```
Function/S NumericWaveToStringList(w)
 Wave w // numeric wave (if text, use /T here and %s below)
 String list
 fprintf list, "%g;" w // semicolon-separated list
 return list
End

Print NumericWaveToStringList(wave0)
0;0.309017;0.587785;0.809017;0.951057;1;0.951057;0.809017;0.587785;0.309017;
```

### See Also

The **Save** operation.

## WhichListItem

```
WhichListItem(itemStr, listStr [, listSepStr [, startIndex [, matchCase]])
```

The WhichListItem function returns the index of the first item of *listStr* that matches *itemStr*. *listStr* should contain items separated by *listSepStr* which typically is ";". If the item is not found in the list, -1 is returned.

Use WhichListItem to locate an item in a string containing a list of items separated by a string (usually a single ASCII character), such as those returned by functions like **TraceNameList** or **AnnotationList**, or a line from a delimited text file.

*listSepStr*, *startIndex*, and *matchCase* are optional; their defaults are ";", 0, and 1 respectively.

### Details

WhichListItem differs from **FindListItem** in that WhichListItem returns a list index, while FindListItem returns a character offset into a string.

*listStr* is searched for *itemStr* bound by *listSepStr* on the left and right.

*listStr* is treated as if it ends with a *listSepStr* even if it doesn't.

Searches for *listSepStr* are always case-sensitive. The comparison of *itemStr* to the contents of *listStr* is usually case-sensitive. Setting the optional *matchCase* parameter to 0 makes the comparison case insensitive.

If *itemStr* is not found, if *listStr* is "", or if *startIndex* is not within the range of 0 to `ItemsInList(listStr)-1`, then -1 is returned.

In Igor6, only the first byte of *listSepStr* was used. In Igor7 and later, all bytes are used.

Items can be empty. In "abc;def;;ghi", the third item, whose zero-based index is 2, is empty. In ";def;;ghi;" the first and third items, whose zero-based indices are 0 and 2, are empty.

If *startIndex* is specified, then *listSepStr* must also be specified. If *matchCase* is specified, *startIndex* and *listSepStr* must be specified.

### Examples

```
Print WhichListItem("wave0", "wave0;wave1;") // prints 0
Print WhichListItem("c", "a;b;") // prints -1
Print WhichListItem("", "a;b;") // prints 1
Print WhichListItem("c", "a,b,c,x,c", ",") // prints 2
Print WhichListItem("c", "a,b,c,x,c", ",", 3) // prints 4
Print WhichListItem("C", "x;c;C;") // prints 2
Print WhichListItem("C", "x;c;C;", ";", 0, 0) // prints 1
```

### WignerTransform

**WignerTransform** [/Z] [/WIDE=*wSize*] [/GAUS=*gaussianWidth*] [/DEST=*destWave*] *srcWave*

The WignerTransform operation computes the Wigner transformation of a 1D signal in *srcWave*, which is the name of a real or complex wave. The result of the WignerTransform is stored in *destWave* or in the wave M\_Wigner in the current data folder.

#### Flags

|                        |                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /DEST= <i>destWave</i> | Creates by default a real wave reference for the destination wave in a user function. See <b>Automatic Creation of WAVE References</b> on page IV-71 for details.                                                                                                                                                                                                                       |
| /GAUS= <i>gWidth</i>   | Computes the Gaussian Wigner Transform, which is a convolution of the Wigner Transform with a two-dimensional Gaussian (in the two parameters of the transform). The computation of the transform simplifies significantly when the product of the widths of the two Gaussians is unity (minimum uncertainty ellipse). <i>gWidth</i> uses the same units as the <i>srcWave</i> scaling. |
| /OUT= <i>type</i>      | Sets the output data type of the standard (not Gaussian) Wigner transform. The following data types are supported:<br>1: Complex<br>2: Real (default)<br>3: Magnitude<br>4: Squared magnitude<br>/OUT is not allowed with the Gaussian Wigner transform (/GAUS) in which the output is always real.<br>The /OUT flag was added in Igor Pro 8.00.                                        |
| /WIDE= <i>wSize</i>    | Computes Wigner Transform and sets the transform width to <i>wSize</i> . This is the default transformation with <i>wSize</i> set to the size of <i>srcWave</i> .                                                                                                                                                                                                                       |
| /Z                     | No error reporting.                                                                                                                                                                                                                                                                                                                                                                     |

#### Details

The Wigner transform maps a time signal  $U(t)$  into a 2D time-frequency representation:

$$W(t, \nu) = \int_{-\infty}^{\infty} U\left(t + \frac{x}{2}\right) U^*\left(t - \frac{x}{2}\right) e^{-2\pi i x \nu} dx.$$

The computation of the Wigner transform evaluates the offset product

$$U\left(t + \frac{x}{2}\right) U^*\left(t - \frac{x}{2}\right)$$

over a finite window and then Fourier transforms the result. The offset product can be evaluated over a finite window width, which can vary from a few elements of the input wave to the full length of the wave. You can control the width of this window using the /WIDE flag. If you do not specify the output destination, WignerTransform saves the results in the wave M\_Wigner in the current data folder.

Although the Wigner transform is real, the output will be complex when *srcWave* is complex. By inspecting the complex wave you can gain some insight into the numerical stability of the algorithm. The X-scaling of the output wave is identical to the scaling of *srcWave*. The Y-scaling of the input wave is taken from the Fourier Transform of the offset product, which in turn is determined by the X-scaling of *srcWave*.

Specifically, if  $dx = \text{DimDelta}(srcWave, 0)$  and *srcWave* has N points then  $dy = \text{DimDelta}(M\_Wigner, 1) = 1 / (dx * N)$ . WignerTransform does not set the units of the output wave.

The Ambiguity Function is related to the Wigner Transform by a Fourier Transform, and is defined by

$$A(\tau, \nu) = \int_{-\infty}^{\infty} U\left(t + \frac{\tau}{2}\right) U^*\left(t - \frac{\tau}{2}\right) e^{-2\pi i \nu t} dt.$$

Convolving the Wigner Transform with a 2D Gaussian leads to what is sometimes called the Gaussian Wigner Transform or GWT. Formally the GWT is given by the equation:

$$GWT(t, \nu; \delta_t, \delta_\nu) = \frac{1}{\delta_t \delta_\nu} \iint dt' d\nu' W(t', \nu') \exp\left\{-2\pi \left[\left(\frac{t-t'}{\delta_t}\right)^2 + \left(\frac{\nu-\nu'}{\delta_\nu}\right)^2\right]\right\}.$$

Computationally this equation simplifies if the respective widths of the two Gaussians satisfy the minimum uncertainty condition  $\delta_t \delta_\nu = 1$ . The /GAUS flag calculates the Gaussian Wigner Transform using your specified width,  $\delta_t$ , and it selects a  $\delta_\nu$  such that it satisfies the minimum uncertainty condition.

## Window

**Window** *macroName*([*parameters*]) [:*macro type*]

The Window keyword introduces a macro that recreates a graph, table, layout, or control panel window. The macro appears in the appropriate submenu of the Windows menu. Window macros are automatically created when you close a graph, table, layout, control panel, or XOP target window. You should use **Macro**, **Proc**, or **Function** instead of Window for your own window macros. Otherwise, it works the same as **Macro**.

#### See Also

The **Macro**, **Proc**, and **Function** keywords. **Data Folders and Window Recreation Macros** on page II-111 for details.

**Macro Syntax** on page IV-118 for further information.

## WindowFunction

**WindowFunction** [/FFT [=f] /DEST=*destWave*] *windowKind*, *srcWave*

The WindowFunction operation multiplies a one-dimensional (real or complex) *srcWave* by the named window function.

By default the result overwrites *srcWave*.

#### Parameters

*srcWave*                      A one-dimensional wave of any numerical type. See **ImageWindow** for windowing two-dimensional data.

*windowKind*                      Specifies the windowing function. Choices for *windowKind* are:  
Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, Riemann, and an assortment of flat-top windows listed under **FFT**.

See **FFT** for window equations and details. The equations assume that /FFT=1.

## Flags

- `/DEST=destWave` Creates or overwrites *destWave* with the result of the multiplication of *srcWave* and the window function.
- When used in a function, the WindowFunction operation by default creates a real wave reference for the destination wave. See **Automatic Creation of WAVE References** on page IV-71 for details.
- `/FFT [=1]` The window interval is  $0 \dots N = \text{numpts}(srcWave)$ . This sets the first value of *srcWave* to zero, but not the last value. This is appropriate for windowing data in preparation for Fourier Transforms, and is the same algorithm used by FFT.
- The window interval is  $0 \dots N = \text{numpts}(srcWave) - 1$  if /FFT is missing or /FFT=0. This sets the first and last value of *srcWave* to 0. This is the (only) algorithm that the Hanning operation uses.

## Details

A “window function” alters the input data by decreasing values near the start and end of the data smoothly towards zero, so that when the FFT of the data is computed the effects of nonintegral-periodic signals are diminished. This improves the ability of the FFT to distinguish among closely-spaced frequencies. Each window function has advantages and disadvantages, usually trading off rejection of “leakage” against the ability to discriminate adjacent frequencies. For more details, see the **References**.

WindowFunction stores the window function’s normalization value (the average squared window value) in `V_value`. This is the value you would get from WaveStats’s `V_rms*V_rms` for a wave of *srcWave*’s length whose values were all equal to 1:

```
Make/O data = 1
WindowFunction Bartlet, data // Bartlet allowed as synonym for Bartlett
Print V_value // Prints 0.330709, mean of squared window values
```

```
WaveStats/Q data
Print V_rms*V_rms // Prints 0.330709
```

# WinList

**WinList(*matchStr*, *separatorStr*, *optionsStr*)**

The WinList function returns a string containing a list of windows selected based on the *matchStr* and *optionsStr* parameters.

## Details

For a window name to appear in the output string, it must match *matchStr* and also must fit the requirements of *optionsStr*. *separatorStr* is appended to each window name as the output string is generated.

The name of each window is compared to *matchStr*, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

"\*" Matches all window names

|           |                                                            |
|-----------|------------------------------------------------------------|
| "xyz"     | Matches window name xyz only                               |
| "*xyz"    | Matches window names which end with xyz                    |
| "xyz*"    | Matches window names which begin with xyz                  |
| "*xyz*"   | Matches window names which contain xyz                     |
| "abc*xyz" | Matches window names which begin with abc and end with xyz |

*matchStr* may begin with the ! character to return items that do not match the rest of *matchStr*. For example:

|         |                                                       |
|---------|-------------------------------------------------------|
| "!*xyz" | Matches window names which <i>do not</i> end with xyz |
|---------|-------------------------------------------------------|

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of *matchStr*.

*optionsStr* is used to further qualify the window. The acceptable values for *optionsStr* are:

|                                 |                                                                                                                                                                                                                                                                    |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| " "                             | Consider all windows.                                                                                                                                                                                                                                              |
| "WIN: "                         | The target window.                                                                                                                                                                                                                                                 |
| "WIN: <i>windowTypes</i> "      | Consider windows that match <i>windowTypes</i> .                                                                                                                                                                                                                   |
| "INCLUDE: <i>includeTypes</i> " | Consider procedure windows that match <i>includeTypes</i> .<br>Using INCLUDE: implies WIN:128.                                                                                                                                                                     |
| "INDEPENDENTMODULE: 1"          | Consider procedure windows that are part of any independent module as well as those that are not. Matching windows names are actually the window titles followed by " [<independent module name>] ".<br>Using INDEPENDENTMODULE: implies WIN:128.                  |
| "INDEPENDENTMODULE: 0"          | Consider procedure windows only if they are not part of any independent module. Matching windows names are actually the window titles, which for an external file includes the file extension, such as "WMMenus.ipf".<br>Using INDEPENDENTMODULE: implies WIN:128. |
| "FLT:1"                         | Return only panels that were created with NewPanel/FLT=1. Specifying "FLT" also implies "WIN:64".<br>Omit FLT or use "FLT:0" to return windows that do not float (and most do not).                                                                                |
| "FLT:2"                         | Return only panels that were created with NewPanel/FLT=2. Specifying "FLT" also implies "WIN:64".                                                                                                                                                                  |
| "VISIBLE:1"                     | Return only visible windows (ignore hidden windows).                                                                                                                                                                                                               |

## WinList

---

*windowTypes* is a literal number. The window name goes into the output string only if it passes the match test and its type is compatible with *windowTypes*. *windowTypes* is a bitwise parameter:

- 1:        Graphs
- 2:        Tables
- 4:        Layouts
- 16:       Notebooks
- 64:       Panels
- 128:      Procedure windows
- 512:      Help windows
- 4096:     XOP target windows
- 16384:    Camera windows in Igor Pro 7.00 or later
- 65536:    Gizmo windows in Igor Pro 7.00 or later

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

Procedure windows and help windows don't have names. WinList returns the window title instead.

*includeTypes* is also a literal number. The window name goes into the output string only if it passes the match test and its type is compatible with *includeTypes*. *includeTypes* is one of:

- 1:        Procedure windows that are not #included.
- 2:        Procedure windows included by #include "someFileName".
- 4:        Procedure windows included by #include <someFileName>.

or a bitwise combination of the above for more than one type of inclusion.

You can combine the WIN, INCLUDE and INDEPENDENTMODULE options by separating them with a comma.

When the INDEPENDENTMODULE option is used, the title of any procedure window that is part of an independent module will be followed by " [<independent module name>]".

For example, if a procedure file contains:

```
#pragma IndependentModule=myIndependentModule
#include <Axis Utilities>
```

A call to WinList like this:

```
String list = WinList("* [myIndependentModule]", ";", "INDEPENDENTMODULE:1")
```

will store "Axis Utilities.ipf [myIndependentModule];" in the list string, along with any other procedure windows that are part of that independent module.

When the INDEPENDENTMODULE option is omitted, the returned procedure window titles do not include any independent module name suffix, and the procedure files "visible" to WinList depend on the setting of SetIgorOption independentModuleDev (which must be done after opening the experiment):

- |                                         |                                                                                                                                              |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| SetIgorOption<br>independentModuleDev=0 | Consider procedure windows only if they are not part of any independent module and if they are not hidden (using #pragma hide, for example). |
| SetIgorOption<br>independentModuleDev=1 | Consider all procedure windows including those in independent modules or hidden.                                                             |

**Examples**

| Command                                               | Returned List                               |
|-------------------------------------------------------|---------------------------------------------|
| <code>WinList ("*", ";", "")</code>                   | All existing non-floating windows.          |
| <code>WinList ("*", ";", "WIN:3")</code>              | All graph and table windows.                |
| <code>WinList ("Result_*", ";", "WIN:1")</code>       | Graphs whose names start with "Result_".    |
| <code>WinList ("*", ";", "WIN:64,FLT:1,FLT:2")</code> | All floating panel windows.                 |
| <code>WinList ("*", ";", "INCLUDE:6")</code>          | All #included procedure windows.            |
| <code>WinList ("*", ";", "WIN:1,INCLUDE:6")</code>    | All graphs and #included procedure windows. |

**See Also**

**Independent Modules** on page IV-236. The **ChildWindowList** and **WinType** functions.

**WinName**

**WinName**(*index*, *windowTypes* [, *visibleWindowsOnly* [, *floatKind*]])

The WinName function returns a string containing the name of the *index*th window of the specified *type*, or an empty string (" ") if no window fits the parameters.

If the optional *visibleWindowsOnly* parameter is nonzero, only visible windows are considered. Otherwise both visible and hidden windows are considered.

If the optional *floatKind* parameter is 1, only floating windows created with NewPanel/FLT=1 are considered. If *floatKind* is 2, only NewPanel/FLT=2 windows are considered. *windowTypes* must contain at least 64 (panels).

If *floatKind* is omitted or is 0 only non-floating ("normal") windows are considered.

Procedure windows don't have names. WinName returns the procedure window title instead.

**Details**

*index* starts from zero, and returns the top-most window matching the parameters.

The window names are ordered in window-stacking order, as returned by WinList.

DoWindow/B moves the window to the back and changes the index needed to retrieve its name to the greatest index that returns any name.

Hiding or showing a window (with SetWindow hide=1 or Notebook visible=0 or by manual means) does not affect the index associated with the window.

*windowTypes* is a bitwise parameter:

- 1:        Graphs.
- 2:        Tables.
- 4:        Layouts.
- 16:       Notebooks.
- 64:       Panels.
- 128:      Procedure windows.
- 4096:     XOP target windows.
- 16384:    Camera windows in Igor Pro 7.00 or later
- 65536:    Gizmo windows in Igor Pro 7.00 or later

See **Setting Bit Parameters** on page IV-12 for details about bit settings.

**Examples**

```
Print WinName(0,1) // Prints the name of the top graph.
Print WinName(0,3) // Prints the name of the top graph or table.
```

## WinRecreation

---

```
String win=WinName(0,1) // The name of the top visible graph.
SetWindow $win hide=1 // Hide the graph (it may already be hidden).
Print WinName(0,1) // Prints the name of the now-hidden graph.
Print WinName(0,1,1) // Prints the name of the top visible graph.
Print WinName(0,64,1,1) // Name of the top visible NewPanel/FLT=1 window.
```

### See Also

**WinList**, **DoWindow** (/F and /B flags), **SetWindow** (hide keyword), **Notebook (Miscellaneous)** (visible keyword), **NewPanel** (/FLT flag).

## WinRecreation

### **WinRecreation**(winStr, options)

The WinRecreation function returns a string containing the window recreation macro (or style macro) for the named window.

### Parameters

*winStr* is the name of a graph, table, page layout, panel, notebook, Gizmo, camera, or XOP target window or the title of a procedure window or help file. If *winStr* is "" and options is 0 or 1, information for the top graph, table, page layout, panel, notebook, or XOP target window is returned.

As of Igor Pro 7.00, *winStr* may be a subwindow path. The returned recreation macro is generated as if the subwindow were extracted from its host as a standalone window. See **Subwindow Syntax** on page III-92 for details on forming the subwindow path.

The meaning of *options* depends on the type of window as described in the following sections.

### Target Window Details

Target windows include graphs, tables, page layouts, panels, notebooks, and XOP target windows.

If *options* is 0, WinRecreation returns the window recreation macro.

If *options* is 1, WinRecreation returns the style macro or an empty string if the window does not support style macros.

### Graphs Details

If *options* is 2, WinRecreation returns a recreation macro in which all occurrences of wave names are replaced with an ID number having the form ##<number>## (for instance, ##25##). These ID numbers can be found easily using the **strsearch** function. This is intended for applications that need to alter the recreation macro by replacing wave names with something else, usually other wave names. The ID numbers are the same as those returned by the **GetWindow** operation with the wavelist keyword.

### Graphs and Panels Details

If *options* is 4, WinRecreation returns the window recreation macro without the default behavior of causing the graph to revert to "normal" mode (as if the GraphNormal operation had been called). This allows the use of WinRecreation when a graph or panel is in drawing tools mode without exiting that mode. For windows other than graphs or panels, this is equivalent to an *options* value of 0.

### Notebooks Details

If *options* is -1, WinRecreation returns the same text that the Generate Commands menu item would generate with the Selected paragraphs radio button selected and all the checkboxes selected (includes text commands).

If *options* is 0, WinRecreation returns the same text that the Generate Commands menu item would generate with the Entire document radio button selected and all the checkboxes *except* "Generate text commands" selected).

If *options* is 1, WinRecreation returns the same text that the Generate Commands menu item would generate with the Entire document radio button selected and all the checkboxes selected (includes text commands).

Regardless of the value of *options* the text returned by WinRecreation for notebook always ends with 5 lines of file-related information formatted as comments:

```
// File Name: MyNotebook.txt
// Path: "Macintosh HD:Desktop Folder:"
// Symbolic Path: home
// Selection Start: paragraph 100, position 31
// Selection End: paragraph 100, position 31
```

## Help Windows Details

WinRecreation returns the same 5 lines of file-related information as described above for notebooks.

Set *options* to -3 to ensure that *winStr* is interpreted as a help window title (help windows have only titles, not window names).

## Procedures Details

WinRecreation returns the same 5 lines of file-related information as described above for notebooks.

Set *options* to -2 to ensure that *winStr* is interpreted as a procedure window title (procedure windows have only titles, not window names).

If SetIgorOption IndependentModuleDev=1 is in effect, *winStr* can also be a procedure window title followed by a space and, in brackets, an independent module name. In such cases WinRecreation returns text from or information about the specified procedure file which is part of that independent module. (See **Independent Modules** on page IV-236 for independent module details.)

For example, in an experiment containing:

```
#pragma IndependentModule=myIM
#include <Axis Utilities>
```

code like this:

```
String text=WinRecreation("Axis Utilities.ipf [myIM]",-2)
```

will return the file-related information for the Axis Utilities.ipf procedure window, which is normally a hidden part of the myIM independent module.

To get the text content of a procedure window, use the **ProcedureText** function.

## Examples

```
WinRecreation("Graph0",0) // Returns recreation macro for Graph0.
WinRecreation("",1) // Style macro for top window.
String win= WinName(0,16,1) // top visible notebook
String str= WinRecreation(str,-1) // Selected Text commands
Variable line= itemsInList(str,"\r")-5 // First file info line
Print StringFromList(line, str,"\r") // Print File Name:
Print StringFromList(line+1, str,"\r") // Print Path:
Print StringFromList(line+2, str,"\r") // Print Symbolic Path:
Print StringFromList(line+3, str,"\r") // Selection Start:
Print StringFromList(line+4, str,"\r") // Selection End:
```

## See Also

**Saving a Window as a Recreation Macro** on page II-47.

# WinType

## WinType(*winNameStr*)

The WinType function returns a value indicating the type of the named window.

## Details

*winNameStr* is a string or string expression containing the name of a window or subwindow, or "" to signify the target window. When identifying a subwindow with *winNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

WinType returns the following values:

- 0: No window by that name.
- 1: Graph
- 2: Table
- 3: Layout
- 5: Notebook
- 7: Panel
- 13: XOP target window

## WMAxisHookStruct

---

- 15: Camera window in Igor Pro 7.00 or later
- 17: Gizmo window in Igor Pro 7.00 or later

Because command and procedure windows do not have *names* (they only have *titles*), WinType can not even be asked about those windows.

### See Also

The **WinName**, **ChildWindowList**, and **WinList** functions.

## WMAxisHookStruct

See **NewFreeAxis** for further explanation of WMAxisHookStruct.

```
Structure WMAxisHookStruct
 char win[200] // Host window or subwindow name
 char axName[32] // Name of axis
 char mastName[32] // Name of controlling axis or ""
 char units[50] // Axis units.
 Variable min // Current axis range minimum value
 Variable max // Current axis range maximum value
EndStructure
```

## WMBackgroundStruct

See **CtrlNamedBackground**, **Background Tasks** on page IV-316, and **Preemptive Background Task** on page IV-332 for further explanation of WMBackgroundStruct.

```
Structure WMBackgroundStruct
 char name[32] // Background task name
 UInt32 curRunTicks // Tick count when task was called
 Int32 started // TRUE when CtrlNamedBackground start is issued
 UInt32 nextRunTicks // Precomputed value for next run
 // but user functions may change this
EndStructure
```

## WMButtonAction

This structure is passed to action procedures for button controls created using the **Button** operation.

```
Structure WMButtonAction
 char ctrlName[32] // Control name
 char win[200] // Host window or subwindow name
 STRUCT Rect winRect // Local coordinates of host window
 STRUCT Rect ctrlRect // Enclosing rectangle of the control
 STRUCT Point mouseLoc // Mouse location
 Int32 eventCode // See details below
 Int32 eventMod // See Control Structure eventMod Field on page III-438
 String userData // Primary unnamed user data.
 Int32 blockReentry // See Control Structure blockReentry Field on page III-439
EndStructure
```

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

### WMButtonAction eventCode Field

Your action function should test the eventCode field and respond only to documented eventCode values because other event codes may be added in the future.

The event code passed to the button action procedure has the following meaning:

| Event Code | Event                                            |
|------------|--------------------------------------------------|
| -3         | Control received keyboard focus (Igor8 or later) |
| -2         | Control received keyboard focus (Igor8 or later) |
| -1         | Control being killed                             |
| 1          | Mouse down                                       |
| 2          | Mouse up                                         |
| 3          | Mouse up outside control                         |
| 4          | Mouse moved                                      |

| Event Code | Event                                   |
|------------|-----------------------------------------|
| 5          | Mouse enter                             |
| 6          | Mouse leave                             |
| 7          | Mouse dragged while outside the control |

Events 2 and 3 happen only after event 1.

Events 4, 5, and 6 happen only when the mouse is over the control but happen regardless of the mouse button state.

Event 7 happens only when the mouse is pressed inside the control and then dragged outside.

## WMCheckboxAction

This structure is passed to action procedures for checkbox controls created using the **CheckBox** operation.

```
Structure WMCheckboxAction
 char ctrlName[32] // Control name
 char win[200] // Host window or subwindow name
 STRUCT Rect winRect // Local coordinates of host window
 STRUCT Rect ctrlRect // Enclosing rectangle of the control
 STRUCT Point mouseLoc // Mouse location
 Int32 eventCode // See details below
 Int32 eventMod // See Control Structure eventMod Field on page III-438
 String userData // Primary unnamed user data
 Int32 blockReentry // See Control Structure blockReentry Field on page III-439
 Int32 checked // Checkbox state
EndStructure
```

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

### WMCheckboxAction eventCode Field

Your action function should test the eventCode field and respond only to documented eventCode values because other event codes may be added in the future.

The event code passed to the checkbox action procedure has the following meaning:

| Event Code | Event                                            |
|------------|--------------------------------------------------|
| -3         | Control received keyboard focus (Igor8 or later) |
| -2         | Control received keyboard focus (Igor8 or later) |
| -1         | Control being killed                             |
| 2          | Mouse up, checkbox toggled                       |

## WMCUSTOMCONTROLACTION

This structure is passed to action procedures for custom controls created using the **CustomControl** operation.

```
Structure WMCUSTOMCONTROLACTION
 char ctrlName[32] // Control name
 char win[200] // Host window or subwindow name
 STRUCT Rect winRect // Local coordinates of host window
 STRUCT Rect ctrlRect // Enclosing rectangle of the control
 STRUCT Point mouseLoc // Mouse location
 Int32 eventCode // See details below
 Int32 eventMod // See Control Structure eventMod Field on page III-438
 String userData // Primary unnamed user data
 Int32 blockReentry // See Control Structure blockReentry Field on page III-439
 Int32 missedEvents // TRUE when events occurred but the user
 // function was not available for action
 Int32 mode // General purpose

 // Used only when eventCode==kCCE_frame
 Int32 curFrame // Input and output

 // Used when eventCode is kCCE_mousemoved, kCCE_mouseenter or kCCE_mouseleave
 Int32 needAction // See below for details

 // These fields are valid only with value=varName
```

## WMCustomControlAction

---

```
 Int32 isVariable // TRUE if varName is a variable
 Int32 isWave // TRUE if varName referenced a wave
 Int32 isString // TRUE if varName is a String type
 NVAR nVal // Valid if isVariable and not isString
 SVAR sVal // Valid if isVariable and isString
 WAVE nWave // Valid if isWave and not isString
 WAVE/T sWave // Valid if isWave and isString
 Int32 rowIndex // If isWave, this is the row index
 // unless rowLabel is not empty
 char rowLabel[32] // Wave row label

 // These fields are valid only when eventCode==kCCE_char
 Int32 kbChar // Keyboard key character code
 Int32 specialKeyCode // See Keyboard Events on page IV-297 - Added in Igor Pro 7
 char keyText[16] // UTF-8 string representing key struck - Added in Igor Pro 7
 Int32 kbMods // Keyboard key modifiers bit field. See details below.
EndStructure
```

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

### WMCustomControlAction eventCode Field

When determining the state of the eventCode member in the WMCustomControlAction structure, the various values you use are listed in the following table. You can define the kCCE symbolic constants by adding this to your procedure file:

```
#include <CustomControl Definitions>
```

| Event Code                   | Description                                                                                                                                                                                                                                                   |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kCCE_mousedown = 1           | Mouse down in control.                                                                                                                                                                                                                                        |
| kCCE_mouseup = 2             | Mouse up in control.                                                                                                                                                                                                                                          |
| kCCE_mouseup_out = 3         | Mouse up outside control.                                                                                                                                                                                                                                     |
| kCCE_mousemoved = 4          | Mouse moved (happens only when mouse is over the control).                                                                                                                                                                                                    |
| kCCE_enter = 5               | Mouse entered control.                                                                                                                                                                                                                                        |
| kCCE_leave = 6               | Mouse left control.                                                                                                                                                                                                                                           |
| kCCE_mouseDraggedOutside = 7 | The mouse moved while it was outside the control. This event is delivered only after the mouse is pressed inside the control and dragged outside. While the mouse is inside the control, kCCE_mousemoved is delivered whether the mouse button is up or down. |
| kCCE_draw = 10               | Time to draw custom content.                                                                                                                                                                                                                                  |
| kCCE_mode = 11               | Sent when executing CustomControl <i>name</i> , mode= <i>m</i> .                                                                                                                                                                                              |
| kCCE_frame = 12              | Sent before drawing a subframe of a custom picture.                                                                                                                                                                                                           |
| kCCE_dispose = 13            | Sent as the control is killed.                                                                                                                                                                                                                                |
| kCCE_modernize = 14          | Sent when dependency (variable or wave set by value= <i>varName</i> parameter) fires. It will also get draw events, which probably don't need a response.                                                                                                     |
| kCCE_tab = 15                | Sent when user tabs into the control. If you want keystrokes (kCCE_char), then set needAction.                                                                                                                                                                |
| kCCE_char = 16               | Sent on keyboard events. Stores the keyboard character in kbChar and modifiers bit field is stored in kbMods. Sets needAction if key event was used and requires a redraw.                                                                                    |
| kCCE_drawOSBM = 17           | Called after drawing <i>pict</i> from picture parameter into an offscreen bitmap. You can draw custom content here.                                                                                                                                           |
| kCCE_idle = 18               | Idle event typically used to blink insertion points etc. Set needAction to force the control to redraw. Sent only when the host window is topmost.                                                                                                            |

---

**WMCustomControl needAction Field**

The meaning of needAction depends on the event.

Events kCCE\_mousemoved, kCCE\_enter, kCCE\_leave, and kCCE\_mouseDraggedOutside set needAction to TRUE to force redraw, which is normally not done for these events.

Events kCCE\_tab and kCCE\_mousedown set needAction to TRUE to request keyboard focus (and get kCCE\_char events).

Event kCCE\_idle sets needAction to TRUE to request redraw.

**WMCustomControl kbMods Field**

- Bit 0: Command (*Macintosh*)
- Bit 1: Shift
- Bit 2: Alpha Lock. Not supported in Igor7 or later.
- Bit 3: Option (*Macintosh*) or Alt (*Windows*)
- Bit 4: Control (*Macintosh*) or Windows key (*Windows*).

**WMDrawUserShapeStruct**

See **DrawUserShape** for further explanation of WMDrawUserShapeStruct.

```
Structure WMDrawUserShapeStruct
 char action[32] // Input: Specifies what action is requested.

 SInt32 options // Input: Value from /MO flag.
 // Output: When action is getInfo, set bits as follows:
 // Set bit 0 if the shape should behave like a simple line.
 // When resizing end-points, you will get live updates.
 // Set bit 1 if the shape is to act like a button;
 // You will get mouse down in normal operate mode.
 // Set bit 2 to get roll-over action.
 // You will get hitTest action and
 // if 1 is returned, the mouse will be captured.

 SInt32 operateMode // Input: If 0, the shape is being edited;
 // if 1, normal operate mode
 // (only if options bit 1 or 2 was set during getInfo).

 PointF mouseLoc // Input: The location of the mouse in normalized coordinates.

 SInt32 doSetCursor // Output: If action is hitTest, set true
 // to use the following cursor number.
 // Also used for mouseMoved in rollover mode.

 SInt32 cursorCode // Output: If action is hitTest and doSetCursor is set,
 // then set this to the desired Igor cursor number.

 double x0,y0,x1,y1 // Input: Coordinates of the enclosing rectangle of the shape.

 RectF objectR // Input: Coordinates of the enclosing rectangle of the shape
 // in device units.

 char winName[MAX_HostChildSpec+1] // Input: Full path to host subwindow

 // Information about the coordinate system
 Rect drawRect // Draw rect in device coordinates
 Rect plotRect // In a graph, this is the plot area
 Rect axRect // In a graph, this is the plot area including axis standoff
 char xcName[MAX_OBJ_NAME+1] // Name of X coordinate system, may be axis name
 char ycName[MAX_OBJ_NAME+1] // Name of Y coordinate system, may be axis name

 double angle // Input: Rotation angle, use when displaying text
 String textString // Input: Use or ignore; special output for "getInfo"
 String privateString // Input and output: Maintained by Igor
 // but defined by user function;
 // may be binary; special output for "getInfo"

EndStructure
```

## WMFitInfoStruct

---

### WMFitInfoStruct

See **The WMFitInfoStruct Structure** on page III-263 for further explanation of WMFitInfoStruct.

```
Structure WMFitInfoStruct
 char IterStarted // Nonzero on the first call of an iteration
 char DoingDestWave // Nonzero when called to evaluate autodest wave
 char StopNow // Fit function sets this to nonzero to
 // indicate that a problem has occurred
 // and fitting should stop
 Int32 IterNumber // Number of iterations completed
 Int32 ParamPerturbed // See The WMFitInfoStruct Structure on page III-263
EndStructure
```

### WMGizmoHookStruct

See **Gizmo Named Hook Functions** on page II-460 for further explanation of WMGizmoHookStruct.

```
Structure WMGizmoHookStruct
 Int32 version
 char winName[MAX_HostChildSpec+1] // Full path to host window or subwindow
 char eventName[32]
 Int32 width
 Int32 height
 Int32 mouseX
 Int32 mouseY
 Variable xmin
 Variable xmax
 Variable ymin
 Variable ymax
 Variable zmin
 Variable zmax
 Variable eulerA
 Variable eulerB
 Variable eulerC
 Variable wheelDx
 Variable wheelDy
EndStructure
```

### WMListboxAction

This structure is passed to action procedures for listbox controls created using the **Listbox** operation.

```
Structure WMListboxAction
 char ctrlName[32] // Control name
 char win[200] // Host window or subwindow name
 STRUCT Rect winRect // Local coordinates of host window
 STRUCT Rect ctrlRect // Enclosing rectangle of the control
 STRUCT Point mouseLoc // Mouse location
 Int32 eventCode // See details below
 Int32 eventMod // See Control Structure eventMod Field on page III-438
 String userData // Primary unnamed user data
 Int32 blockReentry // See Control Structure blockReentry Field on page III-439
 Int32 eventCode2 // Obsolete
 Int32 row // Selection row. See Listbox for details.
 Int32 col // Selection column. See Listbox for details.
 WAVE/T listWave // List wave specified by Listbox command
 WAVE selWave // Selection wave specified by Listbox command
 WAVE colorWave // Color wave specified by Listbox command
 WAVE/T titleWave // Title wave specified by Listbox command
EndStructure
```

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

#### WMListboxAction eventCode Field

Your action function should test the eventCode field and respond only to documented eventCode values because other event codes may be added in the future.

The event code passed to the listbox action procedure has the following meaning:

| Event Code | Event                                                                                                 |
|------------|-------------------------------------------------------------------------------------------------------|
| -3         | Control received keyboard focus (Igor8 or later)                                                      |
| -2         | Control received keyboard focus (Igor8 or later)                                                      |
| -1         | Control being killed.                                                                                 |
| 1          | Mouse down.                                                                                           |
| 2          | Mouse up.                                                                                             |
| 3          | Double click.                                                                                         |
| 4          | Cell selection (mouse or arrow keys).                                                                 |
| 5          | Cell selection plus Shift key.                                                                        |
| 6          | Begin edit.                                                                                           |
| 7          | Finish edit.                                                                                          |
| 8          | Vertical scroll. See <b>Scroll Event Warnings</b> on page V-494.                                      |
| 9          | Horizontal scroll by user or by the hScroll= <i>h</i> keyword.                                        |
| 10         | Top row set by row= <i>r</i> or first column set by col= <i>c</i> keywords.                           |
| 11         | Column divider resized.                                                                               |
| 12         | Keystroke, character code is place in row field.<br>See <b>Note on Keystroke Event</b> on page V-494. |
| 13         | Checkbox was clicked. This event is sent after selWave is updated.                                    |

### WMListboxAction row and col Fields

The row field is the zero-based row number of the first selected row in the list or -1 if the selection is in title area. If an event occurs in the empty space below the last row, the row field is set to the number of rows in the list which is one greater than the row number of the last row. A mouse down event in an empty list reports row=0.

The col field is the column number of the selection.

The meanings of row and col are different for eventCodes 8 through 11:

| Code | row             | col                              |
|------|-----------------|----------------------------------|
| 8    | top visible row | horiz shift in pixels.           |
| 9    | top visible row | horiz shift (user scroll).       |
| 9    | -1              | horiz shift (hScroll keyword).   |
| 10   | top visible row | -1 (row keyword).                |
| 10   | -1              | first visible col (col keyword). |
| 11   | column shift    | column resized by user.          |

If eventCode is 11, row is the horizontal shift in pixels of the column col that was resized, not the total horizontal shift of the list as reported in V\_horizScroll by **ControlInfo**. If row is negative, the divider was moved to the left. col=0 corresponds to adjusting the divider on the right side of the first column. Use ControlInfo to get a list of all column widths.

### Selection Events 4 and 5

These events are sent when a click on the Listbox could result in a change in selection. If it is important to you to respond only when the selection actually changes, you will need to keep track of the selection yourself.

## WMMarkerHookStruct

---

These events are not sent if the list is empty.

## WMMarkerHookStruct

See **Custom Marker Hook Functions** on page IV-306 for further explanation of WMMarkerHookStruct.

```
Structure WMMarkerHookStruct
 Int32 usage // 0 = normal draw, 1 = legend draw
 Int32 marker // Marker number minus start
 float x, y // Location of desired center of marker
 float size // Half width/height of marker
 Int32 opaque // 1 if marker should be opaque
 float penThick // Stroke width
 STRUCT RGBColor mrkRGB // Fill color
 STRUCT RGBColor eraseRGB // Background color
 STRUCT RGBColor penRGB // Stroke color
 WAVE ywave // Trace's y wave
 double ywIndex // Point number on ywave where marker is being drawn
 char winName[MAX_HostChildSpec+1] // Full path to window or subwindow
 char traceName[MAX_OBJ_INST+1] // Full name of trace or "" if no trace
EndStructure
```

## WMPopupAction

This structure is passed to action procedures for popup menu controls created using the **PopupMenu** operation.

```
Structure WMPopupAction
 char ctrlName[32] // Control name
 char win[200] // Host window or subwindow name
 STRUCT Rect winRect // Local coordinates of host window
 STRUCT Rect ctrlRect // Enclosing rectangle of the control
 STRUCT Point mouseLoc // Mouse location
 Int32 eventCode // See details below
 Int32 eventMod // See Control Structure eventMod Field on page III-438
 String userData // Primary unnamed user data
 Int32 blockReentry // See Control Structure blockReentry Field on page III-439
 Int32 popNum // Item number currently selected or hovered over (1-based)
 char popStr[MAXCMDLEN] // Contents of current popup item or item hovered over
EndStructure
```

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

### WMPopupAction eventCode Field

Your action function should test the eventCode field and respond only to documented eventCode values because other event codes may be added in the future.

The event code passed to the pop-up menu action procedure has the following meaning:

| Event Code | Event                                                                                                                                                                                                                                                                        |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -3         | Control received keyboard focus (Igor8 or later)                                                                                                                                                                                                                             |
| -2         | Control received keyboard focus (Igor8 or later)                                                                                                                                                                                                                             |
| -1         | Control being killed                                                                                                                                                                                                                                                         |
| 2          | Mouse up                                                                                                                                                                                                                                                                     |
| 3          | Hovering - sent when the user highlights a menu item by moving the mouse cursor over it but hasn't selected it                                                                                                                                                               |
| 4          | Dismissed - sent when the user closes the menu without making a selection. This is primarily of use in conjunction with the hover event; it allows you to undo any changes made during a hover event when the menu is dismissed. This event code was added in Igor Pro 9.00. |

## WMSetVariableAction

This structure is passed to action procedures for SetVariable controls created using the **SetVariable** operation.

```
Structure WMSetVariableAction
 char ctrlName[32] // Control name
 char win[200] // Host window or subwindow name
```

```

STRUCT Rect winRect // Local coordinates of host window
STRUCT Rect ctrlRect // Enclosing rectangle of the control
STRUCT Point mouseLoc // Mouse location
Int32 eventCode // See details below
Int32 eventMod // See Control Structure eventMod Field on page III-438
String userData // Primary unnamed user data
Int32 blockReentry // See Control Structure blockReentry Field on page III-439
Int32 isStr // TRUE for a string variable
Variable dval // Numeric value of variable
char sval[MAXCMDLEN] // Value of variable as a string
char vName[MAX_OBJ_NAME+2 + (MAXDIMS * (MAX_OBJ_NAME+5)) + 1]
WAVE svWave // Valid if using wave
Int32 rowIndex // Row index for a wave if rowLabel is empty
char rowLabel[MAX_OBJ_NAME+1] // Wave row dimension label
Int32 colIndex // Column index for a wave if colLabel is empty
char colLabel[MAX_OBJ_NAME+1] // Wave column dimension label
Int32 layerIndex // Layer index for a wave if layerLabel is empty
char layerLabel[MAX_OBJ_NAME+1] // Wave layer label
Int32 chunkIndex // Chunk index for a wave if chunkLabel is empty
char chunkLabel[MAX_OBJ_NAME+1] // Wave chunk label
Int32 mousePart // Part of the control where mouse down occurred
EndStructure

```

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

### WMSetVariableAction eventCode Field

Your action function should test the eventCode field and respond only to documented eventCode values because other event codes may be added in the future.

The event code passed to the SetVariable action procedure has the following meaning:

| Event Code | Event                                            |
|------------|--------------------------------------------------|
| -3         | Control received keyboard focus (Igor8 or later) |
| -2         | Control received keyboard focus (Igor8 or later) |
| -1         | Control being killed                             |
| 1          | Mouse up                                         |
| 2          | Enter key                                        |
| 3          | Live update                                      |
| 4          | Mouse scroll wheel up                            |
| 5          | Mouse scroll wheel down                          |
| 6          | Value changed by dependency update               |
| 7          | Begin edit (Igor7 or later)                      |
| 8          | End edit (Igor7 or later)                        |
| 9          | Mouse down (Igor8 or later)                      |

Event code -1 is never sent to an old-style (non-structure parameter) action procedure.

Event code 1 is sent when the mouse is released after clicking the up-arrow or down-arrow buttons. It is also sent for value changes caused by the mouse scroll wheel for a non-live mode control.

Event codes 4 and 5 are sent only for string SetVariables or numeric SetVariables whose increment setting is zero. Otherwise the value change is signaled by event code 1.

For numeric SetVariables whose increment is non-zero, the mouse scroll wheel acts like a mouse click on the up-arrow button or down-arrow button. That is, event code 1, mouse up, is more like "value changed".

Event code 6 is by default sent to only structure-based action procedures.

Use SetIgorOption EnableSVE6=0 to disable sending this event at all and EnableSVE6=2 to send the event to both structure-based and old-style SetVariable action procedures. The default for EnableSVE6 is =1.

The mousePart field is valid for mouse down, mouse scroll wheel, live update, and Enter key events only:

## WMSliderAction

---

| Value | Mouse Part                                                                                                      |
|-------|-----------------------------------------------------------------------------------------------------------------|
| 0     | A part other than 1, 2, or 3 - most likely the title                                                            |
| 1     | The up-arrow button on a numeric SetVariable via a mouse click on the button or the use of the up-arrow key     |
| 2     | The down-arrow button on a numeric SetVariable via a mouse click on the button or the use of the down-arrow key |
| 3     | The value field                                                                                                 |

---

## WMSliderAction

This structure is passed to action procedures for slider controls created using the **Slider** operation.

```
Structure WMSliderAction
 char ctrlName[32] // Control name
 char win[200] // Host window or subwindow name
 STRUCT Rect winRect // Local coordinates of host window
 STRUCT Rect ctrlRect // Enclosing rectangle of the control
 STRUCT Point mouseLoc // Mouse location
 Int32 eventCode // See details below
 Int32 eventMod // See Control Structure eventMod Field on page III-438
 String userData // Primary unnamed user data
 Int32 blockReentry // See Control Structure blockReentry Field on page III-439
 Variable curval // Value of slider
EndStructure
```

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

### WMSliderAction eventCode Field

Your action function should test the eventCode field and respond only to documented eventCode values because other event codes may be added in the future.

The event code passed to slider action procedure has the following meaning:

| Event Code | Event                                                             |
|------------|-------------------------------------------------------------------|
| -3         | Control received keyboard focus (Igor8 or later)                  |
| -2         | Control received keyboard focus (Igor8 or later)                  |
| -1         | Control being killed                                              |
| 1          | Value set                                                         |
| 2          | Mouse down                                                        |
| 4          | Mouse up                                                          |
| 8          | Mouse moved or arrow key moved the slider                         |
| 16         | Repeat timer fired (see <b>Repeating Sliders</b> on page III-418) |

---

The event codes greater than zero are bits that may be combined in certain cases. For instance, if your slider does not have the live mode set, you may receive event code 5 = 1+4. This indicates that a mouse up event was detected, and that mouse up set the slider's value.

For a demo of many of these events, see **Handling Slider Events** on page III-430.

## WMTabControlAction

This structure is passed to action procedures for tab controls created using the **TabControl** operation.

```
Structure WMTabControlAction
 char ctrlName[32] // Control name
 char win[200] // Host window or subwindow name
 STRUCT Rect winRect // Local coordinates of host window
 STRUCT Rect ctrlRect // Enclosing rectangle of the control
 STRUCT Point mouseLoc // Mouse location
 Int32 eventCode // See details below
 Int32 eventMod // See Control Structure eventMod Field on page III-438
 String userData // Primary unnamed user data
 Int32 blockReentry // See Control Structure blockReentry Field on page III-439
```

```
 Int32 tab // Tab number
EndStructure
```

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

### WMTabControlAction eventCode Field

Your action function should test the eventCode field and respond only to documented eventCode values because other event codes may be added in the future.

The event code passed to tab control action procedure has the following meaning:

| Event Code | Event                                            |
|------------|--------------------------------------------------|
| -3         | Control received keyboard focus (Igor8 or later) |
| -2         | Control received keyboard focus (Igor8 or later) |
| -1         | Control being killed                             |
| 2          | Mouse up                                         |

## WMTooltipHookStruct

See **Tooltip Hook Functions** on page IV-307 for further explanation of WMTooltipHookStruct.

```
Structure WMTooltipHookStruct
 char winName[MAX_WIN_PATH+1] // Host window name or subwindow path
 double ticks // Tick count when event happened
 STRUCT Rect winRect // Local coordinates of the window or subwindow
 STRUCT Point mouseLoc // Mouse location
 STRUCT Rect trackRect // Tooltip tracking rect
 double duration_ms // Time to display the tooltip, in milliseconds
 char traceName[MAX_OBJ_NAME+1] // If in a graph window, name of the trace
 char imageName[MAX_OBJ_NAME+1] // If in a graph window, name of the image
 waveHndl yWave // Y wave for trace, image, or table column
 double row // Row in trace, image or wave
 double column // Column in trace, image or wave
 double layer // Layer in trace, image or wave
 double chunk // Chunk in trace, image or wave
 char ctrlName[MAX_OBJ_NAME+1] // Name of control during hover event
 Int32 isHtml // Set to indicate tooltip contains HTML tags
 String tooltip // Set this to your tooltip text
EndStructure
```

## WMWinHookStruct

See **Named Window Hook Functions** on page IV-293 for further explanation of WMWinHookStruct.

```
Structure WMWinHookStruct
 char winName[200] // Host window or subwindow name
 STRUCT Rect winRect // Local coordinates of the affected (sub)window
 STRUCT Point mouseLoc // Mouse location
 Variable ticks // Tick count when event happened
 Int32 eventCode // See Named Window Hook Events on page IV-293
 char eventName[32] // See Named Window Hook Events on page IV-293
 Int32 eventMod // See Control Structure eventMod Field on page III-438
 char menuName[256] // Name of the menu item as for SetIgorMenuMode
 char menuItem[256] // Text of the menu item as for SetIgorMenuMode
 char traceName[32] // See Named Window Hook Functions on page IV-293
 char cursorName[2] // Cursor name A through J
 Variable pointNumber // See Named Window Hook Functions on page IV-293
 Variable yPointNumber // See Named Window Hook Functions on page IV-293
 Int32 isFree // 1 if the cursor is not attached to anything
 Int32 keycode // ASCII value of key struck
 Int32 specialKeyCode // See Keyboard Events on page IV-297 - Igor Pro 7 or later
 char keyText[16] // UTF-8 string representing key struck - Igor Pro 7 or later
 char oldWinName[32] // Simple name of the window or subwindow
 Int32 doSetCursor // Set to 1 to change cursor to cursorCode
 Int32 cursorCode // See Setting the Mouse Cursor on page IV-300
 Variable wheelDx // Vertical lines to scroll
 Variable wheelDy // Horizontal lines to scroll
 char focusCtrl[MAX_WIN_PATH+1] // Added in Igor Pro 9.00. See EarlyKeyboard Events.
EndStructure
```

## wnoise

**wnoise**(*shape*, *scale*)

The wnoise function returns a pseudo-random value from the two-parameter Weibull distribution characterized by the *shape* and *scale*, the respective *gamma* and *alpha* parameters. The two-parameter Weibull probability distribution function is

$$f(x; \alpha, \gamma) = \frac{\gamma}{\alpha} x^{\gamma-1} \exp\left[-\frac{1}{\alpha} x^\gamma\right] \quad \begin{array}{l} x \geq 0 \\ \alpha > 0 \\ \gamma > 0 \end{array}$$

The mean of the Weibull distribution is

$$\alpha^\gamma \Gamma\left(1 + \frac{1}{\gamma}\right),$$

and the variance is

$$\alpha^\gamma \Gamma\left(1 + \frac{2}{\gamma}\right) - \alpha^\gamma \left[\Gamma\left(1 + \frac{1}{\gamma}\right)\right]^2.$$

Note that this definition of the PDF uses different scaling than the one used in StatsWeibullPDF. To match the scaling of StatsWeibullPDF multiply the result from Wnoise by the factor  $\text{scale}^{(1-1/\text{shape})}$ .

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use **SetRandomSeed**. The algorithm uses the Mersenne Twister random number generator.

## x

### x

The x function returns the scaled row index for the current point of the destination wave in a wave assignment statement. This is the same as the X value if the destination wave is a vector (1D wave).

### Details

Outside of a wave assignment statement, x acts like a normal variable. That is, you can assign a value to it and use it in an expression.

### See Also

The **p** function and **Waveform Arithmetic and Assignments** on page II-74.

## x2pnt

**x2pnt**(*waveName*, *x1*)

The x2pnt function returns the integer point number on the wave whose X value is closest to *x1*.

For higher dimensions, use **ScaleToIndex**.

### See Also

For an explanation of waves and X scaling, see **Changing Dimension and Data Scaling** on page II-68.

**XCSR**

**xcsr**(*cursorName* [, *graphNameStr*])

The **xcsr** function returns the X value of the point which the named cursor (A through J) is on in the top or named graph.

**Parameters**

*cursorName* identifies the cursor, which can be cursor A through J.

*graphNameStr* specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Details**

The result is derived from the wave that the cursor is on, not from the X axis of the graph. If the wave is displayed as an XY pair, the X axis and the wave's X scaling will usually be different.

The **hcsr**, **pcsr**, **qcsr**, **vcscr**, and **zcsr** functions.

**Programming With Cursors** on page II-309.

**XLLoadWave**

**XLLoadWave** [*flags*] [*fileNameStr*]

The XLLoadWave operation loads data from the named Excel .xls, .xlsx or .xlsm file into waves.

XLLoadWave does not support .xlsb files and can not load password-protected Excel files.

**Parameters**

The file to be loaded is specified by *fileNameStr* and */P=pathName* where *pathName* is the name of an Igor symbolic path. *fileNameStr* can be a full path to the file, in which case */P* is not needed, a partial path relative to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If XLLoadWave can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-453 for details on forming the path.

If *fileNameStr* is omitted or is "", or if the */I* flag is used, XLLoadWave presents an Open File dialog from which you can choose the file to load.

**Flags**

- |                            |                                                                                                                                                                                                                   |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/A</i>                  | Automatically assigns arbitrary wave names using "wave" as the base name. Skips names already in use.                                                                                                             |
| <i>/A=baseName</i>         | Same as <i>/A</i> but it automatically assigns wave names of the form <i>baseName0</i> , <i>baseName1</i> .                                                                                                       |
| <i>/C=columnType</i>       | XLLoadWave will use the Deduce from Row method of determining the type of the Excel file columns, using the row specified by <i>columnType</i> to deduce column types. See <b>Deduce from row</b> on page II-151. |
| <i>/COLT=columnTypeStr</i> | <i>columnTypeStr</i> specifies how XLLoadWave should treat each column. For example, "1T3N" means 1 text column followed by 3 numeric columns. See <b>Determining Wave Types</b> on page V-1111.                  |
| <i>/D</i>                  | Creates double-precision floating point waves. If omitted, XLLoadWave creates single-precision floating point waves.                                                                                              |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>/F=f</i>             | New programming should use the <i>/I</i> flag instead of the <i>/D</i> , <i>/L</i> and <i>/F</i> flags.<br><i>f</i> specifies the data format of the file:<br><i>f</i> =1: Signed integer (8, 16, 32 bits allowed)<br><i>f</i> =2: Creates double-precision waves<br><i>f</i> =3: Floating point (default, 32, 64 bits allowed)                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>/I</i>               | Forces XLLoadWave to display an Open File dialog even if the file is fully specified via <i>/P</i> and <i>fileNameStr</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>/J=infoMode</i>      | If <i>infoMode</i> is 1, 2 or 3, XLLoadWave does not load the file but instead returns information about the worksheets within the workbook via the string variable <i>S_value</i> . See <b>Getting Information About the Excel File</b> on page V-1112.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>/K=k</i>             | Discards waves with fewer than <i>k</i> points. For historical reasons, <i>k</i> defaults to 2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>/N</i>               | Same as <i>/A</i> except that, instead of choosing names that are not in use, it overwrites existing waves.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>/N=baseName</i>      | Same as <i>/N</i> except that it automatically assigns wave names of the form <i>baseName0</i> , <i>baseName1</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>/NAME=nameList</i>   | <i>nameList</i> is a semicolon-separated list of wave names to be used for the loaded waves. See <b>Wave Names</b> on page V-1110 for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>/O</i>               | Overwrites existing waves in case of a name conflict.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>/P=pathName</i>      | Specifies the folder to look in for <i>fileNameStr</i> . <i>pathName</i> is the name of an existing symbolic path.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>/Q</i>               | Suppresses the normal messages in the history area.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>/R=(cell1,cell2)</i> | Restricts loading to the specified cells, e.g. <i>/R=(A3,D21)</i> . Row and column numbers start from 1.<br><br>The <i>/R</i> flag supports an optional extra parameter that should be used only in very rare cases. XLLoadWave reads the range of defined cells from the file itself and clips <i>cell1</i> and <i>cell2</i> to that range.<br><br>In very rare cases the file does not accurately identify the range of defined cells so the clipping prevents loading cells that exist in the file. In this rare case, use <i>/R=(cell1, cell2,1)</i> . The last parameter tells XLLoadWave to skip the clipping. If you specify incorrect values for <i>cell1</i> or <i>cell2</i> you may get errors or garbage results. |
| <i>/S=sheetNameStr</i>  | Specifies which worksheet to load from a workbook file. If you omit <i>/S=sheetNameStr</i> , or if <i>sheetNameStr</i> is "", XLLoadWave loads the first worksheet in the workbook.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>/T</i>               | Automatically creates a table of loaded waves.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>/V=v</i>             | Controls the handling of blanks at the end of a column.<br><i>v</i> =0: XLLoadWave leaves blanks at the end of a column in the Igor wave.<br><i>v</i> =1: XLLoadWave removes blanks at the end of a column from the Igor wave. If the column has fewer than two remaining points, it is not loaded into a wave. This is the default mode that is used if you omit <i>/V</i> .                                                                                                                                                                                                                                                                                                                                                |
| <i>/W=w</i>             | <i>w</i> specifies the row in which XLLoadWave will look for wave names. The first row is row number 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### Wave Names

The names of the loaded waves are determined by the */A*, */N*, */W* and */NAME* flags. If all of the flags are omitted, default names, like ColumnA and ColumnB, are used.

If */W=w* is present, names are loaded from row *w* of the worksheet and then converted to standard Igor names by replacing spaces and punctuation characters with underscores.

If `/NAME=nameList` is present, the wave names come from *nameList*, a semicolon-separated list of names. For example:

```
/NAME="StartTime;UnitA;UnitB;"
```

The names in *nameList* can be standard or liberal names. For example, this specifies names two standard names and one liberal name which contains a space:

```
/NAME="Signal;Ambient Temp;Response;"
```

If a name in the list is `_skip_`, the corresponding Excel column is skipped. For example, this would load the first and third columns and skip the second:

```
/NAME="Signal;_skip_;Response;"
```

If a name in the list is empty, the name used for the corresponding wave is as it would be if `/NAME` were omitted. This can be used to skip columns while taking wave names from the spreadsheet for loaded columns. In this example, the names of the first and third waves would be determined by row 1 of the spreadsheet while the second column would be skipped:

```
/W=1 /NAME=";_skip_;"
```

The `/N` flag instructs Igor to automatically name new waves "wave", or *baseName* if `/N=baseName` is used, plus a number. The number starts from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten.

The `/A` flag is like `/N` except that it skips names already in use.

`/NAME` overrides `/W`. `/A` or `/N` overrides both `/NAME` and `/W`.

No matter how the wave names are generated, if there is a name conflict and overwrite is off (`/O` is omitted), a unique name is generated. See **XLLoadWave and Wave Names** on page II-152 for further details.

### Determining Wave Types

The `/C` or `/COLT` flag tells XLLoadWave how to decide what kind of wave, numeric, text, or date/time, to make for each Excel column.

Using `/C=columnType` causes XLLoadWave to use the Deduce from Row method of determining the type of the Excel file columns. *columnType* is the Excel row number that XLLoadWave should use to make the deduction.

Using `/COLT=columnTypeStr` causes XLLoadWave treat the columns based on the *columnTypeStr* parameter. If *columnTypeStr* is "N", XLLoadWave uses the Treat all Columns as Numeric method. If *columnTypeStr* is "T", XLLoadWave uses the Treat all Columns as Text method. If *columnTypeStr* is "D", XLLoadWave uses the Treat all Columns as Date method.

For any other value of *columnTypeStr*, XLLoadWave uses the Use Column Type String method. For example, "1T5N" tells XLLoadWave to create a text wave for the first column and numeric waves for the next 5 or more columns.

If you omit `/C` and `/COLT`, XLLoadWave uses the Treat all Columns as Numeric method.

See **What XLLoadWave Loads** on page II-151 for further details.

### Output Variables

XLLoadWave sets the followin output variables:

|                              |                                                                                                          |
|------------------------------|----------------------------------------------------------------------------------------------------------|
| <code>V_flag</code>          | Number of waves loaded.                                                                                  |
| <code>S_fileName</code>      | Name of the file being loaded.                                                                           |
| <code>S_path</code>          | File system path to the folder containing the file.                                                      |
| <code>S_waveNames</code>     | Semicolon-separated list of the names of loaded waves.                                                   |
| <code>S_worksheetName</code> | Name of the loaded worksheet within the workbook file.                                                   |
| <code>S_value</code>         | Set only if you use the <code>/J</code> flag. See <b>Getting Information About the Excel File</b> below. |

`S_path` uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon.

## XWaveName

---

When XLLoadWave presents an Open File dialog and the user cancels, V\_flag is set to 0 and S\_fileName is set to "".

### Getting Information About the Excel File

The /J flag allows you to get information about an Excel file without actually loading it.

If *infoMode* is 1, XLLoadWave does not load the file but instead returns a semicolon-separated list of the names of the worksheets within the workbook via the string variable S\_value.

If *infoMode* is 2, XLLoadWave does not load the file but instead returns information about the first worksheet or the worksheet specified by /S via the string variable S\_value. The format of the returned information is:

```
NAME:<worksheet name>;FIRSTROW:<first row>;FIRSTCOL:<first col>;LASTROW:<last row>;LASTCOL:<last col>;
```

<first row> and <last row> are 1-based row numbers. <first col> and <last col> are 1-based column numbers; 1 refers to Column A. These refer to the defined rows and columns in the worksheet even if some or all cells are blank. If <last col> is zero, this means that there are no defined cells in the worksheet.

If *infoMode* is 3, XLLoadWave does not load the file but instead returns information about the first worksheet or the worksheet specified by /S via the string variable S\_value. The format of the returned information is:

```
NAME:<worksheet name>;FIRST:<first cell>;LAST:<last cell>;
```

<first cell> and <last cell> are expressed in standard Excel notation (A1, B24, etc.). These refer to the defined rows and columns in the worksheet even if some or all cells are blank. If <last cell> is "@0", this means that there are no defined cells in the worksheet.

Use the **StringByKey**, **NumberByKey** functions to extract the information from S\_value. If you use these functions, your code won't break if we later add a keyword/value pair to the returned information.

### Examples

Old versions of Excel came with a number of sample files. One of them was called "Instrument Data". The following procedure loads an area of this file, makes a table and then makes a graph of the loaded waves.

This example assumes that you have the "Instrument Data.xls" file and a symbolic path named Science that points to the folder containing the file.

```
Function InstrumentData()
 // Load Instrument Data file from the Scientific Analysis folder
 XLLoadWave/O/T/R=(C9,M27)/W=8/C=9/P=Science "Instrument Data.xls"

 // Make graph.
 Display M1, M2, M3 vs X Time
 Label bottom, "Time"; Label left, "Mass"
 ModifyGraph dateInfo(bottom)={1,0,0}
End
```

See also **Loading Excel Data Into a 2D Wave** on page II-153.

## XWaveName

**XWaveName**(*graphNameStr*, *traceNameStr*)

The XWaveName function returns a string containing the name of the wave supplying the X coordinates for the named trace in the named graph window or subwindow.

### Parameters

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

*traceNameStr* is the name of the trace in question.

### Details

XWaveName returns an empty string ("") if the trace is not plotted versus an X wave.

For most uses, we recommend that you use **XWaveRefFromTrace** instead of WaveName. XWaveName returns a string containing the wave name only, with no data folder path qualifying it. Thus, you may get

erroneous results if the X wave referred to in the graph has the same name as a different wave in the current data folder. Likewise, if the named wave resides in a folder that is not the current data folder, you will not be able to refer to the named wave.

*graphNameStr* and *traceNameStr* are strings, not names.

### Examples

```
Display ywave vs xwave // XY graph
Print XWaveName("", "ywave") // prints xwave
```

### See also

**Trace Names** on page II-270, **Programming With Trace Names** on page IV-87.

## XWaveRefFromTrace

**XWaveRefFromTrace**(*graphNameStr*, *traceNameStr*)

The XWaveRefFromTrace function returns a wave reference to the wave supplying the X coordinates against which the named trace is displayed in the named graph window or subwindow.

### Parameters

*graphNameStr* can be "" to refer to the top graph window.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

### Details

XWaveRefFromTrace returns a null reference (see **WaveExists**) if the wave is not plotted versus an X wave.

*graphNameStr* and *traceNameStr* are strings, not names.

### Examples

```
Display ywave vs xwave // XY graph
Print XWaveRefFromTrace("", "ywave") [50] // prints value of xwave at point 50
```

## y

### y

The y function returns the Y value for the current column of the destination wave when used in a multidimensional wave assignment statement. Y is the scaled column index whereas **q** is the column index itself.

### Details

Unlike **x**, outside of a wave assignment statement, y does not act like a normal variable.

### See Also

**x**, **z**, and **t** functions for other dimensions.

**p**, **q**, **r**, and **s** functions for the scaled indices.

## Z

---

### Z

#### z

The `z` function returns the `Z` value for the current layer of the destination wave when used in a multidimensional wave assignment statement. `z` is the scaled layer index whereas `r` is the layer index itself.

#### Details

Unlike `x`, outside of a wave assignment statement, `z` does not act like a normal variable.

#### See Also

`x`, `y`, and `t` functions for other dimensions.

`p`, `q`, `r`, and `s` functions for the scaled indices.

### ZCSR

`zcsr(cursorName [, graphNameStr])`

The `zcsr` function returns a `Z` value when the specified cursor is on a contour, image, or waterfall plot. Otherwise, it returns `NaN`.

#### Parameters

`cursorName` identifies the cursor, which can be cursor A through J.

`graphNameStr` specifies the graph window or subwindow.

When identifying a subwindow with `graphNameStr`, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

#### Examples

```
Print zcsr(A) // not zcsr("A")
Print zcsr(A, "Graph0") // specifies the graph
```

#### See Also

The `hcsr`, `pcsr`, `qcsr`, `vcscr`, and `xcscr` functions.

**Programming With Cursors** on page II-309.

### zeta

`zeta(a, b [, terms])`

The zeta function returns the Hurwitz Zeta function for real or complex arguments  $a$  and  $b$

$$\zeta(a, b) = \sum_{k=0}^{\infty} \frac{1}{(k+b)^a},$$

$$\Re(a) > 1,$$

$$b \neq 0, -1, -2, \dots$$

The Riemann zeta function is the special case:

$$\zeta(a) = \zeta(a, 1).$$

The zeta function was added in Igor Pro 7.00.

#### Parameters

The `terms` parameter defaults to 40. In practice evaluation may terminate before the specified number of terms when convergence is achieved.

Dilogarithm

## ZernikeR

**ZernikeR**( $n, m, r$ )

The ZernikeR function returns the Zernike radial polynomials of degree  $n$  that contains no power of  $r$  that is less than  $m$ . Here  $m$  is even or odd according to whether  $n$  is even or odd, and  $r$  is in the range 0 to 1.

Note that the full circle polynomials are complex. For any angle  $t$  (theta), they are given by:  
 $\text{ZernikeR}(n, m, r) * \exp(imt)$ .
