<td>13</td>
<td>Color table name.</td>
</tr>
</tbody>
</table>

In the case of **Specialized Menu Item Definitions** (see page IV-129), S_value will be the title of the menu or submenu, etc.

**V_Red, V_Green, V_Blue, V_Alpha**

If a user-defined color menu ("COLORPOP" menu item) was chosen then these values hold the red, green, and blue values of the selected color. The values range from 0 to 65535.

Will be 0 if the last user-defined menu selection was not a color menu selection.

**S_graphName, S_traceName, V_mouseX, V_mouseY**

These are set only when any user-defined menu is chosen from some graph contextual menus: Menu "TracePopup", Menu "AllTracesPopup", or Menu "GraphPopup" definitions. S_graphName and S_traceName are initially "" until a user-defined menu selection is made from one of these contextual menus, and are not reset for each user-defined menu selection. S_graphName is the full host-child specification for the graph. If the graph is embedded into a host window, S_graphName might be something like “Panel0#G0”. See **Subwindow Syntax** on page III-92.

S_traceName is name of the trace that was selected by the trace contextual menu, or " " if the AllTracesPopup or GraphPopup menu was chosen. See **Subwindow Syntax** on page III-92.

V_mouseX, V_mouseY, added in Igor Pro 8.00, are the mouse location of the click that invoked the contextual menu. The location is in pixels; use **AxisValFromPixel** to determine the X and Y axis values that correspond to the pixel location.
GetLastUserMenuInfo

Examples

A Multiple Menu Items menu definition:
Menu "Wave List", dynamic
   "Menu Item 1", <some command>
   "Menu Item 2", <some command>
   WaveList("**",";"), DoSomethingWithWave()
End

If the user selects one of the (many) menu items created by the “Wave List” menu item definition, the DoSomethingWithWave user function can call GetLastUserMenuInfo to determine which wave was selected:

Function DoSomethingWithWave()
   GetLastUserMenuInfo
   WAVE/Z selectedWave = $S_value
   // Use selectedWave for something
End

A trivial user-defined color menu definition:
Menu "Color"
   "*COLORPOP*", DoSomethingWithColor()
End

Function DoSomethingWithColor()
   GetLastUserMenuInfo
   ... do something with V_Red, V_Green, V_Blue, V_Alpha ...
End

See Specialized Menu Item Definitions on page IV-129 for another color menu example.

A Trace contextual menu Items menu definition:
Menu "TracePopup", dynamic // menu when a trace is right-clicked
   "-" // separator divides this from built-in menu items
   ExportTraceName(), ExportSelectedTrace()
   "Draw XY Here", DrawXYHere()
End

Function/S ExportTraceName()
   GetLastUserMenuInfo // only S_graphName, S_traceName are set
   String item = ""
   if (strlen(S_traceName) > 0)
      item = "Export " + S_traceName
   endif
   return item
End

Function ExportSelectedTrace()
   GetLastUserMenuInfo
   // Do something with S_graphName, S_traceName
   End

Function DrawXYHere()
   GetLastUserMenuInfo
   // Figure out mouse position within graph (requires Igor 8)
   String info = traceinfo(S_graphName, S_traceName, 0)
   String xaxis = stringbykey("XAXIS",info)
   String yaxis = stringbykey("YAXIS",info)
   Variable x_pos = AxisValFromPixel(S_graphName, xaxis, V_mouseX)
   Variable y_pos = AxisValFromPixel(S_graphName, yaxis, V_mouseY)

   // Draw
   GetAxis/W=SS_graphName/Q $yaxis
   GetAxis/W=SS_graphName/Q $xaxis
   Variable miny=V_min, maxy=V_max
   Variable minx=V_min, maxx=V_max
   SetDrawLayer/W=$S_graphName/K userFront
   SetDrawEnv/W=$S_graphName push
   SetDrawEnv/W=$S_graphName xcoord= $xaxis, ycoord=$yaxis, save
   DrawLine/W=SS_graphName minx, y_pos, maxx, y_pos // horizontal line
   DrawLine/W=SS_graphName x_pos, miny, x_pos, maxy // vertical line
   SetDrawEnv/W=SS_graphName pop
End
GetMarquee

GetMarquee [/K=winName/Z] [axisName [, axisName]]

The GetMarquee operation provides a way for you to use the marquee as an input mechanism in graphs and page layout windows. It puts information about the marquee into variables.

Parameters
If you specify axisName (allowed only for graphs) the coordinates are in axis units. If you specify an axis that does not exist, Igor generates an error.

If you specify only one axis then Igor sets only the variables appropriate to that axis. For example, if you execute “GetMarquee left” then Igor sets the V_bottom and V_top variables but does not set V_left and V_right.

Flags
/K Kills the marquee. Usually you will want to kill the marquee when you call GetMarquee, so you should use the /K flag. This is modeled after what happens when you create a marquee in a graph and then choose Expand from the Marquee menu. There may be some situations in which you want the marquee to persist. Igor also automatically kills the marquee anytime the window containing the marquee is deactivated, including when a dialog is summoned.

/W=winName Specifies the named window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/Z No runtime error generated if the target window isn’t a graph or layout, but V_flag will be zero. /Z does not prevent other kinds of problems from generating a runtime error.

Details
GetMarquee is intended to be used in procedures invoked through user menu items added to the graph Marquee menu and the layout Marquee menu.

GetMarquee sets the following variables and strings:

V_flag 0: There was no marquee when GetMarquee was invoked.
1: There was a marquee when GetMarquee was invoked.

V_left Marquee left coordinate.
V_right Marquee right coordinate.
V_top Marquee top coordinate.
V_bottom Marquee bottom coordinate.
S_marqueeWin Name of window containing the marquee, or " " if no marquee. If subwindow, subwindow syntax will be used.

When called from the command line, GetMarquee sets global variables and strings in the current data folder. When called from a procedure, it sets local variables and strings.

In addition, creating, adjusting, or removing a marquee may set additional marquee global variables (see the Marquee Globals section, below).

The target window must be a layout or a graph. Use /Z to avoid generating a runtime-error (V_flag will be 0 if the target window was not a layout or graph).

If the target is a layout then Igor sets the variables in units of points relative to the top/left corner of the paper.
If the target is a graph then Igor sets $V_{\text{left}}$ and $V_{\text{right}}$ based on the specified horizontal axis. If no horizontal axis was specified, $V_{\text{left}}$ and $V_{\text{right}}$ are set relative to the left edge of the base window in points.

If the target is a graph then Igor sets $V_{\text{bottom}}$ and $V_{\text{top}}$ based on the specified vertical axis. If no vertical axis was specified, $V_{\text{top}}$ and $V_{\text{bottom}}$ are set relative to the top edge of the base window in points.

If there is no marquee when you invoke GetMarquee then Igor sets $V_{\text{left}}, V_{\text{top}}, V_{\text{right}}, V_{\text{bottom}}$ based on the last time the marquee was active.

**GetMarquee Example**

Menu "GraphMarquee"

- "Print Marquee Coordinates", PrintMarqueeCoords()

End

Function PrintMarqueeCoords()

GetMarquee left, bottom

if (V_flag == 0)
   Print "There is no marquee"
else
   printf "marquee left in bottom axis terms: %g\r", V_left
   printf "marquee right in bottom axis terms: %g\r", V_right
   printf "marquee top in left axis terms: %g\r", V_top
   printf "marquee bottom in left axis terms: %g\r", V_bottom
endif

End

You can run this procedure by putting it into the procedure window, making a marquee in a graph, clicking in the marquee and choosing Print Marquee Coordinates:

![Image of marquee coordinates]

The procedure calls GetMarquee to set the local marquee variables and then prints their values in the history area:

PrintMarqueeCoords()

- marquee left in bottom axis terms: 32.1149
- marquee right in bottom axis terms: 64.7165
- marquee top in left axis terms: 0.724075
- marquee bottom in left axis terms: -0.131061

**Marquee Globals**

You can cause Igor to update global marquee variables whenever the user adjusts the marquee (without the need for you to invoke GetMarquee) by creating a global variable named $V_{\text{marquee}}$ in the root data folder:

Variable/G root:V_marquee = 1 //Creates $V_{\text{marquee}}$ and sets bit 0 only

When the user adjusts the marquee Igor checks to see if root:$V_{\text{marquee}}$ exists and which bits are set, and updates (and creates if necessary) these globals:

Variable/G root:V_left
Variable/G root:V_right
Variable/G root:V_top
Variable/G root:V_bottom

String/G root:S_marqueeWin

Name of window that contains marquee, or "$\" if no marquee.
Set only if root:$V_{\text{Marquee}}$ has bit 15 (0x8000) set.
Unlike the local variables, for graphs these global variables are never in points. Root:V_left and V_right will be axis coordinates based on the first bottom axis created for the graph (if none, then for the first top axis). The axis creation order is the same as is returned by AxisList. Similarly, root:V_top and root:V_bottom will be axis coordinates based on the first left axis or the first right axis.

Igor examines the global root:V_marquee for bitwise flags to decide which globals to update, and when:

<table>
<thead>
<tr>
<th>root:V_marquee Bit Meaning</th>
<th>Bit Number</th>
<th>Bit Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update global variables for graph marquees</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Update global variables for layout marquees</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>Update S_marqueeWin when updating global variables</td>
<td>15</td>
<td>0x8000</td>
</tr>
</tbody>
</table>

Marquee Globals Example
By creating the global variable root:V_marquee this way:

Variable/G root:V_marquee = 1 + 4 + 0x8000

whenever the user creates, adjusts, or removes a marquee in any graph or layout Igor will create and update the global root:V_left, etc. coordinate variables and set the global string root:S_marqueeWin to the name of the window which has the marquee in it. When the marquee is removed, root:S_marqueeWin will be set to "".

This mechanism does neat things by making a ValDisplay or SetVariable control depend on any of the globals. See the Marquee Demo experiment in the Examples:Feature Demos folder for an example.

You can also cause a function to run whenever the user creates, adjusts, or removes a marquee by setting up a dependency formula using SetFormula to bind one of the marquee globals to one of the function’s input arguments:

Variable/G root:dependencyTarget

SetFormula root:dependencyTarget, "MyMarqueeFunction(root:S_marqueeWin)"

Function MyMarqueeFunction(marqueeWindow)
    String marqueeWindow // this will be root:S_marqueeWin
    if( strlen(marqueeWindow) )
        NVAR V_left= root:V_left, V_right= root:V_right
        NVAR V_top= root:V_top, V_bottom= root:V_bottom
        Printf marqueeWindow + " has a marquee at: ";
        Printf "%d, %d, %d, %d\r", V_left, V_right, V_top, V_bottom
    else
        Print "The marquee has disappeared."
    endif
    return 0 // return value doesn't really matter
End

See Also
The SetMarquee and SetFormula operations. Setting Bit Parameters on page IV-13 for information about bit settings.

GetMouse

GetMouse [/W=winName]
The GetMouse operation returns information about the position of the input mouse, and the state of the mouse buttons.

GetMouse is useful in situations such as background tasks where the mouse position and state aren’t available as they are in control procedures and window hook functions.
GetRTError

Flags

/W=winName  Returns the mouse position relative to the named window or subwindow. When identifying a subwindow with winName, see Subwindow Syntax on page III-92.
/W=kwTopWin Returns the mouse position relative to the currently frontmost non-floating window.
/W=kwCmdHist Returns the mouse position relative to the command window.
/W=Procedure Returns the mouse position relative to the main Procedure window.

Details
GetMouse returns the mouse position in local coordinates relative to the specified window unless /W is omitted in which case the returned coordinates are global.

On Windows, global coordinates are actually relative to the frame window. See GetWindow wsizeDC kwFrameInner.

Information is returned via the following string and numeric variables:

V_left  Horizontal mouse position, in pixels.
V_top  Vertical mouse position, in pixels.
V_flag  Mouse button state. V_flag is a bitwise value with each bit reporting the mouse button states:
  Bit 0: 1 if the primary mouse button (usually the left) is down, 0 if it is up.
  Bit 1: 1 if the secondary mouse button (usually the right) is down, 0 if it is up.

On Macintosh, the secondary mouse button can be invoked by pressing the control key while clicking the primary (often the only) mouse button, but GetMouse does not report this with bit 1 set. Use GetKeyState's bit 4 to test if the control key is pressed.

See Setting Bit Parameters on page IV-13 for details about bit settings.

S_name  Name of the window or subwindow which the position is relative to, or "" if not a nameable window or if /W was omitted. Most useful with /W=kwTopWin. The result can be kwCmdHist or Procedure, or the name of a target window.

Background Tasks on page IV-307, Subwindow Syntax on page III-92

GetRTError

GetRTError(flag)
The GetRTError function returns information about the error state of Igor's user-defined function runtime execution environment.

If flag is 0, GetRTError returns an error code if an error has occurred or 0 if no error has occurred.

If flag is 1, GetRTError returns an error code if an error has occurred or 0 if no error has occurred and it clears the error state of Igor’s runtime execution environment. Use this if you want to detect and handle runtime errors yourself.

If flag is 2, GetRTError returns the state of Igor’s internal abort flag but does not clear it.

For flag=0 and flag=1, you can call GetErrMessage to obtain the error message associated with the returned error code, if any.

In Igor Pro 7.00 or later, using GetRTError(1) on the same line as a command that causes an error overrides the debugger “debug on error” setting and prevents the debugger from activating for that error.

Example
// This illustrates how to detect and handle a runtime error
// rather than allowing it to cause Igor to abort execution.
Function Demo()
  <Call an Igor operation or a user-defined function>
Variable err = GetRTErrMessage(0)
if (err != 0)
    String message = GetErrMessage(err)
    Printf "Error in Demo: %s\r", message
    err = GetRTErrMessage(1) // Clear error state
    Printf "Continuing execution" 
endif
<Call an Igor operation or a user-defined function>
End

See also
The GetErrMessage and GetRTErrMessage functions.

GetRTErrMessage
GetRTErrMessage()
In a user function, GetRTErrMessage returns a string containing the name of the operation that caused the error, a semicolon, and an error message explaining the cause of the error. This is the same information that appears in the alert dialog displayed. If no error has occurred, the string will be of zero length. GetRTErrMessage must be called before the error is cleared by calling GetRTErrMessage with a nonzero argument.

See also
The GetErrMessage and GetRTErrMessage functions.

GetRTLLocation
GetRTLLocation(sleepMS)
GetRTLLocation is used for profiling Igor procedures.
You will typically not call GetRTLLocation directly but instead will use it through FunctionProfiling.ipf which you can access using this include statement:
#include <FunctionProfiling>
GetRTLLocation is called from an Igor preemptive thread to monitor the main thread. It returns a code that identifies the current location in the procedure files corresponding to the procedure line that is executing in the main thread.

Parameters
sleepMs is the number of milliseconds to sleep the preemptive thread after fetching a value.

Details
The result from GetRTLLocation is passed to GetRTLLocInfo to determine the location in the procedures. This samples the main thread only and the location becomes meaningless after any procedure editing.

See Also
GetRTLLocInfo

GetRTLLocInfo
GetRTLLocInfo(code)
GetRTLLocInfo is used for profiling Igor procedures.
You will typically not call GetRTLLocInfo directly but instead will use it through FunctionProfiling.ipf which you can access using this include statement:
#include <FunctionProfiling>
GetRTLLocInfo is called from an Igor preemptive thread to monitor the main thread. It returns a key/value string containing information about the procedure location associated with code or "" if the location could not be found.

Parameters
code is the result from a very recent call to GetRTLLocation.

Details
The format of the result string is:
GetRTStackInfo

"PROCNAMEname;LINEline;FUNCNAMEname;"

As of Igor Pro 7.03, if the code is in an independent module other than ProcGlobal then this appears at the
beginning of the result string:

IMNAMEiname;

The line number is padded with zeros to facilitate sorting.

See Also
GetRTLocation

GetRTStackInfo

GetRTStackInfo(selector)
The GetRTStackInfo function returns information about “runtime stack” (the chain of macros and functions
that are executing).

Details
If selector is 0, GetRTStackInfo returns a semicolon-separated list of the macros and procedures that are
executing. This list is the same you would see in the debugger’s stack list.

The currently executing macro or function is the last item in the list, the macro or function that started
execution is the first item in the list.

If selector is 1, it returns the name of the currently executing function or macro.

If selector is 2, it returns the name of the calling function or macro.

If selector is 3, GetRTStackInfo returns a semicolon-separated list of routine names, procedure file names
and line numbers. This is intended for advanced debugging by advanced programmers only.

For example, if RoutineA in procedure file ProcA.ipf calls RoutineB in procedure file ProcB.ipf, and
RoutineB calls GetRTStackInfo(3), it will return:

RoutineA,ProcA.ipf,7;RoutineB,ProcB.ipf,12;

The numbers 7 and 12 would be the actual numbers of the lines that were executing in each routine. Line
numbers are zero-based.

GetRTStackInfo does not work correctly with string macros executed via the Execute operation.
In future versions of Igor, selector may request other kinds of information.

Examples
Function Called()
    Print "Called by " + GetRTStackInfo(2) + "()"
    Print "Routines in calling chain: " + GetRTStackInfo(0)
End

Function Calling()
    Called()
End

Macro StartItUp()
    Calling()
End

    // Executing StartItUp() prints:
    Called by Calling()
    Routines in calling chain: StartItUp;Calling;Called;

See Also
StringFromList, ItemsInList, and GetRTError functions. The Stack and Variables Lists on page IV-208.

GetScrapText

GetScrapText()
The GetScrapText function returns a string containing any plain text on the Clipboard (aka “scrap”). This
is the text that would be pasted into a text document if you used Paste in the Edit menu.

See Also
The PutScrapText and LoadPICT operations.
GetSelection

GetSelection winType, winName, bitflags
The GetSelection operation returns information about the current selection in the specified window.

Parameters
winType is one of the following keywords:
- graph, panel, table, layout, notebook, procedure
winName is the name of a window of the specified type.
When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
If winType is procedure then winName is actually a procedure window title inside a $""$ wrapper, such as:
GetSelection procedure "$DemoLoader.ipf", 3

bitflags is a bitwise parameter that is used in different ways for different window types, as described in Details.
You should use 0 for undefined bits. Setting Bit Parameters on page IV-13 for further details about bit settings.

Details
For all window types, GetSelection sets V_flag:

<table>
<thead>
<tr>
<th>V_flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No selection when GetSelection was invoked.</td>
</tr>
<tr>
<td>1</td>
<td>There was a selection when GetSelection was invoked.</td>
</tr>
</tbody>
</table>

Here is a description of what GetSelection does for each window type:

<table>
<thead>
<tr>
<th>winType</th>
<th>bitFlags</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>graph</td>
<td></td>
<td>Does nothing.</td>
</tr>
<tr>
<td>panel</td>
<td></td>
<td>Does nothing.</td>
</tr>
<tr>
<td>table</td>
<td>1</td>
<td>Sets V_startRow, V_startCol, V_endRow, and V_endCol based on the selected cells in the table. The top/left cell, not including the Point column, is (0, 0).</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Sets S_selection to a semicolon-separated list of column names.</td>
</tr>
<tr>
<td></td>
<td>4</td>
<td>Sets S_dataFolder to a semicolon-separated list of data folders, one for each column.</td>
</tr>
<tr>
<td>layout</td>
<td>2</td>
<td>Sets S_selection to a semicolon separated list of selected objects in the layout layer (not any drawing layers). S_selection will be &quot;&quot; if no objects are selected.</td>
</tr>
<tr>
<td>notebook</td>
<td>1</td>
<td>Sets V_startParagraph, V_startPos, V_endParagraph, and V_endPos based on the selected text in the notebook.</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Sets S_selection to the selected text.</td>
</tr>
<tr>
<td>procedure</td>
<td>1</td>
<td>Sets V_startParagraph, V_startPos, V_endParagraph, V_endPos based on the selected text in the procedure window.</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Sets S_selection to the selected text.</td>
</tr>
</tbody>
</table>

Examples
In a new experiment, make a table named "Table0" with some columns, and select some combination of rows and columns:

Make wave0 = p
Make wave1 = p + 1
Edit wave0, wave1
ModifyTable selection = (3,0,8,1,3,0)

Now execute these commands in a procedure or in the command line:

GetSelection table, Table0, 3
Print V_flag, V_startRow, V_startCol, V_endRow, V_endCol
Print S_selection

This will print the following in the history area:
GetUserData

GetUserData (winName, objID, userdataName)

The GetUserData function returns a string containing the user data for a window or subwindow. The return string will be empty if no user data exists.

Parameters

winName may specify a window or subwindow name. Use "" for the top window.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

objID is a string specifying the name of a control or graph trace. Use "" for a window or subwindow.

userdataName is the name of the user data or "" for the default unnamed user data.

See Also

The ControlInfo, GetWindow, and SetWindow operations.

GetWavesDataFolder

GetWavesDataFolder (waveName, kind)

The GetWavesDataFolder function returns a string containing the name of a data folder containing the wave named by waveName. Variations on the theme are selected by kind.

The most common use for this is in a procedure, when you want to create a wave or a global variable in the data folder containing a wave passed as a parameter.

GetWavesDataFolderDFR is preferred.

Details

kind GetWavesDataFolder Returns

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>Only the name of the data folder containing waveName.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Full path of data folder containing waveName, without wave name.</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Full path of data folder containing waveName, including possibly quoted wave name.</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Partial path from current data folder to the data folder containing waveName.</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>Partial path including possibly quoted wave name.</td>
<td></td>
</tr>
</tbody>
</table>

Kinds 2 and 4 are especially useful in creating command strings to be passed to Execute.

Examples

Function DuplicateWaveInDataFolder (w)

Wave w
<DFREF dfSav = GetDataFolderDFR()>
SetDataFolder GetWavesDataFolder (w, 1)
Duplicate/O w, $(NameOfWave (w) + "_2")
SetDataFolder dfSav
End

See Also

Chapter II-8, Data Folders.

GetWavesDataFolderDFR

GetWavesDataFolderDFR (waveName)

The GetWavesDataFolderDFR function returns a data folder reference for the data folder containing the specified wave.

GetWavesDataFolderDFR is the same as GetWavesDataFolder except that it returns a data folder reference instead of a string containing a path.
See Also
Chapter II-8, Data Folders and Data Folder References on page IV-77.

GetWindow

GetWindow [/Z] winName, keyword

The GetWindow operation provides information about the named window or subwindow. Information is returned in variables, strings, and waves.

Parameters

winName can be the name of any target window (graph, table, page layout, notebook, control panel, Gizmo, camera, or XOP target window) or subwindow. It can also be the title of a procedure window or one of these four special keywords:

- kwTopWin: Specifies the topmost target window.
- kwCmdHist: Specifies the command history area.
- kwFrameOuter: Specifies the “frame” or “application” window that Igor Pro has only under Windows. This is the window that contains Igor’s menus and status bar.
- kwFrameInner: Specifies the inside of the same “frame” window under Windows. This is the window that all other Igor windows are inside.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Only one of the following keywords may follow winName. The keyword chosen determines the information stored in the output variables:

- active: Sets V_Value to 1 if the window is active or to 0 otherwise. Active usually means the window is the frontmost window.
- activeSW: Stores the window “path” of currently active subwindow in S_Value. See Subwindow Syntax on page III-92 for details on the window hierarchy.
- backRGB: Sets V_Red, V_Green, V_Blue, and V_Alpha to the background color of the window. The values range from 0 to 65535. The background color is set with ModifyGraph (colors) wbRGB, ModifyLayout bgRGB, and Notebook backRGB. Also returns the background color of procedure windows and the command/history windows. Other windows set these values to 65535 (opaque white).
  
  Added in Igor Pro 7.00.
- exterior: Sets V_value to 1 if the window is an exterior panel window or to 0 otherwise. Useful for window hook functions that must work for both regular windows and exterior panel windows, since exterior panels use their own hook function.
- bgRGB: Another name for backRGB.
  
  Added in Igor Pro 7.00.
- cbRGB: Sets V_Red, V_Green, V_Blue, and V_Alpha to the control panel area background color of the window in graphs or panel windows, as set by ModifyGraph (colors) cbRGB and ModifyPanel cbRGB. Other windows set these values to 65535 (opaque white).
  
  Added in Igor Pro 7.00.
- drawLayer: If the specified window is a graph, layout, or panel window then the window’s current drawing layer is returned in S_value. S_value is set to “” for other windows. See Drawing Layers on page III-72.
  
  Added in Igor Pro 7.00.
GetWindow

expand  For graph windows, sets V_Value to the expand value set by ModifyGraph (general) expand=value, a value normally 0 or 1, where 1.5 means 150%.

For notebook, procedure and command windows, sets V_Value to the magnification, normally 100. See the Notebook magnification=m documentation for details.

For layout windows, sets V_Value to the ModifyLayout mag=m value, usually 0.5 (50%).

Table windows set V_Value to 0, panels and other unsupported windows to NaN.

Added in Igor Pro 7.00.

file  Works for notebook and procedure windows only.

Returns via S_value a semicolon-separated list containing:
  - the file name
  - the Mac path to the folder containing the file with a colon at the end
  - the name of a symbolic path pointing to that folder, if any

If the window was never saved to a standalone file then "" is returned in S_value.
If the specified window is not a notebook or procedure window then "" is returned in S_value.

gbRGB  Sets V_Red, V_Green, V_Blue, and V_Alpha to the plot area background color of the window in graph windows, as set by ModifyGraph (colors) gbRGB. Other windows set these values to 65535 (opaque white).

Use wbRGB to get the color of window background (the area outside of the axes).

Added in Igor Pro 7.00.

gsize  Reads graph outer dimensions into V_left, V_right, V_top, and V_bottom in local coordinates. This includes axes but not the tool palette, control bar, or info panel.

Dimensions are in points.

gsizeDC  Same as gsize but dimensions are in device coordinates (pixels).

hide  Sets V_Value bit 0 if the window or subwindow is hidden.

Sets bit 1 if the host window is minimized.

Sets bit 2 if the subwindow is hidden only because an ancestor window or subwindow is hidden. Added in Igor Pro 7.00.

On Macintosh, if you execute MoveWindow 0,0,0,0 to minimize a window to the dock, and then you immediately call GetWindow hide, bit 1 may not be correctly set because of the delay caused by the animation of the window sliding into the dock.

hook  Copies name of window hook function to S_value. See Unnamed Window Hook Functions on page IV-296.

hook(hName)  For the given named hook hName, copies name of window hook function to S_value. See Named Window Hook Functions on page IV-286.

logicalpapersize  Returns logical paper size of the page setup associated with the named window into V_left, V_right, V_top, and V_bottom. Dimensions are in points.

If the Page Setup dialog uses 100% scaling, these are also the physical dimensions of the page. V_left and V_top are 0 and correspond to the left top corner of the physical page.

On the Macintosh, using a Scale of 50% multiplies all of these dimensions by 2.
logicalprintablesize

Returns logical printable size of the page setup associated with the named window into V_left, V_right, V_top, and V_bottom. Dimensions are in points.

If the Page Setup dialog uses 100% scaling, these are also the physical dimensions of the page minus the margins. V_left and V_top are the number of points from the left top corner of the physical page to the left top corner of the printable area of page.

On the Macintosh, using a page setup scale of 50% multiplies all of these dimensions by 2.

magnification

Sets V_Value exactly the same way that expand does.

Added in Igor Pro 7.00.

maximize

Sets V_Value to 1 if the window is maximized, 0 otherwise. On Macintosh, V_Value is always 0.

needUpdate

Sets V_Value to 1 if window or subwindow is marked as needing an update.

note

Copies window note to S_value.

psize

Reads graph plot area dimensions (where the traces are) into V_left, V_right, V_top, and V_bottom in local coordinates. Dimensions are in points.

psizeDC

Same as psize but dimensions are in device coordinates (pixels).

sizeLimit

Returns the size limits imposed on a window via SetWindow sizeLimit in the V_minWidth, V_minHeight, V_maxWidth and V_maxHeight. The values are scaled for screen resolution to the same units as GetWindow wsize, which is points. Very large limits are returned as INF.

The sizeLimit keyword was added in Igor Pro 7.00.

Also returns a sizeLimit status value in V_Value. 0 means no SetWindow sizeLimit command will appear in the window’s recreation macro, usually because no SetWindow sizeLimit command was applied to the window. 1 means a SetWindow sizeLimit command will appear in the window’s recreation macro. -1 means it won’t appear because of conflicts with graph absolute sizing modes.

title

Gets the title (set by as titleStr with NewPanel, Display, etc., or by the Window Control dialog) and puts it into S_value. S_value is set to "" if winName specifies a subwindow. See also the wtitle keyword, below.

userdata

Returns the primary (unnamed) user data for a window in S_value. Use GetUserData to obtain any named user data.

wavelist

Creates a 3 column text wave called W_WaveList containing a list of waves used in the graph in winName. Each wave occupies one row in W_WaveList. This list includes all waves that can be in a graph, including the data waves for contour plots and images.

wbRGB

Another name for backRGB.

Added in Igor Pro 7.00.

wsize

Reads window dimensions into V_left, V_right, V_top, and V_bottom in points from the top left of the screen. For subwindows, values are local coordinates in the host.

wsizeDC

Same as wsize but dimensions are in local device coordinates (pixels). The origin is the top left corner of the host window’s active rectangle.

wsizeOuter

Reads window dimensions into V_left, V_right, V_top, and V_bottom in points from the top left of the screen. Dimensions are for the entire window including any frame and title bar. For subwindows, values are for the host window.
GetWindow

wsizexOuterDC Same as wsizeOuter but dimensions are in local device coordinates (pixels). The origin is the top left corner of the host window’s active rectangle, so V_top will be negative for a window with a title bar. V_left will be negative for windows with a frame; windows on Macintosh OS X have no frame, so V_left will be zero.

wsizexRM Generally the same as wsize, but these are the coordinates that would actually be used by a recreation macro except that the coordinates are in points even if the window is a panel. Also, if the window is minimized or maximized, the coordinates represent the window’s restored location.

On Windows, GetWindow kwFrameOuter wsizeRM returns the pixel coordinates of the MDI frame even when the frame is maximized. wsizeDC returns 2,2,2,2 in this case.

wtitle Gets the actual window title displayed in the window’s title bar, regardless of whether it was set by the user (see the title keyword above) or is the default title created by Igor, and puts it into S_value.

S_value is set to ”” if winName specifies a subwindow.

If winName is kwFrameOuter or kwFrameInner, on Macintosh S_Value is set to the name of the Igor application. On Windows it is set to the full title of the application as seen on the frame’s window, which can be altered using DoWindow/T kwFrame.

Flags
/Z Suppresses error if, for instance, winName doesn’t name an existing window. V_flag is set to zero if no error occurred or to a non-zero error code.

Details

winName can be the title of a procedure window. If the title contains spaces, use:

GetWindow "$Title With Spaces" wsize

However, if another window has a name which matches the given procedure window title, that window’s properties are returned instead of the procedure window.

The wsize parameter is appropriate for all windows.

The gsize, psize, gbRGB, and wavelist parameters are appropriate only for graph windows.

The logicalpapersize, logicalprintablesize and expand/magnification parameters are appropriate for all printable windows except for control panels and Gizmo plots.

Local Coordinates

“Local coordinates” are relative to the top left of the graph area, regardless of where that is on the screen or within the graph window. All dimensions are reported in units of points (1/72 inch) regardless of screen resolution. On the Macintosh, this is the same as screen pixels.

Frame Window Coordinates

kwCmdHist, kwFrameInner, and kwFrameOuter may be used with only the wsize keyword.

On Windows computers, kwFrameInner and kwFrameOuter return coordinates into V_left, V_right, V_top, and V_bottom. On the Macintosh, they always return 0, because Igor has no frame on the Macintosh.

kwFrameOuter coordinates are the location of the outer edges of Igor’s application window, expressed in screen (pixel) coordinates suitable for use with MoveWindow/F to restore, minimize, or maximize the Igor application window.

If Igor is currently minimized, kwFrameOuter returns 0 for all values. If maximized, it returns 2 for all values. Otherwise, the screen (pixel) coordinates of the frame are returned in V_left, V_right, V_top, and V_bottom. This is consistent with MoveWindow/F.

kwFrameInner coordinates, however, are the location of the inner edges of the application window, expressed in Igor window coordinates (points) suitable for positioning graphs and other windows with MoveWindow.

If Igor is currently minimized, kwFrameInner returns the inner frame coordinates Igor would have if Igor were “restored” with MoveWindow/F 1,1,1,1.
GizmoInfo

The Wavelist Keyword

The format of W_WaveList, created with the wavelist keyword, is as follows:

<table>
<thead>
<tr>
<th>Column 1</th>
<th>Column 2</th>
<th>Column 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wave name</td>
<td>partial path to the wave</td>
<td>special ID number</td>
</tr>
</tbody>
</table>

The wave name in column 1 is simply the name of the wave with no path. It may be the same as other waves in the list, if there are waves from different data folders.

The partial path in column 2 includes the wave name and can be used with the $ operator to get access to the wave.

The special ID number in column 3 has the format ##<number>##. A version of the recreation macro for the graph can be generated that uses these ID numbers instead of wave names (see the WinRecreation function). This makes it relatively easy to find every occurrence of a particular wave using a function like strsearch.

Examples

```// These commands draw a red foreground rectangle framing
// the printable area of a page layout window.
GetWindow Layout0 logicalpapersize
DoWindow/F Layout0
SetDrawLayer/K userFront
SetDrawEnv linefgc=(65535,0,0), fillpat=0 // Transparent fill
DrawRect V_left+1, V_top+1, V_right-1, V_bottom-1

// These commands demonstrate the difference between title and wtitle.
Make/O data=x
Display/N=MyGraph data
GetWindow MyGraph title;Print S_Value // Prints nothing (S_Value = "")
GetWindow MyGraph wtitle;Print S_Value // Prints "MyGraph:data"
DoWindow/T MyGraph, "My Title for My Graph"
GetWindow MyGraph title;Print S_Value // Prints "My Title for My Graph"
GetWindow MyGraph wtitle;Print S_Value // Prints "My Title for My Graph"
```

See Also

The SetWindow, GetUserData, MoveWindow and DoWindow operations.

The IgorInfo function.

GizmoInfo

GizmoInfo(nameStr, key)

The GizmoInfo function is used to determine if a particular name is valid and unique as a Gizmo item names.

Documentation for the GizmoInfo function is available in the Igor online help files only. In Igor, execute:

`DisplayHelpTopic "GizmoInfo"`

GizmoPlot

GizmoPlot is a procedure subtype keyword that identifies a macro as being a Gizmo recreation macro. It is automatically used when Igor creates a window recreation macro for a Gizmo plot. See Procedure Subtypes on page IV-199 and Saving and Recreating Graphs on page II-279 for details.

GizmoScale

GizmoScale(dataValue, dimNumber [, gizmoNameStr] )

The GizmoScale function returns a scaled dataValue for the specified dimension. The scaled values are used to position non-data drawing objects in the Gizmo window.

Documentation for the GizmoScale function is available in the Igor online help files only. In Igor, execute:

`DisplayHelpTopic "GizmoScale"`
The gnoise function returns a random value from a Gaussian distribution such that the standard deviation of an infinite number of such values would be $num$.

The random number generator is initialized using the system clock when you start Igor, virtually guaranteeing that you will never get the same sequence twice. If you want repeatable “random” numbers, use `SetRandomSeed`.

The Gaussian distribution is achieved using a Box-Muller transformation of uniform random numbers. The optional parameter `RNG` selects one of two different pseudo-random number generators used to create the uniformly-distributed random numbers used as the input to the Box-Muller transformation. If omitted, the default is 1. The `RNG`'s are:

<table>
<thead>
<tr>
<th>RNG</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Linear Congruential generator by L’Ecuyer with added Bayes-Durham shuffle. The algorithm is described in <em>Numerical Recipes</em> (2nd edition) as the function <code>ran2()</code>. This RNG has nearly $2^{32}$ distinct values and the sequence of random numbers has a period in excess of $10^{18}$.</td>
</tr>
<tr>
<td>2</td>
<td>Mersenne Twister by Matsumoto and Nishimura. It is claimed to have better distribution properties and period of $2^{19937}-1$.</td>
</tr>
</tbody>
</table>

In a complex expression, the gnoise function returns a complex value, as if you had called:

```
cmplx(gnoise(num), gnoise(num))
```

Except for enoise, other noise functions do not have complex implementations.

Details about the Mersene Twister are in:

More information is available online at: <http://en.wikipedia.org/wiki/Mersenne_twister>

### Graph

**Graph**

Graph is a procedure subtype keyword that identifies a macro as being a graph recreation macro. It is automatically used when Igor creates a window recreation macro for a graph. See Procedure Subtypes on page IV-199 and Saving and Recreating Graphs on page II-279 for details.

### GraphMarquee

**GraphMarquee**

GraphMarquee is a procedure subtype keyword that puts the name of the procedure in the graph Marquee menu. See Marquee Menu as Input Device on page IV-157 for details.

### GraphNormal

**GraphNormal**

```
GraphNormal [W=winName]
```

The GraphNormal operation returns the target or named graph to the normal mode, exiting any drawing mode that it may be in.

You would usually enter normal mode by choosing ShowTools from the Graph menu and clicking the crosshair tool.
GraphStyle

GraphStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Graph dialog and in the Graph Macros menu. See Graph Style Macros on page II-279 for details.

GraphWaveDraw

GraphWaveDraw [flags] [yWaveName, xWaveName]

The GraphWaveDraw operation initiates drawing a curve composed of yWaveName vs xWaveName in the target or named graph. The user draws the curve using the mouse, and the values are stored in a pair of waves as XY data.

Normally, you would initiate drawing by choosing ShowTools from the Graph menu and clicking in the appropriate tool rather than using GraphWaveDraw.

Parameters

yWaveName and xWaveName will contain the y and x values of the curve drawn by the user with the mouse.

If yWaveName and xWaveName do not already exist, they are created with two points which are initially set to NaN (Not a Number) and appended to the target.

If yWaveName and xWaveName already exist, an error is generated unless the /O (overwrite) flag is present. If /O is present, the waves are re-created — with two points which are initially set to NaN — and appended to the target if they are not already in it.

If yWaveName and xWaveName are omitted then waves called W_YPoly and W_XPoly are created with two points set to NaN and appended to the target (n is some digit, so Igor might create a wave named W_YPoly0, for example).

Flags

/F[=f] Initiates freehand drawing. In normal drawing, you click where you want a data point. In freehand drawing, you click once and then draw with the mouse button held down. If present, f specifies the smoothing factor. Max value is 8 (which is really slow), min value is 0 (default). The drawing tools use a value of 3 which is the recommended value.

/L/R/B/T Specifies which axes to use (Left, Right, Bottom, Top). Bottom and Left axes are used by default. Can specify free axes using /L=axis name type notation. See AppendToGraph for details. If necessary, the specified axes will be created. If an axis is created its range is set to -1 to 1.

/M Specifies that the curve being edited must be monotonic in the X dimension. The user is not allowed drag points so that they cross horizontally.

/O Overwrites yWaveName and xWaveName if they already exist.

/W=winName Draws in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

Once drawing starts no other user actions are allowed.

In normal mode, drawing stops when you double-click or when you click the first point (in which case the last point is set equal to the first point). When drawing finishes, the edit mode is entered.
GraphWaveEdit

In freehand mode, drawing stops when the mouse is released or when 10000 points have been drawn.
If /O is used and the waves are already on the graph then the first instance on the graph will be used even if they use a different pair of axes than specified.

See Also
The GraphNormal, GraphWaveEdit and DrawAction operations.

GraphWaveEdit

GraphWaveEdit [flags] traceName
The GraphWaveEdit operation initiates editing a wave trace in a graph. The wave trace must already be in
the graph.
Normally, you would initiate editing by choosing ShowTools from the Graph menu and clicking in the
appropriate tool rather than using GraphWaveEdit.

Parameters
traceName is a wave name, optionally followed by the # character and an instance number: “myWave#1” is
the second instance of myWave appended to the graph (“myWave” is the first).
If traceName is omitted then you get to pick the wave trace to edit by clicking it.

Flags

/M       Specifies that the edited trace must be monotonic in the X dimension. You cannot drag
points so that they cross horizontally.
/NI      Suppresses automatic new point insertion when clicking between points.
/T=t     Sets the trace mode.
  t=0: Lines and small square markers (default).
  t=1: User settings unchanged.
/W=winName Edits traces in the named graph window or subwindow. When omitted, action will
affect the active window or subwindow. This must be the first flag specified when
used in a Proc or Macro or on the command line.
When identifying a subwindow with winName, see Subwindow Syntax on page III-92
for details on forming the window hierarchy.

Details
The GraphWaveEdit operation is not multidimensional aware. See Analysis on Multidimensional Waves
on page II-89 for details.

See Also
The GraphNormal, GraphWaveDraw and DrawAction operations.

Trace Names on page II-222, Programming With Trace Names on page IV-86.

Grep

Grep [flags] [srcFileStr] [srcTextWaveName] [ as [destFileOrFolderStr]
[destTextWaveName] ]
The Grep operation copies lines matching a search expression from a file on disk, the Clipboard, or rows
from a text wave to a new or existing file, an existing text wave, the History area, the Clipboard, or to
S_value as a string list.

Source Parameters
The optional srcFileStr can be
• The full path to the file to copy lines from (in which case /P is not needed).
• The partial path relative to the folder associated with pathName.
• The name of a file in the folder associated with pathName.
• “Clipboard” to read lines of text from the Clipboard (in which case /P is ignored).
If Igor cannot determine the location of the source file from `srcFileStr` and `pathName`, it displays a dialog allowing you to specify the source file.

The optional `srcTextWaveName` is the name or path to a text wave.

Only one of `srcFileStr` or `srcTextWaveName` may be specified. If neither is specified then an Open File dialog is presented allowing you to specify a source file.

**Destination Parameters**

The optional `destFileOrFolderStr` can be

- The name of (or path to) an existing folder when `/D` is specified.
- The name of (or path to) a possibly existing file.
- “Clipboard”, in which case the matching lines are copied to the Clipboard (and `/P` and `/D` are ignored).
- The text can be retrieved with the `GetScrapText` function.

If `destFileOrFolderStr` is a partial path, it is relative to the folder associated with `pathName`.

If `/D` is specified, the source file is created inside the folder using the source file name.

If Igor cannot determine the location of the destination file from `pathName`, `srcFileStr`, and `destFileOrFolderStr`, it displays a Save File dialog allowing you to specify the destination file (and folder).

The optional `destTextWaveName` is the name or path to an existing text wave. It may be the same wave as `srcTextWaveName`.

Only one of `destFileOrFolderStr` or `destTextWaveName` may be specified.

If no destination file or text wave is specified then matching lines are printed in the history area, unless the `/Q` flag is specified, in which case the matching lines aren’t printed or copied anywhere (though the output variables are still set).

Use `/LIST` to set `S_value` to a string list containing the matching lines or rows.

Use `/INDX` to create a wave `W_index` containing the zero-based row or line number where matches were found.

**Parameter Details**

If you use a full or partial path for either `srcFileStr` or `destFileOrFolderStr`, see [Path Separators](#) on page III-429 for details on forming the path.

Folder paths should not end with single path separators. See [MoveFolder](#)’s Details section.

**Flags**

/A 
Appends matching lines to the destination file, creating it if necessary, appends text to the Clipboard if the `destFileOrFolderStr` is “Clipboard”, or appends rows to the destination text wave. Has no effect on output to the History area.

/D 
Interprets `destFileOrFolderStr` as the name of (or path to) an existing folder (or directory). Without `/D`, `destFileOrFolderStr` is the name of (or path to) a file. It is ignored if the destination is a text wave, the Clipboard, or the History area.

If `destFileOrFolderStr` is not a full path to a folder, it is relative to the folder associated with `pathName`.

/DCOL={colNum} 
Useful only when the destination is `destTextWaveName`.

Copies matching lines of text from the source file, Clipboard, or `srcTextWaveName` to column `colNum` of `destTextWaveName`, with any terminator characters removed.

The default when the source is a file or the Clipboard is `/DCOL={0}`, which copies matching lines into the first column of `destTextWaveName`.

The default when the source is `srcTextWaveName` is to copy each column of a matched row to the corresponding column in `destTextWaveName`.

/DCOL must be used with the `/A` flag, otherwise the destination wave will have only 1 column.

/DCOL=[[colNum] [, delimStr], …]
Useful only when the source is \texttt{srcTextWaveName} and the destination is a file, the Clipboard, History area, or S_value.

Copies multiple columns in any order from matching rows of \texttt{srcTextWaveName} to the destination file, Clipboard, History area, or S_value.

Construct the line by appending the contents of the numbered column and the \texttt{delimStr} parameters in the order specified. The output line is terminated as described in \textbf{Line Termination}.

\texttt{/E=regExprStr} specifies the Perl-compatible regular expression string. A line must match the regular expression to be copied to the output file. See \textbf{Regular Expressions}.

\emph{Multiple /E flags may be specified}, in which case a line is copied only if it matches every regular expression.

\texttt{/E=[regExprStr, reverse]} specifies the Perl-compatible regular expression string, \texttt{regExprStr}, for which the sense of the match can be changed by \texttt{reverse}.

\texttt{reverse=1: } Matching expressions are taken to \textbf{not} match, and vice versa. For example, use \texttt{/E=\{"CheckBox", 1\}} to list all lines that do not contain “CheckBox”.

\texttt{reverse=0: } Same as \texttt{/E=regExprStr}.

\texttt{/ENCG=textEncoding} specifies the text encoding of named text file. This flag applies if the source is a file and is ignored if the source is the clipboard or a text wave.

See \textbf{Text Encoding Names and Codes} on page III-463 for a list of accepted values for \texttt{textEncoding}.

If you omit \texttt{/ENCG}, Grep uses the default text encoding as specified by the Misc\textemdash{}Text Encoding\textemdash{}Default Text Encoding menu.

Passing 0 for \texttt{textEncoding} acts as if \texttt{/ENCG} were omitted. Passing 255 (binary) for \texttt{textEncoding} is treated as an error because the source text must be internally converted to UTF-8 and there is no valid conversion from binary to UTF-8.

\texttt{/GCOL=grepCol} Greps the specified column of \texttt{srcTextWaveName}, which is a two-dimensional text wave. The default search is on the first column (\texttt{grepCol}=0). Use \texttt{grepCol=-1} to match against any column of \texttt{srcTextWaveName}.

Does not apply if the source is a file or Clipboard.

\texttt{/I} Requires interactive searching even if \texttt{srcFileStr} and \texttt{destFileOrFolderStr} are specified and if the source file exists. Same as \texttt{/I=3}.

\texttt{/I=i} Specifies the degree of file search interactivity with the user.

\texttt{i=0: } Default; interactive only if \texttt{srcFileStr} is not specified or if the source file is missing. Same as if \texttt{/I} were not specified.

\textbf{Note: } This is different behavior than other commands such as \textbf{CopyFile}.

\texttt{i=1: } Interactive even if \texttt{srcFileStr} is specified and the source file exists.

\texttt{i=2: } Interactive even if \texttt{destFileOrFolderStr} is specified.

\texttt{i=3: } Interactive even if \texttt{srcFileStr} is specified, the source file exists, and \texttt{destFileOrFolderStr} is specified.

\texttt{/INDX} Creates in the current data folder an output wave \texttt{W_Index} containing the line numbers (or row numbers) where matching lines were found. If this is the only output you need, also use the \texttt{/Q} flag.
Line Termination

Line termination applies mostly to source and destination files. (The Clipboard and history area delimit lines with CR, and text waves have no line terminators.)

If /T is omitted, Grep will break file lines on any of the following: CR, LF, CRLF, LFCR. (Most Macintosh files use CR. Most Windows files use CRLF. Most UNIX files use LF. LFCR is an invalid terminator but some buggy programs generate files that use it.)

Grep reads whichever of these terminator(s) appear in the source file and use them to write lines to any output file.

The terminator(s) are removed before the line is matched against the regular expression.

For lines that match regExprStr, terminator(s) in the input file are transferred to the output file unless the output is the Clipboard or history area, in which case the output terminator is always only CR (like LoadWave). This means you can transparently handle files that use CR, LF, CRLF, or LFCR as the terminator, and omitting /T will be suitable for most cases.

If you use the /T flag, then Grep will terminate line-from-file reads on the specified character only and will output the specified character into any output file.

“Lines” in One-dimensional Text Waves

Grep considers each row of srcTextWaveName or destTextWaveName to be a “line” of input or output.
When the destination is a file, the Clipboard, or the History area, Grep copies all of the text in a matching row of `srcTextWaveName` to the file and terminates the line. See `Line Termination` for the rules on line terminators.

When the destination is a `destTextWaveName`, Grep simply copies all the text in a matching row to a row in `destTextWaveName`, without adding or omitting any terminators.

“Lines” and Columns in Two-Dimensional Text Waves
Grep by default matches against only the first column (column 0) of each row of `srcTextWaveName`. You can use the `/GCOL=grepCol` flag to specify a different column to match against. Use `/GCOL=-1` to match against any column of `srcTextWaveName`.

When the source is a text wave and the destination is a file, the Clipboard, or the History area, Grep by default copies only the first column (column 0) to the destination.

Use the `/DCOL={colNum1, delimStr1, colNum2, delimStr2,...colNumN}` to print multiple columns (in any order) with delimiters after each column (the last column number need not be followed by a delimiter string). The output line is terminated with CR or `termcharStr` as described in `Line Termination`.

When both the source and destination are text waves and append (/A) is not specified, the destination text wave is redimensioned to have the same number of columns as the source text wave, and all columns of matching rows of `srcTextWaveName` are copied to `destTextWaveName`.

When both the source and destination are text waves and append /A is specified, then the number of columns in `destTextWaveName` is left unchanged, and each column of `srcTextWaveName` is copied to the corresponding column of `destTextWaveName`.

If the destination is a text wave and the source is a file or the Clipboard, each line (without the terminator) is copied to the first column of the destination text wave, or use `/DCOL={destColNum}` to put the text into a different column.

Output Variables
The Grep operation returns information in the following variables. When running in a user-defined function these are created as local variables. Otherwise they are created as global variables in the current data folder.

`V_flag` 0: Output successfully generated.
         -1: User cancelled either the Open File or Save File dialogs.
         Other: An error occurred, such as the specified file does not exist.

`V_value` The number of input lines that matched the regular expression.

`V_startParagraph` Zero-based line number into the file or Clipboard (or the row number of a source text wave) where the first regular expression was matched. Also see the `/INDX` flag.

`S_fileName` Full path to the source file, the source text wave, or “Clipboard”. If an error occurred or if the user cancelled, it is an empty string.

`S_path` Full path to the destination file or destination text wave.
"Clipboard": If `destFileOrFolderStr` was the Clipboard.
"History": If the output was printed to the history area of the window.
"": If an error occurred, if the user cancelled, or if /Q was specified.

`S_value` Contains matching lines as a string list only if /LIST is specified.

Regular Expressions
A regular expression is a pattern that is matched against a subject string from left to right. Most characters stand for themselves in a pattern, and match the corresponding characters in the “subject”.

In the case of Grep, the “subject” is each line of the source file or Clipboard, or each row in the source text wave.

The regular expression syntax supported by Grep, `GreplList`, and `GreplString` is based on the “Perl-Compatible Regular Expression” (PCRE) library.

The syntax is similar to regular expressions supported by various UNIX and POSIX `egrep(1)` commands. See `Regular Expressions` on page IV-170 for more details.
As a trivial example, the pattern “Fred” as specified here:

Grep/P=myPath/E="Fred" "afile.txt" as "FredFile.txt"

matches lines that contain the string “Fred” anywhere on the line.

Character matching is case-sensitive by default, similar to strsearch. Prepend the Perl 5 modifier (?i) to match upper and lower-case versions of “Fred”:

// Copy lines that contain "Fred", "fred", "FRED", "fRd", etc.
Grep/P=myPath/E="(?i)fred" "afile.txt" as "AnyFredFile.txt"

To copy lines that do not match the regular expression, set the /E flag’s reverse parameter:

// Copy lines that do NOT contain "Fred", "fred", "fRd", etc.
Grep/P=myPath/E=/{(?i)fred},1} "afile.txt" as "NotFredFile.txt"

Note: Igor doesn’t use the opening and closing regular expression delimiters that UNIX grep or Perl use: they would have used "/Fred/" and "/(?i)fred/".

Regular expressions in Igor support the expected metacharacters and character classes that make the whole grep paradigm so useful. For example:

// Copy lines that START with a space or tab character
Grep/P=myPath/E=":[ \t]" "afile.txt" as "LeadingTabsFile.txt"

For a complete description of regular expressions, see Regular Expressions on page IV-170, especially for a description of the many uses of the regular expression backslash character (see Backslash in Regular Expressions on page IV-173).

Note: Because Igor Pro also has special uses for backslash (see Escape Sequences in Strings on page IV-15), you must double the number of backslashes you would normally use for a Perl or grep pattern. Each pair of backslashes identifies a single backslash for the Grep command.

For example, to copy lines that contain “\z”, the Perl pattern would be \\z, but the equivalent Grep expression would be /E="\\\\z".

See Backslash in Regular Expressions on page IV-173 for a more complete description of backslash behavior in Igor Pro.

Examples

// Copy lines in afile.txt containing "Fred" (case sensitive)
// to an output file named "AnyFredFile.txt" in the same directory.
Grep/P=myPath/E="Fred" "afile.txt" as "AnyFredFile.txt"

// Copy lines in afile.txt containing "Fred" and "Wilma" (case-insensitive)
// to a text wave (which must exist and is overwritten):
Make/O/N=0/T outputTextWave
Grep/P=myPath/E="(?i)fred"/E="(?i)wilma" "afile.txt" as outputTextWave

// Print lines in afile.txt containing "Fred" and "Wilma" (case-insensitive)
// to the history area
Make/O/N=0/T outputTextWave
Grep/P=myPath/E="(?i)fred"/E="(?i)wilma" "afile.txt"

// Test whether afile.txt contains the word "boondoggle", and if so,
// on which line the first occurrence was found, WITHOUT creating any output.
//
// Note: the \b sequences limit matches to a word boundary before and after
// "boondoggle", so "boondoggles" and "aboondoggle" won't match.
//
Grep/P=myPath/Q/E="(?i)\bBoondoggle\b" "afile.txt"
if( V_value ) // at least one instance was found
  Print "First instance of "boondoggle" was found on line", V_startParagraph
endif

// Create in S_value a string list of the lines as \r - separated list items:
Grep/P=myPath/LIST="\r"Q/E="(?i)\bBoondoggle\b" "afile.txt"
if( V_Value ) // some were found
  Print S_value
endif
// Create in W_index a list of the 0-based line numbers where "boondoggle"
// or "boondoggles", etc was found in afiile.txt.
Grep/P=myPath/INDX/Q/E="(?i)boondoggle" "afile.txt"
if( V_flag == 0 ) // grep succeeded, perhaps none were found; let's see where
    WAVE W_Index // needed if in a function
    Edit W_Index    // show line numbers in a table.
endif

// (Create a string list and text wave for the following examples.)
String list= CTabList() // "Grays;Rainbow;YellowHot;...
Variable items= ItemsInList(list)
Make/O/T/N=(items) textWave= StringFromList(p,list)

// Copy rows of textWave that contain "Red" (case sensitive)
// to the Clipboard as carriage-return separated lines.
Grep/E="Red" textWave as "Clipboard"

// Copy lines of the Clipboard that do NOT contain "Blue"
// (case in-sensitive) back to the Clipboard, overwriting what was there:
Grep/E="(?i)blue",1" Clipboard" as "Clipboard"

// Format matching text wave row to the history area
Grep/E=("Red")/DCOL={"prefix text --- ", 0, " --- suffix text"} textWave
    // Printed output:
    prefix text --- BlueRedGreen --- suffix text
    prefix text --- RedWhiteBlue --- suffix text
    prefix text --- BlueGreen256 --- suffix text
    prefix text --- RedWhiteBlue256 --- suffix text
    prefix text --- Red --- suffix text
    prefix text --- RedWhiteGreen --- suffix text
    prefix text --- BlueBlackRed --- suffix text

// Re-copy rows of textWave that contain "Red" (case sensitive)
// to the Clipboard as carriage-return separated lines.
Grep/E="Red" textWave as "Clipboard"
// Create a 2-column text wave whose column 1 (the second column)
// contains the matching text from the Clipboard
Make/O/N=(0,2)/T outputTextWave
    // GreP with /A to preserve 2 columns of outputTextWave
    Grep/A/E="Red"/GCOL=1/DCOL={1} "Clipboard" as outputTextWave
    Edit outputTextWave

    // Examples with two-dimensional source text waves
    Make/O/T/N=(10, 3) sourceTW= StringFromList(p+10*q,list)
    Edit sourceTW

    // Copy rows of textWave that contain "Red" in column 2 to outputTextWave.
    Make/O/N=0/T outputTextWave
    Grep/E="Red"/GCOL=2 sourceTW as outputTextWave
    Edit outputTextWave

    // Format matching text wave columns to the history area.
    // Match lines that contain "Red" in any column of sourceTW:
    Grep/E=("Red")/GCOL=-1/DCOL={0," ,"," ,",} sourceTW
    // Printed output:
    YellowHot, BlueRedGreen256, Magenta
    BlueHot, RedWhiteBlue256, Yellow
    BlueRedGreen, PlanetEarth256, Copper
    RedWhiteBlue, Terrain256, Gold
    Terrain, Rainbow16, RedWhiteGreen
    Grays256, Red, BlueBlackRed

References
The regular expression syntax supported by Grep, GrepString, and GrepList is based on the PCRE — Perl-Compatible Regular Expression Library by Philip Hazel, University of Cambridge, Cambridge, England. The PCRE library is a set of functions that implement regular expression pattern matching using the same syntax and semantics as Perl 5.
Visit <http://pcre.org/> for more information about the PCRE library.

A helpful web site is: http://www.regular-expressions.info

**See Also**

Regular Expressions on page IV-170 and Symbolic Paths on page II-21.

Demo, CopyFile, PutScrapText, LoadWave operations. The GrepString, GrepList, StringMatch, and CmpStr functions.

**GrepList**

GrepList(\textit{listStr}, \textit{regExprStr} [, \textit{reverse} [, \textit{listSepStr}]]

The GrepList function returns each list item in \textit{listStr} that matches the regular expression \textit{regExprStr}.

- \textit{ListStr} should contain items separated by \textit{listSepStr} which typically is ";".
- \textit{regExprStr} is a regular expression such as is used by the UNIX \texttt{grep(1)} command. It is much more powerful than the wildcard syntax used for ListMatch. See Regular Expressions on page IV-170 for \textit{regExprStr} details.
- \textit{reverse} is optional. If missing, it is taken to be 0. If \textit{reverse} is nonzero then the sense of the match is reversed. For example, if \textit{regExprStr} is "^abc" and \textit{reverse} is 1, then all list items that do not start with “abc” are returned.
- \textit{listSepStr} is optional; the default is ";". In order to specify \textit{listSepStr}, you must precede it with \textit{reverse}.

**Examples**

To list ColorTables containing “Red”, “red”, or “RED” (etc.):

```text
Print GrepList(CTabList(),"(?i)red") // case-insensitive matching
```

To list window recreation commands starting with “\texttt{\textbackslash tCursor}”:

```text
Print GrepList(WinRecreation("Graph0", 0), "^\texttt{\textbackslash tCursor}", 0 , "\texttt{\textbackslash r}")
```

**See Also**

Regular Expressions on page IV-170.

ListMatch, StringFromList, and WhichListItem functions and the Grep operation.

**GrepString**

GrepString(\textit{string}, \textit{regExprStr})

The GrepString function tests \textit{string} for a match to the regular expression \textit{regExprStr}. Returns 1 to indicate a match, or 0 for no match.

**Details**

- \textit{regExprStr} is a regular expression such as is used by the UNIX \texttt{grep(1)} command. It is much more powerful than the wildcard syntax used for StringMatch. See Regular Expressions on page IV-170 for \textit{regExprStr} details.

Character matching is case-sensitive by default, similar to \texttt{strsearch}. Prepend the Perl 5 modifier "(?i)" to match upper and lower-case text

**Examples**

Test for truth that the string contains at least one digit:

```text
if( GrepString(str,\"[0-9]\*\") )
```

Test for truth that the string contains at least one “abc”, “Abc”, “ABC”, etc.:

```text
if( GrepString(str,\"(?i)abc\") ) // case-insensitive test
```

**See Also**

Regular Expressions on page IV-170.

The StringMatch, CmpStr, strsearch, ListMatch, and ReplaceString functions and the Demo and sscanf operations.
GridStyle

GridStyle
GridStyle is a procedure subtype keyword that puts the name of the procedure in the Grid->Style Function submenu of the mover pop-up menu in the drawing tool palette. You can have Igor automatically create a grid style function for you by choosing Save Style Function from that submenu.

GroupBox
GroupBox [/Z] ctrlName [keyword = value [, keyword = value ...]]
The GroupBox operation creates a box to surround and group related controls.
For information about the state or status of the control, use the ControlInfo operation.

Parameters
ctrlName is the name of the GroupBox control to be created or changed.
The following keyword=value parameters are supported:

align=alignment     Sets the alignment mode of the control. The alignment mode controls the interpretation of the leftOrRight parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.
If alignment=0 (default), leftOrRight specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.
If alignment=1, leftOrRight specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

appearance={kind [, platform]}
Sets the appearance of the control. platform is optional. Both parameters are names, not strings.
kind can be one of default, native, or os9.
platform can be one of Mac, Win, or All.
See DefaultGUIControls Default Fonts and Sizes for how enclosed controls are affected by native groupbox appearance.
See Button for more appearance details.

disable=d     Sets user editability of the control.
  d=0: Normal.
  d=1: Hide.
  d=2: Draw in gray state.

cColor=(r,g,b)     Sets color of the title text. r, g, and b are integers from 0 to 65535.

font="fontName"     Sets font used for the box title, e.g., font="Helvetica".

frame=f     Sets frame mode. If 1 (default), the frame has a 3D look. If 0, then a simple gray line is used. Generally, you should not use frame=0 with a title if you want to be in accordance with human interface guidelines.

fsize=s     Sets font size for box title.

fstyle=fs     Sets the font style of the title text. fs is a bitwise parameter with each bit controlling one aspect of the font style for the tick mark labels as follows:
  Bit 0: Bold
  Bit 1: Italic
  Bit 2: Underline
  Bit 4: Strikethrough
See Setting Bit Parameters on page IV-13 for details about bit settings.
GuideInfo

GuideInfo(\textit{winNameStr}, \textit{guideNameStr})

The GuideInfo function returns a string containing a semicolon-separated list of information about the named guide line in the named host window or subwindow.

\textbf{Parameters}

\textit{winNameStr} can be "" to refer to the top host window.

When identifying a subwindow with \textit{winNameStr}, see \textbf{Subwindow Syntax} on page III-92 for details on forming the window hierarchy.

\textit{guideNameStr} is the name of the guide line for which you want information.

\textbf{Details}

The returned string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

The following keywords will be present only for user-defined guides:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>labelBack=(r,g,b) or 0</td>
<td>Sets fill color for the interior. $r$, $g$, and $b$ are integers from 0 to 65535. If not set, then interior is transparent. Note that if a fill color is used, draw objects can not be used because they will be covered up. Also, you will have to make sure the GroupBox is drawn before any interior controls.</td>
</tr>
<tr>
<td>pos=[leftOrRight,top]</td>
<td>Sets the position in pixels of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.</td>
</tr>
<tr>
<td>pos+={dx,dy}</td>
<td>Offsets the position of the box in pixels.</td>
</tr>
<tr>
<td>size={width,height}</td>
<td>Sets box size in pixels.</td>
</tr>
<tr>
<td>userdata(UDName)=UDStr</td>
<td>Sets the unnamed user data to \textit{UDStr}. Use the optional (\textit{UDName}) to specify a named user data to create.</td>
</tr>
<tr>
<td>userdata(UDName)+=UDStr</td>
<td>Appends \textit{UDStr} to the current unnamed user data. Use the optional (\textit{UDName}) to append to the named \textit{UDStr}.</td>
</tr>
<tr>
<td>title=titleStr</td>
<td>Sets title to \textit{titleStr}. Use &quot;&quot; for no title.</td>
</tr>
<tr>
<td>win=winName</td>
<td>Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed. When identifying a subwindow with \textit{winName}, see \textbf{Subwindow Syntax} on page III-92 for details on forming the window hierarchy.</td>
</tr>
</tbody>
</table>

\textbf{Flags}

\(/\mathbf{Z}\) No error reporting.

\textbf{Details}

If no title is given and the width is less than 11 or height is specified as less than 6, then a vertical or horizontal separator line will be drawn rather than a box.

\textbf{Note:} Like TabControls, you need to click near the top of a GroupBox to select it.

\textbf{See Also}

The \textbf{ControlInfo} operation for information about the control. Chapter III-14, \textbf{Controls and Control Panels}, for details about control panels and controls. The \textbf{GetUserData} operation for retrieving named user data.
GuideNameList

**Keyword** | **Information Following Keyword**
---|---
NAME | Name of the guide.
WIN | Name of the window or subwindow containing the guide.
TYPE | The value associated with this keyword is either User or Builtin. A User type denotes a guide created by the DefineGuide operation, equivalent to dragging a new guide from an existing one.
HORIZONTAL | Either 0 for a vertical guide, or 1 for a horizontal guide.
POSITION | The position of the guide in points. This is the actual position relative to the left or bottom edge of the window, not the relative position specified to DefineGuide.

See Also
The GuideNameList, StringByKey and NumberByKey functions; the DefineGuide operation.

GuideNameList

**GuideNameList**(winNameStr, optionsStr)
The GuideNameList function returns a string containing a semicolon-separated list of guide names from the named host window or subwindow.

**Parameters**

*winNameStr* can be "" to refer to the top host window.

When identifying a subwindow with *winNameStr*, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

*optionsStr* is used to further qualify the list of guides. It is a string containing keyword-value pairs separated by commas. Use "" to list all guides. Available options are:

- **TYPE:**
  - type = BuiltIn: List only built-in guides.
  - type = User: List only user-defined guides, those created by the DefineGuide operation or by manually dragging a new guide from an existing one.
- **HORIZONTAL:**
  - h = 0: List only non-horizontal (that is, vertical) guides.
  - h = 1: List only horizontal guides.

**Example**
String list = GuideNameList("Graph0", "TYPE:Builtin,HORIZONTAL:1")

See Also
The DefineGuide operation and the GuideInfo function.

Hanning

**Hanning** waveName [, waveName]...

**Note:** The WindowFunction operation has replaced the Hanning operation.

The Hanning operation multiplies the named waves by a Hanning window (which is a raised cosine function).
You can use Hanning in preparation for performing an FFT on a wave if the wave is not an integral number of cycles long.

The Hanning operation is not multidimensional aware. See Chapter II-6, *Multidimensional Waves*, particularly *Analysis on Multidimensional Waves* on page II-89 for details.

**See Also**

The **WindowFunction** operation implements the Hanning window as well as other forms such as Hamming, Parzen, and Bartlet (triangle).

**ImageWindow, DPSS**

---

### Hash

**Hash**(inputStr, method)

The Hash function returns a cryptographic hash of the data in inputStr.

**Parameters**

- *inputStr* is string of length up to $2^{31}$ bytes. *inputStr* can contain binary or text data.
- *method* is a number indicating the hash algorithm to use:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SHA-256 (SHA-2)</td>
</tr>
<tr>
<td>2</td>
<td>MD4</td>
</tr>
<tr>
<td>3</td>
<td>MD5</td>
</tr>
<tr>
<td>4</td>
<td>SHA-1</td>
</tr>
<tr>
<td>5</td>
<td>SHA-224 (SHA-2)</td>
</tr>
<tr>
<td>6</td>
<td>SHA-384 (SHA-2)</td>
</tr>
<tr>
<td>7</td>
<td>SHA-512 (SHA-2)</td>
</tr>
</tbody>
</table>

Prior to Igor Pro 7.00, only method 1 was supported.

**See Also**

**WaveHash, StringCRC, WaveCRC**

---

### hcsr

**hcsr**(cursorName [, graphNameStr])

The hcsr function returns the horizontal coordinate of the named cursor (A through J) in the coordinate system of the top (or named) graph’s X axis.

**Parameters**

- *cursorName* identifies the cursor, which can be cursor A through J.
- *graphNameStr* specifies the graph window or subwindow.

When identifying a subwindow with *graphNameStr*, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Details**

The X axis used is the one that controls the trace on which the cursor is placed.

**Examples**

Variable xAxisValueAtCursorA = hcsr(A)       // not hcsr("A")
String str="A"
Variable xA= hcsr(str,"Graph0")           // $str is a name, too

**See Also**

The **pcsr, qcsr, vcsr, xcsr, and zcsr** functions.

**Programming With Cursors** on page II-256.
The hermite function returns the Hermite polynomial of order \( n \):

\[
H_n(x) = (-1)^n \exp\left(x^2\right) \frac{d^n}{dx^n} \exp\left(-x^2\right).
\]

The first few polynomials are:

1
2x
4x^2 - 2
8x^3 - 12x

See Also
The \texttt{hermiteGauss} function.

The \texttt{hermiteGauss} function returns the normalized Hermite polynomial of order \( n \):

\[
H_n(x) = \frac{1}{\sqrt{\sqrt{\pi} 2^n n!}} (-1)^n \exp\left(x^2\right) \frac{d^n}{dx^n} \exp\left(-x^2\right).
\]

Here the normalization was chosen such that

\[
\int_{-\infty}^{\infty} e^{-x^2} H_n(x) H_m(x) dx = \delta_{nm},
\]

where \( \delta_{nm} \) is the Kronecker symbol.

You can verify the Hermite-Gauss normalization using the following functions:

Function TestNormalization(order)
    Variable order
    Variable/G theOrder = order
        // The integrand vanishes in double-precision outside [-30,30]
        Print/D Integrate1D(hermiteIntegrand,-30,30,2)
End

Function HermiteIntegrand(inX)
    Variable inX
    NVAR n = root:theOrder
    return HermiteGauss(n,inX)^2*exp(-inx*inx)
End

See Also
The \texttt{hermite} function.

The \texttt{hide} pragma allows you to make a procedure file invisible.
HideIgorMenus

HideIgorMenus [MenuNameStr [, MenuNameStr ] ...]
The HideIgorMenus operation hides the named built-in menus or, if none are explicitly named, hides all built-in menus in the menu bar.

The effect of HideIgorMenus is lost when a new experiment is opened. The state of HideIgorMenus is saved with the experiment.

User-defined menus are not hidden by HideIgorMenus unless attached to built-in menus and the menu definition uses the hideable keyword.

Parameters

MenuNameStr The name of an Igor menu, like “File”, “Data”, or “Graph”.

Details

The optional menu names are in English and not abbreviated. This ensures that code developed for a localized version of Igor will run on all versions.

The built-in menus that can be shown or hidden (the Help menu can be hidden only on Windows) are those that appear in the menu bar:

File Edit Data Analysis Macros Windows Graph
Layout Notebook Panel Procedure Table Misc Help

Hiding a built-in menu to which a user-defined menu is attached results in a built-in menu with only the user-defined items. For example, if this menu definition attaches items to the built-in Graph menu:

Menu "Graph"
  "Do My Graph Thing", ThingFunction()
End

Calling HideIgorMenus "Graph" will still leave a Graph menu showing (when a Graph is the top-most target window) with only the user-defined menu(s) in it: in this example the one “Do My Graph Thing” item.

Hiding the Macros menu hides menus created from Macro definitions like:

Macro MyMacro()
  Print "Hello, world."
End

but does not hide normal user-defined “Macros” definitions like:

Menu "Macros"
  "Macro 1", MyMacro(1)
End

You can set user-defined menus to hide and show along with built-in menus by adding the optional hideable keyword to the menu definition:

Menu "Graph", hideable
  "Do My Graph Thing", ThingFunction()
End

Then HideIgorMenus "Graph" will hide those items, too. If all user-defined Graph menu definitions use the hideable keyword, then no Graph menu will appear in the menu bar.

Some WaveMetrics procedures use the hideable keyword so that only customer-defined menus remain when HideIgorMenus is executed.

See Also

ShowIgorMenus, DoIgorMenu, SetIgorMenuMode, Chapter IV-5, User-Defined Menus
HideInfo

HideInfo  [/W=winName]
The HideInfo operation removes the info panel from a graph if it was previously shown by the ShowInfo operation.

Flags
/W=winName  Hides the info panel in the named window.

See Also
The ShowInfo operation.
Programming With Cursors on page II-256.

HideProcedures

HideProcedures
The HideProcedures operation hides all procedure windows without closing or killing them.

See Also
The DisplayProcedure and DoWindow operations.

HideTools

HideTools  [/A/W=winName]
The HideTools operation hides the tool palette in the top graph or control panel if it was previously shown by the ShowTools operation.

Flags
/A  Sizes the window automatically to make extra room for the tool palette. This preserves the proportion and size of the actual graph area.
/W=winName  Hides the tool palette in the named window. This must be the first flag specified when used in a Proc or Macro or on the command line.

winName must be either the name of a top-level window or a path leading to an exterior panel window (see Exterior Control Panels on page III-423).

See Also
The ShowTools operation.

HilbertTransform

The HilbertTransform operation computes the Hilbert transformation of srcWave, which is a real or complex (single or double precision) wave of 1-3 dimensions. The result of the HilbertTransform is stored in destWave, or in the wave W_Hilbert (1D) or M_Hilbert in the current data folder.
The Hilbert transform of a function \( f(x) \) is defined by:

\[
F(t) = \frac{1}{\pi t} \int_{-\infty}^{\infty} \frac{f(x)dx}{x-t}.
\]

Theoretically, the integral is evaluated as a Cauchy principal value. Computationally one can write the Hilbert transform as the convolution:

\[
F(t) = \frac{-1}{\pi t} * f(t),
\]

which by the convolution theorem of Fourier transforms, may be evaluated as the product of the transform of \( f(x) \) with \(-i\)sgn\( (x)\) where:

\[
\text{sgn}(x) = \begin{cases} 
-1 & x < 0 \\
0 & x = 0 \\
1 & x > 0 
\end{cases}
\]

Note that the Hilbert transform of a constant is zero. If you compute the Hilbert transform in more than one dimension and one of the dimensions does not vary (is a constant), the transform will be zero (or at least numerically close to zero).

There are various definitions for the extension of the Hilbert transform to more than one dimension. In two dimensions this operation computes the transform by multiplying the 2D Fourier transform of the input by the factor \(-i\)sgn\( (x)\)(-i)sgn\( (y)\) and then computing the inverse Fourier Transform. A similar procedure is used when the input is 3D.

**Examples**

Extract the instantaneous amplitude and frequency of a narrow-band signal.

Make/O/N=1000 w0,amp,phase
SetScale/I x 0,50,"", w0,amp,phase
w0 = exp(-x/10)*cos(2*pi*x)
HilbertTransform /DEST=w0h w0 // w0+i*w0h is the "analytic signal", i=cmplx(0,1)
amp = sqrt(w0^2 + w0h^2) // extract the envelope
phase = atan2(-w0h,w0) // extract the phase [SIGN CONVENTION?]
Unwrap 2*pi, phase // eliminate the 2*pi phase jumps
Differentiate phase /D=freq // would have less noise if fit to a line
// over interior points
freq /= 2*pi // phase = 2*pi*freq*time
Display w0,amp // original waveform and its envelope; note boundary effects
Display freq // instantaneous frequency estimate, with boundary effects

See Also
The FFT operation.

References

Histogram

Histogram [flags] srcWaveName, destWaveName

The Histogram operation generates a histogram of the data in srcWaveName and puts the result in destWaveName or in W_Histogram or in the wave specified by /DEST.

Parameters
srcWaveName specifies the wave containing the data to be histogrammed.

For historical reasons the meaning and use of destWaveName depend on the binning mode as specified by /B. See Histogram Destination Wave on page V-320 below for details.

Flags

/A Accumulates the histogram result with the existing values in the destination wave instead of replacing the existing values with the result. Assumes /B=2 unless the /B flag is present.

Note: The result will be incorrect if you also use /P.

/B=mode Controls binning:

mode=1: Semi-automatic mode that sets the bin range based on the range of the Y values in srcWaveName. The number of bins is determined by the number of points in the destination wave.

mode=2: Uses the bin range and number of bins determined by the X scaling and number of points in the destination wave.

mode=3: Uses Sturges' method to determine optimal number of bins and redimensions the destination wave as necessary. By this method numBins=1+log2(N)

where N is the number of data points in srcWaveName. The bins will be distributed so that they include the minimum and maximum values.

mode=4: Uses a method due to Scott, which determines the optimal bin width as

binWidth=3.49*σ*N^{-1/3}

where N is the number of data points in srcWaveName and σ is the standard deviation of the distribution. The bins will be distributed so that they include the minimum and maximum values.

method=5: Uses the Freedman-Diaconis method where

binWidth=2*IQR*N^{-1/3}

where IQR is the interquartile distance (see StatsQuantiles) and the bins are evenly distributed between the minimum and maximum values.

/B=[binStart,binWidth,numBins]

Sets the histogram bins from these parameters rather than from destWaveName. Changes the X scaling and length of the destination wave.

/C Sets the X scaling so that X values are in the centers of the bins, which is required when you do a curve fit to the histogram output. Ordinarily, wave scaling of the output wave is set with X values at the left bin edges.
Histogram

/CUM Requests a cumulative histogram in which each bin is the sum of bins to the left. The last bin will contain the total number of input data points, or, with /P, 1.0.

/CUM cannot be used with a weighted histogram (/W flag).

When used with /A, the destination wave must be the result of a histogram created with /CUM.

Note that if you use a binning mode (/B flag) that sets a bin range that does not include the entire range of the input data, then the output will not count all of input points and the last bin will not contain the total number of input points. Input points whose values fall below the left edge of the first bin or above the right edge of the last bin will not be counted.

/DEST=destWave Saves the histogram output in a wave specified by destWave. The destination wave is created or overwritten if it already exists.

Creates a wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-71 for details.

See Histogram Destination Wave on page V-320 below for further discussion.

The /DEST flag was added in Igor Pro 7.00.

/DP Causes Histogram to create the destination wave as double-precision floating point instead of single-precision floating point. The /DP flag was added in Igor Pro 8.00.

Single-precision precisely represents integers up to 16,677,721 only. Double-precision precisely represents integers up to about 9 trillion.

/N Creates a wave (W_SqrtN) containing the square root of the number of counts in each bin. This is an appropriate wave to use as a weighting wave when doing a curve fit to the histogram results.

/NLIN=binsWave Computes a non-linear histogram using the bins specified in the wave binsWave. This option is not compatible with the flags /A, /B, /C, /CUM, /N, /P, /W.

The bins must be contiguous and non-overlapping so that binsWave contains monotonically increasing values with no NaNs and INFs. For example, if you want the 3 bins [1,10),[10,100),[100,1000), execute:

Make/O/N=4 bins=[1,10,100,1000]

The upper end of each bin is open.

The /NLIN flag was added in Igor Pro 7.00.

/P Normalizes the histogram as a probability distribution function, and shifts wave scaling so that data correspond to the bin centers.

When using the results with Integrate, you must use /METH=0 or /METH=2 to select rectangular integration methods.

/R=(startX,endX) Specifies the range of X values of srcWaveName over which the histogram is to be computed.

/R=[startP,endP] Specifies the range of points of srcWaveName over which the histogram is to be computed.

/RMD=[[firstRow,lastRow]][[firstColumn,lastColumn]][[firstLayer,lastLayer]][firstChunk,lastChunk]
Histogram

Designates a contiguous range of data in the source wave to which the operation is to be applied. This flag was added in Igor Pro 7.00.

You can include all higher dimensions by leaving off the corresponding brackets. For example:

/RMD=[firstRow,lastRow]

includes all available columns, layers and chunks.

You can use empty brackets to include all of a given dimension. For example:

/RMD[]= [firstColumn,lastColumn]

means "all rows from column A to column B".

You can use a * to specify the end of any dimension. For example:

/RMD=[firstRow,*]

means "from firstRow through the last row".

/W=weightWave Creates a “weighted” histogram. In this case, instead of adding a single count to the appropriate bin, the corresponding value from weightWave is added to the bin. weightWave may be any number type, and it may be complex. If it is complex, then the destination wave will be complex.

/W cannot be used with a cumulative histogram (/CUM flag).

Histogram Destination Wave

For historical reasons there are multiple ways to specify the destination wave and the meaning and use of destWaveName depend on the binning mode as specified by /B. This section explains the details and then provides guidance and when to use which mode.

In binning modes 1 and 2 (/B=1 and /B=2, described above), the destination wave plays a role in determining the binning and destWaveName must be the name of an existing wave. If you omit /DEST then the output is written to destWaveName. If you provide /DEST then the output is written to the wave specified by /DEST.

In binning modes 3, 4 and 5 (/B=3, /B=4 and /B=5, described above), the destination wave plays no role in determining the binning. If you omit destWaveName and /DEST, Histogram stores its output in a wave named W_Histogram in the current data folder. If you omit /DEST and provide destWaveName, then destWaveName must name an existing wave to which the output is written. If you provide /DEST, you can omit destWaveName. If you provide both /DEST and destWaveName then destWaveName must name an existing wave but the operation ignores it.

Here is the recommended usage:

If you want to use specific binning that you have determined, use /B={binStart,binWidth,numBins}, use /DEST to specify the destination wave, and omit destWaveName. If you provide /DEST then the output is written to the wave specified by /DEST.

If you want Igor to determine the binning, use /B=3, /B=4 or /B=5, use /DEST to specify the destination wave, and omit destWaveName.

For backward compatibility with Igor Pro 6, use /B=1, /B=2, /B=3, /B=4 or /B={binStart,binWidth,numBins}, create a destination wave, use it as destWaveName and omit /DEST.

Details

If you use /B={binStart, binWidth, numBins}, then the initial number of data points in the wave is immaterial since the Histogram operation changes the number of points.

Only one /B and only one /R flag is allowed.

If both /A and /B flags are missing, the bin range and number of bins is calculated as if /B=1 had been specified.

When accumulating multiple histograms in one output wave, typically you will want to use /B={binStart,binWidth,numBins} for the first histogram, and /A for successive histograms.

The Histogram operation works on single precision floating point destination waves. If necessary, Histogram/A redimensions the destination wave to be single precision floating point. However, Histogram/A requires that the destination wave already be single precision floating point.
For a weighted histogram, the destination wave will be double-precision. If you specify the range as \(/R=\{\text{start}\}\), then the end of the range is taken as the end of srcWaveName.

In an ordinary histogram, input data is examined one data point at a time. The operation determines which bin a data value falls into and a single count is added to that bin. A weighted histogram works similarly, except that it adds to the bin a value from another wave in which each row corresponds to the same row in the input wave.

The Histogram operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-89 for details. In fact, the Histogram operation can be usefully applied to multidimensional waves, such as those that represent images. The /R flag will not work as expected, however.

Examples

// Create histogram of two sets of data.
Make/N=1000 data1=gnoise(1), data2=gnoise(1)
Make/N=1 histResult
// Sets bins, does histogram.
Histogram/B=\{-5,1,10\} data1, histResult
Display histResult; ModifyGraph mode=5
// Accumulates into existing bins.
Histogram/A data2, histResult

i

i
The i function returns the loop index of the inner most iterate loop in a macro. Not to be used in a function. Iterate loops are archaic and should not be used.
ICA

ICA \([\text{flags}] \ srcWave\)

The ICA operation performs independent component analysis using the FastICA algorithm. Input data is in the form of a 2D wave where each column represents the equivalent of a single data acquisition channel. The results of the operation are stored in the waves M_ICAComponents, M_ICAUnMix and M_matrixW in the current data folder.

The ICA operation was added in Igor Pro 7.00.

Flags

/A\=alpha \(\alpha\) is a constant used as a factor in the argument of the logCosh function. It is not used with the exp function.

\(\alpha\) is in the range [1,2] and its default value is 1.

You will rarely need to change this value to affect the rate of convergence or the quality of the results.

/CF\=num Specifies the contrast function, also called the non-quadratic function, used by ICA.

num\=0: \ logCosh (default)

num\=1: \ exp

/COLS Preconditions the input by subtracting the mean and then normalizing the input on a column-by-column basis. The algorithm appears to converge and produce better results when this flag is used.

/DFLT Use the deflation/vector method where iterations solve for a single vector of the "unmixing" matrix at a time. By default the operation uses the matrix method which solves for the complete unmixing matrix at one time.

/PCA Save the output of the "PCA" stage which is also the form of the data before the fastICA iterations. The data are saved in the wave M_PCA in the current data folder.

/Q Quiet mode; do not print anything in the history.

/TOL\=tolerance The tolerance value is used to determine when iterations converge.

In the deflation/vector method the tolerance measures the difference between the values of vectors in consecutive iterations.

In the matrix method the tolerance measures the average deviation of all components.

By default tolerance = 1e-5 for both methods.

/WINT\=w Provides an initial unmixing matrix W. If you do not provide this matrix the algorithm initializes using enoise.

The wave w must be 2D having the same number type as srcWave and having dimensions nCols x nCols, where nCols is the number of columns of srcWave. Providing an initial matrix is useful if you have obtained one from a previous set of iterations which may have converged using inadequate tolerance.

/Z No error reporting.

Details

srcWave is a 2D wave of nRows by nCols. It must be a single or double precision real-valued wave containing no NaNs or INFs. Each column of srcWave corresponds to a single data acquisition channel that is assumed to consist of a linear superposition of independent components. This can be expressed as a matrix product

\[X=A(S^t)\]

where \(S\) is an nRows by nCols matrix of independent components, \(^t\) denotes the transpose, \(A\) is an nCols by nCols mixing matrix and \(X\) is the "mixed" input. The ICA operation attempts to find the independent components of \(S\) from the transformation.
so that the mutual information between the resulting columns of $S$ is minimized. Since mutual information is not affected by a multiplication of components by scalar constants, the resulting independent components can be specified up to a scalar factor.

The operation uses the FastICA algorithm to compute the independent components.

The algorithm has two available methods for computation. The default is to attempt to evaluate the full $W$ matrix at once. The second method (/DFLT flag) also known as "deflation" computes one row of $W$ at a time. The deflation method might have advantages in cases where there are fewer independent components than there are columns in the input.

Example

```c
// Create the source
Make/O/N=(1000,3) ddd
ddd[0]=sin(2*pi*x/13)
ddd[1]=sin(2*pi*x/17)
ddd[2]=sin(2*pi*x/23)

// Create mixing matrix
Make/O/N=(3,3) AA
AA[0] = {0.291, 0.6557, -0.5439}
AA[1] = {0.5572, 0.3, -0.2}
AA[2] = {-0.1, -0.7, 0.4}

// Do the mixing
MatrixOp/O xx=ddd x AA

// Try the ICA
ICA/DFLT/COLS xx
Wave ICARes
Display M_ICAComponents[0]
Display M_ICAComponents[1]
Display M_ICAComponents[2]
```

if-elseif-endif

In an if-elseif-endif conditional statement, when an expression first evaluates as TRUE (nonzero), then only code corresponding to the TRUE part of that expression is executed, and then the conditional statement is exited. If all expressions evaluate as FALSE (zero) then FALSE part is executed when present. After executing code in any TRUE part or the FALSE part, execution will next continue with any code following the if-elseif-endif statement.

See Also

If-Elseif-Endif on page IV-42 for more usage details.
if-endif

if-endif
    if ( <expression> )
        <TRUE part>
    [else
        <FALSE part>]
endif

An if-endif conditional statement evaluates expression. If expression is TRUE (nonzero) then the code in TRUE part is executed, or if FALSE (zero) then the optional FALSE part is executed.

See Also
If-Else-Endif on page IV-42 for more usage details.

IFFT

IFFT [flags] srcWave

The IFFT operation calculates the Inverse Discrete Fourier Transform of srcWave using a multidimensional fast prime factor decomposition algorithm. This operation is the inverse of the FFT operation.

Output Wave Name
For compatibility with earlier versions of Igor, if you use IFFT without /ROWS or /COLS, the operation overwrites srcWave.

If you use the /ROWS flag, IFFT uses the default output wave name M_RowFFT and if you use the /COLS flag, IFFT uses the default output wave name M_ColFFT.

We recommend that you use the /DEST flag to make the output wave explicit and to prevent overwriting srcWave.

Parameters
srcWave is a complex wave. The IFFT of srcWave is a either a real or complex wave, according to the length and flags.

Flags
/C       Forces the result of the IFFT to be complex. Normally, the IFFT produces a real result unless certain special conditions are detected as described in Details.
/COLS    Computes the 1D IFFT of 2D srcWave one column at a time, storing the results in the destination wave. You must specify a destination wave using the /DEST flag (no other flags are allowed). See the /ROWS flag and corresponding flags of the FFT operation.
/DEST=destWave  Specifies the output wave created by the IFFT operation.
               It is an error to specify the same wave as both srcWave and destWave.
               In a function, IFFT by default creates a real wave reference for the destination wave. See Automatic Creation of WAVE References on page IV-71 for details.
/FREE     Creates destWave as a free wave.
/FREE is allowed only in functions and only if destWave, as specified by /DEST, is a simple name or wave reference structure field.
See Free Waves on page IV-89 for more discussion.
The /FREE flag was added in Igor Pro 7.00.
/R       Forces real output when, due to a power of 2 number of points, IFFT would otherwise automatically produce a complex result.
/ROWS    Calculates the IFFT of only the first dimension of 2D srcWave. It computes the 1D FFT one row at a time. You must specify a destination wave using the /DEST flag (no other flags are allowed). See the /COLS flag and corresponding flags of the FFT operation.
The data type of `srcWave` must be complex and must not be an integer type. You should be aware that an IFFT on a number of points that is prime can be slow.

By default, IFFT assumes you are performing an inverse transform on data that was originally real and therefore it produces a real result. However, for historical and compatibility reasons, IFFT detects the special conditions of a one-dimensional wave containing an integral power of 2 data points and automatically creates a complex result.

When the result is complex, the number of points (N) in the resulting wave will be of the same length. Otherwise the resulting wave will be real and of length (N-1)*2.

In either the complex or real case the X units of the output wave are changed to “s”. The X scaling also is changed appropriately, cancelling out the adjustments made by the FFT operation. When the data is multidimensional, the same considerations apply to the additional dimensions. The scaling description and IDFT equation below pretend that the IFFT is not performed in-place. After computing the IFFT values, the X scaling of `waveOut` is changed as if Igor had executed these commands:

```plaintext
Variable points // time-domain points, N_{timeDomain}
if( waveIn was complex wave )
    points= numpnts(waveIn)
else // waveIn was real wave
    points= (numpnts(waveIn) - 1) * 2
endif
Variable deltaT= 1 / (points*deltaX(waveIn)) // 1/(N_{timeDomain}dx)
SetScale/P waveOut 0,deltaT,"s"
```

The IDFT equation is:

\[
waveOut[n] = \frac{1}{N} \sum_{k=0}^{N-1} waveIn[k] \exp \left( \frac{2\pi i kn}{N} \right), \quad \text{where} \quad i = \sqrt{-1}.
\]

**IgorInfo**

**IgorInfo(selector)**
The IgorInfo function returns information about the Igor application and the environment in which it is running.

**Details**

*selector* is a number from 0 to 6.

Always pass 0, 1, 2, 3, 4, 5, 6 or 7 as the input parameter. In future versions of Igor Pro, this parameter may request other kinds of information.

If *selector* is 0, IgorInfo returns a collection of assorted information. The result string contains five kinds of information. Each group is prefaced by a keyword and a colon, and terminated with a semicolon.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword For IgorInfo(0)</th>
</tr>
</thead>
<tbody>
<tr>
<td>FREEMEM</td>
<td>The amount of free memory available to Igor.</td>
</tr>
<tr>
<td>PHYSMEM</td>
<td>The amount of total physical memory available to Igor. Added in Igor Pro 7.00.</td>
</tr>
</tbody>
</table>
If selector is 1, IgorInfo returns the name of the current Igor experiment.

If selector is 2, IgorInfo returns the name of the current platform: “Macintosh” or “Windows”.

If selector is 3, IgorInfo returns a collection of more detailed information about the operating system, localization information, and the actual file version of the Igor executable. The keywords are OS, OSVERSION, LOCALE, and IGORFILEVERSION.

If selector is 4, IgorInfo returns the name of the current processor architecture. Currently this is always “Intel”.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

On Macintosh, the version number is a floating point number with a possible suffix. Igor Pro 7.00, for example, returns “7.00”. Igor Pro 8.01 Beta 1 returns “8.01B01”.

On Windows, the version format is a period-separated list of four numbers. Igor Pro 7.02 returns “7.0.2.X” where X is a subminor revision number. A revision to Igor Pro 7.02 would be indicated in the last digit, such as “7.0.2.12”.

On Windows, this might be “Windows 10 Home”. The actual build number and format of the text will vary with the operating system.

On Macintosh, this is something like “10.13.1”.

On Windows, this is something like “6.3.16299”.

On Windows, this might be “Windows 10 Home”. The actual build number and format of the text will vary with the operating system.
If `selector` is 5, `IgorInfo` returns, as a string, the serial number of the program if it is registered or "_none_" if it isn't registered. Use `str2num` to store the result in a numeric variable. `str2num` returns NaN if the program isn't registered.

If `selector` is 6, `IgorInfo` returns, as a string, the version of the Qt library under which Igor is running, for example "5.9.4". This selector value was added in Igor Pro 7.00.

If `selector` is 7, `IgorInfo` returns, as a string, the name of the current user. This selector value was added in Igor Pro 7.00.

If `selector` is 8, `IgorInfo` returns, as a string, the group of the current user on Macintosh. On Windows, an empty string is always returned. This selector value was added in Igor Pro 8.00.

If `selector` is 9, `IgorInfo` returns "admin" if Igor's process is being run as an administrator (Windows) or if the user that started Igor’s process is an administrator (Macintosh). Otherwise it returns "". This selector value was added in Igor Pro 8.00.

If `selector` is 10, `IgorInfo` returns a semicolon-separated list containing the names of activated XOPs. This selector value was added in Igor Pro 8.00.

**Examples**

```
Print NumberByKey("NSCREENS", IgorInfo(0)) // Number of active displays
Function RunningWindows()
    String platform = UpperStr(IgorInfo(2))
    Variable pos = strsearch(platform,"WINDOWS",0)
    return pos >= 0
End
```

**IgorVersion**

```
#pragma IgorVersion = versNum
```

When a procedure file contains the directive, `#pragma IgorVersion=versNum`, an error will be generated if `versNum` is greater than the current Igor Pro version number. It prevents procedures that use new features added in later versions from running under older versions of Igor in which these features are missing. However, this version check is limited because it does not work with versions of Igor older than 4.0.

**See Also**

The [The IgorVersion Pragma](#) on page IV-54 and `#pragma`.

**IgorVersion**

The `IgorVersion` function returns version number of the Igor application as a floating point number. Igor Pro 8.00 returns 8.00, as does Igor Pro 8.00A.

**Details**

You can use `IgorVersion` in conditionally compile code expressions, which can be used to omit calls to new Igor features or to provide backwards compatibility code.

```
#if (IgorVersion() >= 8.00)
    [Code that compiles only on Igor Pro 8.00 or later]
#else
    [Code that compiles only on earlier versions of Igor]
#endif
```

If at all possible, it is better to require your users to use a later version of Igor rather than writing conditional code. Attempting this kind of backward-compatibility multiplies your testing requirements and the chances for bugs.

**See Also**

`IgorInfo`, [Conditional Compilation](#) on page IV-106, The [IgorVersion Pragma](#) on page IV-54

**ilim**

The `ilim` function returns the ending loop count for the inner most iterate loop. **Not to be used in a function. Iterate loops are archaic and should not be used.**
**imag**

`imag(z)`

The `imag` function returns the imaginary component of the complex number `z` as a real (not complex) number.

**See Also**

The `cmplx`, `conj`, `p2rect`, `r2polar`, and `real` functions.

**ImageAnalyzeParticles**

**ImageAnalyzeParticles [flags] keyword imageMatrix**

The `ImageAnalyzeParticles` operation performs one of two particle analysis operations on a 2D or 3D source wave `imageMatrix`. The source image wave must be binary, i.e., an unsigned char format where the particles are designated by 0 and the background by 255 (the operation will produce erroneous results if your data uses the opposite designation). Note that all nonzero values in the source image will be considered part of the background. Grayscale images must be thresholded before invoking this operation (you may need to use the `/I` flag with the `ImageThreshold` operation).

**Note:** `ImageAnalyzeParticles` does not take into account wave scaling. All image metrics are in pixels and all pixels are assumed to be square.

**Parameters**

- **keyword** is one of the following names:
  - `mark`: Creates a masking image for a single particle, which is specified by an internal (seed) pixel using the `/L` flag. The masking image is stored in the wave `M_ParticleMarker`, which is an unsigned char wave. All points in `M_ParticleMarker` are set to 64 (image operations on binary waves use the value 64 to designate the equivalent of NaN) except points in the particle which are set to the 0. This wave is designed to be used as an overlay on the original image (using the `explicit=1` mode of `ModifyImage`). This keyword is superseded by the `ImageSeedFill` operation.
  - `stats`: Measures the particles in the image. See `ImageAnalyzeParticles Stats` on page V-332 for details.

**Flags**

- **/A=minArea**: Specifies a minimum area as a threshold that must be exceeded for a particle to be counted (e.g., use `minArea=0` to find single pixel particles). The minimum area is measured in pixels; its default value is `minArea=5`.

  When the source wave is 3D, `minArea` specifies the minimum number of voxels that constitute a particle.

  `/A` has no effect when used with the `mark` method.

- **/B**: Erases a 1 pixel wide frame inset from the boundary. This insures that no particles will have boundary pixels (see `/EBPC` below) and all boundary waves will describe close contours.

- **/CIRC={minCircularity,maxCircularity}**: Use this flag to filter the output so that only particles in the range of the specified circularity are counted.

- **/D=dataWave**: Specify a wave from which the minimum, maximum, and total particle intensity are sampled when used with the `stats` keyword. `dataWave` must be of the same dimensions as the input binary image `imageMatrix`. It can be of any real numeric type. Results are returned in the waves `W_IntMax`, `W_IntMin`, and `W_IntAvg`.

V-330
Calculates an ellipse that best fits each particle. The equivalent ellipse is calculated by first finding the moments of the particle (i.e., average x-value, average y-value, average $x^2$, average $y^2$, and average $x*y$), and then requiring that the area of the ellipse be equal to that of the particle. The resulting ellipses are saved in the wave M_Moments. When imageMatrix is a 2D wave, the results returned in M_Moments are the columns: the X-center of the ellipse, the Y-center of the ellipse, the major axis, the minor axis, and the angle (radians) that the major axis makes with the X-direction. When imageMatrix is a 3D wave, the results in M_Moments include the sum of the X, Y, and Z components as well as all second order permutations of their products. They are arranged in the order: sumX, sumY, sumZ, sumXX, sumYY, sumZZ, sumXY, sumXZ, and sumYZ.

Use this flag to exclude from counting any particle that has one or more pixels on any boundary of the image.

Fills 2D particles having internal holes and adjusts their area measure for the removal of holes. Internal boundaries around the holes are also eliminated. When the boundary of the particle consists of thin elements that cannot be traversed as a single closed path which passes each boundary pixel only once, the particle will not be filled. Note that filling particles may increase execution time considerably and on some images it may require large amount of memory. It is likely that a more efficient approach would be to preprocess the binary image and remove holes using morphology operations. This flag is not supported when imageMatrix is a 3D wave.

Use /FILL to fill holes inside particles. The reported values of area and perimeter are computed as if there are no holes. The filling algorithm could fail if, for example, there is a closed contour of zeros around the particles.

If you specify both /F and /FILL the operation used /FILL only.

Added in Igor Pro 7.00.

Specifies a 2D particle location in connection with the mark method. (row, col) is a seed value corresponding to any pixel inside the particle. If the seed belongs to the particle boundary, the particle will not be filled. This flag is not supported when imageMatrix is a 3D wave.

Use this flag with the stats mode for 2D images. See stats keyword for a full description of the following waves:

- markerVal=0: No marker waves.
- markerVal=1: M_ParticlePerimeter.
- markerVal=2: M_ParticleArea.
- markerVal=3: M_Particle.

This flag does not apply to 3D waves.

Specifies an upper limit of the area of an acceptable particle when used with the stats keyword. The area is measured in pixels and the default value of maxArea is the number of pixels in the image. In 3D the maximum value applies to the number of voxels.

Creates the marker wave (see /M flag) but not the particle statistics waves when used with the stats keyword. This should reduce execution time in images containing many particles.

Specifies the plane when operating on a single layer of a 3D wave.
Particle analysis is accomplished by first converting the data from its original format into a binary representation where the particle is designated by zero and the background by any nonzero value. The algorithm searches for the first pixel or voxel that belongs to a particle and then grows the particle from that seed while keeping count of the area, perimeter and count of pixels or voxels in the particle. If you use additional flags, the algorithm must compute additional quantities for each pixel or voxel belonging to the particle.

If your goal is to mask only the particle, a more efficient approach is to use the ImageSeedFill operation, which similarly follows the particle but does not spend processing time on computing unrelated particle properties. ImageSeedFill also has the additional advantage of not requiring that the input wave be binary, which will save time on performing the initial threshold and, in fact, may produce much better results with the adaptive/fuzzy features that are not available in ImageAnalyzeParticles.

ImageAnalyzeParticles Stats
The ImageAnalyzeParticles stats keyword measures the particles in the image. Results of the measurements are reported for all particles whose area exceeds the minArea specified by the /A flag. The results of the measurements are:

- **V_NumParticles**: Number of particles that exceed the minArea limit.
- **W_ImageObjArea**: Area (in pixels) for each particle.
- **W_ImageObjPerimeter**: Perimeter (in pixels) of each particle. The perimeter calculation involves estimates for 45-degree pixel edges resulting in noninteger values.
V-333

One of the following waves can be created depending on the /M specification. The waves are designed to be used as an overlay on the original image (using the explicit=1 mode of ModifyImage). Note: the additional time required to create these waves is negligible compared with the time it takes to generate the stats data.

When imageMatrix is a 3D wave, the different results are packed into a single 2D wave M_3DParticleInfo, which consists of one row and 11 columns for each particle. Columns are arranged in the following order: minRow, maxRow, minCol, maxCol, minLayer, maxLayer, xSeed, ySeed, zSeed, volume, and area. Use Edit M_3DParticleInfo.ld to display the results in a table with dimension labels describing the different columns.

Examples

Convert a grayscale image (blobs) into a proper binary input:
ImageThreshold/M=4/Q/I blobs

Get the statistics on the thresholded image of blobs and create an image mask output wave for the perimeter of the particles:
ImageAnalyzeParticles/M=1 stats M_ImageThresh

Display an image of the blobs with a red overlay of the perimeter image:
NewImage/F blobs; AppendImage M_ParticlePerimeter
ModifyImage M_ParticlePerimeter explicit=1, eval={0,65000,0,0}

The ImageThreshold, ImageGenerateROI, ImageSeedFill, and ModifyImage operations. For more usage details see Particle Analysis on page III-356.
ImageBlend

ImageBlend

ImageBlend [/A=alpha /W=alphaWave] srcWaveA, srcWaveB [, destWave]
The ImageBlend operation takes two RGB images (3D waves) in srcWaveA and srcWaveB and computes the alpha blending so that

destWave = srcWaveA * (1 - alpha) + srcWaveB * alpha

for each color component. If destWave is not specified or does not already exist, the result is saved in the current data folder in the wave M_alphaBlend.

The source and destination waves must be of the same data types and the same dimensions. The alphaWave, if used, must be a single precision (SP) float wave and it must have the same number of rows and columns as the source waves.

Flags

/A=alpha Specifies a single alpha value for the whole image

/W=alphaWave Single precision wave that specifies an alpha value for each pixel.

See Also

ImageComposite

ImageBoundaryToMask

ImageBoundaryToMask width=w, height=h, xwave=xwavename, ywave=ywavename [, scalingWave=scalingWaveName, [seedX=xVal, seedY=yVal]]
The ImageBoundaryToMask operation scan-converts a pair of XY waves into an ROI mask wave.

Parameters

height = h Specifies the mask height in pixels.

scalingWave = scalingWaveName 2D or 3D wave that provides scaling for the mask. If specified, the scaling of the first two dimensions of scalingWave are copied to M_ROIMask, and both the X and Y waves are assumed to describe pixels in the scaled domain.

seedX = xVal Specifies seed pixel location. The operation fills the region defined by the seed and the boundary with the value 1. Background pixels are set to zero. Requires seedY.

seedY = yVal Specifies seed pixel location. The operation fills the region defined by the seed and the boundary with the value 1. Background pixels are set to zero. Requires seedX.

width = w Specifies the mask width in pixels.

xwave = xwavename Name of X wave for mask region.

ywavename Name of Y wave for mask region.

Details

ImageBoundaryToMask generates an unsigned char 2D wave named M_ROIMask, of dimensions specified by width and height. The wave consists of a background pixels that are set to 0 and pixels representing the mask that are set to 1.

The x and y waves can be of any type. However, if the waves describe disjoint regions there must be at least one NaN entry in each wave corresponding to the discontinuity, which requires that you use either single or double precision waves. The values stored in the waves must correspond to zero-based integer pixel values.

If the x and y waves include a vertex that lies outside the mask rectangle, the offending vertex is moved to the boundary before the associated line segment is scan converted.
If you want to obtain a true ROI mask in which closed regions are filled, you can specify the seedX and seedY keywords. The ROI mask is set with zero outside the boundary of the domain and 1 everywhere inside the domain.

**Examples**

```plaintext
Make/O/N=(100,200) src=gnoise(5) // create a test image
SetScale/P x 500,1,"", src;DelayUpdate // give it some funny scaling
SetScale/P y 600,1,"", src
Display; AppendImage src
Make/O/N=201 xxx,yyy // create boundary waves
xxx=550+25*sin(p*pi/100) // representing a close ellipse
yyy=700+35*cos(p*pi/100)
AppendToGraph yyy vs xxx
Now create a mask from the ellipse and scale it so that it will be appropriate for src:
ImageBoundaryToMask ywave=yyy,xwave=xxx,width=100,height=200,scalingwave=src
To generate an ROI masked filled with 1 in a region defined by a seed value and the boundary curves:
ImageBoundaryToMask
  ywave=yyy,xwave=xxx,width=100,height=200,scalingwave=src,seedx=550,seedy=700
```

**See Also**
The ImageAnalyzeParticles and ImageSeedFill operations. For another example see Converting Boundary to a Mask on page III-359.

**ImageComposite**

ImageComposite [/Z /FREE /DEST=destWave] srcImageA, srcImageB

The ImageComposite operation creates a new image by combining srcImageA and srcImageB subject to one of 12 Porter-Duff compositing modes.

The ImageComposite operation was added in Igor Pro 8.00.

**Flags**

- **/AALP=aWave** Specifies a 2D single-precision wave as the alpha associated with srcImageA. Alpha values are in the range 0 (transparent) to 1 (opaque).
- **/ACON=a1** Specifies a single alpha value for the whole srcImageA. a1 is in the range 0 (transparent) to 1 (opaque).
- **/BALP=aWave** Specifies a 2D single-precision wave as the alpha associated with srcImageB. Alpha values are in the range 0 (transparent) to 1 (opaque).
- **/BCON=a1** Specifies a single alpha value for the whole srcImageB. a1 is in the range 0 (transparent) to 1 (opaque).
- **/DEST=destWave** Specifies the wave to hold the composite image. If you omit /DEST the operation stores the image in the wave M_ImageComposite in the current data folder.
- **/FREE** Creates output wave as free waves.
  /FREE is permitted in user-defined functions only, not from the command line or in macros.
  If you use /FREE then destWave must be simple name, not a path.
- **/NMOD=mode** Selects one of the 12 Porter-Duff compositing modes. mode is a value from 1 to 12. The default is mode=4 corresponding to "A over B". See Compositing Modes on page V-336.
- **/OUT=layers** Specifies the number of layers of the output image. Valid values are 3 (RGB) or 4 (RGBA). By default the operation creates an RGB image.
- **/PMA=pmState** Set pmState to 1 if the RGB components in srcImageA are pre-multiplied. Use pmState=0 otherwise. By default srcImageA is assumed to be pre-multiplied. See Pre-multiplication on page V-336.
ImageComposite

/PMB=pmState Set pmState to 1 if the RGB components in srcImageB are pre-multiplied. Use pmStates=0 otherwise. By default srcImageB is assumed to be pre-multiplied. See Pre-multiplication on page V-336.

/Z No error reporting. The operation sets V_Flag to 0 if it succeeds or to an error code otherwise. You can use GetErrMessage to obtain a description of the error.

Pre-multiplication
An RGB value can be raw or pre-multiplied. "Pre-multiplied" means that the red, green, and blue values have been multiplied by normalized alpha values in the range 0 (transparent) to 1 (opaque). ImageComposite operation is faster when working with pre-multiplied values. ImageComposite assumes that your RGB values are pre-multiplied unless you specify otherwise using /PMA=0 and /PMB=0.

Compositing Modes
Here are the 12 compositing modes supported by ImageComposite:

Details
ImageComposite computes an output RGB or RGBA image that result from compositing srcImageA and srcImageB using one of the Porter-Duff compositing modes shown in the table above. The waves srcImageA and srcImageB must have the same number of pixels and the same number type.

Supported number types are: unsigned char, unsigned short, unsigned int, single precision floating point and double precision floating point. When using integer waves expected alpha values are in the range [0,2^N-1] where N is the number of bits of the number type. Floating point waves should include alpha in the range [0,1].

There are three options to specify the alpha associated with each image:
1. The alpha can be expressed as the 4th layer in the wave.
2. The alpha can be specified by a single-precision wave that has the same number of pixels as the image using the /AALP and /BALP flags.
3. The alpha can be specified by a single number in the range [0,1] using the /ACON and /BCON flags.
Options 2 and 3 cannot override an alpha channel that is present in a source wave. To use these options you must delete the alpha channel in the source wave, if any.

Example
Function SetupImageCompositeDemo() // Setup - Create two sample images
Make/O/N=(128,128,4)/B/U imageA=0, imageB=0
imageA[0,64][0]=255
imageA[0,64][3]=128
NewImage/S=0/N=imageAW imageA
imageB[0,64][1]=255
imageB[0,64][3]=128
NewImage/S=0/N=imageBW imageB
AutoPositionWindow/M=0/R=imageAW imageBW
End

Function CompositeAOverB() // Composite A over B
Wave imageA, imageB
ImageComposite/PMA=0/PMB=0/DEST=M_Comp1/NMOD=4 imageA,imageB
NewImage/S=0/N=comp1 M_Comp1
AutoPositionWindow/M=0/R=imageBW
End

Function CompositeAInB() // Composite A in B
Wave imageA, imageB
ImageComposite/PMA=0/PMB=0/DEST=M_Comp2/NMOD=6 imageA,imageB
NewImage/S=0/N=comp2 M_Comp2
AutoPositionWindow/M=0/R=comp1
End

Function RemoveAlphaChannel() // Remove the alpha channel from imageA
Wave imageA
Duplicate/R=[0,2] imageA, imageA_rgb
NewImage/S=0 imageA_rgb
End

ImageEdgeDetection

ImageEdgeDetection [flags] Method imageMatrix
The ImageEdgeDetection operation performs one of several standard image edge detection operations on the source wave imageMatrix.

Unless the /O flag is specified, the resulting image is saved in the wave M_ImageEdges.

The edge detection methods produce binary images on output; the background is set to 0 and the edges to 255. This is due, in most cases to a thresholding performed in the final stage.

Except for the case of marr and shen detectors, you can use the /M flag to specify a method for automatic thresholding; see the ImageThreshold /M flag.

Parameters
Method selects type of edge detection. Method is one of the following names:
canny Canny edge detector uses smoothing before edge detection and thresholding. You can optionally specify the threshold using the /T flag and the smoothing factor using /S.
frei Calculates the Frei-Chen edge operator (see Pratt p. 503) using only the row and column filters.
kirsch Kirsch edge detector (see Pratt p. 509). Performs convolution with 8 masks calculating gradients.
marr Marr-Hildreth edge detector. Performs two convolutions with Laplacian of Gaussian and then detects zero crossings. Use the /S flag to define the width of the convolution kernel.
prewitt Calculates the Prewitt compass gradient filters. Returns the result for the largest filter response.
roberts Calculates the square root of the magnitude squared of the convolution with the Robert’s row and column edge detectors.
ImageEdgeDetection

shen  Shen-Castan optimized edge detector. Supposed to be effective in the presence of noise. The flags that modify this operation are: /F for the threshold ratio (0.9 by default), /S for smoothness factor (0.9 by default), /W for window width (default is 10), /H for thinning factor which by default is 1.

sobel  Sobel edge detector using convolutions with row and column edge gradient masks (see Pratt p. 501).

Flags

/F=fraction  Determines the threshold value for the shen algorithm by starting from the histogram of the image and choosing a threshold such that fraction specifies the portion of the image pixels whose values are below the threshold. Valid values are in the interval (0 < fraction < 1).

/H=thinning  Thins edges when used with shen edge detector. By default the thinning value is 1. Higher values produce thinner edges.

/I  Inverts the output, i.e., sets the edges to 255 and the background to 0.

/M=threshMethod  See the ImageThreshold automatic methods for obtaining a threshold value. Methods 1, 2, 4 and 5 are supported in this operation. If you use threshMethod = -1, threshold is not applied.

If you want to apply your own thresholding algorithm, use /M=6 to bypass the thresholding completely. The wave M_RawCanny contains the result regardless of any other flags you may have used.

/N  Sets the background level to 64 (i.e., NaN)

/O  Overwrites the source image with the output image.

/P=layer  Applies the operation to the specified layer of a 3D wave.

/P was added in Igor Pro 7.00.

/R=roiSpec  Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u). The ROI wave must have the same number of rows and columns as the image wave. The ROI itself is defined by entries/pixels whose values are 0. Pixels outside the ROI can be any nonzero value. The ROI does not have to be contiguous and can be any arbitrary shape. See ImageGenerateROIMask for more information on creating ROI waves.

In general, the roiSpec has the form [roiWaveName, roiFlag], where roiFlag can take the following values:

roiFlag=0: Set pixels outside the ROI to 0.
roiFlag=1: Set pixels outside the ROI as in original image.
roiFlag=2: Set pixels outside the ROI to NaN (=64).

By default roiFlag is set to 1 and it is then possible to use the /R flag using the abbreviated form /R=roiWave.

/S=smoothVal  Specifies the standard deviation or the width of the smoothing filter. By default the operation uses 1. Larger values require longer computation time. In the shen operation the default value is 0.9 and the valid range is (0 < smoothVal < 1).

/T=thresh  Sets a manual threshold for any method above that uses a single threshold. This is faster than using /M.

/W=width  Specifies window width when used in the shen operation. By default width is set to 10 and it is clipped to 49.

Edge Detectors on page III-346 for a number of examples.

References

ImageFileInfo

ImageFileInfo [/P=pathName] fileNameStr
ImageFileInfo is no longer supported and always returns an error.
It is obsolete because it used QuickTime to obtain graphics file information and Apple is phasing out QuickTime.

ImageFilter

ImageFilter [flags] Method dataMatrix
The ImageFilter operation is identical to MatrixFilter, accepting the same parameters and flags, with the exception of the additional features described below.

Parameters
Method selects the filter type. *Method* is one of the following names:

- avg3d  \( n \times n \times n \) average filter for 3D waves.
- gauss3d  \( n \times n \times n \) gaussian filter for 3D waves.
- hybridmedian
  Implements ranking pixel values between two groups of pixels in a 5x5 neighborhood. The first group includes horizontal and vertical lines through the center, the second group includes diagonal lines through the center, and both groups include the center pixel itself. The resulting median value is the ranked median of both groups and the center pixel.
- max3d  \( n \times n \times n \) maximum rank filter for 3D waves.
- median3d  \( n \times n \times n \) median filter for 3D waves where \( n \) must be of the form \( 3^r \) (integer \( r \)), e.g., 3x3x3, 9x9x9 etc. The filter does not change the value of the voxel it is centered on if any of the filter voxels lies outside the domain of the data.
- min3d  \( n \times n \times n \) minimum rank filter for 3D waves.
- point3d  \( n \times n \times n \) point finding filter using normalized \((n^3-1) \ast \text{center-outer}\) for 3D waves.

Flags

- /N=n  Specifies the filter size. By default \( n=3 \). In most situations it will be useful to set \( n \) to an odd number in order to preserve the symmetry in the filters.
- /O  Overwrites the source image with the output image. Used only with the hybridmedian filter, which does not automatically overwrite the source wave.

Details
You can operate on 3D waves using the 3D filters listed above. These filters are extensions of the 2D filters available under MatrixFilter. The avg3d, gauss3d, and point3d filters are implemented by a 3D convolution that uses an averaging compensation at the edges.

This operation does not support complex waves.

See Also
MatrixFilter for descriptions of the other available parameters and flags.
MatrixConvolve for information about convolving your own 3D kernels.

References
**ImageFocus**

The ImageFocus operation creates in focus image(s) from a stack of images that contain in and out of focus regions. It computes the variance in a small neighborhood around each pixel and then takes the pixel value from the plane in which the highest variance is found.

**Flags**

/ED=edepth  Sets the effective depth in planes. For example, an effective depth of one means that it computes the best focus for each plane using a stack of three planes, which includes the current plane and any one adjacent plane above and below it. Does not affect the default method (/METH=0).

/METH=method  Specifies the calculation method.

- method=0: Computes a single plane output for the stack (default).
- method=1: Computes the best image for each plane using /ED.

/Q  Quiet mode; no output to history area.

/Z  No error reporting.

**See Also**

Chapter III-11, *Image Processing* contains links to and descriptions of other image operations.

**ImageFromXYZ**

ImageFromXYZ converts XYZ data to matrix form. You might use it, for example, to convert a "sparse matrix" to an actual matrix for easier display and processing.

You provide the input data in the XYZ triplet xyzWave or in 1D waves xWave, yWave, and zWave. dataMatrix and countMatrix receive output data but you must create them prior to calling ImageFromXYZ.

For each XY location in the input data, ImageFromXYZ adds the corresponding Z value to an element of dataMatrix. The element is determined based on the input XY location and the X and Y scaling of dataMatrix.

For each XY location in the input data, ImageFromXYZ increments the corresponding element of countMatrix. This permits you to obtain an average Z value if multiple input values fall into a given element of dataMatrix.

**Parameters**

- xyzWave is a triplet wave containing the input XYZ data.
- xWave, yWave and zWave are 1D input waves containing XYZ data.
- dataMatrix is a 2D wave to which the Z values are added. It must be either single-precision or double-precision floating point. The X and Y scaling of dataMatrix determines how input values are mapped to output matrix elements.
- countMatrix is a 2D wave the elements of which store the number of Z values added to each corresponding element of dataMatrix. ImageFromXYZ sets it to 32-bit integer if it is not already so.

**Flags**

/AS  If /AS (autoscale) is specified, ImageFromXYZ clears both dataMatrix and countMatrix and sets the X and Y scaling of dataMatrix based on the range of X and Y input values.

**Details**

For each point in the XYZ input data, ImageFromXYZ adds the Z value to the appropriate element of dataMatrix and increments the corresponding element of countMatrix. Normally you will clear dataMatrix and countMatrix before calling it.
You can combine multiple XYZ datasets in one matrix by calling ImageFromXYZ multiple times with different input data and the same `dataMatrix` and `countMatrix`. In this case you would clear `dataMatrix` and `countMatrix` before the first call to ImageFromXYZ only.

What you do with the output is up to you but one technique is to divide `dataMatrix` by `countMatrix` to get the average and then use `MatrixFilter NanZapMedian` to eliminate any NaN values that result from zero divided by zero.

**Example**

Make /N=1000 /O \(wx=enoise(2), wy=enoise(2), wz= \exp(-wx^2+wy^2)\))

Make /O /N=(100,100) dataMat=0
SetScale x,-2,2,dataMat
Duplicate /O dataMat,countMat
ImageFromXYZ /AS \{wx,wy,wz\}, dataMat, countMat

// Execute these one at a time
NewImage dataMat
dataMat /= countMat // Replace cumulative z value with average
MatrixFilter NanZapMedian, dataMat // Apply median filter, zapping NaNs

**See Also**

`SetScale`, `Image X and Y Coordinates` on page II-319.

---

**ImageGenerateROIMask**

ImageGenerateROIMask \([/W=winName/E=e/I=i]\) imageInstance

The ImageGenerateROIMask operation creates a Region Of Interest (ROI) mask for use with other ImageXXX commands. It assumes the top (or `/W` specified) graph contains an image and that the user has drawn shapes using Igor’s drawing tools in a specific manner.

ImageGenerateROIMask creates an unsigned byte mask matrix with the same x and y dimensions and scaling as the specified image. The mask is initially filled with zeros. Then the drawing layer, progFront, in the graph is scanned for suitable fillable draw objects. The area inside each shape is filled with ones unless the fill mode for the shape is set to erase in which case the area is filled with zeros.

**Flags**

/E=e Changes value used for the exterior from the default zero values to \(e\).
/I=i Changes value used for the interior from the default one values to \(i\).
/W=winName Looks for the named graph window or subwindow containing appropriate image masks drawn by the user. If /W is omitted, ImageGenerateROIMask uses the top graph window or subwindow.

When identifying a subwindow with `winName`, see `Subwindow Syntax` on page III-92 for details on forming the window hierarchy.

**Details**

To generate an ROI wave for use with most image processing operations you need to set the values of interior pixels to zero and exterior pixels to one using `/E=1/I=0`.

Suitable objects are those that can be filled (rectangles, ovals, etc.) and which are plotted in axis coordinate mode specified using the same axes by which the specified image instance is displayed. Objects plotted in plot relative mode are also used, However, this is not recommended because it will give correct results only if the image exactly fills the plot rectangle. If you use axis coordinate mode then you can zoom in or out as desired and the resulting mask will still be correct.

Note that the shapes can have their fill mode set to none. This still results in a fill of ones. This is to allow the drawn ROI to be visible on the graph without obscuring the image. However cutouts (fills with erase mode) will obscure the image.

Note also that nonfill drawing objects are ignored. You can use this fact to create callouts and other annotations. In a future version of Igor, we may create a new drawing layer in graphs dedicated to ROIs.

The mask generated is named M_ROIMask and is generated in the current data folder.
Variable V_flag is set to 1 if the top graph contained draw objects in the correct layer and 0 if not. If 0 then the M_ROIMask wave was not generated.

Examples
Make/O/N=(200,400) jack=x*y; NewImage jack; ShowTools
SetDrawLayer ProgFront
SetDrawEnv linefgc=(65535,65535,0),fillpat=0,xcoord=top,ycoord=left,save
DrawRect 63.5,79.5,140.5,191.5
DrawRRect 61.5,206.5,141.5,280.5
SetDrawEnv fillpat= -1
DrawOval 80.5,169.5,126.5,226.5
ImageGenerateROIMask jack
NewImage M_ROIMask
AutoPositionWindow/E

See Also
For another example see Generating ROI Masks on page III-359.

ImageGLCM

ImageGLCM [flags] srcWave
The ImageGLCM operation calculates the gray-level co-occurrence matrix for an 8-bit grayscale image and optionally evaluates Haralick's texture parameters.

The ImageGLCM operation was added in Igor Pro 7.00.

Flags
/D=distance Sets the offset in pixels for which the co-occurrence matrix is calculated. The default value is 1.

/DEST=destGLCM Specifies the wave to hold the co-occurrence matrix. If you omit /DEST the operation stores the matrix in the wave M_GLCM in the current data folder.

/DETP=destParamWave Specifies the wave to hold the computed texture parameters. If you omit /DETP the operation stores the texture parameters in the wave W_TextureParams in the current data folder.

If the destination wave already exists it is overwritten. Note that you must specify the /HTFP flag to compute the texture parameters.

/E=structureBits structureBits is a bitwise setting that lets you control the combination of co-occurrences that you want to compute.

Consider a wave displayed in a table and a pixel at position x

0 3 5
1 x 6
2 4 7

The structureBits corresponding to co-occurrence between x and any direction is simply 2^direction. By default the operation computes all combinations. This is equivalent to structureBits=255.

Note that the structureBits only define directions. The combination of the distance (/D) and the structureBits define the full co-occurrence calculation.

See Setting Bit Parameters on page IV-13 for details about bit settings.
ImageGLCM

/FREE

Creates output waves as free waves.

/FREE is permitted in user-defined functions only, not from the command line or in macros.

If you use /FREE then destGLCM and destParamWave must be simple names, not paths.

See Free Waves on page IV-89 for details on free waves.

/HTFP

Computes Haralick’s texture parameters. See the discussion in the Details section below for more information about the texture parameters.

/P=plane

If the image consists of more than one plane you can use this flag to determine which plane in srcWave is analysed. By default it is plane zero.

/Z

No error reporting.

Details

ImageGLCM computes the co-occurrence matrix for the image in srcWave and optionally evaluates Haralick’s texture parameters. The operation supports 8-bit grayscale images and generates a 256x256 single-precision floating point co-occurrence matrix.

The elements of the matrix P[i][j] are defined as the normalized number of pixels that have a spatial relationship defined by the distance (/D) and the structure (/E) such that the first pixel has gray-level i and the second pixel has gray-level j. The matrix is normalized so that the sum of all its elements is 1.

If you specify the /HTFP flag the operation computes the 13 Haralick texture parameters and stores them sequentially in the destination wave (see /DETP). The wave is saved with dimension labels defining each element. The expressions for the texture parameters are:

\[
\begin{align*}
  f_1 &= \sum_i \sum_j (p[i][j])^2, \\
  f_2 &= \sum_{n=0}^{254} n^2 \left\{ \sum_{i=0}^{255} \sum_{j=0}^{255} p[i][j] \right\}, \\
  f_3 &= \sum_i \sum_j \frac{(i - \mu_x)(j - \mu_y)p[i][j]}{\sigma_x \sigma_y}, \\
  f_4 &= \sum_i \sum_j (i - \mu)^2 p[i][j], \\
  f_5 &= \sum_i \sum_j \frac{1}{1 + (i - j)^2} p[i][j], \\
  f_6 &= \sum_i ip_{x+y}(i),
\end{align*}
\]
\[ f_7 = \sum_i (i - f_6)^2 p_{x+y}(i), \]

\[ f_8 = -\sum_i p_{x+y}(i) \log(p_{x+y}(i)), \]

\[ f_9 = -\sum_i \sum_j p[i][j] \log(p[i][j]), \]

\[ f_{10} = \text{Variance}(p_{x-y}), \]

\[ f_{11} = \sum_i p_{x-y}(i) \log(p_{x-y}(i)), \]

\[ f_{12} = \frac{f_9 - HXY1}{\max(HX,HY)}, \]

\[ f_{13} = \sqrt{1 - \exp(-2(HXY2 - f_9))}. \]

Here

\[ p_x(i) = \sum_j p[i][j], \quad p_y(j) = \sum_i p[i][j], \]

\[ \mu_x = \sum_i ip_x(i), \quad \mu_y = \sum_i ip_y(i), \quad \mu = (\mu_x + \mu_y)/2. \]

\[ \sigma_x = \sqrt{\sum_i (1-\mu_x)^2 p_x(i)}, \quad \sigma_y = \sqrt{\sum_i (1-\mu_y)^2 p_y(i)}, \]

\[ p_{x+y}(k) = \sum_i \sum_j p[i][j], \]

\[ p_{x-y}(k) = \sum_i \sum_{|i-j|=k} p[i][j], \]
There are at least two versions of f7 used in the literature and in software. We know of at least three versions of f14 so ImageGLCM does not compute it.

References

ImageHistModification

ImageHistModification [flags] imageMatrix

The ImageHistModification operation performs a modification of the image histogram and saves the results in the wave M_ImageHistEq. If /W is not specified, the operation is a simple histogram equalization of imageMatrix. If /W is specified, the operation attempts to produce an image with a histogram close to waveName. If /A is specified, the operation performs an adaptive histogram equalization. imageMatrix is a wave of any noncomplex numeric type. Adaptive histogram equalization applies only to 2D waves and the other parts apply to both 2D and 3D waves.

Flags

/A Performs an adaptive histogram equalization by subdividing the image into a minimum of 4 rectangular domains and using interpolation to account for the boundaries between adjacent domains. When the /C flag is specified with contrast factor greater than 1, this operation amounts to contrast-limited adaptive histogram equalization. By default the operation divides the image into 8 horizontal and 8 vertical regions. See /H and /V.

/B=bins Specifies the number of bins used with the /A flag. If not specified, this value defaults to 256.

/C=cFactor Specifies a contrast factor (or clipping value) above which pixels are equally distributed over the whole range. cFactor must be greater than 1, in the limit as cFactor approaches 1 the operation is a regular adaptive histogram equalization. Note: this flag is used only with the /A flag.

/H=hRegions Specifies the number of horizontal subdivisions to be used with the /A feature. Note, the number of image pixels in the horizontal direction must be an integer multiple of hRegions.

/I Extends the standard histogram equalization by using 2^{16} bins instead of 2^8 when calculating histogram equalization. This feature does not apply to the adaptive histogram equalization (/A flag).

/O Overwrites the source image. If this flag is not specified, the resulting image is saved in the wave M_ImageHistEq.

\[
HXY_1 = -\sum_i \sum_j p[i][j] \log(p_x(i)p_y(j)),
\]

\[
HXY_2 = -\sum_i \sum_j p_x(i)p_y(j) \log(p_x(i)p_y(j)),
\]

\[
HX = -\sum_i p_x(i) \log(p_x(i)), \quad HY = -\sum_i p_y(i) \log(p_y(i)).
\]
ImageHistogram

/R=roiSpec
Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u). The ROI wave must have the same number of rows and columns as imageMatrix. The ROI itself is defined by the entries whose values are 0. Regions outside the ROI can take any nonzero value. The ROI does not have to be contiguous and can take any arbitrary shape.

In general, the roiSpec has the form [roiWaveName, roiFlag], where roiFlag can take the following values:
- roiFlag=0: Set pixels outside the ROI to 0.
- roiFlag=1: Set pixels outside the ROI as in original image (default).
- roiFlag=2: Set pixels outside the ROI to NaN (=64).

By default roiFlag is set to 1 and it is then possible to use the /R flag with the abbreviated form /R=roiWave. When imageMatrix is a 3D wave, roiWave can be either a 2D wave (matching the number of rows and columns in imageMatrix) or it can be a 3D wave which must have the same number of rows, columns, and layers as imageMatrix. When using a 2D roiWave with a 3D imageMatrix, the ROI is understood to be defined by roiWave for each layer in the 3D wave.

See ImageGenerateROIWave for more information on creating ROI waves.

/N=vRegions
Specifies the number of vertical subdivisions to be used with the /A flag. The number of image pixels in the horizontal direction must be an integer multiple of vRegions. If the image dimensions are not divisible by the number of regions that you want, you can pad the image using ImageTransform padImage.

/W=waveName
Specifies a 256-point wave that provides the desired histogram. The operation will attempt to produce an image having approximately the desired histogram values. This flag does not apply to the adaptive histogram equalization (/A flag).

See Also
The ImageGenerateROIWave and ImageTransform operations for creating ROIs. For examples see Histograms on page III-353 and Adaptive Histogram Equalization on page III-335.

ImageHistogram

ImageHistogram [flags] imageMatrix

The ImageHistogram operation calculates the histogram of imageMatrix. The results are saved in the wave W_ImageHist. If imageMatrix is an RGB image stored as a 3D wave, the resulting histograms for each color plane are saved in W_ImageHistR, W_ImageHistG, W_ImageHistB.

imageMatrix must be a real-valued numeric wave.

Flags

/I
Calculates a histogram with 65536 bins evenly distributed between the minimum and maximum data values. The operation first finds the extrema and then calculates the bins and the resulting histogram. Data can be a 2D wave of any type including float or double.

/P=plane
Restricts the calculation of the histogram to a specific plane when imageMatrix is a non RGB 3D wave.
The ImageHistogram operation works on images, but it handles both 2D and 3D waves of any data type. Unless you use one of the special features of this operation (e.g., ROI or /P or /I) you could alternatively use the Histogram operation, which computes the histogram for the full wave and includes additional options for controlling the number of bins.

If the data type of imageMatrix is single byte, the histogram will have 256 bins from 0 to 255. Otherwise, the 256 bins will be distributed between the minimum and maximum values encountered in the data. Use the /I flag to increase the number of bins to 65536, which may be useful for unsigned short (/W/U) data.

See ImageGenerateROIMask for more information on creating 2D ROI waves.

/S
Computes the histogram for a whole 3D wave possibly subject to 2D or 3D ROI masking. The /S and /P flags are mutually exclusive.

Details
The ImageHistogram operation works on images, but it handles both 2D and 3D waves of any data type. Unless you use one of the special features of this operation (e.g., ROI or /P or /I) you could alternatively use the Histogram operation, which computes the histogram for the full wave and includes additional options for controlling the number of bins.

If the data type of imageMatrix is single byte, the histogram will have 256 bins from 0 to 255. Otherwise, the 256 bins will be distributed between the minimum and maximum values encountered in the data. Use the /I flag to increase the number of bins to 65536, which may be useful for unsigned short (/W/U) data.

ImageHistModification, ImageGenerateROIMask, JointHistogram, Histograms on page III-353

ImageInfo
ImageInfo(graphNameStr, imageWaveNameStr, instanceNumber)
The ImageInfo function returns a string containing a semicolon-separated list of information about the specified image in the named graph window or subwindow.

Parameters
graphNameStr can be "" to refer to the top graph.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
imageWaveNameStr contains either the name of a wave displayed as an image in the named graph, or an image instance name (wave name with "#n" appended to distinguish the nth image of the wave in the graph). You might get an image instance name from the ImageNameList function.
If imageWaveNameStr contains a wave name, instanceNumber identifies which instance you want information about. instanceNumber is usually 0 because there is normally only one instance of a wave displayed as an image in a graph. Set instanceNumber to 1 for information about the second image of the wave, etc. If imageWaveNameStr is "", then information is returned on the instanceNumberth image in the graph.
If imageWaveNameStr contains an instance name, and instanceNumber is zero, the instance is taken from imageWaveNameStr. If instanceNumber is greater than zero, the wave name is extracted from imageWaveNameStr, and information is returned concerning the instanceNumberth instance of the wave.
The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon for ease of use with StringByKey. The keywords are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>AXISFLAGS</td>
<td>Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.</td>
</tr>
<tr>
<td>COLORMODE</td>
<td>A number indicating how the image colors are derived:</td>
</tr>
<tr>
<td></td>
<td>1: Color table (see Image Color Tables on page II-323).</td>
</tr>
<tr>
<td></td>
<td>2: Scaled color index wave (see Indexed Color Details on page II-330).</td>
</tr>
<tr>
<td></td>
<td>3: Point-scaled color index (See Example: Point-Scaled Color Index Wave on page II-331).</td>
</tr>
<tr>
<td></td>
<td>4: Direct color (see Direct Color Details on page II-331).</td>
</tr>
<tr>
<td></td>
<td>5: Explicit Mode (See ModifyImage explicit keyword).</td>
</tr>
<tr>
<td>RECREATION</td>
<td>Semicolon-separated list of keyword=modifyParameters commands for the ModifyImage command.</td>
</tr>
<tr>
<td>XAXIS</td>
<td>X axis name.</td>
</tr>
<tr>
<td>XWAVE</td>
<td>X wave name if any, else blank.</td>
</tr>
<tr>
<td>XWAVEDF</td>
<td>The full path to the data folder containing the X wave or blank if there is no X wave.</td>
</tr>
<tr>
<td>YAXIS</td>
<td>Y axis name.</td>
</tr>
<tr>
<td>YWAVE</td>
<td>Y wave name if any, else blank.</td>
</tr>
<tr>
<td>YWAVEDF</td>
<td>The full path to the data folder containing the Y wave or blank if there is no Y wave.</td>
</tr>
<tr>
<td>ZWAVE</td>
<td>Name of wave containing Z data used to calculate the image plot.</td>
</tr>
<tr>
<td>ZWAVEDF</td>
<td>The full path to the data folder containing the Z data wave.</td>
</tr>
</tbody>
</table>

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the “;”, prepend “ModifyImage ”, replace the “x” with the name of a image plot (“data#1” for instance) and then Execute the resultant string as a command.

Example 1
This example gets the image information for the second image plot of the wave "jack" (which has an instance number of 1) and applies its ModifyImage settings to the first image plot.

```c
#include <Graph Utility Procs>, version>=6.1 // For WMGetRECREATIONFromInfo

// Make two image plots of the same data on different left and right axes
Make/O/N=(20,20) jack=sin(x/5)+cos(y/4)
Display;AppendImage jack // bottom and left axes
AppendImage/R jack // bottom and right axes

// Put image plot jack#0 above jack#1
ModifyGraph axisEnab(left)={0.5,1},axisEnab(right)={0,0.5}

// Set jack#1 to use the Rainbow color table instead of the default Grays
ModifyImage jack#1 ctab={*,*,Rainbow,0}
```

![Image Plot Example](image.png)
Now we peek at some of the image information for the second image plot of the wave "jack" (which has an instance number of 1) displayed in the top graph:

\[
\text{Print ImageInfo("","jack",1)[69,148]} \quad \text{// Just the interesting stuff}
\]

;ZWAVE:jack;ZWAVEDF:root:;COLORMODE:1;RECREATION:ctab= {*,*,Rainbow,0};plane= 0;

// Apply the color table, etc from jack#1 to jack:
String info= WMGetRECREATIONFromInfo(ImageInfo("","jack",1))
info= RemoveEnding(info) \quad \text{// Remove trailing semicolon}

// Use comma instead of semicolon separators
String text = ReplaceString(";", info, ",")
Execute "ModifyImage jack " + text

Example 2
This example gets the full path to the wave containing the Z data from which the first image plot in the top graph was calculated.

\[
\text{String info= ImageInfo("","",0)} \quad \text{// 0 is index of first image plot}
\]

String pathToZ= StringByKey("ZWAVEDF",info)+StringByKey("ZWAVE",info)
Print pathToZ
root:jack

Image Plots on page II-315.
Image Instance Names on page II-333.

ImageInterpolate

**ImageInterpolate** [flags] **Method srcWave**

The ImageInterpolate operation interpolates the source srcWave and stores the results in the wave M_InterpolatedImage in the current data folder unless you specify a different destination wave using the /DEST flag.
Parameters

*Method* selects type of interpolation. *Method* is one of the following names:

- **Affine2D**
  Performs an affine transformation on *srcWave* using parameters specified by the /APRM flag. The transformation applies to a general combination of rotation, scaling, and translation represented by a 3x3 matrix

\[
M = \begin{bmatrix}
  r_{11} & r_{12} & t_x \\
  r_{21} & r_{22} & t_y \\
  0 & 0 & w
\end{bmatrix}.
\]

The upper 2x2 matrix is a composite of rotation and scaling, *tx* and *ty* are composite translations and *w* is usually 1. It computes the dimensions of the output wave and then uses the inverse transformation and bilinear interpolation to compute the value of each output pixel. When an output pixel does not map back into the source domain it is set to the user-specified background value. It supports 2D and 3D input waves. If *srcWave* is a 3D wave it applies on a layer by layer basis.

The output is stored in the wave M_Affine in the current data folder.

- **/ATOL**
  Allows ImageInterpolate to use a tolerance value if the result of the interpolation at any point is NaN. The algorithm returns the first non-NaN value it finds by adding or subtracting 1/10000th of the size of the X or Y interpolation step. At worst this algorithm is 5 times slower than the default algorithm if the interpolation is performed in a region which is completely outside the convex source domain.

/ATOL was added in Igor Pro 7.00.

- **/CMSH**
  Use this flag in Voronoi interpolation to create a triangle mesh surface representing the input data. After triangulating the X, Y locations (in a plane z=const), the mesh is generated from a sequence of XYZ vertices of all the resulting triangles. The output is stored in the wave M_ScatterMesh in the current data folder. It is in the form of a triplet wave where every consecutive 3 rows represent a disjoint triangle.

If the input contains a NaN or INF in any column, the corresponding row is excluded from the triangulation.

If you want to generate this mesh without generating the interpolated matrix you can omit the /S flag.

/CMSH was added in Igor Pro 7.00.

- **Bilinear**
  Performs a bilinear interpolation subject to the specified flag. You can use either the /F or /S flag, but not both.

- **Kriging**
  Uses Kriging to generate an interpolated matrix from a sparse data set. Kriging calculates interpolated values for a rectangular domain specified by the /S flag. The Kriging parameters are specified via the /K flag.

Kriging is computed globally for a single user-selected variogram model. If there are significant spatial variances within the domain occupied by the data, you should consider subdividing the domain along natural boundaries and use a single variogram model in each subdivision.

If there are N data points, the algorithm first computes the NxN matrix containing the distances between the data and then inverts an associated matrix of similar size to compute the result for the selected variogram model. Because inversion of an NxN matrix can be computationally expensive, you should consider restricting the calculation to regions that are similar to the range implied by the variogram. Such an approach can also be justified in the sense that the local interpolation should not be affected by a remote datum.

**Note:** Kriging does not support data containing NaNs or INFs. Wave scaling has no effect.
### Pixelate

Creates a lower resolution (pixelated) version of \( srcWave \) by averaging the pixels inside domain specified by \(/PXSZ\) flag. The results are saved in the wave \( M_{\text{PixelatedImage}} \) in the current data folder.

The computed wave has the same numeric type as \( srcWave \) so the averaging may be inaccurate in the case of integer waves.

When \( srcWave \) is a 3D wave you have the option of averaging only over data in each layer using \(/PXSZ=\{nx,ny\} \) or averaging over data in a rectangular cube using \(/PXSZ=\{nx,ny,nz\} \).

When not averaging over layers, the number of rows and columns of the new image are obtained by integer division of the original number by the respective size of the averaging rectangle and adding one more pixel for any remainder.

When averaging over layers the resulting rows and columns are obtained by truncated integer division ignoring remainders (if any).

### Resample

Computes a new image based on the selected interpolation function and transformation parameters. Set the interpolation function with the \(/FUNC\) flag. Use the \(/TRNS\) flag to specify transformation parameters for grayscale images, or \(/TRNR, /TRNG, /TRNB\) for the red, green, and blue components, respectively, of RGB images. \( M_{\text{InterpolatedImage}} \) contains the output image in the current data folder.

There are currently two transformation functions: the first magnifies an image and the second applies a radial polynomial sampling. The radial polynomial affects pixels based on their position relative to the image center. A linear polynomial reproduces the same image. Any nonlinear terms contribute to distortion (or correction thereof).

### Spline

Computes a 2D spline interpolation for 2D matrix data. The degree of the spline is specified by the \(/D\) flag.

### Voronoi

Generates an interpolated matrix from a sparse data set (\( srcWave \) must be a triplet wave) using Voronoi polygons. It calculates interpolated values for a rectangular domain as specified by the \(/S\) or \(/RESL\) flags.

It first computes the Delaunay triangulation of \( X, Y \) locations in the \( Z=0 \) plane (assuming that \( X, Y \) positions occupy a convex domain in the plane). It then uses the Voronoi dual to interpolate the \( Z \) values for \( X \) and \( Y \) pairs from the grid defined by the \(/S\) flag. The computed grid may exceed the bounds of the convex domain defined by the triangulation. Interpolated values for points outside the convex domain are set to NaN or the value specified by the \(/E\) flag.

Use the \(/I\) flag to iterate to finer triangulation by subdividing the original triangles into smaller domains. Each iteration increases computation time by approximately a factor of two, but improves the smoothness of the interpolation.

If you have multiple sets of data in which \( X,Y \) locations are unchanged, you can use the \(/STW\) flag to store one triangulation and then use the \(/PTW\) flag to apply the precomputed triangulation to a new interpolation. To use this option you should use the Voronoi keyword first with a triplet wave for \( srcWave \) and set \( xn=x0 \) and \( yn=y0 \). The operation creates the wave \( W_{\text{TriangulationData}} \) that you use in the next triangulation with a 1D wave as \( srcWave \).

Voronoi interpolation is similar to what can be accomplished with the \texttt{ContourZ} function except that it does not require an existing contour plot, it computes the whole output matrix in one call, and it has the option of controlling the subdivision iterations.

See \texttt{Voronoi Interpolation Example} below.

### XYWaves

Performs bilinear interpolation on a matrix scaled using two \( X \) and \( Y \) 1D waves (specified by \(/W\)). The interpolation range is defined by \(/S\). The data domain is defined between the centers of the first and last pixels (\( X \) in this example):

\[
\begin{align*}
\text{xmin} &= \frac{xWave[0] + xWave[1]}{2} \\
\text{xmax} &= \frac{xWave[\text{last}] + xWave[\text{last}-1]}{2}
\end{align*}
\]

Values outside the domain of the data are set to NaN. The interpolation is contained in the \( M_{\text{InterpolatedImage}} \) wave, which is single precision floating point or double precision if \( srcWave \) is double precision.
Warp  Performs image warping interpolation using a two step algorithm with three optional interpolation methods. The operation warps the image based on the relative positions of source and destination grids. The warped image has the same size as the source image. The source and destination grids are each specified by a pair of 2D X and Y waves where the rows and columns correspond to the relative location of the source grid. The smallest supported dimensions of grid waves are 2x2. All grid waves must be double-precision floating point and must have the same number of points corresponding to pixel positions within the image. Grid waves must not contain NaNs or INFs. Wave scaling is ignored.

Flags

/APRM={r11,r12,fx,r21,r22,ty,background}  
Sets elements of the affine transformation matrix and the background value.

/D=splineDeg  
Specifies the spline degree with the Spline method. The default spline degree is 2. Supported values are 2, 3, 4, and 5.

/DEST=destWave  
Specifies the wave to contain the output of the operation. If the specified wave already exists, it is overwritten.

Creates a wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-71 for details.

/E=outerValue  
Assigns outerValue to all points outside the convex domain of the Delaunay triangulation. By default outerValue = NaN.

/F={fx,fy}  
Calculates a bilinear interpolation of all the source data. Here fx is the sampling factor for the X-direction and fy is the sampling factor in the Y-direction. The output number of points in a dimension is factor*(number of data intervals) +1. The number of data intervals is one less than the number of points in that dimension.

For example, if srcWave is a 2x2 matrix (you have a single data interval in each direction) and you use /F={2,2}, then the output wave is a 3x3 matrix (i.e., 2x2 intervals) which is a factor of 2 of the input. Sampling factors can be noninteger values.

/FDS  
Performs spline interpolation to a “local” cubic spline that depends only on the 2D neighboring data. The interpolation goes exactly through the original data and provides continuity of the function and its first derivative. The second derivative is set to vanish on the boundary. The implemented algorithm was provided by Francis Dalaulder. /FDS was added in Igor Pro 7.00.

/FUNC=funcName  
Specifies the interpolation function. funcName can be:

- nn  Nearest neighbor interpolation uses the value of the nearest neighbor without interpolation. This is the fastest function.
- bilinear  Bilinear interpolation uses the immediately surrounding pixels and computes a linear interpolation in each dimension. This is the second fastest function.
- cubic  Cubic polynomial (photoshop-like) uses a 4x4 neighborhood value to compute the sampled pixel value.
- spline  Spline smoothed sampled value uses a 4x4 neighborhood around the pixel.
- sinc  Slowest function using a 16x16 neighborhood.

/I=iterations  
Specifies the number of times the original triangulation is subdivided with the Voronoi interpolation method. By default the Voronoi interpolation computes the original triangulation without subdivision.

/K={model, nugget, sill, range}
Specifies the variogram parameters for kriging using standard notation, models are expressed in terms of the nugget value \( C_0 \), sill value \( C_0 + C_1 \), and range \( a \).

\[
\gamma(h) = C_0 + C_1 \cdot (3h/2a - 0.5 \cdot h^3/a^3)
\]

1: Spherical.

\[
\gamma(h) = C_0 + C_1 \cdot (1 - \exp[-3 \cdot h/a])
\]

2: Exponential.

\[
\gamma(h) = C_0 + C_1 \cdot (1 - \exp[-3 \cdot (h/a)^2])
\]

3: Gaussian.

model Selects the variogram model. Values and models are:

- 1: Spherical.
- 2: Exponential.
- 3: Gaussian.

nugget Specifies the lowest value in the variogram.

sill Specifies the maximum (plateau) value in the variogram range the characteristic length of the different variogram models.

Wave scaling has no effect on kriging calculations.

/PFTL=tol

In Voronoi interpolation, controls the rectangular neighborhood about each datum position XY where the algorithm returns the original Z-value. The tolerance value \( 0 \leq tol < 1 \) is tested separately in X and Y (i.e., it is not a geometric distance) when both X and Y are normalized to the range \([0,1]\). By default \( tol=1\text{e-15}\).

Added in Igor Pro 7.00.

/PTW=tWave

Uses a previous triangulation wave with Voronoi interpolation. \( tWave \) will be the wave saved by the /STW flag. You can’t use a triangulation wave that was computed and saved on a different computer platform.

See PTW Flag Example on page V-355.

/PXSZ=\{nx,ny\}

Specifies the size in pixels of the averaging rectangle used by the Pixelate operation. \( nx \) is the number of rows and \( ny \) is the number of columns that are averaged to yield a single output pixel. If srcWave is a 3D wave the resulting wave has the same number of layers as srcWave with pixelation computed on a layer-by-layer basis.

/PXSZ=\{nx,ny,nz\}

Specifies the size in pixels of the averaging rectangle used by the Pixelate operation. \( nx \) is the number of rows and \( ny \) is the number of columns and \( nz \) is the number of layers that are averaged to yield a single output pixel.

This form of the /PXSZ flag was added in Igor Pro 7.00.

/RESL=\{nx, ny\}

Specifies resampling the full input image to an output image having \( nx \) rows by \( ny \) columns.

/S=\{x0,dx,xn,y0,dy,yn\}

Calculates a bilinear interpolation of a subset of the source data. Here \( x0 \) is the starting point in the X-direction, \( dx \) is the sampling increment, \( xn \) is the end point in the X-direction and the corresponding values for the Y-direction. If you set \( x0 \) equal to \( xn \) the operation will compute the triangulation but not the interpolation.
**ImageInterpolate**

/SPRT Skips the XY perturbation step. The perturbation step is designed to break degeneracies that originate when the XY data are sampled on a rectangular grid. If your data are not sampled on a rectangular grid you can skip the perturbation and get better accuracy in reproducing the Z-values at the sampled locations. See also ModifyContour with the keyword Perturbation.

Added in Igor Pro 7.00.

/STW Saves the triangulation information in the wave W_TriangulationData in the current data folder. W_TriangulationData can only be used on the computer platform where it was created.

/SV Saves the Voronoi interpolation in the 2D wave M_VoronoiEdges, which contains sequential edges of the Voronoi polygons. Edges are separated from each other by a row of NaNs. The outer most polygons share one or more edges with a large triangle containing the convex domain.

/TRNS={transformFunc,p1,p2,p3,p4}

Determines the mapping between a pixel in the destination image and the source pixel. transformFunc can be:

- **scaleShift** Sets image scaling which could be anamorphic if the X and Y scaling are different.
- **radialPoly** Corrects both color as well as barrel and pincushion distortion. In radialPoly the mapping from a destination pixel to a source pixel is a polynomial in the pixel’s radius relative to the center of the image.

A source pixel, sr, satisfies the equation:

\[ sr = ar + br^2 + cr^3 + dr^4, \]

where r is the radius of a destination pixel having an origin at the center of the destination image.

The corresponding parameters are:

<table>
<thead>
<tr>
<th>transformFunc</th>
<th>p1</th>
<th>p2</th>
<th>p3</th>
<th>p4</th>
</tr>
</thead>
<tbody>
<tr>
<td>scaleShift</td>
<td>xOffset</td>
<td>xScale</td>
<td>yOffset</td>
<td>yScale</td>
</tr>
<tr>
<td>radialPoly</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

/U=uniformScale Calculates a bilinear interpolation of all the source data as with the /F flag but with two exceptions: A single uniform scale factor applies in both dimensions, and the scale factor applies to the number of points — not the intervals of the data.

/W={xWave, yWave} Provides the scaling waves for XYWaves interpolation. Both waves must be monotonic and must have one more point than the corresponding dimension in srcWave. The waves contain values corresponding to the edges of data points in srcWave, so that the X value at the first data point is equal to \((xWave[0] + xWave[1]) / 2\).

**Flags for Warp**

/idgrx=wave Sets the wave containing the destination grid X data.

/idgry=wave Sets the wave containing the destination grid Y data.

/sgrx=wave Sets the wave containing the source grid X data.

/sgry=wave Sets the wave containing the source grid Y data.
When computing Bilinear or Spline interpolation, `srcWave` can be a 2D or a 3D wave. When `srcWave` is a 3D wave, the interpolation is computed on a layer by layer basis and the result is stored in a corresponding 3D wave. When the interpolation method is Kriging or Voronoi, `srcWave` is a 2D triplet wave (3-column wave) where each row specifies the X, Y, Z values of a datum. `srcWave` can be of any real data type. Results are stored in the wave `M_InterpolatedImage`. If `srcWave` is double precision so is `M_InterpolatedImage`; otherwise, `M_InterpolatedImage` is a single precision wave.

**Voronoi Interpolation Example**

Function `DemoVoronoiInterpolation()`

```plaintext
Make/O/N=(100,3) sampleTriplet
sampleTriplet[0] = enoise(5)
sampleTriplet[1] = enoise(5)
sampleTriplet[2] = sqrt(sampleTriplet[p][0]^2 + sampleTriplet[p][1]^2)

// Interpolate the data to a rectangular grid of 50x50 pixels
ImageInterpolate/RESL={50,50}/DEST=firstImage voronoi, sampleTriplet

// Triangulate the XY locations and save the triangulation wave
ImageInterpolate/STW voronoi, sampleTriplet

// Use the previous triangulation on the Z column of the sample
MatrixOp/O zData=col(sampleTriplet,2)
Wave W_TriangulationData
ImageInterpolate/PTW=W_TriangulationData/RESL={50,50}/DEST=secondImage voronoi, zData
```

**PTW Flag Example**

Function `DemoPTW()`

```plaintext
// Create some random data
Make/O/N=(100,3) eee = enoise(5)

// Compute triangulation wave
ImageInterpolate/RESL={1,1}/STW voronoi, eee
Wave W_TriangulationData

// Copy the Z-column to a 1D wave
MatrixOp/O e3 = col(eee,2)

// Use the previous triangulation with 1D wave
ImageInterpolate/PTW=W_TriangulationData/RESL={100,100} voronoi, e3
Wave M_InterpolatedImage
Duplicate/O M_InterpolatedImage, oneD

// Direct computation for comparison
ImageInterpolate/RESL={100,100} voronoi, eee

// Display
NewImage M_InterpolatedImage
NewImage oneD
```

**References**

The ImageLineProfile operation provides sampling of a source image along an arbitrary path specified by the two waves: \( xWave \) and \( yWave \). The arbitrary path is made of line segments between every two consecutive vertices of \( xWave \) and \( yWave \). In each segment the profile is calculated at a number of points (profile points) equivalent to the sampling density of the original image (unless the /\( V \) flag is used). Both \( xWave \) and \( yWave \) should have the same scaling as \( srcWave \). If \( srcWave \) does not have the same scaling in both dimensions you should remove the scaling to compute an accurate profile.

At each profile point, the profile value is calculated by averaging samples along the normal to the profile line segment. The number of samples in the average is determined by the keyword width. The operation actually averages the interpolated values at \( N \) equidistant points on the normal to profile line segment, with \( N=2 (width+0.5) \). Samples outside the domain of the source image do not contribute to the profile value.

The profile values are stored in the wave \( W_{\text{ImageLineProfile}} \). The actual locations of the profile points are stored in the waves \( W_{\text{LineProfileX}} \) and \( W_{\text{LineProfileY}} \). The scaled distance measured along the path is stored in the wave \( W_{\text{LineProfileDisplacement}} \).

When the averaging width is greater than zero, the operation can also calculate at each profile point the standard deviation of the values sampled for that point (see /\( S \) flag). The results are then stored in the wave \( W_{\text{LineProfileStdv}} \). When using this operation on 3D RGB images, the profile values are stored in the 3 column waves \( M_{\text{ImageLineProfile}} \) and \( M_{\text{LineProfileStdv}} \) respectively.

**Parameters**

- **srcWave** Specifies the image for which the line profile is evaluated. The image may be a 2D wave of any type or a 3D wave or RGB data.
- **xWave** Specifies the wave containing the x coordinate of the line segments along the path.
- **yWave** Specifies the wave containing the y coordinate of the line segments along the path.
- **width** Specifies the width (diameter) in pixels (need not be an integer value) in a direction perpendicular to the path over which the data is interpolated and averaged for each path point. If you do not specify width or use width=0, only the interpolated value at the path point is used.
- **widthWave** Specifies the width of the profile (see definition above) on a segment by segment basis. \( wWave \) should be a 1D wave that has the same number of entries as \( xWave \) and \( yWave \). If you provide a widthWave any value assigned with the width keyword is ignored. All values in the wave must be positive and finite.

**Flags**

- **P=plane** Specifies which plane (layer) of a 3D wave is to be profiled. By default \( plane = -1 \) and the profiles are of either the single layer of a 2D wave or all three layers of a 3D RGB wave. Use \( plane = -2 \) if you want to profile all layers of a 3D wave.
- **S** Calculates standard deviations for each profile point.
- **SC** Saves \( W_{\text{LineProfileX}} \) and \( W_{\text{LineProfileY}} \) using the X and Y scaling of \( srcWave \).
- **V** Calculate profile points only at the vertices of \( xWave \) and \( yWave \).

**Examples**

```
Make/N=(50,50) sampleData
sampleData = sin((x-25) / 10) * cos((y-25) / 10)
NewImage sampleData
Make/n=2 xTrace={0,50},yTrace={20,20}
ImageLineProfile srcWave=sampleData, xWave=xTrace, yWave=yTrace
AppendtoGraph/T yTrace vs xTrace
Display W_{\text{ImageLineProfile}}
```
See Also
For additional examples see ImageLineProfile Operation on page III-353.

ImageLoad

ImageLoad [flags] [fileNameStr]
The ImageLoad operation loads an image file into an Igor wave. It can load PNG, JPEG, BMP, TIFF, and Sun Raster Files.

Parameters
The file to be loaded is specified by fileNameStr and /P=PathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-429 for details on forming the path.

If you want to force a dialog to select the file, omit the fileNameStr parameter or pass "" for it.

Flags

/AINF Loads all of the image files in a disk folder into the current data folder. For example, if you have created an Igor symbolic path named ImagePath that points to a folder containing image files, you can execute:

ImageLoad/P=ImagePath/T=TIFF/AINF

When using /AINF, you must omit fileNameStr and you must include /T to specify the type of image file to be loaded.

This flag requires Igor Pro 7.03 or later.

/BIGT=mode
When mode is 1, ImageLoad uses the LibTIFF library to load TIFF files. This library supports the traditional TIFF file format and the Big TIFF file format, which supports file sizes greater than 4 GB.

When mode is 0, ImageLoad uses Igor’s internal TIFF code to load image data. This internal code does not support Big TIFF and is limited to file sizes less than 2 GB.

If you omit /BIGT, ImageLoad first attempts to load the file using LibTIFF. If an error occurs, it automatically attempts to load the file using Igor’s internal TIFF code.

The /SCNL, /STRP and /TILE flags require using LibTIFF. If you use any of these flags, /BIGT=1 is automatically in effect.

The /RAT and /RTIO flags require using Igor’s internal TIFF code. If you use these flags, /BIGT=0 is automatically in effect.

/BIGT=1 supports 8, 16, 32, and 64 bits per color component.

/BIGT=0 supports 8, 16, and 32 bits per color component.

/C=count Specifies the number of images to load from a TIFF stack containing multiple images. The images are stored in individual waves if /LR3D is omitted or in a single 3D wave if /LR3D is present.

By default, it loads only a single image (i.e., /C=1). Use /C=-1 to load all images. Images must be either 8 bits, 16 bits, or 32 bits/pixel for this option.

To load a subset of the images in a TIFF stack, use /S to specify the starting image.

If you specify a count that exceeds the number of images in the file, ImageLoad loads all images beginning with the first image or the image specified by /S.

/G Displays the loaded image in a new image plot window.
### ImageLoad

**/LR3D** Specifies that the images in a TIFF stack are to be loaded into a 3D wave rather than into multiple 2D waves. This option works with grayscale images only, not with full color (e.g., RGB).

To load a subset of the images into the 3D wave, also use /S and /C.

**/LTMD** Reads data stored in TIFF tags belonging to the main Image File Directory. /LTMD works only when you use /BIGT=1 and is ignored otherwise. It was added in Igor Pro 8.00.

/LTMD creates a data folder named "Tagn" for each loaded image. The name of the data folder has the numeric suffix n starting from zero.

The "Tagn" data folder contains a text wave named T_Tags where each row contains the metadata associated with a single tag. The order of the rows in the wave T_Tags is indeterminate.

If you need to parse the metadata, you can search for the tag descriptor which always appears at the start of the line and is followed by a colon and one space (": ").

**/N=baseName** Stores the waves using baseName as the wave name. Only when baseName conflicts with an existing wave name will a numeric suffix be appended to the new wave names.

If you omit /N, ImageLoad uses the name of the file as the base name.

**/O** Overwrites an existing wave with the same name.

If you omit /O and there is an existing wave with the same name, a numeric suffix is appended to the image name to create a unique name.

**/P=pathName** Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

**/Q** Quiet mode. Suppresses printing a description of the loaded data to the history area.
/RAT

Read All Tags reads all of the tags in a TIFF file into one or more waves. If you use /RAT, /BIGT=0 is automatically in effect. To load tags with /BIGT=1, use /LTMD instead of /RAT.

/RAT creates a data folder named “Tagn” with a numeric suffix, n, starting from zero for each loaded image. When reading multiple images from a stack TIFF file, /RAT creates a corresponding number of data folders.

Each data folder contains a text wave named T_Tags consisting of 5 columns. The first row contains the offset of the current Image File Directory (IFD) from the start of the file. The remaining rows describe the individual TIFF Tags as they appear in the IFD.

The first column contains the tag number, the second contains the tag description, the third contains the tag type, the fourth contains the tag length, and the fifth contains either the value of the tag or a statement identifying the name of the wave in which the data was stored. For example, a simple tag that contains a single value has the form:

<table>
<thead>
<tr>
<th>Num</th>
<th>Desc</th>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>256</td>
<td>IMAGEWIDTH</td>
<td>4</td>
<td>1</td>
<td>2560</td>
</tr>
</tbody>
</table>

A tag that contains more data, such as an array of values has the form:

<table>
<thead>
<tr>
<th>Num</th>
<th>Desc</th>
<th>Type</th>
<th>Length</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>273</td>
<td>STRIPOFFSETS</td>
<td>4</td>
<td>-120</td>
<td>tifTag273</td>
</tr>
</tbody>
</table>

Here the Length field is negative (-1*realLength) and the Value field contains the name of the wave tifTag273 which contains the array of strip offsets.

When the Value field consists of ASCII characters it is stored in the T_Tags wave itself. All other types are stored in a wave in the same Tag data folder.

Private tags are usually designated by negative tag numbers. If their data type is anything other than ASCII, they are saved in separate waves.

/RTIO

Reads tag information only from a TIFF file. /RTIO is similar to /RAT but it loads tag information only without loading any images.

If you use /RTIO, /BIGT=0 is automatically in effect. To load tags with /BIGT=1, use /LTMD instead of /RAT.

If you are loading a stack of images you can use the /C and /S flags to obtain tags from a specific range of images.

/S=start

Specifies the first image to load from a TIFF stack containing multiple images.

start is zero-based and defaults to 0.

Use /C to specify the number of images to load.

/SCNL=num

Reads the specified scanline from a TIFF file using LibTiff.

Added in Igor Pro 7.00.

/STRP=num

Reads the specified strip from a TIFF file using LibTiff.

Added in Igor Pro 7.00.
ImageLoad

/T=type

Identifies what kind of image file to load. *type* is one of the following image file formats:

<table>
<thead>
<tr>
<th><em>type</em></th>
<th>Loads this Image Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>any</td>
<td>Any graphic file type</td>
</tr>
<tr>
<td>bmp</td>
<td>Windows bitmap file</td>
</tr>
<tr>
<td>jpeg</td>
<td>JPEG file</td>
</tr>
<tr>
<td>png</td>
<td>PNG file</td>
</tr>
<tr>
<td>rpng</td>
<td>Raw PNG file (see <strong>Details</strong>)</td>
</tr>
<tr>
<td>sunraster</td>
<td>Sun Raster file</td>
</tr>
<tr>
<td>tiff</td>
<td>TIFF file (see also <strong>Loading TIFF Files</strong>).</td>
</tr>
</tbody>
</table>

If you omit /T or specify /T=any, Igor makes a guess based on the file name extension. ImageLoad reports an error if it is unable to determine the image file type.

/T=any allows the user to choose any file, regardless of its file name extension, if ImageLoad displays an Open File dialog.

When loading TIFF, we recommend that you use /T=tiff. See **Loading TIFF Files** below for details.

/TILE=num

Reads the specified tile from a TIFF file using LibTiff.

Added in Igor Pro 7.00.

/Z

No error reporting.

**Details**

The name of the wave created by ImageLoad is based on the file name or on *baseName* if you provide the /N=baseName flag. In either case, if and only if there is a name conflict, ImageLoad appends a number to create a unique wave name.

If you use /P=pathname, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See **Symbolic Paths** on page II-21 for details.

**Output Variables**

ImageLoad sets the following variables:

- **V_flag** Set to 1 if the image was successfully loaded or to 0 otherwise.
- **S_fileName** Set to the name of the file that was loaded.
- **V_numImages** Set to the number of images loaded. Applies to TIFF files only.
- **S_path** Set to the file system path to the folder containing the file.
- **S_waveNames** Set to a semicolon-separated list of the names of loaded waves.

*S_path* uses Macintosh path syntax (e.g., “hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon.

**Loading PNG Files**

If you use /T=rpng (“raw PNG”) or if you omit /T and the file as a .png extension, ImageLoad interprets the PNG file as raw data.

We recommend that you use /T=rpng and use /T=png only if /T=rpng does not produce the desired results.

/T=rpng creates an 8-bit or 16-bit unsigned integer wave with 1 to 4 layers.

PNG images with physical units produce waves with X and Y units of meters.

If a PNG image has a color table, ImageLoad creates two waves: a main image wave with one layer and a color table wave of the same name but with an “_pal” suffix. If the name is too long it creates a wave named PNG_pal instead.
Loading TIFF Files
ImageLoad supports 1-bit, 8-bit, 16-bit, 24-bit, and 32-bit TIFF files as well as floating point TIFFs.
1-bit/pixel images are loaded into a unsigned byte waves.
8-bit/pixel images are loaded into a unsigned byte waves.
16-bit/pixel images are loaded into unsigned 16-bit waves.
24-bit/pixel images and 32-bit/pixel images loaded into 3D RGB and RGBA waves respectively.

Loading a TIFF File With a Color Table
If your TIFF file includes a color table, ImageLoad /T=tiff loads the data into a 2D wave and loads the color table into a separate color table wave which can be used when creating an image plot.
If you want to load the TIFF file into a 3D RGB wave, use /T=tiff to load it into a 2D wave plus a color table and then use ImageTransform cmap2RGB to create the 3D RGB wave.

Loading TIFF Stacks
A TIFF stack is a TIFF file that contains multiple images. When loading a stack, you can:
- Load all images
- Load a range of images specified by /S (starting image) and /C (image count)
You can also load the images into:
- Separate 2D waves by omitting the /LR3D flag
- A single 3D wave by using the /LR3D flag
When you use /LR3D, ImageLoad stores each image from the TIFF file in a layer of the 3D output wave. This option works with grayscale images only, not with full color (e.g., RGB).

EXIF Metadata
Some applications embed metadata (information about the image) in EXIF format. In both JPEG and TIFF files, the metadata is stored using TIFF tags. To read the metadata, use the /RAT flag, even if you are loading a JPEG file.

Examples
// Load all images from a TIFF stack into separate 2D waves
ImageLoad /C=-1 /T=TIFF

// Load a single image from a TIFF stack into a 2D wave
ImageLoad/S=10/C=1/T=TIFF  // Load image 10 (zero based)

// Load all images from a TIFF stack into a single 3D wave
ImageLoad/LR3D/S=0/C=-1/T=TIFF

// Read all tags without loading any images
ImageLoad/C=-1/T=TIFF/RTIO

// Get the number of images in a TIFF stack
NewDataFolder/O/S tmp
ImageLoad/C=-1/T=TIFF/RTIO
Print V_numImages
KillDataFolder :

Loading Image Files on page II-142.
The ImageSave operation for saving waves as image files.

ImageMorphology
ImageMorphology [flags] Method imageMatrix
The ImageMorphology operation performs one of several standard image morphology operations on the source imageMatrix. Unless the /O flag is specified, the resulting image is saved in the wave M_ImageMorph. The operation applies only to waves of type unsigned byte. All ImageMorphology methods except for watershed use a structure element. The structure element may be one of the built-in elements (see /E flag) or a user specified element.
Erosion, Dilation, Opening, and Closing are the only methods supported for a 3D imageMatrix.
### Image Morphology

**Parameters**

*Method* is one of the following names:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BinaryErosion</td>
<td>Erodes the source binary image using a built-in or user specified structure element (see /E and /S flags).</td>
</tr>
<tr>
<td>BinaryDilation</td>
<td>Dilates the source binary image using a built-in or user specified structure element (see /E and /S flags).</td>
</tr>
<tr>
<td>Closing</td>
<td>Performs the closing operation (dilation followed by erosion). The same structure element is used in both erosion and dilation. Note that this operation is an idempotent, which means that there is no point of executing it more than once.</td>
</tr>
<tr>
<td>Dilation</td>
<td>Performs a dilation of the source grayscale image using either a built-in structure element or a user specified structure element. The operation supports only 8-bit gray images.</td>
</tr>
<tr>
<td>Erosion</td>
<td>Erodes the source grayscale image using either a built-in structure element or a user specified structure element. The operation supports only 8-bit gray images.</td>
</tr>
<tr>
<td>Opening</td>
<td>Performs an opening operation (erosion followed by dilation). The same structure element is used in both erosion and dilation. Note that this operation is an idempotent which means that there is no point of executing it more than once.</td>
</tr>
<tr>
<td>TopHat</td>
<td>Calculates the difference between the eroded image and dilated image using the same structure element.</td>
</tr>
<tr>
<td>Watershed</td>
<td>Calculates the watershed regions for grayscale or binary image. Use the /N flag to mark all nonwatershed lines as NaNs. The /L flag switches from using 4 neighboring pixels (default) to 8 neighboring pixels.</td>
</tr>
</tbody>
</table>
Flags

/E=id

Uses a particular built in structure element. The following are the built-in structure elements: make sure to use the appropriate id for the dimensionality of imageMatrix:

<table>
<thead>
<tr>
<th>id</th>
<th>Element</th>
<th>Origin</th>
<th>Shape</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2x2</td>
<td>(0,0)</td>
<td>square (default)</td>
</tr>
<tr>
<td>2</td>
<td>1x3</td>
<td>(1,1)</td>
<td>row (in 3x3 square)</td>
</tr>
<tr>
<td>3</td>
<td>3x1</td>
<td>(1,1)</td>
<td>column (in 3x3 square)</td>
</tr>
<tr>
<td>4</td>
<td>3x3</td>
<td>(1,1)</td>
<td>cross (in 3x3 square)</td>
</tr>
<tr>
<td>5</td>
<td>5x5</td>
<td>(2,2)</td>
<td>circle (in 5x5 square)</td>
</tr>
<tr>
<td>6</td>
<td>3x3</td>
<td>(1,1)</td>
<td>full 3x3 square</td>
</tr>
<tr>
<td>200</td>
<td>2x2x2</td>
<td>(1,1,1)</td>
<td>symmetric cube</td>
</tr>
<tr>
<td>202</td>
<td>2x2x2</td>
<td>(1,1,1)</td>
<td>2 voxel column in Y direction</td>
</tr>
<tr>
<td>203</td>
<td>2x2x2</td>
<td>(1,1,1)</td>
<td>2 voxel column in X direction</td>
</tr>
<tr>
<td>204</td>
<td>2x2x2</td>
<td>(1,1,1)</td>
<td>2 voxel column in Z direction</td>
</tr>
<tr>
<td>205</td>
<td>2x2x2</td>
<td>(1,1,1)</td>
<td>XY plane</td>
</tr>
<tr>
<td>206</td>
<td>2x2x2</td>
<td>(1,1,1)</td>
<td>YZ plane</td>
</tr>
<tr>
<td>207</td>
<td>2x2x2</td>
<td>(1,1,1)</td>
<td>XZ plane</td>
</tr>
<tr>
<td>300</td>
<td>3x3x3</td>
<td>(1,1,1)</td>
<td>symmetric cube</td>
</tr>
<tr>
<td>301</td>
<td>3x3x3</td>
<td>(1,1,1)</td>
<td>symmetric ball</td>
</tr>
<tr>
<td>302</td>
<td>3x3x3</td>
<td>(1,1,1)</td>
<td>3 voxel column in Y direction</td>
</tr>
<tr>
<td>303</td>
<td>3x3x3</td>
<td>(1,1,1)</td>
<td>3 voxel column in X direction</td>
</tr>
<tr>
<td>304</td>
<td>3x3x3</td>
<td>(1,1,1)</td>
<td>3 voxel column in Z direction</td>
</tr>
<tr>
<td>305</td>
<td>3x3x3</td>
<td>(1,1,1)</td>
<td>XY plane</td>
</tr>
<tr>
<td>306</td>
<td>3x3x3</td>
<td>(1,1,1)</td>
<td>YZ plane</td>
</tr>
<tr>
<td>307</td>
<td>3x3x3</td>
<td>(1,1,1)</td>
<td>XY plane</td>
</tr>
<tr>
<td>500</td>
<td>5x5x5</td>
<td>(2,2,2)</td>
<td>symmetric cube</td>
</tr>
<tr>
<td>501</td>
<td>5x5x5</td>
<td>(2,2,2)</td>
<td>symmetric ball</td>
</tr>
<tr>
<td>700</td>
<td>7x7x7</td>
<td>(3,3,3)</td>
<td>symmetric cube</td>
</tr>
<tr>
<td>701</td>
<td>7x7x7</td>
<td>(3,3,3)</td>
<td>symmetric ball</td>
</tr>
</tbody>
</table>

Note that this flag has no effect on watershed calculations.

/I=iterations

Repeats the operation the specified number of iterations.

/L

Uses 8-connected neighbors instead of 4.

/N

Sets the background level to 64 (= NaN).

/O

Overwrites the source wave with the output.
If you would like to apply a morphological operation to a wave whose data type is not an unsigned byte and you wish to retain the wave's dynamic range, you can use the following approach:

Function ScaledErosion(inWave)
  Wave inWave
  WaveStats/Q inWave
  Variable nor=255/(V_max-V_min)
  MatrixOp/O tmp=nor*(inWave-V_min)
  Redimension/B/U tmp
  ImageMorphology/E=5 Erosion tmp
  Wave M_ImageMorph
  MatrixOp/O inWave=(M_ImageMorph/nor)+V_min
  KillWaves/Z tmp,M_ImageMorph
End

Example

In general, the roiSpec has the form {roiWaveName, roiFlag}, where roiFlag can take the following values:

roiFlag=0: Set pixels outside the ROI to 0.
roiFlag=1: Set pixels outside the ROI as in original image.
roiFlag=2: Set pixels outside the ROI to NaN (=64).

By default roiFlag is set to 1 and it is then possible to use the /R flag using the abbreviated form /R=roiWave.

See Also

The ImageGenerateROIMask operation for creating ROIs. For details and usage examples see Morphological Operations on page III-349 and Particle Analysis on page III-356.

ImageNameList

ImageNameList(graphNameStr, separatorStr)

The ImageNameList function returns a string containing a list of image names in the graph window or subwindow identified by graphNameStr.
Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

separatorStr should contain a single ASCII character such as “,” or “;” to separate the names.

An image name is defined as the name of the 2D wave that defines the image with an optional #ddd suffix that distinguishes between two or more images that have the same wave name. Since the image name has to be parsed, it is quoted if necessary.

Examples

The following command lines create a very unlikely image display. If you did this, you would want to put each image on different axes, and arrange the axes such that they don’t overlap. That would greatly complicate the example.

```
Make/O/N=(20,20) jack,"jack # 2";
Display;AppendImage jack
AppendImage/T/R jack
AppendImage/T/R "jack # 2"
AppendImage/T/R "jack # 2"
Print ImageNameList("",";"

prints jack;jack#1;'jack # 2';'jack # 2'#1;
```

See Also

Another command related to images and waves: ImageNameToWaveRef.

For commands referencing other waves in a graph: TraceNameList, WaveRefIndexed, XWaveRefFromTrace, TraceNameToWaveRef, CsrWaveRef, CsrXWaveRef, ContourNameList, and ContourNameToWaveRef.

ImageNameToWaveRef

```
ImageNameToWaveRef(graphNameStr, imageNameStr)
```

The ImageNameToWaveRef function returns a wave reference to the 2D wave corresponding to the given image name in the graph window or subwindow named by graphNameStr.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

The image is identified by the string in imageNameStr, which could be a string determined using ImageNameList. Note that the same image name can refer to different waves in different graphs.

See Also

The ImageNameList function.

For a discussion of wave references, see Wave Reference Functions on page IV-192.

ImageRegistration

```
ImageRegistration [flags] [testMask=testMaskWave] [refMask=refMaskWave] testWave=imageWave1, refWave=imageWave2
```

The ImageRegistration operation adjusts the test image wave, testWave, to match the reference image wave, refWave, possibly subject to auxiliary mask waves. The registration may involve offset, rotation, scaling or skewing.

Image data may be in two or three dimensions.

ImageRegistration is designed to find accurate registration for relatively small variation on the order of a few degrees of rotation and a few pixels offset between the reference and test images.

All the input waves are expected to be single precision float (SP) so you may have to redimension your images before using ImageRegistration.
ImageRegistration does not tolerate NaNs or INFs; use the masks if you need to exclude pixels from the registration process.

### Parameters

- **refMask=refMaskWave**
  Specifies an optional ROI wave used to mask refWave. Omit refMask to use all of the refWave.
  The wave must have the same dimensions as refWave. refMask is a single precision floating point wave with nonzero entries marking the “ON” state. Note that the operation modifies this wave and that you should not use the same wave for both the reference and the test masks.

- **refWave=imageWave2**
  Specifies the name of the reference image wave used to adjust testWave.

- **testMask=testMaskWave**
  Specifies an optional ROI wave used to mask testWave. Omit testMask to use all of the testWave.
  The wave must have the same dimensions as refWave. testMask is a single precision floating point wave with nonzero entries marking the “ON” state. Note that the operation modifies this wave and that you should not use the same wave for both the reference and the test masks.

- **testWave=imageWave1**
  Specifies the name of the image wave that will be adjusted to match refWave.

*testMaskWave* and *refMaskWave* are optional ROI waves. The waves must have the same dimensions as testWave and refWave respectively. They must be single precision floating point waves with nonzero entries marking the “ON” state. If you need to include the whole region described by testWave or the whole region described by refWave you can omit the respective mask wave.

### Flags

- **/ASTP=val**
  Sets the adaptation step for the Levenberg-Marquardt algorithm. Default value is 4.

- **/BVAL=val**
  Enables clipping and sets the background values to which masked out voxels of the test data will be set.

- **/CONV=val**
  Sets the convergence method.
  - *val=0*: Gravity, use if the difference between the images is only in translation. This option is frequently useful as a first step when the test and reference data are too far apart for accurate registration. The result of this registration is then passed to a subsequent ImageRegistration with /CONV=1.
  - *val=1*: Marquardt.

- **/CSNR=val**
  Determines if the operation calculates the signal to noise ratio (SNR)
  - *val=0*: The SNR is not calculated.
  - *val=1*: The SNR is calculated (default).
  Skipping the SNR calculation saves time and may be particularly useful when performing the registration on a stack of images.

- **/FLVL=val**
  Specifies the finest level on which the optimization is to be performed.
  If this is the same as /PRDL, then only the coarsest registration calculation is done.
  If /FLVL=1 (default), then the full multiresolution pyramid is processed. You can use this flag to terminate the computation at a specified coarseness level greater than 1.

- **/GRYM**
  Optimizes the gray level scaling factor.
  It is sometimes dangerous to let the program adjust for gray levels because in some situations it might result in a null image.

- **/GARYR**
  Renders output using the gray scaling parameter. This is more meaningful if the operation computes the optimal gray scaling (see /GRYM).
/GWDT=[sx,sy,sz] Sets the three fields to the half-width of a Gaussian window that is used to smooth the data when computing the default masks. Defaults are \{1,1,1\}. See /REFM and /TSTM for more details.

/INTR=val Sets the interpolation method.

\(val=0\): Nearest neighbor. Used when registering the center of gravity of the test and reference images.

\(val=1\): Trilinear.

\(val=2\): Tricubic (default).

/ISOS Optimizes the isometric scaling. This option is inappropriate if voxels are not cubic.

/ISR Computes the multiresolution pyramid with isotropic size reduction. If the flag is not specified, the size reduction is in the XY plane only.

/MING=val Sets the minimum gain at which the computations will stop. Default value is zero, but you can use a slightly larger value to stop the iterations earlier.

/MSKC=val Sets mask combination value. During computation the masks for the test data and the mask for the reference data are also transformed. This flag determines how the two masks are to be combined. The registration criteria are computed for the combination of the two masks.

\(val=0\): or.

\(val=1\): nor.

\(val=2\): and (default).

\(val=3\): nand.

\(val=4\): xor.

\(val=5\): nxor.

/PRDL=depth Specifies the depth of the multiresolution pyramid. The finest level is \(depth=1\). Each level of the pyramid decreases the resolution by a factor of 2. By default, the pyramid \(depth=4\), which corresponds to a resolution reduction by a factor of \(2^{(depth-1)}=8\).

The algorithm starts by computing the first registration on large scale features in the image (deepest level of the pyramid). It then makes small corrections to the registration at each consecutive pyramid level.

For best results, the coarsest representation the data should be between 30 and 60 pixels on a side. For example, for an image that is \(H\) by \(V\) pixels, you should choose the depth such that \(H/2^{(depth-1)} \approx 30\).

/PSTK When performing registration of a stack of images, use this flag to apply the registration parameters of the previous layer as the initial guess for the registration of each layer after the first in the 3D stack.

/Q Quiet mode; no messages printed in the history area.

/REFM=val Sets the reference mask.

\(val=0\): To leave blank and then every pixel is taken into account.

\(val=1\): Value will be set if a valid reference mask is provided.

\(val=2\): The test mask is computed (default).

When computing the reference mask it is assumed that brighter features are more important. This is done by using a low pass filter on the data (using the parameters in /GWDT) which is then converted into a binary mask. Note that you do not need to specify /REFM=1 if you are providing a reference mask wave. See also /TSTM.

/ROT=[rotX,rotY,rotZ]
Determines if optimization will take into account rotation about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding rotation parameter. Defaults are \{0,0,1\}, which are the appropriate values for rotating images.

/SKEW={skewX,skewY,skewZ}

Determines if optimization will take into account skewness about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding skewness parameter. Defaults are \{0,0,0\}. Note that skewing and rotation or isometric scaling are mutually exclusive operations.

/STCK

Use /STCK to perform the registration between a 2D reference image and each of the layers in a 3D image. The number of rows and columns of the refWave must match exactly the number of rows and columns in testWave. The transformation parameters are saved in the wave M_RegParams where each column contains the parameters for the corresponding layer in testWave.

/STRT=val

Sets the first value of the adaptation parameter in the Levenberg-Marquardt algorithm.

The default value of this parameter is 1.

/TRNS={transX,transY,transZ}

Determines if optimization will take into account translation about the X, Y, or Z axes. A value of one allows optimization and zero prevents optimization from affecting the corresponding translation parameter. Defaults are \{1,1,0\}, which are appropriate for finding the X and Y translations of an image.

/TSTM=val

Sets the test mask.

val=0: To leave blank and then every pixel is taken into account.
val=1: This value will be set if a valid reference mask is provided.
val=2: The reference mask is computed. This is the default value.

The test image mask is computed in the same way as the reference image mask (see /REFM) using the same set of smoothing parameters. Note that you do not need to specify /TSTM=1 if you are providing a test mask wave.

/USER=pWave

Provides a user transformation that will be applied to the input testWave in order to create the transformed image. pWave must be a double precision wave which contains the same number of rows as W_RegParams.

Note: If you use a previously created W_RegParams make sure to change its name as it is overwritten by the operation.

If pWave has only one column and testWave contains multiple layers, then the same transformation applies to all layers. If pWave contains more than one column, then each layer of testWave is processed with corresponding column. If there are more layers than columns the first column is used in place of the missing columns.

/ZMAN

Modifies the test and reference data by subtracting their mean values prior to optimization.

Details

ImageRegistration will register images that have sufficiently similar features. It will not work if key features are too different. For example, ImageRegistration can handle two images that are rotated relative to each other by a few degrees, but cannot register images if the relative rotation is as large as 45 degrees. The algorithm is capable of subpixel resolution but it does not handle large variations between the test image and the reference image. If the centers of the two images are too far from each other, you should first try ImageRegistration using /CON=0 to remove the translation offset before proceeding with a finer registration of details.

The algorithm is based on an iterative processing that proceeds from coarse to fine detail. Optimization uses a modified Levenberg-Marquardt algorithm and produces an affine transformation for the relative rotation
and translation as well as for isometric scaling and contrast adjustment. The algorithm is most effective with square images where the center of rotation is not far from the center of the image.

When using gravity for convergence, skew parameters can’t be evaluated (only translation is supported). Skew and isoscaling are mutually exclusive options. Mask waves are defined to have zero entries for pixels outside the region of interest and nonzero entries otherwise. If a mask is not provided, every pixel is used.

ImageRegistration creates the waves M_RegOut and M_RegMaskOut, which are both single precision waves. In addition, the operation creates the wave W_RegParams which stores 20 double precision registration parameters. M_RegOut contains the transformed (registered) test image and M_RegMaskOut contains the transformed mask (which is not affected by mask combination). ImageRegistration ignores wave scaling; images are compared and registered based on pixel values only.

The results printed in the history include:

- dx, dy, dz translation offsets measured in pixels.
- aij Elements in the skewing transformation matrix.
- phi Rotation angle in degrees about the X-axis. Zero for 2D waves.
- tht Rotation angle in degrees about the Y-axis. Zero for 2D waves.
- psi Rotation angle in degrees about the Z-axis.
- det Absolute value of determinant of the skewing matrix (aij).
- err Mean square error defined as
  \[ \frac{1}{N} \sum (x_i - y_i)^2, \]
  where \( x_i \) is the original pixel value, \( y_i \) the computed value, and \( N \) is the number of pixels.
- snr Signal to noise ratio in dB. It is given by:
  \[ 10 \log \left( \frac{\sum x_i^2}{\sum (x_i - y_i)^2} \right). \]

These parameters are stored in the wave W_RegParams (or M_RegParams in the case of registering a stack). Angles are in radians. Dimension labels are used to describe the contents of each row of the output wave. Each column of the wave consists of the following rows (also indicated by dimension labels):

<table>
<thead>
<tr>
<th>Point</th>
<th>Contents</th>

You can view the output waves with dimension labels by executing:

Edit W_RegParams.ld

**See Also**
The ImageInterpolate Warp operation.
**ImageRemoveBackground**

**References**
The ImageRegistration operation is based on an algorithm described by:

**ImageRemoveBackground**

ImageRemoveBackground /R=roiWave [flags] srcWave

The ImageRemoveBackground operation removes a general background level, described by a polynomial of a specified order, from the image in srcWave. The result of the operation are stored in the wave M_RemovedBackground.

**Flags**

/F Computes only the background surface fit. Will only store the resulting fit in M_RemovedBackground. This will not subtract the fit from the image.

/O Overwrites the original wave.

/P=polynomial order Specifies the order of the polynomial fit to the background surface. If omitted, the order is assumed to be 1.

/R=roiWave Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/B/U), which has the same number of rows and columns as the image wave.

Set the pixels that define the background region to 1. The remaining pixels can be any value other than 1. We recommend using 64 which Igor image processing operations often interpret as "blank" in unsigned byte image waves.

The ROI does not have to be contiguous.

See ImageGenerateROIMask for more information on creating ROI waves.

/W Specifies that polynomial coefficients are to be saved in the wave W_BackgroundCoeff.

**Details**
The identification of the background is done via the ROI wave. Set the pixels that define the background region to 1. The remaining pixels can be any value other than 1. We recommend using 64 which Igor image processing operations often interpret as "blank" in unsigned byte image waves.

The operation first performs a polynomial fit to the points designated by the ROI wave using the specified polynomial order. A polynomial of order N corresponds to the function:

$$F_N(x, y) = \sum_{m=0}^{N} \sum_{n=0}^{m} c_{mn} x^{m-n} y^n.$$  

Using the polynomial fit, a surface corresponding to the polynomial is subtracted from the source wave and the result is saved in M_RemovedBackground, unless the /O flag is used, in which case the original wave is overwritten.

Use the /W flag if you want polynomial coefficients to be saved in the W_BackgroundCoeff wave. Coefficients are stored in the same order as the terms in the sums above.

If you do not specify the polynomial order using the /P flag, the default order is 1, which means that the operation subtracts a plane (fitted to the ROI data) from the source image.

Note, if the image is stored as a wave of unsigned byte, short, or long, you might consider converting it into single precision (using Redimension/s) before removing the background. To see why this is important, consider an image containing a region of pixels equal to zero and subtracting a background plane corresponding to a nonconstant value. After subtraction, at least some of the pixels in the zero region should become negative, but because they are stored as unsigned quantities, they appear incorrectly as large values.

**Examples**

See Background Removal on page III-360.
See Also
The ImageGenerateROIMask operation for creating ROIs.

ImageRestore

ImageRestore [flags] srcWave=wSrc, psfWave=wPSF [, relaxationGamma=h, startingImage=wRecon ]

The ImageRestore operation performs the Richardson-Lucy iterative image restoration.

Flags

/DEST=destWave    Specifies the desired output wave.
                      If /DEST is omitted, the output from the operation is stored in the wave M_Reconstructed in the current data folder.
/ITER=iterations   Specifies the number of iterations. The default number of iterations is 100.
/Z                 Do not report errors.

Parameters

psfWave=wPSF        Specifies a known point spread function. wPSF must be a 2D (square NxN) wave of the same numeric type as wSRC. N must be an odd number greater than 1.
relaxationGamma=h   Specifies positive power gamma of in the relaxation mapping (see Details).
startingImage=wRecon Use this keyword to specify a starting image that could be for example the output from a previous call to this operation. wRecon must have the same dimensions as wSRC and the same numeric type.
                      You must make sure that wRecon is not the user-specified or the default destination wave of the operation.
srcWave=wSrc        Specifies the degraded image which must be a 2D single-precision or double-precision real wave.

Details

ImageRestore performs the Richardson-Lucy iteration solution to the deconvolution of an image. The input consists of the degraded image and point spread function as well as the desired number of iterations.

The operation allows you to apply additional iterations by setting the starting image to the restored output wave from a previous call to ImageRestore using the startingImage keyword. If startingImage is omitted, the starting image is created by ImageRestore with each pixel set to the value 1.

In the case of stellar images it may be useful to apply a relaxation step that involves scaling the correction evaluated at each iteration by

\[
\text{factor}(v) = \sin \left( \pi \frac{v - v_{\text{min}}}{v_{\text{max}} - v_{\text{min}}} \right)^\gamma,
\]

where \(v\) is pixel value, \(v_{\text{max}}\) and \(v_{\text{min}}\) are the maximum and minimum level pixels in the image and \(\gamma\) is the user-specified relaxationGamma.

References

ImageRotate

ImageRotate [flags] imageMatrix
The ImageRotate operation rotates the image clockwise by angle (degrees) or counter-clockwise if /W is used.
The resulting image is saved in the wave M_RotatedImage unless the /O flag is specified. The size of the resulting image depends on the angle of rotation.
The portions of the image corresponding to points outside the domain of the original image are set to the default value 64 or the value specified by the /E flag.
You can apply ImageRotate to 2D and 3D waves of any data type.

Flags

/A=angle Specifies the rotation angle measured in degrees in a clockwise direction. For rotations by exactly 90 degrees use /C or /W instead.
/C Specifies clockwise rotation.
Clockwise is the default direction so the rotation will be clockwise whether you use /C or not, so long as you do not use /W.
/E=val Specifies the value for pixels that are outside the domain of the original image. By default pixels are set to 64. If you specify /E=(NaN) and your data is of type char, short, or long, the operation sets the external values to 64.
/F Rotates image by 180 degrees.
/H Flip the image horizontally.
/O Overwrites the original image with the rotated image.
/Q Quiet mode. Without this flag the operation writes warnings in the history area.
/RGBA=[R, G, B [, A]]
Specifies the RGB or RGBA values of pixels that lie outside the domain occupied by the original image. This flag was added in Igor Pro 7.00.
/S Uses source image wave scaling to preserve scaling and relative locations of objects in the image for rotation angles that are multiples of 90 degrees.
/V Flip the image vertically.
/W Specifies counter-clockwise rotation.
/Z Ignore errors.

See Also
The MatrixTranspose operation.

ImageSave

ImageSave [flags] waveName [[as]fileNameStr]
The ImageSave operation saves the named wave as an image file.
Previously this operation used QuickTime to implement the saving of some file formats. As of Igor Pro 7.00, it no longer uses QuickTime. Consequently, some file formats re no longer supported and some flags have changed.

Parameters
The file to be written is specified by fileNameStr and /P=pathname where pathname is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathname, or the name of a file in the folder associated with pathname. If Igor can not determine the location of the file from fileNameStr and pathname, it displays a dialog allowing you to specify the file.
If you use a full or partial path for `fileNameStr`, see **Path Separators** on page III-429 for details on forming the path.

If you want to force a dialog to select the file, omit the `fileNameStr` parameter or specify "" for `fileNameStr` or use the /I flag. The “as” keyword before `fileNameStr` is optional.

In Igor Pro 7.00 or later, if you specify “Clipboard” for `fileNameStr` and the file type is JPEG or PNG, Igor writes the image to the clipboard.

In Igor Pro 7.00 or later, if the file type is PNG or JPEG you can write the image to the picture gallery using the magic path name _PictGallery_. For example

```
ImageSave/T=PNG/P=_PictGallery_ waveName
```

### Flags

- `/ALPH=mode` Sets the value used for the ExtraSamples tag (338) in the TIFF file format. This flag was added in Igor Pro 7.00.
  
  The tag tells a TIFF file reader how to use the alpha values. Supported modes are 1 for premultiplied and 2 for unassociated alpha. Premultiplied means that the RGB components have already been multiplied by alpha. Unassociated means that the RGB components are raw.
  
  By default, alpha is assumed to be premultiplied (mode=1).

- `/D=depth` This flag is deprecated and should not be used in new code.
  
  Specifies color depth in bits-per-pixel. Integer values of 1, 8, 16, 24, 32, and 40 are supported. A depth of 40 specifies 8-bit grayscale; a depth of 8 saves the file as 8-bits/pixel with a color lookup table. If /D is omitted, it acts like /D=8.
  
  Saving with a color table may cause some loss of fidelity.
  
  See also the discussion of saving TIFF files below.

- `/DS=depth` Saves TIFF data in depth bits/sample.
  
  Values for depth of 8, 16, 32 and 64 are supported. The default is 8.
  
  The total number of bits/pixel is: (bits/sample) * (samples/pixel).
  
  When using 32 or 64 bits/sample, `srcWave` is saved without normalization.

- `/F` This flag is deprecated and should not be used in new code.
  
  Saves the wave as single precision float. The data is not normalized. Applies only to TIFF files.

- `/I` Interactive mode. Forces ImageSave to display a Save File dialog, even if the file and folder location are fully specified.

- `/IGOR` In Igor6 this flag told Igor to use internal code rather than QuickTime to write TIFF files. Igor no longer uses QuickTime and always uses internal code. This flag is still accepted but has no effect.

- `/O` Overwrites the specified file if it exists. If /O is omitted and the file exists, ImageSave displays a Save File dialog.

- `/P=pathName` Specifies the folder in which to save the image file. `pathName` is the name of an existing symbolic path.

- `/Q=quality` Specifies the quality of the compressed image. `quality` is a number between 0 and 1, with 1 being the highest quality. This is only applicable when saving in formats with lossy compression like JPEG.

- `/S` Saves as stack. Applies only to 3D or 4D source waves saved as TIFF files.
ImageSave

/T=fileTypeStr

Specifies the type of file to be saved.

<table>
<thead>
<tr>
<th>fileTypeStr</th>
<th>Saved Image Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;jpeg&quot;</td>
<td>JPEG file</td>
</tr>
<tr>
<td>&quot;png&quot;</td>
<td>PNG file</td>
</tr>
<tr>
<td>&quot;rpng&quot;</td>
<td>raw PNG file (see Saving as Raw PNG)</td>
</tr>
<tr>
<td>&quot;tiff&quot;</td>
<td>TIFF file</td>
</tr>
</tbody>
</table>

If /T is omitted, the default type is "tiff".

/U

Prevents normalization. This works when saving TIFF only. See Saving as TIFF below.

/WT=tagWave

Saves TIFF files with file tags as specified by tagWave, which is a text wave consisting of a row and 5 columns for each tag (see description of the /RAT flag under ImageLoad). It ignores any information in the second column but will write the tags sequentially (only in the first Image File Directory (IFD) if there is more than one image). If the fourth column contains a negative number, there must be a wave, whose name is given in the fifth column of tagWave, in the same data folder as tagWave. You must make sure that: (1) tag numbers are legal and do not conflict with any existing tags; (2) the data type and data size are consistent with the amount of data saved in external waves.

/Z

No error reporting.

Details

Image files are characterized by the number of color components per pixel and the bit-depth of each component. Igor displays images that consist of 1 component (gray-scale/false color), 3 components (RGB) or 4 components (RGBA) per pixel. You can display waves of all real numeric types as images, but wave data are assumed to be either in the range of \([0,255]\) for 8-bits/components or \([0,65535]\) for all other numeric types. For more information see Creating an Image Plot on page II-317.

When you save a numeric wave as image file your options depend on the number of components (layers) of your wave and its number type.

Saving as PNG

You can save an Igor wave as a PNG file with 24 bits per pixel or 32 bits per pixel. The following table describes how the wave’s data type corresponds to the PNG pixel format.

<table>
<thead>
<tr>
<th>Source Wave</th>
<th>PNG Pixel Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-layer any type</td>
<td>RGB 24 bits per pixel gray normalized ([0,255])</td>
</tr>
<tr>
<td>3-layer unsigned byte</td>
<td>RGB 24 bits per pixel no scaling</td>
</tr>
<tr>
<td>3-layer unsigned short</td>
<td>RGB 24 bits per pixel data divided by 256</td>
</tr>
<tr>
<td>3-layer all other types</td>
<td>RGB 24 bits per pixel data normalized ([0,255])</td>
</tr>
<tr>
<td>4-layer unsigned byte</td>
<td>RGBA 32 bits per pixel no scaling</td>
</tr>
<tr>
<td>4-layer unsigned short</td>
<td>RGBA 32 bits per pixel data divided by 256</td>
</tr>
<tr>
<td>4-layer all other types</td>
<td>RGBA 32 bits per pixel data normalized ([0,255])</td>
</tr>
</tbody>
</table>

Gray means that the three components of each pixel have the identical value. Data normalization consists of finding the global (over all layers) minimum and maximum values of srcWave followed by scaling to the full range, e.g.,

\[
\text{minValue} = \text{WaveMin}(\text{srcWave}) \\
\text{maxValue} = \text{WaveMax}(\text{srcWave}) \\
\text{outValue}[i][j][k] = 255 \times (\text{srcWave}[i][j][k] - \text{minValue}) / (\text{maxValue} - \text{minValue})
\]
Saving as Raw PNG
The rpng image format requires a wave in 8- or 16-bit unsigned integer format with 1 to 4 layers. Use one layer for grayscale, 3 layers for rgb color, and the extra layer for an alpha channel. If X or Y scaling is not unity, they both must be valid and must be either inches per pixel or meters per pixel. If the units are not inches they are taken to be meters.

Saving as TIFF
ImageSave supports saving uncompressed TIFF images of 8, 16, 32 and 64 bits per color component with 1, 3 or 4 components per pixel.

Depending on the data type of your wave and the depth of the image file being created, ImageSave may save a “normalized” version of your data. The normalized version is scaled to fit in the range of the image file data type. For example, if you save a 16-bit Igor wave containing pixel values from -1000 to +1000 in an 8-bit grayscale TIFF file, ImageSave will map the wave values -1000 to +1000 to the file values 0 and 255 respectively. When saving an image file of 16-bits/component, Igor normalizes to 65535 as the full-scale value.

There is no normalization when you save in floating point (32 or 64 bits/component). Normalization is also not done when saving 8-bit wave data to an 8-bit image file. You can disable normalization with the /U flag.

Saving in floating point can lead to large image files (e.g., 64-bit/component RGBA has 256 bits/pixel) which are not supported by many applications.

Saving 3D or 4D Waves as a Stack of TIFF Images
If your Igor data is a 3D wave other than an RGB wave or a 4D wave, you can save it as a stack of grayscale images without a color map.

Use /S to indicate that you want to save a stack of images rather than a single image from the first layer of the wave.
Use /D=8 to save as 8 bits. Normalization is done except if the wave data is 8 bits.
Use /D=16 to save as 16 bits with normalization.
Use /F to save as single-precision floating point without normalization. Many programs can not read this format.
Use /U to prevent normalization.
Stacked images are normalized on a layer by layer basis. If you want to have uniform scaling and normalization you should convert your wave to the file data type before executing ImageSave.

See Also
The ImageLoad operation for loading image files into waves.

ImageSeedFill

ImageSeedFill [flags] [keyword], seedX=xLoc, seedY=yLoc, target=setValue, srcWave=srcImage

The ImageSeedFill operation takes a seed pixel and fills a contiguous region with the target value, storing the result in the wave M_SeedFill. The filled region is defined by all contiguous pixels that include the seed pixel and whose pixel values lie between the specified minimum and maximum values (inclusive). ImageSeedFill works on 2D and 3D waves.

Parameters
**ImageSeedFill**

*keyword* is one of the following names:

- **adaptive=factor** Invokes the adaptive algorithm where a pixel or voxel is accepted if its value is between the specified minimum and maximum or its value satisfies:

\[|val - avg| < factor \times stdv.\]

Here *val* is the value of the pixel or voxel in question, *avg* is the average value of the pixels or voxels in the neighborhood and *stdv* is the standard deviation of these values. By choosing a small *factor* you can constrain the acceptable values to be very close to the neighborhood average. A large *factor* allows for more deviation assuming that the *stdv* is greater than zero.

This requirement means that a connected pixel has to be between the specified minimum and maximum value and satisfy the adaptive relationship. In most situations it is best to set wide limits on the minimum and maximum values and allow the adaptive parameter to control the local connectivity.

- **fillNumber=num** Specifies the number, in the range 1 to 26, of voxels in each 3x3x3 cube that belong to the set. If fillNumber is exceeded, the operation fills the remaining members of the cube. If you do not specify this keyword, the operation does not fill the cube. Used only in the fuzzy algorithm.

- **fuzzyCenter=fcVal** Specifies the center value for the fuzzy probability with the fuzzy algorithm (see Details). The default value is 0.25. Its standard range is 0 to 0.5, although interesting results might be obtained outside this range.

- **fuzzyProb=fpVal** Specifies a probability threshold that must be met by a voxel to be accepted to the seeded set. The value must be in the range 0 to 1. The default value is 0.75.

- **fuzzyScale=fsVal** Determines if a voxel is to be considered in a second stage using fuzzy probability. *fsVal* must be nonzero in order to invoke the fuzzy algorithm. The scale is used in comparing the value of the voxel to the value of the seed voxel. The scale should normally be in the range 0.5 to 2.0.

- **fuzzyWidth=fwVal** Defines the width of the fuzzy probability distribution with the fuzzy algorithm (see Details). In most situations you should not need to specify this parameter. The default value is 1.

- **min=minval** Specifies the minimum value that is accepted in the seeded set. Not needed when using fuzzy algorithm.

- **max=maxval** Specifies the maximum value that is accepted to the seeded set. Not needed when using the fuzzy algorithm.

- **seedP=row** Specifies the integer row location of the seed pixel or voxel. This avoids roundoff issues when srcWave has wave scaling. You must provide either seedP or seedX with all algorithms. It is sometimes convenient to use this with cursors e.g.,

\[
seedP=pcs r(a).
\]

- **seedQ=col** Specifies the integer column location of the seed pixel or voxel. This avoids roundoff difficulties when srcWave has wave scaling. You must provide either seedQ or seedY with all algorithms.

- **seedR=layer** Specifies the integer layer position of the seed voxel. When srcWave is a 3D wave you must use either seedR or seedZ.

- **seedX=xLoc** Specifies the pixel or voxel index. If srcWave has wave scaling, seedX must be expressed in terms of the scaled coordinate. This keyword or seedP is required with all algorithms.

- **seedY=yLoc** Specifies the pixel or voxel index. If srcWave has wave scaling, seedY must be expressed in terms of the scaled coordinate. This keyword or seedQ is required with all algorithms.
In two dimensions, the operation takes a seed pixel, optional minimum and maximum pixel values and optional adaptive coefficient. It then fills a contiguous region (in a copy of the source image) with the target value. There are two algorithms for 2D seed fill. In direct seed fill (only min, max, seedX and seedY are specified) the filled region is defined by all contiguous pixels that include the seed pixel and whose pixel values lie between the specified minimum and maximum values (inclusive). In adaptive fill, there is an additional condition for the pixel or voxel to be selected, which requires that the pixel value must be within the standard deviation of the average in the 3x3 (2D) or 3x3x3 (3D) nearest neighbors. If you do not specify the minimum and maximum values then the operation selects only values identical to that of the seed pixel.

In 3D, there are three available algorithms. The direct seed fill algorithm uses the limits specified by the user to fill the seeded domain. In adaptive seed fill the algorithm requires the limits as well as the adaptive parameter. It fills the domain by accepting only voxels that lie within the adaptive factor times the standard deviation of the immediate voxel neighborhood. To invoke the third algorithm you must set fuzzyScale to a nonzero value. The fuzzy seed fill uses two steps to determine if a voxel should be in the filled domain. In the first step the value of the voxel is compared to the seed value using the fuzzy scale. If accepted, it passes to the second stage where a fuzzy probability is calculated based on the number of voxels in the 3x3x3 cell which passed the first step together with the user-specified probability center (fuzzyCenter) and width (fuzzyWidth). If the result is greater than fuzzyProb, the voxel is set to belong to the filled domain.

If the /O flag is not specified, the result is stored in the wave M_SeedFill.

If you specify a background value with the /B flag, the resulting image consists of the background value and the target value in the area corresponding to the seed fill. Although the wave is now bi-level, it retains the same number type as the source image.

ImageSeedFill returns a “bad seed pixel specification” if the seed pixel location derived from the various keywords above satisfies one or more of the following conditions:

- The computed integer pixel/voxel is outside the image.
- The value stored in the computed integer pixel/voxel location does not satisfy the min/max or fuzzy conditions. This is the most common condition when srcWave has wave scaling. To avoid this difficulty you should use the keywords seedP, seedQ, and seedR.

Examples
Using Cursor A position and value to supply parameter inputs for a 2D seedFill (Warning: command wrapped over two lines):

```
ImageSeedFill
```
Using the fuzzy algorithm for a 3D wave (Warning: command wrapped over two lines):

```
ImageSeedFill seedX=232,seedY=175,seedZ=42,target=1,fillnumber=10,fuzzycenter=.25,
      fuzzywidth=1,threshold=1,fuzzyprob=0.4,srcWave=ddd
```

See Also
For an additional example see Seed Fill on page III-358. To display the result of the operation for 3D waves it is useful to convert the 3D wave M_SeedFill into an array of quads. See ImageTransform vol2surf.

**ImageSnake**

ImageSnake [flags] srcWave

The ImageSnake operation creates or modifies an active contour/snake in the grayscale image srcWave. The operation iterates to find the “lowest total energy” snake. The energy is defined by a range of optional flags, each corresponding to an individual term in the total energy expression. Iterations terminate by reaching the maximum number of iterations, when the snake does not move between iterations or when the user aborts the operation.

**Flags**

- **/ALPH=alpha**
  Sets the coefficient of the energy term arising from the “tightness” of the snake.

- **/BETA=beta**
  Sets the coefficient of the energy term corresponding to curvature of the snake. A high value for beta makes the snake more rounded.

- **/DELT=delta**
  Sets the coefficient of the repulsion energy. A high value of delta keeps nonconsecutive snake points far from each other.

- **/EPS=num**
  Sets the maximum number of vertices which are allowed to move in one iteration. If the number of vertices which move during an iteration is smaller than num then iterations terminate.

- **/EXEF=eta**
  Sets the coefficient of the optional external energy component. By default this value is set to zero and there is no external energy contribution to the snakes energy. Note, this component is referred to as “external” because it is completely up to the user to specify both its coefficient and the value associated with each pixel. It should not be confused with what is called external snake energy in the literature, which usually applies to energy proportional to the gradient image (see /GAMM and /GRDI).

- **/EXEN=wave**
  Specify a wave that contains energy values that will be added to the snakes energy calculation. The wave must have the same dimensions as srcWave and must be single precision float. Each pixel value corresponds to user defined energy which will be multiplied by the /EXEF coefficient and added to the sum which the snake minimizes. Note that when /EXEF is set to zero this component is ignored. An external energy wave may be useful, for example, if you want to attract the snake to the picture boundaries. In that case you can set:

  ```
  Duplicate/O srcWave,extWave
  Redimension/S extWave
  Variable rows=DimSize(srcWave,0)-1
  Variable cols=DimSize(srcWave,1)-1
  extWave=(p==0 || q==0 || p==rows || q==cols) ? 0:1
  ```

- **/GAMM=gamma**
  Sets the coefficient of the energy term corresponding to the gradient. A high value of gamma makes the snake follow lines of high image gradient.

- **/GRDI=gWave**
  Specify the gradient image. This wave must have the same dimensions as srcWave and it must be single precision float. The wave corresponds to the quantity abs(grad(gauss**srcWave)), where grad is the gradient operator and ** denotes convolution of the source wave with a Gaussian kernel. It is best to run the operation the first time without specifying this wave. When the operation executes, it creates the wave M_GradImage which can then be used in subsequent executions of this operation. If you want to modify the wave to express some other form of energy that you want the operation to minimize, you should use the /EXEN and /EXEF flags.
Details

A snake is a two-dimensional, usually closed, path drawn over an image. The snake is described by a pair of XY waves consisting of N vertices (sometimes called “snake elements” or “snaksels”). In this implementation it is assumed that the snake is closed so that the last point in the snake is connected to the first. Snakes are used in image segmentation, when you want to automatically select a contiguous portion of the plane based on some criteria. Unlike the classic contours, snakes do not have to follow a constant level. Their structure (or path) is found by associating the concept of energy with every snake configuration and attempting to find the configuration for which the associated energy is a minimum. The search for a minimum energy configuration is usually time consuming and it strongly depends on the format of the energy function and the initial conditions (as defined by the starting snake). The operation computes the energy as a sum of the following 5 terms:

1. The coefficient alpha times a sum of absolute deviations from the average snake segment length. This term tends to distribute the vertices of the snake at even intervals.
2. The coefficient beta times a sum of energies associated with the curvature of the snake at each vertex.
3. The coefficient gamma times a sum of energies computed from the negative magnitude of the gradient of a Gaussian kernel convolved with the image. This term is usually referred to in the literature as the external energy and usually drives the snake to follow the direction of high image gradients.
4. The coefficient delta times a repulsion energy. Repulsion is computed as an inverse square law by adding contributions from all vertices except the two that are immediately connected to each vertex. This energy term is designed to make sure that the snake does not fold itself into “valleys”.

5. The coefficient eta times the sum of values corresponding to the positions of all snake vertices in the wave you provide in /EXEN.

The energy calculation skips all terms for which the coefficient is zero. In addition there is a built-in scan which adds a very high penalty for configurations in which the snake crosses itself.

ImageSkeleton3D

The ImageSkeleton3D operation computes the skeleton of a 3D binary object in srcWave by “thinning”. Thinning is a layer-by-layer erosion until only the “skeleton” of an object remains. (See reference below.) It is used in neuroscience to trace neurons.

The ImageSkeleton3D operation was added in Igor Pro 7.00.

**Parameters**

srcWave is a 3D unsigned-byte wave where object voxels are set to 1 and the background is set to 0.

**Flags**

/DEST=destWave Specifies the wave to contain the output of the operation. If the specified wave already exists, it is overwritten.

When used in a user-defined function, ImageSkeleton3D creates wave reference for destWave if it is a simple name. See Automatic Creation of WAVE References on page IV-71 for details.

If you omit /DEST the output wave is M_Skeleton in the current data folder.

/METH=m Sets the method used to compute the skeleton.

m=1: Uses elements of an algorithm by Kalman Palagyi (default).

This is currently the only supported method.

/Z Do not report any errors.

**Details**

The output is stored in the wave M_Skeleton in the current data folder or in the wave specified by /DEST.

Skeleton voxels are set to the value 1 and background voxels are set to 0.

**Example**

// Create a cube with orthogonal square holes
Make/B/U/N=(30,30,30) ddd=0
ddd[2,27] [2,27] [2,27]=1
ddd[2,27] [10,20] [10,20]=0
ddd[10,20] [2,27] [10,20]=0
ddd[10,20] [10,20] [2,27]=0
ImageSkeleton3D ddd

ImageStats

ImageStats [ flags ] imageWave

The ImageStats operation calculates wave statistics for specified regions of interest in a real matrix wave. The operation applies to image pixels whose corresponding pixels in the ROI wave are set to zero. It does not print any results in the history area.
Flags

/BEAM Computes the average, minimum, and maximum pixel values in each layer of a 3D wave and 2D ROI. Output is to waves W_ISBeamAvg, W_ISBeamMax, and W_ISBeamMin in the current data folder. Use /RECT to improve efficiency for simple ROI domains. V_ variable results correspond to the last evaluated layer of the 3D wave. Do not use /G, /GS, or /P with this flag. Set /M=1 for maximum efficiency.

/BRXY={xWave, yWave} Use this option with a 3D imageWave. It provides a more efficient method for computing average, minimum and maximum values when the set of points of interest is much smaller than the dimensions of an image.

Here xWave and yWave are 1D waves with the same number of points containing XY integer pixel locations specifying arbitrary pixels for which the statistics are calculated on a plane by plane basis as follows:

\[ W_{ISBeamAvg}[k] = \frac{1}{n} \sum_{i=1}^{n} Image[xWave[i]][yWave[i]]. \]

Pixel locations are zero-based; non-integer entries may produce unpredictable results.

The calculated statistics for each plane are stored in the current data folder in the waves W_ISBeamAvg, W_ISBeamMax and W_ISBeamMin.

Note: This flag is not compatible with any other flag except /BEAM.

/C=chunk When imageWave is a 4D wave, /C specifies the chunk for which statistics are calculated. By default chunk = 0.

Added in Igor Pro 7.00.

/G={startP, endP, startQ, endQ} Specifies the corners of a rectangular ROI. When this flag is used an ROI wave is not required. This flag requires that startP ≤ endP and startQ ≤ endQ. When the parameters extend beyond the image area, the command will not execute and V_flag will be set to -1. You should therefore verify that V_flag=0 before using the results of this operation.

/GS={sMinRow, sMaxRow, sMinCol, sMaxCol} Specifies a rectangular region of interest in terms of the scaled image coordinates. Each one of the 4 values will be translated to an integer pixel using truncation.

This flag, /G, and an ROI specification are mutually exclusive.

/M=val Calculates the average and locates the minimum and the maximum in the ROI when /M=1. This will save you the computation time associated with the higher order statistical moments.

/P=planeNumber Restricts the calculation to a particular layer of a 3D wave. By default, planeNumber = -1 and only the first layer of the wave is processed.

/R=roiWave Specifies a region of interest (ROI) in the image. The ROI is defined by a wave of type unsigned byte (/b/u), which has the same number of rows and columns as the image wave. The ROI itself is defined by the entries/pixels whose value are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous. See ImageGenerateROIWave for more information on creating ROI waves.

/RECT={minRow, maxRow, minCol, maxCol} Limits the range of the ROI to a rectangular pixel range with /BEAM.
ImageThreshold

Details
The image statistics are returned via the following variables:

- **V_aDev**: Average deviation of pixel values.
- **V_avg**: Average of pixel values.
- **V_kurt**: Kurtosis of pixel values.
- **V_min**: Minimum pixel value.
- **V_minColLoc**: Specifies the location of the column in which the minimum pixel value was found or the first eligible column if no single column was found.
- **V_minRowLoc**: Specifies the location of the row in which the minimum pixel value was found or the first eligible row if no single minimum was found.
- **V_max**: Maximum pixel value.
- **V_maxColLoc**: Specifies the location of the column in which the maximum pixel value was found or the first eligible column if no single column was found.
- **V_maxRowLoc**: Specifies the location of the row in which the maximum pixel value was found or the first eligible row if no single maximum was found.
- **V_npnts**: Number of points in the ROI.
- **V_rms**: Root mean squared of pixel values.
- **V_sdev**: Standard deviation of pixel values.
- **V_skew**: Skewness of pixel values.

Most of these statistical results are similarly defined as for the WaveStats operation. WaveStats will be more convenient to use when calculating statistics for an entire wave.

If `imageWave` is 4D it is often useful to use the reversible conversion:

```plaintext
Redimension/N=(rows,cols,layers*chunks) ImageWave
```

which allows you to obtain the statistics for each layer and all chunks of the wave. To convert back to 4D, execute:

```plaintext
Redimension/N=(rows,cols,layers,chunks) ImageWave
```

ImageThreshold

**ImageThreshold [flags] imageMatrix**

The ImageThreshold operation converts a grayscale `imageMatrix` into a binary image. The operation supports all data types. However, the source wave must be a 2D matrix. If `imageMatrix` contains NaNs, the pixels corresponding to NaN values are mapped into the value 64. The values for the On and Off pixels are 255 and 0 respectively. The resulting image is stored in the wave `M_ImageThresh`.

Flags

- **/C**: Calculates the correlation coefficient between the original image and the image generated by the threshold operation. The correlation value is printed to the history area (unless the `/Q` flag is specified), it is also stored in the variable `V_correlation`.
- **/I**: Inverts values written to the image, i.e., sets to zero all pixels above threshold.
**ImageThreshold**

<table>
<thead>
<tr>

</tr>
<tr>
<td>/method=5:</td>
<td>Fuzzy thresholding using a method that minimizes a “fuzziness” measure involving the mean gray level in the object and background.</td>
</tr>
<tr>
<td>/method=6:</td>
<td>Determines an ideal threshold by histogramming the data and representing the image as a set of clusters that is iteratively reduced until there are two clusters left. The threshold value is then set to the highest level of the lower cluster. This method is based on a paper by A.Z. Arifin and A. Asano (see reference below) but modified for handling images with relatively flat histograms. If the image histogram results in less than two clusters, it is impossible to determine a threshold using this method and the threshold value is set to NaN. Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td>/method=7:</td>
<td>Determines the ideal threshold value by maximizing the total variance between the “object” and the “background”. See <a href="http://en.wikipedia.org/wiki/Otsu%27s_method">http://en.wikipedia.org/wiki/Otsu%27s_method</a>.</td>
</tr>
</tbody>
</table>

| /N | Sets the background level to 64 (i.e., NaN). |

| /O | Overwrites the original image with the calculated threshold image. If you do not specify the /O flag, the threshold image is written into the wave `M_ImageThresh`. |

| /P=layer | When `imageMatrix` is a 3D wave /P selects a specific layer for which to compute the threshold. `layer` is the zero-based layer index. If `layer` is -1, which is the default value, the threshold is computed for all layers of `imageMatrix`. The /P flag is not compatible with /O. The /P flag was added in Igor Pro 7.00. |

| /Q | Suppresses printing calculated correlation coefficients (/C) and calculated thresholds (/M) to the history area. |

| /R=roiSpec | Specifies a region of interest (ROI). The ROI is defined by a wave of type unsigned byte (/b/u). The ROI wave must have the same number of rows and columns as the image wave. The ROI itself is defined by the entries/pixels whose values are 0. Pixels outside the ROI can take any nonzero value. The ROI does not have to be contiguous and can take any arbitrary shape. See `ImageGenerateROIMask` for more information on creating ROI waves. |
ImageTransform

In general, the roiSpec has the form [roiWaveName, roiFlag], where roiFlag can take the following values:

roiFlag=0: Set pixels outside the ROI to 0.
roiFlag=1: Set pixels outside the ROI as in original image.
roiFlag=2: Set pixels outside the ROI to NaN (=64).

By default roiFlag is set to 1 and it is then possible to use the /R flag using the abbreviated form /R=roiWave.

/T=thresh Sets the threshold value.
/W= Twave Sets the threshold intervals. Each interval is specified by a pair of values in the wave Twave. The first element in each pair is the low value and the second element is the high value. Pixel values that lie outside all the specified intervals are set to 0.

ImageTransform

ImageTransform [flags] Method imageMatrix
The ImageTransform operation performs one of a number of transformations on imageMatrix. The result of using most keywords is a new wave stored in the current data folder. Most flags in this operation are exclusive to the keywords in which they are mentioned.

Parameters
Method selects type of transform. It is one of the following names:

averageImage Computes an average image for a stack of images contained in 3D imageMatrix. The average image is stored in the wave M_AveImage and the standard deviation for each pixel is stored in the wave M_StdvImage in the current data folder. You can use this keyword together with the optional /R flag where a region of interest is defined by zero value points in a ROI wave. The operation sets to NaN the entries in M_AveImage and M_StdvImage that correspond to pixels outside the ROI. imageMatrix must have at least three layers.

averageRGBImage Computes an average image from a sequence of RGB images represented by a 4D wave. The average is computed separately for the R, G and B channels and the resulting RGB image is stored in the wave M_AverageRGBImage in the current data folder. The operation supports all real data types.

Added in Igor Pro 7.00.

<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>backProjection</td>
<td>Reconstructs the source image from a projection slice and stores the result in the wave M_BackProjection. The projection slice should either be a wave produced by the projectionSlice keyword of this operation or a wave that would be similarly scaled. The input must be a single or double precision real 2D wave. Row scaling must range symmetrically about zero. For example, if the reconstructed image is expected to have 256 rows then the row scaling of the input should be from -128 to 127. Similarly, the column scaling of the input should range between zero and $\pi$. An equivalent implementation as a user function is provided in the demo experiment. You can use this implementation as a starting point if you want to develop filtered back projection. See the projectionSlice keyword and the RadonTransformDemo experiment. For algorithm details see the chapter “Reconstruction of cross-sections and the projection-slice theorem of computerized tomography” in Born and Wolf, 1999.</td>
</tr>
<tr>
<td>ccs subdivision</td>
<td>Performs a Catmull-Clark recursive generation of B-spline surfaces. There are two valid inputs: triangular meshes or quad meshes. Quad meshes are assumed to be in the form of a 3D wave where the first plane contains the X-values, the second the Y-values and the third the Z-values. Triangle meshes are much more complicated to convert into face-edge-vertex arrays so they are less desirable. They are stored in a three column (triplet) wave where the first column corresponds to the X coordinate, the second to the Y coordinate and the third to the Z coordinate. Each triangle is described by three rows in the wave and common vertices have to be repeated so that each sequential three rows in the triplet wave correspond to a single triangle. You can also associate a scalar value with each vertex and it will be suitably interpolated as new vertices are computed and old ones are shifted. In this case the input source wave contains one more column in the case of a triplet wave or one more plane in the case of a quad wave. The scalar value is added everywhere as an additional dimension to the spatial part of any point calculation. You can specify the number of iterations using the /I flag. By default the operation executes a single iteration. The output is saved in a quad wave M_CCBSplines that consists of 4 columns. Each row corresponds to a Quad where the 3 planes contain the X, Y, and Z components. If you are using an optional scalar in the input, the scalar result is stored in the wave M_CCBScalar.</td>
</tr>

</tr>
<tr>
<td>CMYK2RGB</td>
<td>Converts a CMYK image, stored as 4 layer unsigned byte wave, into a 3 layer, standard RGB image wave. The output wave is M_CMYK2RGB that is stored in the current data folder.</td>
</tr>
<tr>
<td>compress</td>
<td>Compresses the data in the imageWave using a nonlossy algorithm and stores it in the wave W_Compressed in the current data folder. The compressed wave includes all data associated with imageWave including its units and wavenote. Use the decompress keyword to recover the original wave. The operation supports all numeric data types. <strong>NOTE:</strong> The compression format for waves greater than 2GB in size was changed in version 6.30B02. If you compressed a wave greater than 2 GB in IGOR64 6.30B01, you will need to decompress it using the same version. You can not decompress it in 6.30B02 or later.</td>
</tr>
<tr>
<td>convert2gray</td>
<td>Converts an arbitrary 2D wave into an 8-bit normalized 2D wave. The default output wave name is M_Image2Gray.</td>
</tr>
<tr>
<td>decompress</td>
<td>Decompresses a compressed wave. It saves a copy of the decompressed wave under the name W_DeCompressed in the current data folder. <strong>NOTE:</strong> The compression format for waves greater than 2GB in size was changed in version 6.30B02. If you compressed a wave greater than 2 GB in IGOR64 6.30B01, you will need to decompress it using the same version. You can not decompress it in 6.30B02 or later.</td>
</tr>
</tbody>
</table>
**distance**

Computes the distance transform, also called "distance map", for the input image. Added in Igor Pro 7.00.

The distance transform/map is an image where every pixel belonging to the "object" is replaced by the shortest distance of that pixel from the background/boundary.

`imageMatrix` must be a 2D wave of type unsigned byte (Make/B/U) where pixels corresponding to the object are set to zero and pixels corresponding to the background are set to 255. Such an image can be obtained, for example, using **ImageThreshold** with the `/f` flag.

The resulting distance map is stored in the wave M_DistanceMap in the current data folder. The operation supports three metrics (Manhattan, Euclidean, Euclidean + scaling) set via the `/METR` flag.

---

**extractSurface**

Extracts values corresponding to a plane that intersects a 3D volume wave (`imageMatrix`). You must specify the extraction parameters using the `/X` flag. The volume is defined by the wave scaling of the 3D wave. The result, obtained by trilinear interpolation, is stored in the wave M_ExtractedSurface and is of the type NT_FP64. Points in the plane that lie outside the volume are set to NaN.

---

**fht**

Performs a Fast Hartley Transform subject to the `/T` flag. The source wave must be a 2D real matrix with a power of 2 number of rows and columns. Default output is saved in the double-precision wave M_Hartley in the current data folder. If you use the `/O` flag the result overwrites `imageMatrix` without changing the numeric type. If `imageMatrix` is single-precision float the conversion is straightforward. All other numeric types are scaled. Single- and double-byte types are scaled to the full dynamic range. 32 bit integers are scaled to the range of the equivalent 16 bit types (i.e., unsigned int is scaled to unsigned short range etc.). It does not support wave scaling or NaN entries.

---

**fillImage**

Fills a 2D target image wave with data from a 1D image wave (specified using `/D`). Both waves must be the same data type, and the number of data points in the target wave must match the number of points in the data wave. There are four fill modes that are specified via the `/M` flag. The operation supports all noncomplex numeric data types.

---

**findLakes**

Originally intended to identify lakes in geographical data, this operation creates a mask for a 2D wave for all the contiguous points whose values are close to each other. You can determine the minimum number of pixels within a contiguous region using the `/LARA=minPixels` flag (default is 100). You can determine how close values must be in order to belong to a contiguous region using the `/LTOL=tolerance` flag (default is zero). You can also limit the search region using the `/LRCT` flag. Use the flag `/LTAR=target` to set the value of the masked regions. By default, the algorithm uses 4-connectivity when looking at adjacent pixels. You can set it to 8-connectivity using the `/LCVT` flag. The result of the operation is saved in the wave M_LakeFill. It has the same data type as the source wave and contains all the source values outside the masked pixels.

---

**flipCols**

Rearrange pixels by exchanging columns symmetrically about a center column or the center of the image (if the number of columns is even). The exchange is performed in place and can be reverted by repeating the operation. When working with 3D waves, use the `/P` flag to specify the plane that you want to operate on.

---

**flipRows**

Rearrange pixels in the image by exchanging rows symmetrically about the middle row or the middle of the image (if the image has an even number of rows). The exchange is performed in place and can be reverted by repeating the operation. When working with 3D waves, use the `/P` flag to specify the plane that you want to operate on.

---

**flipPlanes**

Rearrange data in a 3D wave by exchanging planes symmetrically about the middle plane. The operation is performed in place and can be reverted by repeating the operation.
fuzzyClassify  Segments grayscale and color images using fuzzy logic. Iteration stops when it reaches convergence defined by /TOL or the maximum number of iterations specified by /I. It is a good practice to specify the tolerance and the number of iterations. If the number of classes is small, the operation prints the class values in the history. Use /Q to eliminate printing and increase performance. Use /CLAS to specify the number of classes and optionally use /CLAM to modify the fuzzy probability values. Use /SEG to generate the segmentation image. The classes are stored in the wave W_FuzzyClasses in the current data folder and it will be overwritten if it already exists.

When imageMatrix is a grayscale image, each class is a single wave entry. When imageMatrix is a RGB image, classes are stored consecutively in the wave W_FuzzyClasses. If you request more classes than are present in imageMatrix, you will likely find a degeneracy where the space of a data class is spanned by more than one class. It is a good idea to compute the Euclidean distance between every possible pair of classes and eliminate degeneracies when the distance falls below some threshold.

Any real data type is allowed but values in the range [0,255] are optimal. You can segment 3D waves of more than 3 layers in which a class will be a vector of dimensionality equal to the number of layers in imageMatrix.

For examples see Examples/Imaging/fuzzyClassifyDemo.pxp.

getBeam  Extracts a beam from a 3D wave.

A “beam” is a 1D array in the Z-direction. If a row is a 1D array in the first dimension and a column is a 1D array in the second dimension then a beam is a 1D array in the third dimension.

The number of points in a beam is equal to the number of layers in imageWave. Specify the beam with the /BEAM={row,column} flag. It stores the result in the wave W_Beam in the current data folder. W_Beam has the same numeric type as imageWave. Use setBeam to set beam values. (See also, MatrixOp beam.)

getChunk  Extracts the chunk specified by chunk index /CHIX from imageMatrix and stores it in the wave M_Chunk in the current data folder. For example, if imageMatrix has the dimensions (10,20,3,10), the resulting M_Chunk has the dimensions (10,20,3). See also setChunk and insertChunk.

getCol  Extracts a 1D wave, named W_ExtractedCol, from any type of 2D or 3D wave. You specify the column using the /G flag. For a 3D source wave, it will use the first plane unless you specify a plane using the /P flag. imageMatrix can be real or complex. (See also putCol keyword, MatrixOp col.)

getPlane  Creates a new wave, named M_ImagePlane, that contains data in the plane specified by the /P flag. The new wave is of the same data type as the source wave. You can specify the type of plane using the /PTYP flag. (See also setPlane keyword, MatrixOp.)

getRow  Extracts a 1D wave, named W_ExtractedRow, from any type of 2D or 3D wave. You specify the row using the /G flag. For a 3D source wave, it will use the first plane unless you specify a plane using the /P flag. imageMatrix can be real or complex. (See also setRow keyword, MatrixOp row.)
**Hough**

Performs the Hough transform of the input wave. The result is saved to a 2D wave M_Hough in which the columns correspond to angle and the rows correspond to the radial domain.

By default the output consists of 180 columns. Use the /F flag to modify the angular resolution.

If the input image has N rows and M columns then the number of rows in the M_Hough is set to 1+sqrt(N^2+M^2).

It is assumed that the input wave has square pixels of unit size and that is binary (/B/U) where the background value is 0.

See also **Hough Transform** on page III-345.

**hsl2rgb**

Transforms a 3-plane HSL wave into a 3-plane RGB wave. If the source wave for this operation is of any type other than byte or unsigned byte, the HSL values are expected to be between 0 and 65535. For all source wave types the resulting RGB wave is of type unsigned short. The result of the operation is the wave M_HSL2RGB (of type unsigned word), where the RGB values are in the range 0 to 65535.

**hslSegment**

Creates a binary image of the same dimensions as the source image, in which all pixels that belong to all three of the specified Hue, Saturation, and Lightness ranges are set to 255 and the others to zero. You can specify the HSL ranges using the /H, /S, and /L flags. Each flag takes as an argument either a pair of values or a wave containing pairs of values. You must specify the /H flag but you can omit the /S and /L flags in which case the default values (corresponding to full range 0 to 1) are used. imageMatrix is assumed to be an RGB image.

**imageToTexture**

Transforms a 2D or 3D image wave into a 1D wave of contiguous pixel components. The transformation is useful for creating an OpenGL texture (for Gizmo) or for saving a color image in a format requiring either RGB or RGBA sequences.

The /O flag does not apply to imageToTexture.

Use the /TEXT flag to specify the type of transformation. imageMatrix must be an unsigned byte wave. A 1D unsigned byte wave named W_Texture is created in the current data folder.

W_Texture's wave note is set to a semicolon-separated list of keyword-value pairs that can be parsed using **StringByKey** and **NumberByKey**:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>WIDTHPIXELS</td>
<td>DimSize(imageMatrix,0) or truncated to nearest power of 2 if /TEXT value is odd</td>
</tr>
<tr>
<td>HEIGHTPIXELS</td>
<td>DimSize(imageMatrix,1) or truncated to nearest power of 2</td>
</tr>
<tr>
<td>LAYERS</td>
<td>DimSize(imageMatrix,2)</td>
</tr>
<tr>
<td>TEXTUREMODE</td>
<td>val parameter from /TEXT flag</td>
</tr>
<tr>
<td>SOURCEWAVE</td>
<td>GetWavesDataFolder(imageMatrix, 2)</td>
</tr>
</tbody>
</table>

**indexWave**

Creates a 1D wave W_IndexedValues in the current data folder containing values from imageMatrix that are pointed to by the index wave (see /IWAV). Each row in the index wave corresponds to a single value of imageMatrix. If any row does not point to a valid index (within the dimensions of imageMatrix), the corresponding value is set to zero and the operation returns an error. Indices are zero based integers; the operation does not support interpolation and ignores wave scaling.

**insertChunk**

Inserts a chunk (a 3D wave specified by the /D flag) into imageMatrix at chunk index specified by the /CHIX flag. The dimensions of the inserted chunk must match the first three dimensions of imageMatrix. The wave must also have the same numeric type. The 4th dimension of imageMatrix is incremented by 1 to accommodate the new data. See also **getChunk** and **setChunk**.
insertImage  
Inserts the image specified by the flag /INSI into imageMatrix starting at the position specified by the flags /INSX and /INSY. If the imageMatrix is a 3D wave then it inserts the image in the layer specified by the /P flag. The inserted image and imageMatrix must be the same data type. The inserted data is clipped to the boundaries of imageMatrix.

insertXplane  
Inserts a 2D wave as a new plane perpendicular to the X-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be cols x layers of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 20x30. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder.

insertYplane  
Inserts a 2D wave as a new plane perpendicular to the Y-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be rows x layers of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 10x30. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder.

insertZplane  
Inserts a 2D wave as a new plane perpendicular to the Z-axis in a 3D wave. The /P flag specifies the insertion point and the /INSW flag specifies the inserted wave. The 2D wave must be the same numeric data type as the 3D wave and its dimensions must be rows x cols of the 3D wave. For example, if the 3D wave has the dimensions (10x20x30) the 2D wave must be 10x20. If you do not use the /O flag, it stores the result in the wave M_InsertedWave in the current data folder. This keyword is included for completeness. You can accomplish the same task using InsertPoints.

invert  
Converts pixel values using the formula newValue=255-oldValue. Works on waves of any dimension, but only on waves of type unsigned byte. The result is stored in the wave M_Inverted unless specifying the /O flag.

matchPlanes  
Finds pixels that match test conditions in all layers of a 3D wave. It creates a 2D unsigned byte output wave, M_matchPlanes, that is set to the values 0 and 255. A value of 255 indicates that the corresponding pixel has satisfied test conditions in all layers of the wave for which conditions were provided. Otherwise the pixel value is 0.

Test conditions are entered as a 2D wave using the /D flag. The condition wave must be double precision and it must contain the same number of columns as the number of layers in the 3D source wave. A condition for layer j of the source wave is specified by two rows in column j of the condition wave. The first row entry, say A, and the second row entry, say B, imply a condition on pixels in layer j such that A ≤ x < B. You can have more than one condition for a given layer by adding pairs of rows to the condition wave. For example, if you add in consecutive rows the values C and D, this implies the test:

\[(A \leq x \leq B) \lor (C \leq x \leq D)\].

If you do not have any conditions for some layer, set its corresponding condition column to NaN. Similarly, if you have two conditions for the first layer and one condition for the second layer, pad the bottom of column 1 in the condition wave with NaNs. See Examples for use of this keyword to perform hue/saturation segmentation.

offsetImage  
Shifts an image in the XY plane by dx, dy pixels (specified by the /IOFF flag). Pixels outside the shifted image will be set to the specified background value. The operation works on 2D waves or on 3D waves with the optional /P flag. When shifting a 3D wave with no specified plane, it creates a 3D wave with all planes offset by the same amount. The wave M_OffsetImage contains the result in the current data folder.

The /O flag is not supported with offsetImage.
### ImageTransform

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>padImage</td>
<td>Resizes the source image. When enlarged, values from the last row and column fill in the new area. The /N flag specifies the new image size in terms of the rows and columns change. The /W flag specifies whether data should be wrapped when padding the image. Unless you use the /O flag, the result is stored in the wave M_PaddedImage in the current data folder.</td>
</tr>
<tr>
<td>projectionSlice</td>
<td>Computes a projection slice for a parallel fan of rays going through the image at various angles. For every ray in the fan the operation computes a line integral through the image (equivalent to the sum of the line profile along the ray). The operation computes the line integrals for multiple fans defined by the number and position of the rays as well as the angle that they make with the positive X-direction. Use the /PSL flag to specify the projection parameters. The projection slice itself is stored in a 2D wave M_ProjectionSlice where the rows correspond to the rays and the columns correspond to the selected range of angles. The operation does not support wave scaling. If the source wave is 3D the projection slice currently supports slices that are perpendicular to the z-axis and specified by their plane number. See the backProjection keyword and the RadonTransformDemo experiment. For algorithm details see the chapter “Reconstruction of cross-sections and the projection-slice theorem of computerized tomography” in Born and Wolf, 1999.</td>
</tr>
<tr>
<td>putCol</td>
<td>Sets a column of imageMatrix to the values in the wave specified by the /D flag. Use the /G flag to specify column number and the /P flag to specify the plane. Note that if there is a mismatch in the number of entries between the specified waves, the operation uses the smaller number. See also getCol keyword.</td>
</tr>
<tr>
<td>putRow</td>
<td>Sets a row of imageMatrix to the values in the wave specified by the /D flag. Use the /G flag to specify column number and the /P flag to specify the plane. Note that if there is a mismatch in the number of entries between the specified waves, the operation uses the smaller number. See also getRow keyword.</td>
</tr>
<tr>
<td>removeXplane</td>
<td>Removes one or more planes perpendicular to the X-axis from a 3D wave. The /P flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the /NP flag. If you do not use the /O flag, it saves the result in the wave M_ReducedWave in the current data folder.</td>
</tr>
<tr>
<td>removeYplane</td>
<td>Removes one or more planes perpendicular to the Y-axis from a 3D wave. The /P flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the /NP flag. If you do not use the /O flag, it saves the result in the wave M_ReducedWave in the current data folder.</td>
</tr>
<tr>
<td>removeZplane</td>
<td>Removes one or more planes perpendicular to the Z-axis from a 3D wave. The /P flag specifies the starting position. By default, it removes a single plane but you can remove more planes with the /NP flag. If you do not use the /O flag, it saves the result in the wave M_ReducedWave in the current data folder.</td>
</tr>
<tr>
<td>rgb2cmap</td>
<td>Computes a default color map of 256 colors to represent the input RGB image. The colors are computed by clustering the input pixels in RGB space. The resulting color map is stored in the wave M_ColorIndex in the current data folder. The operation also saves the wave M_IndexImage which contains an index into the colormap that can be used to display the image using the commands: NewImage M_IndexImage ModifyImage M_IndexImage cindex= M_ColorIndex To change the default number of colors use the /NCLR flag. When the number of colors are greater than 256, M_IndexImage will be a 16-bit unsigned integer or a 32 bit integer wave depending on the number. rgb2cmap supports input images in the form of 3D waves of type unsigned byte or single precision float. The floating point option may be used to input images in colorspace that use signed numeric data.</td>
</tr>
</tbody>
</table>
rgb2gray

When the input `imageMatrix` is a 3D RGB wave, rgb2gray produces a 2D wave of type unsigned byte containing the grayscale representation of the input. By default, the operation stores the output in the wave `M_RGB2Gray` in the current data folder. The RGB values are converted into the luminance $Y$ of the YIQ standard using:

$$Y = 0.299R + 0.587G + 0.114B$$

When the input imageMatrix is a 4D wave containing multiple (3 layer) RGB chunks, the conversion produces a 3D wave where each layer corresponds to the grayscale conversion of the corresponding chunk in the input wave. In this case the numeric type of the output is the same as that of the input but the conversion formula is the same. The /O flag is not supported when transforming a 4D RGB wave.

rgb2hsl

Converts an RGB image stored in a 3D wave into another 3D wave in which the three planes correspond to Hue, Saturation and Lightness in the HSL color model. Values of all components are normalized to the range 0 to 255 unless the /U flag is used or if the source wave is not 8-bit, in which case the range is 0 to 65535. The default output wave name is M_RGB2HSL.

rgb2i123

Performs a colorspace conversion of an RGB image into the following quantities:

$$I_1 = |R - G| \cdot D$$
$$I_2 = |R - B| \cdot D$$
$$I_3 = |G - B| \cdot D,$$

where $D = \frac{255}{|R - G| + |R - B| + |G - B|}$.

$I_1$, $I_2$, and $I_3$ are stored in the wave M_I123 (using the same data type as the original RGB wave) in the current data folder. $I_1$ is stored in the first layer, $I_2$ in the second and $I_3$ in the third. This color transformation is said to have useful applications in machine vision.

For more information see: Gevers and Smeulders (1999).

rgb2xyz

Converts a 3D RGB image wave into a 3D wave containing the XYZ color space equivalent. The conversion is based on the D65 white point and uses the following transformation:

$$\begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 0.412453 & 0.357580 & 0.180423 \\ 0.212671 & 0.715160 & 0.072169 \\ 0.019334 & 0.119193 & 0.950227 \end{bmatrix} \begin{bmatrix} R \\ G \\ B \end{bmatrix}.$$  

The XYZ values are stored in a wave named “M_RGB2XYZ” unless the /O flag is used, in which case the source image is overwritten and converted into single precision wave (NT_FP32).

roiTo1D

Copies all pixels in an ROI and saves them sequentially in a 1D wave. The ROI is specified by /R. The ROI wave must have the same dimensions as `imageMatrix`. If `imageMatrix` is a 3D wave, the ROI must have as many layers as `imageMatrix`. The wave `W_roi_to_1d` contains the output in the current data folder, has the same numeric type as `imageMatrix`, and contains the selected pixels in a column-major order.

rotateCols

Rotates rows in place. This operation is analogous to the Rotate operation except that it works on images and rotates an integer number of rows. The number of rows is specified by the /G flag.

When `imageMatrix` contains multiple layers you can use the /P flag to specify the layer of the wave that will undergo rotation. By default, if you do not specify the /P flag and if `imageMatrix` consists of three layers (RGB), then all three layers are rotated. Otherwise the operation rotates only the first layer of the wave.
rotateRows

Rotates columns in place. This operation is analogous to the Rotate operation except that it works on images and rotates an integer number of columns. The number of columns is specified by the /G flag.

When imageMatrix contains multiple layers you can use the /P flag to specify the layer of the wave that will undergo rotation. By default, if you do not specify the /P flag and if imageMatrix consists of three layers (RGB), then all three layers are rotated. Otherwise the operation rotates only the first layer of the wave.

circlePlanes

Scales each plane of the 3D wave, imageMatrix, by a constant taken from the corresponding entry in the 1D wave specified by the /D flag. The result is stored in the wave M_ScaledPlanes unless the /O flag is specified, in which case scaling is done in place.

When using /O, first redimension the wave to a different data type to make sure there are no artifacts due to type clipping.

If imageMatrix is double precision, M_ScaledPlanes is double precision. Otherwise M_ScaledPlanes is single precision.

This operation also supports the optional flag.

Note that when you display M_ScaledPlanes, which has three planes that originated from scaling byte data, you will have to multiply the wave by 255 to see the image because the RGB format for single and double precision data requires values in the range 0 to 65535.

selectColor

Creates a mask for the image in which pixel values depend on the proximity of the color of the image to a given central color. The central color, the tolerance and a grayscale indicator must be specified using the /E flag.

For example, /E={174, 187, 75, 10, 1} specifies an RGB of (174,187,75), a tolerance level of 10 and a requested grayscale output.

RGB values must be provided in a range appropriate for the source image. If the source wave type is not byte or unsigned byte, then the range of the RGB components should be 0 to 65535.

The color proximity is calculated in the nonuniform RGB space and the tolerance applies to the maximum component difference from the corresponding component of the central color.

The tolerance, just like the central color, should be appropriate to the type of the source wave.

The generated mask is stored in the wave M_SelectColor in the current data folder. If a wave by that name exists prior to the execution of this operation, it is overwritten. You can also use the /R flag with this operation to limit the color selection to pixels in the ROI wave whose value is zero.

setBeam

Sets the data of a particular beam in imageMatrix.

A “beam” is a 1D array in the Z-direction. If a row is a 1D array in the first dimension and a column is a 1D array in the second dimension then a beam is a 1D array in the third dimension.

Specify the beam with the /BEAM={row, column} flag and the 1D beam data wave with the /D flag. The beam data wave must have the same number of elements as the number of layers and same numeric type as imageMatrix. Use getBeam to extract the beam.

setChunk

Overwrites the data in the wave imageMatrix at chunk index specified by /CHIX with the data contained in a 3D wave specified by the /D flag. The assigned data must be contained in a wave that matches the first three dimensions of imageMatrix and must have the same number type. See also getChunk and insertChunk.
setPlane  
Sets a plane (given by the /P flag) in the designated image with the data in a wave specified by the /D flag. It is designed as a complement of the `getPlane` keyword to provide an easier (faster) way to create multiplane images. Note that the operation supports setting a plane when the source data is smaller than the destination plane in which case the source data is placed in memory contiguously starting from the corner pixel of the destination plane. If the source data is larger than the destination plane it is clipped to the appropriate rows and columns. If you are setting all planes in the destination wave using algorithmically named source waves you could use the `stackImages` keyword instead. See also `getPlane` keyword.

shading  
Calculates relative reflectance of a surface for a light source position defined by the /A flag.

The operation estimates the slope of the surface and then computes a relative reflectance defined as the dot product of the direction of the light and the normal to the surface at the point of interest. Reflectivity is scaled using the expression:

\[ \text{outPixel} = \text{shadingA} \times (\text{sunDirection} \cdot \text{surfaceNormal}) + \text{shadingB} \]

By default `shadingA`=1, `shadingB`=0.

The result is stored in the wave `M_ShadedImage`, which has the same data type as the source wave.

If the source wave is any integer type, and the value of `shadingA`=1 the operation sets that value to 255.

The smallest supported wave size is 4x4 elements.

Values along the boundary (1 pixel wide) are arbitrary because there are no derivatives calculable for those pixels, so these pixels are filled with duplicates of the inner rows and columns.

shrinkBox  
Shrinks 3D `imageMatrix` to include only the minimum three dimension rectangular range that contains all the voxels whose values are different from an outer value. The outer value is specified with the /F flag. This feature is useful in situations where `ImageSeedFill` has set the voxels around an object of interest to some outer value and it is desired to extract the smallest box that contains interesting data. The output is stored in the wave `M_shrunkBox`.

Added in Igor Pro 7.00.

shrinkRect  
Shrinks `imageMatrix` to include only the minimum rectangle that contains all the pixels whose value is different from an outer value. The outer value is specified with the /F flag. This is useful in situations where `ImageSeedFill` has set the pixels around the object of interest to some outer value and it is desired to extract the smallest rectangle that contains interesting data. The output is stored in the wave `M_Shrunk`.

stackImages  
Creates a 3D or 4D stack from individual image waves in the current data folder. The waves should be of the form `baseNameN`, where `N` is a numeric suffix specifying the sequence order. `imageMatrix` should be the name of the first wave that you want to add to the stack. You can use the /NP flag to specify the number of waves that you want to add to the stack.

The result is a 3D or 4D wave named `M_Stack`, which overwrites any existing wave of that name in the current data folder.

With /K, it kills all waves copied into the stack.

sumAllCols  
Creates a wave `W_sumCols` in which every entry is the sum of the pixels on the corresponding image column. For a 3D wave, unless you specify a plane using the /P flag it will use the first plane by default.

sumAllRows  
Creates a wave `W_sumRows` in which every entry is the sum of the pixels on the corresponding image row. For a 3D wave, unless you specify a plane using the /P flag it will use the first plane by default.
sumCol Stores in the variable V_value the sum of the elements in the column specified by /G flag and optionally the /P flag.

sumPlane Stores in the variable V_value the sum of the elements in the plane specified by the /P flag.

sumPlanes Creates a 2D wave M_SumPlanes which contains the same number of rows and columns as the 3D source wave. Each entry in M_SumPlanes is the sum of the corresponding pixels in all the planes of the source wave. M_SumPlanes is a double precision wave if the source wave is double precision. Otherwise it is a single precision wave.

sumRow Stores in the variable V_value the sum of the elements of a row specified by /G flag and optionally the /P flag.

swap Swaps image data following a 2D FFT. The transform swaps diagonal quadrants of the image in one or more planes. This keyword does not support any flags. The swapping is done in place and it overwrites the source wave.

swap3D Swaps data following a 3D FFT. The transform swaps diagonal quadrants of the data. This keyword does not support any flags. The swapping is done in place and the source wave is overwritten.

transpose4D Converts a 4D wave into a new 4D wave where the data are reordered by dimensions specified by the /TM4D flag. The results are stored in the wave M_4DTranspose in the current data folder. There is no option to overwrite the input wave so /O has no effect with transpose4D.

Added in Igor Pro 7.00.

transposeVol Transposes a 3D wave. The transposed wave is stored in M_VolumeTranspose. The /O flag does not apply. The operation supports the following 5 transpose modes which are specified using the /G flag:

<table>
<thead>
<tr>
<th>mode</th>
<th>Equivalent Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>M_VolumeTranspose=imageMatrix[p][r][q]</td>
</tr>
<tr>
<td>2</td>
<td>M_VolumeTranspose=imageMatrix[r][p][q]</td>
</tr>
<tr>
<td>3</td>
<td>M_VolumeTranspose=imageMatrix[r][q][p]</td>
</tr>
<tr>
<td>4</td>
<td>M_VolumeTranspose=imageMatrix[q][r][p]</td>
</tr>
<tr>
<td>5</td>
<td>M_VolumeTranspose=imageMatrix[q][p][r]</td>
</tr>
</tbody>
</table>

vol2surf Creates a quad-wave output (appropriate for display in Gizmo) that wraps around 3D “particles”. A particle is defined as a region of nonzero value voxels in a 3D wave. The algorithm effectively computes a box at the resolution of the input wave which completely encloses the data. The output wave M_Boxy is a 2D single precision wave of 12 columns where each row corresponds to one disjoint quad and the columns provide the sequential X, Y, and Z coordinates of the quad vertices.

evoronoi Computes the voronoi tesselation of a convex domain defined by the X, Y positions of the input wave. imageMatrix must be a triplet wave where the first column contains the X-values, the second column contains the Y-values and the third column is an arbitrary (zero is recommended) constant. The result of the operation is stored in the two column wave M_VoronoiEdges which contains sequential edges of the Voronoi polygons. Edges are separated from each other by a row of NaNs. The outer most polygons share one or more edges with a large triangle which contains the convex domain.

xProjection Computes the projection in the X-direction and stores the result in the wave M_xProjection. See zProjection for more information.
xyz2rgb
Converts a 3D single precision XYZ color-space data into RGB based on the D65 white point. The transformation used is:

\[
\begin{bmatrix}
R \\
G \\
B
\end{bmatrix} = \begin{bmatrix}
3.240479 & -1.537150 & -0.498535 \\
-0.969256 & 1.875992 & 0.041556 \\
0.055648 & -0.204043 & 1.057311
\end{bmatrix}\begin{bmatrix}
x \\
y \\
z
\end{bmatrix}.
\]

If you do not specify the /O flag, the results are saved in a single precision 3D wave (NT_FP32) “M_XYZ2RGB”.

Note that not all XYZ values map into positive RGB triplets (consider colors that reside outside the RGB triangle in the XYZ diagram). This operation gives you the following choices: by default, the output wave is a single precision wave that will include possible negative RGB values. If you specify the /U flag, for unsigned short output wave, the operation will set to zero all negative components and scale the remaining ones in the range 0 to 65535.

yProjection
Computes the projection in the Y-direction and stores the result in the wave M_yProjection. See zProjection for more information.

zDot
Computes the dot product of a beam in srcWave with a 1D zVector wave (specified with the /D flag). This will convert stacked images of spectral scans into RGB or XYZ depending on the scaling in zVector. The srcWave and zVector must be the same data type (float or double). The wave M_StackDot contains the result in the current data folder.

zProjection
Computes the projection in the Z-direction and stores the result in the wave M_zProjection. The source wave must be a 3D wave of arbitrary data type. The value of the projection depends on the method specified via the /METH flag.

Flags

/A={azimuth, elevation [, shadingA, shadingB]}
Specifies parameters for shade. Position of the light source is given by azimuth (measured in degrees counter-clockwise) and elevation (measured in degrees above the horizon).

The parameters shadingA and shadingB are optional. By default their values are 1 and 0, respectively.

/Beam={row, column} Designates a beam in a 3D wave; both row and column are zero based.

/BPJ={width, height} Specifies the backProjection parameters: width and height are the width and height of the reconstructed image and should be equal to the size of the original wave.

/C=CMapWave Specifies the colormap wave for cmap2rgb keyword. The CMapWave is expected to be a 2D wave consisting of three columns corresponding to the RGB entries.

/CHIX=chunkIndex Identifies the chunk index for getting, inserting or setting a chunk of data in a 4D wave. chunkIndex ranges from 0 to the number of chunks in imageMatrix.

/CLAM=fuzzy Sets the value used to compute the fuzzy probability in fuzzyClassify. It must satisfy fuzzy > 1 (default is 2).

/CLAS=num Sets the number of requested classes in fuzzyClassify. If you don’t know the number of expected classes and num is too high, fuzzyClassify will likely produce some degenerate classes.

/D=waveName Specifies a data wave. Check the appropriate keyword documentation for more information about this wave.
**ImageTransform**

-/F=value

Increases the sampling in the angle domain when used with the Hough keyword. By default value=1 and the operation results in single degree increments in the interval 0 to 180, and if value=1.5 there will be 180*1.5 rows in the transform.

Specifies the outer pixel value surrounding the region of interest when used with shrinkRect keyword.

-/G=colNumber

Specifies either the row or column number used in connection with getRow or getCol keywords. This flag also specifies the transpose mode with the transposeVol keyword.

-/H={minHue, maxHue}

Specifies the range of hue values for selecting pixels. The hue values are specified in degrees in the range 0 to 360. Hue intervals that contain the zero point should be specified with the higher value first, e.g., /H={330,10}. Use hueWave when you have more than one pair of hue values that bracket the pixels that you want to select.

See HSL Segmentation on page III-355 for an example.

-/I=iterations

Sets the number of iterations in ccsubdivision and in fuzzyClassify.

-/INSI=imageWave

Specifies the wave, imageWave, to be used with the insertImage keyword. imageWave is a 2D wave of the same numeric data type as imageMatrix.

-/INSW=wave

Specifies the 2D wave to be inserted into a 3D wave using the keywords: insertXplane, insertYplane, or insertZplane.

-/INSX=xPos

Specifies the pixel position at which the first row is inserted. Ignores wave scaling.

-/INSY=yPos

Specifies the pixel position at which the first column is inserted. Ignores wave scaling.

-/IOFF={dx, dy, bgValue}

Specifies the amount of positive or negative integer offset with dx and dy and the new background value, bgValue, with the offsetImage keyword.

-/IWAV=wave

Specifies the wave which provides the indices when used with the keyword indexWave. The wave should have as many columns as the dimensions of imageMatrix (2, 3, or 4). For example, to specify indices for pixels in an image, the wave should have two columns. The first column corresponds to the row designation and the second to the column designation of the pixel. The wave can be of any number type (other than complex) and entries are assumed to be integer indices; there is no support for interpolation or for wave scaling.

-/L={minLight, maxLight}

/L=lightnessWave

Specifies the range of lightness for selecting pixels. The lightness values are in the range 0-1. If you do not use the /L flag than the default full range is used. Use lightnessWave when you have more than one pair of lightness values corresponding to the pixels that you want to select. For each pair, values should be arranged so that the smaller one is first and the larger is second. There is no restriction on the order of pairs in the wave except that they match the other waves used by the operation.

-/LARA=minPixels

Specifies the minimum number of pixels required for an area to be masked by the findLakes keyword. If you do not specify this flag, the default value used is 100.

-/LCVT

Use 8-connectivity instead of 4-connectivity.

-/LRCT={minX, minY, maxX, maxY}

Sets the rectangular region of interest for the findLakes keyword. The operation will not affect the original data outside the specified rectangle. The X and Y values are the scaled values (i.e., using wave scaling).

-/LTAR=target

Set the target value for the masked region in the findLakes keyword.
/LTOL=tol
Specifies the tolerance for the **findLakes** keyword. By default the tolerance is zero. The tolerance must be a positive number. The operation uses the tolerance by requiring neighboring pixels to have a value between that of the current pixel V and V+tol.

/M=n
Specifies the method by which a 2D target image is filled with data from a 1D wave using the **fillImage** keyword.

- **n=0**: Straight column fill, which you can also accomplish by a redimension operation.
- **n=1**: Straight row fill.
- **n=2**: Serpentine column fill. The points from the data wave are sequentially loaded onto the first column and continue from the last to the first point of the second column, and then sequentially through the third column, etc.
- **n=3**: Serpentine row fill.

/METH=method
Determines the values of the projected pixels for **xProjection**, **yProjection**, and **zProjection** keywords.

- **method=1**: Pixel (i,j) in M_zProjection is assigned the maximum value that (i,j,*) takes among all layers of imageMatrix (default).
- **method=2**: Pixel (i,j) in M_zProjection is assigned the average value that (i,j,*) takes among all layers of imageMatrix.
- **method=3**: Pixel (i,j) in M_zProjection is assigned the minimum value that (i,j,*) takes among all layers of imageMatrix.

/METR=method
Sets the metric used by the distance transform. Added in Igor Pro 7.00.

- **method=0**: Manhattan distance. Default.
- **method=1**: Euclidean distance where the distance is measured between centers of pixels (assumed square).
- **method=2**: Euclidean distance that also takes into account actual pixel size using the input’s wave scaling.

**method=0** executes faster than the other methods. **method=2** can be 2x slower especially if different scaling is applied along the two axes.

/N={rowsToAdd, colsToAdd}
Creates an image that is larger or smaller by **rowsToAdd**, **colsToAdd**. The additional pixels are set by duplicating the values in the last row and the last column of the source image.

/NCLR=M
Specifies the maximum number of colors to find with the **rgb2cmap** keyword. M must be a positive number; the default value is 256 colors.

The result of the operation is saved in the wave **M_paddedImage**.

/NP=numPlanes
Specifies the number of planes to remove from a 3D wave when using the **removeXplane**, **removeYplane**, or **removeZplane** keywords. Specifies the number of waves to be added to the stack with the **stackImages** keyword.

/O
Overwrites the input wave with the result except in the cases of **Hough** transform and **cmap2rgb**. Does not apply to the transposeVol parameter.

/P=planeNum
Specifies the plane on which you want to operate with the **rgb2gray** or **getPlane** keywords. Also used for **getRow** or **getCol** if the source wave is 3D.

/PSL={xStart,dx,Nx,aStart,da,Na}
Specifies projection slice parameters. $x_{\text{Start}}$ is the first offset of the parallel rays measured from the center of the image. $dx$ is the directed offset to the next ray in the fan and $Nx$ is the number of rays in the fan. $a_{\text{Start}}$ is the first angle for which the projection is calculated. The angle is measured between the positive X-direction and the direction of the ray. $da$ is the offset to the next angle at which the fan of rays is rotated and $Na$ is the total number of angles for which the projection is computed.

/PTYP=num

Specifies the plane to use with the getPlane keyword.

- num=0: XY plane.
- num=1: XZ plane.
- num=2: YZ plane.

/Q

Quiet flag. When used with the Hough transform, it suppresses report to the history of the angle corresponding to the maximum.

/R=roiWave

Specifies a region of interest (ROI) defined by roiWave. For use with the keywords: averageImage, scalePlanes and selectColor.

/S={minSat, maxSat}

/S=saturationWave

Specifies the range of saturation values for selecting pixels. The saturation values are in the range 0 to 1. If you do not use the /S flag, the default value is the full saturation range.

Use saturationWave when you have more than one pair of saturation values. If you use a saturation wave you must also use a lightness wave (see /L). saturationWave should consist of pairs of values where the first point is the lower saturation value and the second point is the higher saturation value. There is no restriction on the order of pairs within the wave.

/SEG

Computes the segmentation image for fuzzyClassify. The image is stored in the 2D wave M_FuzzySegments. The value of each pixel is $255 \times \text{classIndex}/\text{number of classes}$. Here classIndex is the index of the class to which the pixel belongs with the highest probability.

/T=flag

Use one or more of the following flags.

- 1: Swaps the data so that the DC is at the center of the image.
- 2: Calculates the power defined as: $P(f) = 0.5 \cdot (H(f)^2 + H(-f)^2)$.

/TEXT=val

Specifies the type of texture to create with the imageToTexture keyword. val is a binary flag that can be a combination of the following values.

<table>
<thead>
<tr>
<th>val</th>
<th>Texture</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Truncates each dimension to the nearest power of 2, which is required for OpenGL textures.</td>
</tr>
<tr>
<td>2</td>
<td>Creates a 1D texture (all other textures are for 2D applications).</td>
</tr>
<tr>
<td>4</td>
<td>Creates a single channel texture suitable for alpha or luminance channels.</td>
</tr>
<tr>
<td>8</td>
<td>Creates a RGB texture from a 3 (or more) layer data.</td>
</tr>
<tr>
<td>16</td>
<td>Creates a RGBA texture. If imageMatrix does not have a 4th layer, alpha is set to 255.</td>
</tr>
</tbody>
</table>

/TOL=tolerance

Sets the tolerance for iteration convergence with fuzzyClassify. Convergence is satisfied when the sum of the squared differences of all classes drops below tolerance, which must not be negative.
ImageTransform

/TM4D=mode

Used with transpose4D to specify the format of the output wave. Here mode is a 4 digit integer that describes the mapping of the transformation. The digit 1 is used to represent the first dimension, 2 for the second, 4 for the third and 8 for the 4th dimension such that the original wave corresponds to mode=1248. All other modes are obtained by permuting one or more of the four digits and mode must consist of 4 distinct digits.

Added in Igor Pro 7.00.

/U

Creates an HSL wave of type unsigned short that contains values between 0 and 65535 when used with rgb2hsl.

/W

Pads the image by wrapping the data. If you are adding more rows or more columns than are available in the source wave, the operation cycles through the source data as many times as necessary.

/X=[Nx,Ny,x1,y1,z1,x2,y2,z2,x3,y3,z3]

Nx and Ny are the rows and columns of the wave M_ExtractedSurface. The remaining parameters specify three 3D points on the extracted plane. The three points must be chosen at the vertices of the plane and entered in clock-wise order without skipping a vertex.

/Z

Ignores errors.

Examples

If you want to insert a 2D (M x N) wave, plane0, into plane number 0 of an (M x N x 3) wave, rgbWave:

ImageTransform /P=0/D=plane0 setPlane rgbWave

If your source wave is 100 rows by 100 columns and you want to create a montage of this image use:

ImageTransform /W/N={200,200} padImage srcWaveName

An example of hue and saturation segmentation on an HSL wave.

Function hueSatSegment(hslW,lowH,highH,lowS,highS)

Wave hslW
Variable lowH,highH,lowS,highS

References

Details about the rgb2i123 transform:

The ImageUnwrapPhase operation unwraps the 2D phase in srcWave and stores the result in the wave M_UnwrappedPhase in the current data folder. srcWave must be a real valued wave of single or double precision. Phase is measured in cycles (units of $2\pi$).

**Parameters**

- **qualityWave=qWave**: Specifies a wave, qWave, containing numbers that rate the quality of the phase stored in the pixels. qWave is 2D wave of the same dimensions as srcWave that can be any real data type and values can have an arbitrary scale. If used with /M=1 the quality values determine the order of phase unwrapping subject to branch cuts, with higher quality unwrapped first. If used with /M=2 the unwrapping is guided by the quality values only. This wave must not contain any NaNs or INFs.
- **srcwave=waveName**: Specifies a real-valued SP or DP wave that may contain NaNs or INFs but is otherwise assumed to contain the phase modulo 1.

**Flags**

- **/E**: Eliminate dipoles. Only applies to Goldstein’s method (/M=1). Dipoles are a pair of a positive and negative residues that are side by side. They are eliminated from the unwrapping process by replacing them with a branch cut. The variable V_numResidues contains the number of residues remaining after removal of the dipoles.
- **/L**: Saves the lookup table (LUT) used in the analysis with /M=1. This information may be useful in analyzing your results. The LUT is saved as a 2D unsigned byte wave M_PhaseLUT in the current data folder. Each entry consists of 8-bit fields:
  - bit=0: Positive residue.
  - bit=1: Negative residue.
  - bit=2: Branch cut.
  - bit=3: Image boundary exclusion.

Other bits are reserved and subject to change. See [Setting Bit Parameters](#) on page IV-13 for details about bit settings.

- **/M=method**: Determines the method for computing the unwrapped phase:
  - **method =0**: Modified Itoh’s algorithm, which assumes that there are no residues in the phase. The phase is unwrapped in a contiguous way subject only to the ROI or singularities in the data (e.g., NaNs or INFs). You will get wrong results for the unwrapped phase if you use this method and your data contains residues.
  - **method =1**: Modified Goldstein’s algorithm. Creates the variables V_numResidues and V_numRegions. Optional qWave can determine order of unwrapping around the branch cuts.
  - **method =2**: Uses a quality map to decide the unwrapping path priority. The quality map is a 2D wave that has the same dimensions as the source wave but could have an arbitrary data type. The phase is unwrapped starting from the largest value in the quality map.
- **/MAX=len**: Specifies the maximum length of a branch cut. Only applicable to Goldstein’s method (/M=1). By default this is set to the largest of rows or columns.
- **/Q**: Suppresses messages to the history.
Details

Phase unwrapping in two dimensions is difficult because the result of the operation needs to be such that any path integral over a closed contour will vanish. In many practical situations, certain points in the plane have the property that a path integral around them is not zero. These nonzero points are residues. We use the definition that when a counterclockwise path integral leads to a positive value the residue is called a positive residue.

ImageUnwrapPhase uses the modified Itoh’s method by default. Phase is unwrapped with an offset equal to the first element that is allowed by the ROI starting at (0,0) and scanning by rows. If there are no residues or if you unwrap the phase using Itoh’s algorithm, then the phase is unwrapped only subject to the optional ROI using a seed-fill type algorithm that unwraps by growing a region outward from the seed pixel. Each time that the region growing is terminated by boundaries (external or due to the ROI), the algorithm returns to the row scanning to find a new starting point.

If there are residues and you choose Goldstein’s method, the residues are first mapped into a lookup table (LUT) and branch-cuts are determined between residues and boundaries. It is also possible to remove some residues (dipoles) using the /E flag. Phase is then unwrapped in regions bounded by branch cuts using a seed-fill type algorithm that does not cross branch cuts. With a quality wave, the algorithm follows the same seed-fill approach except that it gives priority to pixels with high quality level. The phase on the branch cuts themselves is subsequently calculated.

The output wave M_UnwrappedPhase has the same wave scaling and dimension units as srcWave. The unwrapped phase is units of cycles; you will have to multiply it by \(2\pi\) if you need the results in radians.

The operation creates two variables:

- **V_numResidues**: Number of residues encountered (if using /M=1).
- **V_numRegions**: Number of independent phase regions. In Goldstein’s method the regions are bounded by branch cuts, but in Itoh’s method they depend on the content of the ROI wave.

Examples

To unwrap a complex wave wCmplx:

```makefile
Make/O/N=(DimSize(wCmplx,0),DimSize(wCmplx,1) phaseWave
phaseWave=atan2(imag(wCmplx),real(wCmplx))/2*pi
ImageUnwrapPhase/N=1 srcWave=phaseWave
```

To find the locations of positive residues in the phase:

```makefile
ImageUnwrapPhase/N=1/L srcWave=phaseWave
Duplicate/O M_PhaseLUT ee
ee=M_PhaseLUT&3 ? 1:0
```

To find the branch cuts:

```makefile
Duplicate/O M_PhaseLUT bc
bc=M_PhaseLUT&4 ? 1:0
```

The following reference is an excellent text containing in-depth theory and detailed explanation of many two-dimensional phase unwrapping algorithms:
ImageWindow

**ImageWindow**

\[\text{ImageWindow} \ [\text{I/O/P=param}] \ \text{method} \ \text{srcWave}\]

The ImageWindow operation multiplies the named waves by the specified windowing method. ImageWindow is useful in preparing an image for FFT analysis by reducing FFT artifacts produced at the image boundaries.

**Parameters**

- **srcWave**: Two-dimensional wave of any numerical type. See WindowFunction for windowing one-dimensional data.
- **method**: Selects the type of windowing filter. See ImageWindow Methods on page V-403.

**Flags**

- **/I**: Creates only the output wave containing the windowing filter values that are used to multiply each pixel in srcWave. It does not filter the source image.
- **/O**: Overwrites the source image with the output image. If /O is not used then the operation creates the M_WindowedImage wave containing the filtered source image.
- **/P=param**: Specifies the design parameter for the Kaiser window.

**Details**

The 1-dimensional window for each column is multiplied by the value of the corresponding row’s window value. In other words, each point is multiplied by the both the row-oriented and column-oriented window value. This means that all four edges of the image are decreased while the center remains at or near its original value. For example, applying the Bartlett window to an image whose values are all equal results in a trapezoidal pyramid of values:

![Image Window Graph](ImageWindow Graph)

The default output wave is created with the same data type as the source image. Therefore, if the source image is of type unsigned byte (/b/u) the result of using /I will be identically zero (except possibly for the middle-most pixel). If you keep in mind that you need to convert the source image to a wave type of single or double precision in order to perform the FFT, it is best if you convert your source image (e.g., Redimension/S srcImage) before using the ImageWindow operation.

The windowed output is in the M_WindowedImage wave unless the source is overwritten using the /O flag. The necessary normalization value (equals to the average squared window factor) is stored in V_value.
ImageWindow Methods
This section describes the supported keywords for the method parameter. In all equations, $L$ is the array width and $n$ is the pixel number.

Hanning:

$$w(n) = \frac{1}{2} \left[ 1 - \cos \left( \frac{2\pi n}{L-1} \right) \right] \quad 0 \leq n \leq L-1$$

Hamming:

$$w(n) = 0.54 - 0.46 \cos \left( \frac{2\pi n}{L-1} \right) \quad 0 \leq n \leq L-1$$

Bartlet:

Synonym for Bartlett.

Bartlett:

$$w(n) = \begin{cases} 
\frac{2n}{L-1} & 0 \leq n \leq \frac{L-1}{2} \\
2 - \frac{2n}{L-1} & \frac{L-1}{2} \leq n \leq L-1 
\end{cases}$$

Blackman:

$$w(n) = 0.42 - 0.5 \cos \left( \frac{2\pi n}{L-1} \right) + 0.08 \cos \left( \frac{4\pi n}{L-1} \right) \quad 0 \leq n \leq L-1$$

Kaiser:

$$w(n) = \frac{I_0 \left( \omega_a \sqrt{\left( \frac{L-1}{2} \right)^2 - \left( n - \frac{L-1}{2} \right)^2} \right)}{I_0 \left( \omega_a \left( \frac{L-1}{2} \right) \right)} \quad 0 \leq n \leq L-1$$

where $I_0[...]$ is the zeroth-order Bessel function of the first kind and $\omega_a$ is the design parameter specified by /P=param.

KaiserBessel20: $\alpha = 2.0$
KaiserBessel25: $\alpha = 2.5$
KaiserBessel30: $\alpha = 3.0$

$$w(n) = \frac{I_0 \left( \pi \alpha \sqrt{1 - \left( \frac{n}{L/2} \right)^2} \right)}{I_0 (\pi \alpha)} \quad 0 \leq \left| n \right| \leq \frac{L}{2}$$

$$I_0(x) = \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{(k!)^2}.$$
Examples
To see what one of the windowing filters looks like:
```
Make/N=(80,80) wShape // Make a matrix
ImageWindow/I/O Blackman wShape // Replace with windowing filter
Display;AppendImage wShape // Display windowing filter
Make/N=2 xTrace={0,79},yTrace={39,39} // Prepare for 1D section
AppendToGraph yTrace vs xTrace
ImageLineProfile srcWave=wShape, xWave=xTrace, yWave=yTrace
Display W_ImageLineProfile // Display 1D section of filter
```

References

IndependentModule
```
#pragma IndependentModule = imName
```
The IndependentModule pragma designates groups of one or more procedure files that are compiled and linked separately. Once compiled and linked, the code remains in place and is usable even though other procedures may fail to compile. This allows functioning control panels and menus to continue to work regardless of user programming errors.

See Also
Independent Modules on page IV-231, The IndependentModule Pragma on page IV-55 and #pragma.

IndependentModuleList
```
IndependentModuleList(listSepStr)
```
The IndependentModuleList function returns a string containing a list of independent module names separated by listSepStr.

Use StringFromList to access individual names.

Parameters
listSepStr contains the character, usually ";", to be used to to separate the names in the returned list.

Details
In Igor6, only the first byte of listSepStr was used. In Igor7 and later, all bytes are used.
ProcGlobal is not in the returned list, and the order of returned names is not defined.

See Also
Independent Modules on page IV-231.

GetIndependentModuleName, StringFromList, FunctionList.

IndexedDir
```
IndexedDir(pathName, index, flags)
```
The IndexedDir function returns a string containing the name of or the full path to the indexth folder in the folder referenced by pathName.

Parameters
pathName is the name of an Igor symbolic path pointing to the parent directory.
IndexedDir

index is the index number of the directory (within the parent directory) of interest starting from 0. If index is -1, IndexedDir will return the name of all of the folders in the parent, separated by semicolons.

flags is a bitwise parameter:

Bit 0: Set if you want a full path. Cleared if you want just the directory name.

All other bits are reserved and should be cleared.

See Setting Bit Parameters on page IV-13 for details about bit settings.

Details

You create the symbolic path identifying the parent directory using the NewPath operation or the New Path dialog (Misc menu).

Prior to Igor Pro 3.1, IndexedDir was an external function and took a string as the first parameter rather than a name. The pathName parameter can now be either a name or a string containing a name. Any of the following will work:

String str = "IGOR"
Print IndexedDir(IGOR, 0, 0) // First parameter is a name.
Print IndexedDir($str, 0, 0) // First parameter is a name.
Print IndexedDir("IGOR", 0, 0) // First parameter is a string.
Print IndexedDir(str, 0, 0) // First parameter is a string.

The acceptance of a string is for backward compatibility only. New code should be written using a name. The returned path uses the native conventions of the OS under which Igor is running.

Examples

Example: Recursively Listing Directories and Files

Here is an example for heavy-duty Igor Pro programmers. It is an Igor Pro user-defined function that prints the paths of all of the files and folders in a given folder with or without recursion. You can rework this to do something with each file instead of just printing its path.

To try the function, copy and paste it into the Procedure window. Then execute the example shown in the comments.

// PrintFoldersAndFiles(pathName, extension, recurse, level)
// Shows how to recursively find all files in a folder and subfolders.
// pathName is the name of an Igor symbolic path that you created
// using NewPath or the Misc-New Path menu item.
// extension is a file name extension like ".txt" or "????" for all files.
// recurse is 1 to recurse or 0 to list just the top-level folder.
// level is the recursion level - pass 0 when calling PrintFoldersAndFiles.
// Example: PrintFoldersAndFiles("Igor", ".ihf", 1, 0)
Function PrintFoldersAndFiles(pathName, extension, recurse, level)
  String pathName // Name of symbolic path in which to look for folders and files.
  String extension // File name extension (e.g., ".txt") or "????" for all files.
  Variable recurse // True to recurse (do it for subfolders too).
  Variable level // Recursion level. Pass 0 for the top level.
  Variable folderIndex, fileIndex

  String prefix

  // Build a prefix (a number of tabs to indicate the folder level by indentation)
  prefix = ""
  folderIndex = 0
  do
    if (folderIndex >= level)
      break
    endif
    prefix += "\t" // Indent one more tab
  folderIndex += 1
  while(1)

  // Print folder
  String path
  PathInfo $pathName // Sets S_path
  path = S_path
  Printf "%s\r", prefix, path
// Print files
fileIndex = 0
do
    String fileName
    fileName = IndexedFile($pathName, fileIndex, extension)
    if (strlen(fileName) == 0)
        break
    endif
    Printf "%s\t%s\r", prefix, path, fileName
    fileIndex += 1
while(1)
if (recurse) // Do we want to go into subfolder?
    folderIndex = 0
    do
        path = IndexedDir($pathName, folderIndex, 1)
        if (strlen(path) == 0)
            break // No more folders
        endif
        String subFolderPathName = "tempPrintFoldersPath_" + num2istr(level+1)
        // Now we get the path to the new parent folder
        String subFolderPath
        subFolderPath = path
        NewPath/Q/O $subFolderPathName, subFolderPath
        PrintFoldersAndFiles(subFolderPathName, extension, recurse, level+1)
        KillPath/Z $subFolderPathName
        folderIndex += 1
    while(1)
    endif
End

Example: Fast Scan of Directories
Calling IndexedDir for each directory is an O(N^2) problem because to get the nth directory the OS routines
underlying IndexedDir need to iterate through directories 0..n-1. This becomes an issue only if you are
dealing with hundreds or thousands of directories.

This function illustrates a technique for converting this to an O(N) problem by getting a complete list of
paths from IndexedDir in one call and storing them in a text wave. This approach could also be used with
IndexedFile.

Function ScanDirectories(pathName, printDirNames)
    String pathName    // Name of Igor symbolic path
    Variable printDirNames    // True if you want to print the directory names
    Variable t0 = StopMSTimer(-2)
    String dirList = IndexedDir($pathName, -1, 0)
    Variable numDirs = ItemsInList(dirList)
    // Store directory list in a free text wave.
    // The free wave is automatically killed when the function returns.
    Make/N=(numDirs)/T/FREE dirs = StringFromList(p, dirList)
    String dirName
    Variable i
    for(i=0; i<numDirs; i+=1)
        dirName = dirs[i]
        Print i, dirName
    endfor
    Variable t1 = StopMSTimer(-2)
    Variable elapsed = (t1 - t0) / 1E6
    Printf "Took %g seconds\r", elapsed
End
IndexedFile

IndexedFile(pathName, index, fileTypeOrExtStr [, creatorStr])

If index is greater than or equal to zero, IndexedFile returns a string containing the name of the indexth file in the folder specified by pathName which matches the file type or extension specified by fileTypeOrExtStr.

If index is -1, IndexedFile returns a semicolon-separated list of all matching files. IndexedFile returns an empty string (""") if there is no such file.

Parameters

pathName is the name of an Igor symbolic path. It is not a string.

index normally starts from zero. However, if index is -1, IndexedFile returns a string containing a semicolon-separated list of the names of all files in the folder associated with the specified symbolic path which match fileTypeOrExtStr.

fileTypeOrExtStr is either:
• A string starting with ".", such as ".txt", ".bwav", or ".c". Only files with a matching file name extension are indexed. Set fileTypeOrExtStr to "." to index file names that end with "." such as "myFileNameEndsWithThisDot."
• A string containing exactly four ASCII characters, such as "TEXT" or "IGBW". Only files of the specified Macintosh file type are indexed. However, if fileTypeOrExtStr is "????", files of any type are indexed.
• On Windows, Igor considers files with ".txt" extensions to be of type TEXT. It does similar mappings for other extensions. See File Types and Extensions on page III-432 for details.

creatorStr is an optional string argument containing four ASCII characters such as "IGR0". Only files with the specified Macintosh creator code are indexed. Set creatorStr to "????" to index all files (or omit the argument altogether). This argument is ignored on Windows systems.

Order of Files Returned By IndexedFile

The order in which files are returned by IndexedFile is determined by the operating system. If the order matters to you, you should explicitly sort the file names.

For example, assume you have files named "File1.txt", "File2.txt" and "File10.txt". An alphabetic order gives you: "File1.txt;File10.txt;File2.txt;". Often what you really want is a combination of alphabetic and numeric sorting returning "File1.txt;File2.txt;File10.txt;". Here is a function that does that:

Function DemoIndexedFile()
    String pathName = "Igor" // Refers to "Igor Pro Folder"
    // Get a semicolon-separated list of all files in the folder
    String list = IndexedFile(pathName, -1, ".txt")
    // Sort using combined alpha and numeric sort
    list = SortList(list, ";", 16)
    // Process the list
    Variable numItems = ItemsInList(list)
    Variable i
    for(i=0; i<numItems; i+=1)
        String fileName = StringFromList(i, list)
        Print i, fileName
    endfor
End

Treatment of Macintosh Dot-Underscore Files

IndexedFile ignores "dot-underscore" files unless fileTypeOrExtStr is "????".

A dot-underscore file is a file created by Macintosh when it writes to a non-HFS volume, for example, when it writes to a Windows volume via SMB file sharing. The dot-underscore file stores Macintosh HFS-specific data such as the file's type and creator codes, and the file's resource fork, if it has one.

For example, if a file named "wave0.ibw" is copied via SMB to a Windows volume, Mac OS X creates two files on the Windows volume: "wave0.ibw" and "._wave0.ibw". Mac OS X makes these two files appear as one to Macintosh applications. However, Windows does not do this. As a consequence, when a Windows program sees "._wave0.ibw", it expects it to be a valid .ibw file, but it is not. This causes problems.
By ignoring dot-underscore files, IndexedFile prevents this type of problem. However, if fileTypeOrExtStr is "????", IndexedFile will return dot-underscore files on Windows.

**Examples**

```plaintext
NewPath/O myPath "MyDisk:MyFolder:" Print IndexedFile(myPath,-1,"TEXT") // all text-type files Print IndexedFile(myPath,0,"TEXT") // only the first text file Print IndexedFile(myPath,-1,".dat") // *.datPrint IndexedFile(myPath,-1,"TEXT","IGR0") // all Igor text files Print IndexedFile(myPath,-1,"????") // all files, all creators
```

See [IndexedDir](#) for another example using IndexedFile and for a method for speeding up scanning of very large numbers of files.

**See Also**

The [TextFile](#) and [IndexedDir](#) functions.

---

### IndexSort

**IndexSort** [ /DIML ] `indexWaveName`, `sortedWaveName` [, `sortedWaveName`]...

The IndexSort operation sorts the values in each `sortedWaveName` wave according to the Y values of `indexWaveName`.

**Flags**

- **/DIML** Moves the dimension labels with the values (keeps any row dimension label with the row's value).

**Details**

`indexWaveName` can not be complex. `indexWaveName` is presumed to have been the destination of a previous [MakeIndex](#) operation.

This has the effect of putting the `sortedWaveName` waves in the same order as the wave from which the index values in `indexWaveName` was made.

All of the `sortedWaveName` waves must be of equal length.

**See Also**

[MakeIndex](#) and [IndexSort Operations](#) on page III-133.

### IndexToScale

**IndexToScale** `wave`, `index`, `dim`

The IndexToScale function returns the scaled coordinate value corresponding to wave element index in the specified dimension.

The IndexToScale function was added in Igor Pro 7.00.

**Details**

The function returns the expression:

\[
\text{DimOffset}(\text{wave}, \text{dim}) + \text{index} \times \text{DimDelta}(\text{wave}, \text{dim})
\]

- `index` is an integer.
- `dim` is 0 for rows, 1 for columns, 2 for layers or 3 for chunks.

The function returns NaN if `dim` is not a valid dimension or if `index` is greater than the number of elements in the specified dimension.

**Examples**

```plaintext
Make/N=(10,20,30,40) w4D SetScale/P y 2,3,",", w4D SetScale/P z 4,5,"", w4D SetScale/P t 6,7,",", w4D Print IndexToScale(w4D,1,0) Print IndexToScale(w4D,1,1) Print IndexToScale(w4D,1,2) Print IndexToScale(w4D,1,3)
```
Print IndexToScale(w4D, 1, 4)
Print IndexToScale(w4D, -1, 0)
Print IndexToScale(w4D, 11, 0)

Inf

Inf
The Inf function returns the “infinity” value.

InsertPoints

InsertPoints [/M=dim /V=value] beforePoint, numPoints, waveName [, waveName]...
The InsertPoints operation inserts numPoints points in front of point beforePoint in each waveName. The new points have the value zero.

Flags

/M=dim Specifies the dimension into which elements are to be inserted. Values are 0 for rows, 1 for columns, 2 for layers, 3 for chunks. If /M is omitted, InsertPoints inserts in the rows dimension.

/V=value When used with numeric waves, value specifies the value for new elements. If you omit /V, new elements are set to zero. The /V flag was added in Igor Pro 8.00.

Details
Trying to insert points into any but the rows of a zero-point wave results in a zero-point wave. You must first make the number of rows nonzero before anything else has an effect.

See Also
Lists of Values on page II-73.

Int

int localName
In a user-defined function or structure, declares a local 32-bit integer in IGOR32, a local 64-bit integer in IGOR64.

Int is available in Igor Pro 7 and later. See Integer Expressions on page IV-40 for details.

See Also
Int64, UInt64

Int64

int64 localName
Declares a local 64-bit integer in a user-defined function or structure.

Int64 is available in Igor Pro 7 and later. See Integer Expressions on page IV-40 for details.

See Also
Int, UInt64
Integrate

The Integrate operation calculates the 1D numeric integral of a wave. X values may be supplied by the X-scaling of the source wave or by an optional X wave. Rectangular integration is used by default.
Integrate is multi-dimension-aware in the sense that it computes a 1D integration along the dimension specified by the /DIM flag or along the rows dimension if you omit /DIM.
Complex waves have their real and imaginary components integrated individually.

Flags

/DIM=d  Specifies the wave dimension along which to integrate when yWave is multidimensional.
  d=-1: Treats entire wave as 1D (default).
  d=0: Integrates along rows.
  d=1: Integrates along columns.
  d=2: Integrates along layers.
  d=3: Integrates along rows.

For example, for a 2D wave, /DIM=0 integrates each row and /DIM=1 integrates each column.

/METH=m  Sets the integration method.
  m=0: Rectangular integration (default). Results at a point are stored at the same point (rather than at the next point as for /METH=2). This method keeps the dimension size the same.
  m=1: Trapezoidal integration.
  m=2: Rectangular integration. Results at a point are stored at the next point (rather than at the same point as for /METH=0). This method increases the dimension size by one to provide a place for the last bin.

/P  Forces point scaling.

/T  Trapezoidal integration. Same as /METH=1.

Type Flags (used only in functions)
Integrate also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See WAVE Reference Types on page IV-72 and WAVE Reference Type Flags on page IV-73 for a complete list of type flags and further details.

For example, when the input (and output) waves are complex, the output wave will be complex. To get the Igor compiler to create a complex output wave reference, use the /C type flag with /D=destwave:

Make/O/C cInput=complx(sin(p/8), cos(p/8))
Make/O/C/N=0 cOutput
Integrate/C cInput /D=cOutput
**Wave Parameters**

**Note**: All wave parameters must follow `yWave` in the command. All wave parameter flags and type flags must appear immediately after the operation name (Integrate).

`/D=destWave` Specifies the name of the wave to hold the integrated data. It creates `destWave` if it does not already exist or overwrites it if it exists.

`/X=xWave` Specifies the name of corresponding X wave. For rectangular integration, the number of points in the X wave must be one greater than the number of elements in the Y wave dimension being integrated.

**Details**

The computation equation for rectangular integration using `/METH=0` is:

\[
\text{waveOut}[p] = \sum_{i=0}^{p} \text{waveIn}[i] \cdot \Delta x.
\]

The computation equation for rectangular integration using `/METH=2` is:

\[
\text{waveOut}[0] = 0
\]

\[
\text{waveOut}[p+1] = \sum_{i=0}^{p} (x_{i+1} - x_i) \text{waveIn}[i].
\]

The inverse of this rectangular integration is the backwards difference.

Trapezoidal integration (`/METH=1`) is a more accurate method of computing the integral than rectangular integration. The computation equation is:

\[
\text{waveOut}[0] = 0
\]

\[
\text{waveOut}[p] = \text{waveOut}[p-1] + \frac{\Delta x}{2} (\text{waveIn}[p-1] + \text{waveIn}[p]).
\]

If the optional `/D = destWave` flag is omitted, then the wave is integrated in place overwriting the source wave.

When using an X wave, the X wave must be a 1D wave with data type matching the Y wave (excluding the complex type flag). Rectangular integration (`/METH=0 or 2`) requires an X wave having one more point than the number of elements in the dimension of the Y wave being integrated. X waves with number points plus one are allowed for rectangular integration with methods needing only the number of points. X waves are not used with integer source waves.

Although it is mathematically suspect, rectangular integration using `/METH=0` would be correct if the X scaling of the output wave is offset by \(\Delta X\).

**Differentiate/METH=1/EP=1** is the inverse of **Integrate/METH=2**, but **Integrate/METH=2** is the inverse of **Differentiate/METH=1/EP=1** only if the original first data point is added to the output wave.

Integrate applied to an XY pair of waves does not check the ordering of the X values and doesn’t care about it. However, it is usually the case that your X values should be monotonic. If your X values are not monotonic, you should be aware that the X values will be taken from your X wave in the order they are found, which will result in random X intervals for the X differences. It is usually best to sort the X and Y waves first (see **Sort**).

Differentiate, Integrate2D, Integrate1D, area, areaXY
Integrate1D

Integrate1D(\text{UserFunctionName}, \min_x, \max_x [, \text{options} [, \text{count} [, \text{pWave}]}})

The Integrate1D function performs numerical integration of a user function between the specified limits ($\min_x$ and $\max_x$).

**Parameters**

\text{UserFunctionName} must have this format:

Function UserFunctionName(inX)
    Variable inX
    ... do something
    return result
End

However, if you supply the optional \text{pWave} parameter then it must have this format:

Function UserFunctionName(pWave, inX)
    Wave pWave
    Variable inX
    ... do something
    return result
End

\text{options} is one of the following:

0: Trapezoidal integration (default).
1: Romberg integration.
2: Gaussian Quadrature integration.

By default, \text{options} is 0 and the function performs trapezoidal integration. In this case Igor evaluates the integral iteratively. In each iteration the number of points where Igor evaluates the function increases by a factor of 2. The iterations terminate at convergence to tolerance or when the number of evaluations is $2^{23}$.

The \text{count} parameter specifies the number of subintervals in which the integral is evaluated. If you specify 0 or a negative number for \text{count}, the function performs an adaptive Gaussian Quadrature integration in which Igor bisects the interval and performs a recursive refining of the integration only in parts of the interval where the integral does not converge to tolerance.

\text{pWave} is an optional parameter that, if present, is passed to your function as the first parameter. It is intended for your private use, to pass one or more values to your function, and is not modified by Igor. The \text{pWave} parameter was added in Igor Pro 7.00.

**Details**

You can integrate complex-valued functions using a function with the format:

Function/C complexUserFunction(inX)
    Variable inX
    Variable/C result
    //... do something
    return result
End

The syntax used to invoke the function is:

Variable/C cIntegralResult=Integrate1D(complexUserFunction, \min_x, \max_x...)

You can also use Integrate1D to perform a higher dimensional integrals. For example, consider the function:

$F(x,y) = 2x + 3y + xy$.

In this case, the integral

$h = \int dy \int f(x,y) dx$

can be performed by establishing two user functions:

Function Do2dIntegration(xmin, xmax, ymin, ymax)
    Variable xmin, xmax, ymin, ymax
    Variable/G globalXmin=xmin
    Variable/G globalXmax=xmax
    Variable/G globalY
Function UserFunction1(inX)
    Variable inX
    NVAR globalY=globalY
    return (3*inX+2*globalY+inX*globalY)
End

Function UserFunction2(inY)
    Variable inY
    NVAR globalY=globalY
globalY=inY
    NVAR globalXmin=globalXmin
    NVAR globalXmax=globalXmax
    // Romberg integration
    return Integrate1D(userFunction1,globalXmin,globalXmax,1)
End

This method can be extended to higher dimensions.

If the integration fails to converge or if the integrand diverges, Integrate1D returns NaN. When a function
fails to converge it is a good idea to try another integration method or to use a user-defined number of
intervals (as specified by the count parameter). Note that the trapezoidal method is prone to convergence
problems when the absolute value of the integral is very small.

Integrate2D

Integrate2D [flags] [keyword = value [, keyword = value ...]]
The Integrate2D operation calculates a two-dimensional numeric integral of a real-valued user-defined
function or a wave. The result of the operation is stored in the variable V_value and the variable V_Flag is
set to zero if there are no errors.

This operation was added in Igor Pro 7.00.

Flags

/OPTS=op Sets the integration options. By default, both the x and the y integrations are
performed using the adaptive trapezoidal method.

op is a bitwise parameter that you set to select the x and y integration methods. Set
one bit for x and one bit for y:

Bit 0: Trapezoidal in Y (1)
Bit 1: Romberg in Y (2)
Bit 2: Gaussian Quadrature in Y (4)
Bit 3: Trapezoidal in X (8)
Bit 4: Romberg in X (16)
Bit 5: Gaussian Quadrature in X (32)

See Setting Bit Parameters on page IV-13 for details about bit settings.

Using these constants you can specify, for example, Romberg integration in the Y
direction and Gaussian Quadrature in the X direction using /OPTS=(2 | 32).

/Q Suppress printing to the history area.

/Z=zFlag Set zFlag to 1 to suppress error reporting.
Integrate2D

Keywords

epsilon=ep

Specifies the convergence parameter. By default ep=1e-5. Smaller values lead to more accurate integration result but the tradeoff is longer computation time.

integrand=intFunc

Specifies the user function to be integrated. See The Integrand Function below for details.

innerLowerLimit=y1

Specifies the lower limit of the inner integral if this limit is fixed, i.e., if it is not a function of x. See the innerLowerFunc keyword if you need to specify a function for this limit.

innerUpperLimit=y2

Specifies the upper limit of the inner integral if this limit is fixed, i.e., if it is not a function of x. See the innerUpperFunc keyword if you need to specify a function for this limit.

innerLowerFunc=y1Func

Specifies a user-defined function for the lower limit of the inner integral. See The Limit Functions below.

innerUpperFunc=y2Func

Specifies a user-defined function for the upper limit of the inner integral. See The Limit Functions below.

outerLowerLimit=x1

Specifies the lower limit of the outer integral.

outerUpperLimit=x2

Specifies the upper limit of the outer integral.

paramWave=pWave

Specifies a wave to be passed to the integrand and limit user-defined functions as the pWave parameter. The wave may contain any number of values that you might need to evaluate the integrand or the integration limits. If you omit paramWave then the pWave parameter to the functions will be NULL.

srcWave=mWave

If you need to perform 2D integration of some data, you can specify the data directly instead of providing a user-defined function that returns interpolated data. mWave must be a 2D wave. Higher dimensional waves are accepted but only the first layer of the wave is used in the integration.

The Integrand Function

Integrate2D computes the general two-dimensional integral of a user-defined integrand function which you specify using the integrand keyword. The integrand function has this form:

```c
Function integrandFunc(pWave,inX,inY)
    Wave/Z pWave
    Variable inX,inY
    ... do something
    return result
End
```

The function can have any name - integrandFunc is just an example. The function must take the parameters shown and must return a real numeric result. Returning a NaN terminates the integration.

pWave is a parameter wave that you specify using the paramWave keyword. The operation passes this wave on every call to the integrand function. If you omit paramWave when invoking Integrate2D then pWave will be NULL.

The Limit Functions

The limit functions provide lower and/or upper limits of integration for the inner integral if they are functions of x rather than fixed values. You specify a limit function using the innerLowerFunc and innerUpperFunc keywords. The form of the limit function is:

```c
Function limitFunction(pWave,inX)
    Wave/Z pWave
    Variable inX
    ... do something
```

V-414
return result
End

Details

The operation computes the general two-dimensional integral of the form

\[
I = \int_{x_1}^{x_2} \int_{y_1(x)}^{y_2(x)} f(x,y) dy.
\]

Here \(y_1\) and \(y_2\) are in general functions of \(x\) but could also be simple constants, and \(f(x,y)\) is real valued function. The integral is evaluated by considering the “outer” integral

\[
I = \int_{x_1}^{x_2} G(x) dx,
\]

where \(G(x)\) is the “inner” integral

\[
G(x) = \int_{y_1(x)}^{y_2(x)} f(x,y) dy.
\]

The operation allows you to specify different algorithms for integrating the inner and outer integrals. The simplest integration algorithm is the Trapezoidal method. You can typically improve on the accuracy of the calculation using Romberg integration and the performance of Gaussian quadrature depends significantly on the nature of the integrand.

Example 1: Integrating a 2D function over fixed limits

Suppose we wanted to check the normalization of the built-in two-dimensional Gauss function. The user-defined function would be:

Function myIntegrand1(pWave,inX,inY)
  Wave/Z pWave
  Variable inX,inY
  return Gauss(inX,50,10,inY,50,10)
End

To perform the integration, execute:

Integrate2D outerLowerLimit=0, outerUpperLimit=100, innerLowerLimit=0,
  innerUpperLimit=100, integrand=myIntegrand1
Print/D V_Value

Example 2: Integrating a 2D function using function limits

In this example we compute the volume of a sphere of radius 1. To do so we use symmetry and integrate the volume in one octant only. The limits of integration are \([0,1]\) in the x direction and \([0,\sqrt{1-x^2}]\) in the y direction. In this case we need to define two user-defined functions: one for the integrand and one for the upper limit of the inner integral:

Function myIntegrand2(pWave,inX,inY)
  Wave/Z pWave
  Variable inx,iny
  Variable r2=inX^2+inY^2
  if(r2>=1)
    return 0
  else
    return sqrt(1-r2)
  endif
End

Function y2Func(pWave,inX)
  Wave pWave
  Variable inX
  return sqrt(1-inX^2)
End

To perform the integration, execute:
Integrate2D outerLowerLimit=0, outerUpperLimit=1, innerLowerLimit=0, innerUpperFunc=y2Func, integrand=myIntegrand2
Print/D 4*pi/3 -8*V_Value // Calculation error

Note that the integrand function tests that r^2 does not exceed 1. This is because the sqrt function would return a NaN if r^2>1 which can happen due to floating point rounding errors. Returning a NaN terminates the integration.

Example 3: Integrating a 2D wave using fixed limits
In this example we compute the volume between the surface defined by the wave my2DWave and the plane z=0 with integration limits [0,1] in the x-direction and [0,2] in the y-direction. For simplicity we set the wave's value to be a constant (pi).

Make/O/N=(5,9) my2DWave=pi
SetScale/P x 0,0.3,"", my2DWave
SetScale/P y 0,0.4,"", my2DWave
Integrate2D outerLowerLimit=0, outerupperLimit=1, innerlowerLimit=0, innerUpperLimit=2, srcWave=my2DWave
Print/D 2*pi-V_Value // Calculation error

Integrate, Differentiate, Integrate1D, area, areaXY

IntegrateODE

`IntegrateODE [flags] derivFunc, cwaveName, ywaveSpec`

The IntegrateODE operation calculates a numerical solution to a set of coupled ordinary differential equations by integrating derivatives. The derivatives are user-specified via a user-defined function, `derivFunc`. The equations must be a set of first-order equations; a single second-order equation must be recast as two first-order equations, a third-order equation to three first order equations, etc. For more details on how to write the function, see Solving Differential Equations on page III-302.

IntegrateODE offers two ways to specify the values of the independent variable (commonly called X or t) at which output Y values are recorded. You can specify the X values or you can request a “free-run” mode.

The algorithms used by IntegrateODE calculate results at intervals that vary according to the characteristics of the ODE system and the required accuracy. You can set specific X values where you need output (see the /X flag below) and arrangements will be made to get values at those specific X values. In between those values, IntegrateODE will calculate whatever spacing is needed, but intermediate values will not be output to you.

If you specify free-run mode, IntegrateODE will simply output all steps taken regardless of the spacing of the X values that results.

Parameters

- `cwaveName` Name of wave containing constant coefficients to be passed to `derivFunc`.
- `derivFunc` Name of user function that calculates derivatives. For details on the form of the function, see Solving Differential Equations on page III-302.
- `ywaveSpec` Specifies a wave or waves to receive calculated results. The waves also contain initial conditions. The `ywaveSpec` can have either of two forms:

  - `ywaveName`: `ywaveName` is a single, multicolumn wave having one column for each equation in your equation set (if you have just one equation, the wave will be a simple 1D wave).

  - `{ywave0, ywave1, ...}`: The `ywaveSpec` is a list of 1D waves, one wave for each equation. The ordering is important — it must correspond to the elements of the y and dydx wave passed to `derivFunc`.

Unless you use the /R flag to alter the start point, the solution to the equations is calculated at each point in the waves, starting with row 1. You must store the initial conditions in row 0.

Flags

`/CVOP=[solver, jacobian, extendedErrors [, maxStep]]`
Selects options that affect how the Adams-Moulton and BDF integration schemes operate. This flag applies only when using /M = 2 or /M = 3. These methods are based on the CVODE package, hence the flag letters “CV”.

The `solver` parameter selects a solver method for each step. The values of `solver` can be:

- `solver=0`: Select the default for the integration method. That is functional for /M=2 or Newton for /M=3.
- `solver=1`: Functional solver.
- `solver=2`: Newton solver.

The `jacobian` parameter selects the method used to approximate the jacobian matrix (matrix of $df/dy_i$ where $f$ is the derivative function).

- `jacobian=0`: Full jacobian matrix.
- `jacobian=1`: Diagonal approximation.

In both cases, the derivatives are approximated by finite differences.

In our experience, `jacobian = 1` causes the integration to proceed by much smaller steps. It might decrease overall integration time by reducing the computation required to approximate the jacobian matrix.

If the `extendedErrors` parameter is nonzero, extra error information will be printed to the history area in case of an error during integration using /M=2 or /M=3. This extra information is mostly of the sort that will be meaningful only to WaveMetrics software engineers, but may occasionally help you to solve problems. It is printed out as a bug message (BUG: ...) regardless of whether it is our bug or yours.

If `maxStep` is present and greater than zero, this option sets the maximum internal step size that the CVODE package is allowed to take. This is particularly useful with /M=3, as the BDF method is capable of taking extremely large steps if the derivatives don’t change much. Use of this option may be necessary to make sure that the CVODE package doesn’t step right over a brief excursion in, say, a forcing function. If you have something in your derivative function that may be step-like and brief, set `maxStep` to something smaller than the duration of the excursion.

If you want to set `maxStep` only, set the other three options to zero.

`/E=eps` Adjusts the step size used in the calculations by comparing an estimate of the truncation error against a fraction of a scaled number. The fraction is `eps`. For instance, to achieve error less than one part in a thousand, set `eps` to 0.001. The number itself is set by a combination of the `/F` flag and possibly the wave specified with the `/S` flag. See **Solving Differential Equations** on page III-302 for details.

If you do not use the `/E` flag, `eps` is set to $10^{-6}$.

For details, see **Error Monitoring** on page III-312.
IntegrateODE

/F=errMethod Adjusts the step size used in the calculations by comparing an estimate of the truncation error against a scaled number. errMethod is a bitwise parameter that specifies what to include in that number:

bit 0: Add a constant from the error scaling wave set by the /S flag.
bit 1: Add the current value of the results.
bit 2: Add the current value of the derivatives.
bit 3: Multiply by the current step size (/M=0 or /M=1 only).

Each bit that you set of bits 0, 1, or 2 adds a term to the number; setting bit 3 multiplies the sum by the current step size to achieve a global error limit. Note that bit 3 has no effect if you use the Adams or BDF integrators (/M=2 or /M=3). See Setting Bit Parameters on page IV-13 for further details about bit settings.

If you don’t include the /F flag, a constant is used. Unless you use the /S flag, that constant is set to 1.0.

For details, see Error Monitoring on page III-312.

/M=m Specifies the method to use in calculating the solution.

m=0: Fifth-order Runge-Kutta-Fehlberg (default).

m=1: Bulirsch-Stoer method using Richardson extrapolation.

m=2: Adams-Moulton method.

m=3: BDF (Backwards Differentiation Formula, or Gear method). This method is the preferred method for stiff problems.

If you don’t specify a method, the default is the Runge-Kutta method (m=0). Bulirsch-Stoer (m=1) should be faster than Runge-Kutta for problems with smooth solutions, but we find that this is often not the case. Simple experiments indicate that Adams-Moulton (m=2) may be fastest for nonstiff problems. BDF (m=3) is definitely the preferred one for stiff problems. Runge-Kutta is a robust method that may work on problems that fail with other methods.

/Q [= quiet] quiet = 1 or simply /Q sets quiet mode. In quiet mode, no messages are printed in the history, and errors do not cause macro abort. The variable V_flag returns an error code. See Details for the meanings of the V_flag error codes.

/R=(startX,endX) Specifies an X range of the waves in ywaveSpec.

/R=[startP,endP] Specifies a point range in ywaveSpec.

If you specify the range as /R=[startP] then the end of the range is taken as the end of the wave. If /R is omitted, the entire wave is evaluated. If you specify only the end point (/R=[endP]) the start point is taken as point 0.

You must store initial conditions in startP. The first point is startP+1.

/S=errScaleWaveName

If you set bit 0 of errMethod using the /F flag, or if you don’t include the /F flag, a constant is required for scaling the estimated error for each differential equation. By default, the constants are simply set to 1.0.

You provide custom values of the constants via the /S flag and a wave. Make a wave having one element for each derivative, set a reasonable scale factor for the corresponding equation, and set errScaleWaveName to the name of that wave.

If you don’t use the /S flag, the constants are all set to 1.0.

/STOP = {stopWave, mode}
Requests that IntegrateODE stop when certain conditions are met on either the solution values (Y values) or the derivatives.

stopWave contains information that IntegrateODE uses to determine when to stop.

mode controls the logical operations applied to the elements of stopWave:

mode=0: OR mode. If stopWave contains more than one condition, any one condition will stop the integration when it is satisfied.

mode=1: AND mode. If stopWave contains more than one condition, all conditions must be satisfied to cause the integration to stop.

See Details, below, for more information.

/U=u
Update the display every u points. By default, it will update the display every 10 points. To disable updates, set u to a very large number.

/X=xvaluespec
Specifies the values of the independent variable (commonly called x or t) at which values are to be calculated (see parameter ywaveSpec).

You can provide a wave or x0 and deltaX:

/X = xWaveName
Use this form to provide a list of values for the independent variable. They can have arbitrary spacing and may increase or decrease, but should be monotonic.

If you use the /XRUN flag to specify free-run mode, /X = xWaveName is required. In this case, the X wave becomes an output wave and any contents are overwritten. See the description of /XRUN for details.

/X = {x0, deltaX}
If you use this form, x0 is the initial value of the independent variable. This is the value at which the initial conditions apply. It will calculate the first result at x0+deltaX, and subsequent results with spacing of deltaX.

deltaX can be negative.

If you do not use the xValues keyword, it reads independent variable values from the X scaling of the results wave (see ywaveSpec parameter).

/XRUN={dx0, Xmax}

If dx0 is nonzero, the output is generated in a free-running mode. That is, the output values are generated at whatever values if the independent variable (x or t) the integration method requires to achieve the requested accuracy. Thus, you will get solution points at variably-spaced X values.

The parameter dx0 sets the step size for the first integration step. If this is smaller than necessary, the step size will increase rapidly. If it is too large for the requested accuracy, the integration method will decrease the step size as necessary.

If dx0 is set to zero, free-run mode is not used; this is the same as if the XRUN flag is not used.

When using free-run mode, you must provide an X wave using /X = xWaveName. Set the first value of the wave (this is usually point zero, but may not be if you use the /R flag) to the initial value of X.

As the integration proceeds, the X value reached for each output point is written into the X wave. The integration stops when the latest step taken goes beyond Xmax or when the output waves are filled.

Details
The various waves you may use with the IntegrateODE operation must meet certain criteria. The wave to receive the results (ywaveSpec), and which contains the initial conditions, must have exactly one column for each equation in your system of equations, or you must supply a list of waves containing one wave for each equation. Because IntegrateODE can’t determine how many equations there are from your function, it uses the number of columns or the number of waves in the list to determine the number of equations.
If you supply a list of waves for ywaveSpec, all the waves must have the same number of rows. If you supply a wave containing values of the independent variable or to receive X values in free-run mode (using /X=waveName) the wave must have the same number of rows as the ywaveSpec waves.

The wave you provide for error scaling via the /S flag must have one point for each equation. That is, one point for each ywaveSpec wave, or one point for each column of a multicolumn ywaveSpec.

By default, the display will update after each tenth point is calculated. If you display one of your ywaveSpec waves in a graph, you can watch the progress of the integration.

The display update may slow down the calculation considerably. Use the /U flag to change the interval between updates. To disable the updates entirely, set the update interval to a number larger than the length of the waves in ywaveSpec.

In free-run mode, it is impossible to predict how many output values you will get. IntegrateODE will stop when either your waves are filled, or when the X value exceeds Xmax set in the /XRUN flag. The best strategy is to make the waves quite large; unused rows in the waves will not be touched. To avoid having “funny” traces on a graph, you can prefill your waves with NaN. Make sure that you don’t set the initial condition row and initial X value row to Nan!

Stopping IntegrateODE

In some circumstances it is useful to be able to stop the integration early, before the full number of output values has been computed. You can do this two ways: using the /STOP flag to put conditions on the solution, or by returning 1 from your derivative function.

When using /STOP=[stopWave, mode], stopWave must have one column for each equation in your system or, equivalently, a number of columns equal to the order of your system. Each column represents a condition on either the solution value or the derivatives for a given equation in your system.

Row 0 of stopWave contains a flag telling what sort of condition to apply to the solution values. If the flag is zero, that value is ignored. If the flag is 1, the integration is stopped if the solution value exceeds the value you put in row 1. If the flag is -1, integration is stopped when the solution value is less than the value in row 1.

Rows 2 and 3 work just like rows 0 and 1, but the conditions are applied to the derivatives rather than to the solution values.

If stopWave has two rows, only the solution values are checked. If stopWave has four rows, you can specify conditions on both solution values and derivatives.

You can set more than one flag value non-zero. If you do that, then mode determines how the multiple conditions are applied. If mode is 0, then any one condition can stop integration when it is satisfied. If mode is 1, all conditions with a non-zero flag value must be satisfied at the same time. If row 0 and row 2 have nothing but zeroes, then stopWave is ignored.

For further discussion, see Stopping IntegrateODE on a Condition on page III-315.

Output Variables

The IntegrateODE operation sets a variety of variables to give you information about the integration. These variables are updated at the same time as the display so you can monitor an integration in progress. They are:

- V_ODEStepCompleted: Point number of the last result calculated.
- V_ODEStepSize: Size of the last step in the calculation.
- V_ODETotaSteps: Total number of steps required to arrive at the current result. In free-run mode, this is the same as V_ODEStepCompleted.
- V_ODEMinStep: Minimum step size used during the entire calculation.
- V_ODEFunctioCalls: The total number of calls made to your derivative function.
- V_Flag: Indicates why IntegrateODE stopped.

The values for V_Flag are:

0: Finished normally.
1: User aborted the integration.

Solving Differential Equations on page III-302 gives the form of the derivative function, details on the error specifications and what they mean, along with several examples.

References

The Runge-Kutta (/M=0) and Bulirsh-Stoer (/M=1) methods are based on routines in Press, William H., et al., Numerical Recipes in C, 2nd ed., 994 pp., Cambridge University Press, New York, 1992, and are used by permission.

The Adams-Moulton (/M=2) and BDF methods (/M=3) are based on the CVODE package developed at Lawrence Livermore National Laboratory:

The CVODE package was derived in part from the VODE package. The parts used in Igor are described in this paper:

interp

interp(x1, xwaveName, ywaveName)
The interp function returns a linearly interpolated value at the location x = x1 of a curve whose X components come from the Y values of xwaveName and whose y components come from the Y values of ywaveName.

Details

interp returns nonsense if the waves are complex or if xwaveName is not monotonic or if either wave contains NaNs.

The interp function is not multidimensional aware. See Analysis on Multidimensional Waves on page II-89 for details.
Interp2D

**Examples**

```
Make/O/N=(10,20,30) ddd=gnoise(10)
Print interp3D(ddd,1,0,0)
Print interp3D(ddd,1,1,1)
```

See Also
The Interpolate2 operation. Interpolation on page III-115.

**Interp2D**

**Interp2D(srcWaveName, xValue, yValue)**

The Interp2D function returns a double precision number as the interpolated value for the xValue, yValue point in the source wave. Returns NaN if the point is outside the source wave domain or if the source wave is complex.

**Parameters**
- **srcWaveName** is the name of a 2D wave. The wave can not be complex.
- **xValue** is the X-location of the interpolated point.
- **yValue** is the Y-location of the interpolated point.

See Also
The ImageInterpolate operation. Interpolation on page III-115.

**Interp3D**

**Interp3D(srcWave, x, y, z [, triangulationWave])**

The Interp3D function returns an interpolated value for location P=(x, y, z) in a 3D scalar distribution srcWave.

If srcWave is a 3D wave containing a scalar distribution sampled on a regular lattice, the function returns a linearly interpolated value for any P=(x, y, z) location within the domain of srcWave. If P is outside the domain, the function returns NaN.

To interpolate a 3D scalar distribution that is not sampled on a regular lattice, srcWave is a four column 2D wave where the columns correspond to x, y, z, f(z, y, z), respectively. You must also use a “triangulation” wave for srcWave (use Triangulate3D/out=1 to obtain the triangulation wave). If P falls within the convex domain defined by the tetrahedra in triangulationWave, the function returns the barycentric linear interpolation for P using the tetrahedron where P is found. If P is outside the convex domain the function returns NaN.

**Examples**

```
Make/O/N=(10,20,30) ddd=gnoise(10)
Triangulate3D/OUT=1 ddd
Print interp3D(ddd,1,0,0,M_3DVertexList)
Print interp3D(ddd,1,1,1,M_3DVertexList)
```

See Also
The Interpolate3D operation. Interpolation on page III-115.
**Interp3DPath**

Interp3DPath computes the trilinear interpolated values of 3dWave for each position specified by a row in tripletPathWave, which is a 3 column wave in which the first column represents the X coordinate, the second represents the Y coordinate and the third represents the Z coordinate. Interp3DPath stores the resulting interpolated values in the wave W_Interpolated. Interp3DPath is equivalent to calling the Interp3D() function for each row in tripletPathWave but it is computationally more efficient.

If the position specified by the tripletPathWave is outside the definition of the 3dWave or if it contains a NaN, the operation stores a NaN in the corresponding output entry.

Both 3dWave and tripletPathWave can be of any numeric type. W_Interpolated is always of type NT_FP64.

**See Also**
The ImageInterpolate operation and the Interp3D and interp functions. Interpolation on page III-115.

**Interpolate2**

Interpolate2 performs linear, cubic spline and smoothing cubic spline interpolation on 1D waveform or XY data. It produces output in the form of a waveform or an XY pair.

The cubic spline interpolation is based on a routine from "Numerical Recipes in C".

The smoothing spline is based on "Smoothing by Spline Functions", Christian H. Reinsch, Numerische Mathematische 10, 177-183 (1967).

For background information, see The Interpolate2 Operation on page III-116.

**Parameters**

- **xWave** specifies the wave which supplies the X coordinates for the input curve. If you omit it, X coordinates are taken from the X values of yWave.
- **yWave** specifies the wave which supplies the Y coordinates for the input curve.

**Flags**

- **/A=a** Controls pre-averaging. Pre-averaging is deprecated - use the smoothing spline (/T=3) instead.
  
  If a is zero, Interpolate2 does no pre-averaging. If a is greater than one, it specifies the number of nodes through which you want the output curve to go. Interpolate2 creates the nodes by averaging the raw input data.

  Pre-averaging does not work correctly with the log-spaced output mode (/I=2). This is because the pre-averaging is done on linearly-spaced intervals but the input data is log-spaced.

- **/E=e** Controls how the end points are determined for cubic spline interpolation only.
  
  e=1: Match first derivative (default)

  e=2: Match second derivative (natural)

- **/F=f** $f$ is the smoothing factor used for the smoothing spline.

  $f=0$ is nearly identical to the cubic spline.

  $f>0$ gives increasing amounts of smoothing as $f$ increases.

  See Smoothing Spline Parameters on page III-119 for details.
/I=i

Determines at what X coordinates the interpolation is done.

i=0: Gives output values at evenly-spaced X coordinates that span the X range of the input data. This is the default setting if /I is omitted.

i=1: Same as i=0 except that the X input values are included in the list of X coordinates at which to interpolate. This is rarely needed and is not available if no X destination wave is specified. /I is equivalent to /I=1.

Both are not recommended.

i=2: Gives output values at X coordinates evenly-spaced on a logarithmic scale. Use this if your data is plotted on a logarithmic X axis. This mode ignores any non-positive values in your input X data.

i=3: Gives output values at X coordinates that you specify by setting the X coordinates of the destination wave before calling Interpolate2. You must create your destination wave or waves before doing the interpolation for this mode.

If you omit /X=xDest then the X coordinates come from the X values of the output waveform designated by /Y=yDest.

If you include /X=xDest then the X coordinates come from the data values of the specified X output wave.

When using /I=3, the number of output points is determined by the destination wave and the /N flag is ignored.

See Destination X Coordinates from Destination Wave on page III-120 for further details.

/J=j

Controls the use of end nodes with pre-averaging (/A). Pre-averaging is deprecated - use the smoothing spline (/T=3) instead.

j=0: Turns end nodes off.

j=1: Creates end nodes by cubic extrapolation.

j=2: Creates end nodes equal to the first and last data points of the input data set, not counting points that contain NaNs or INFs.

/N=n

Controls the number of points in the output wave or waves. n defaults to the larger of 200 and the number of points in the source waves. This value is ignored if you /I=3 (X from dest mode).

/S=s

s is the estimated standard deviation of the noise of the Y data. It is used for the smoothing spline only. s is used as the estimated standard deviation for all points in the Y data.

If neither /S nor /SWAV are present, Interpolate2 arbitrarily assumes an s equal to .05 times the amplitude of the Y data.

/SWAV=stdDevWave

stdDevWave is a wave containing the standard deviation of the noise of the Y data on a point-by-point basis. It is used for the smoothing spline only. stdDevWave must have the same number of points as the Y data wave.

If neither /S nor /SWAV are present, Interpolate2 arbitrarily assumes an s equal to .05 times the amplitude of the Y data.

/T=t

Controls the type of interpolation performed.

t=1: Linear interpolation

T=2: Cubic spline interpolation (default)

T=3: Smoothing spline interpolation
Interpolate3D

Interpolate3D [/Z] /RNGX={x0,dx,nx}/RNGY={y0,dy,ny}/RNGZ={z0,dz,nz} /DEST=dataFolderAndName, triangulationWave=tWave, srcWave=sWave

The Interpolate3D operation uses a precomputed triangulation of sWave (see Triangulate3D) to calculate regularly spaced interpolated values from an irregularly spaced source. The interpolated values are calculated for a lattice defined by the range flags /RNGX, /RNGY, and /RNGZ. sWave is a 4 column wave where the first three columns contain the spatial coordinates and the fourth column contains the associated scalar value. Interpolate3D is essentially equivalent to calling the Interp3D function for each interpolated point in the range but it is much more efficient.

Parameters

triangulationWave=tWave

Specifies a 2D index wave, tWave, in which each row corresponds to one tetrahedron and each column (tetrahedron vertex) is represented by an index of a row in sWave. Use Triangulate3D with /OUT=1 to obtain tWave.

csrcWave=sWave

Specifies a real-valued 4 column 2D source wave, sWave, in which columns correspond to x, y, z, f(x, y, z). Requires that the domain occupied by the set of {x, y, z} be convex.

Flags

/DEST=dataFolderAndName

Saves the result in the specified destination wave. The destination wave will be created or overwritten if it already exists. dataFolderAndName can include a full or partial path with the wave name.

/RNGX={x0,dx,nx} Specifies the range along the X-axis. The interpolated values start at x0. There are nx equally spaced interpolated values where the last value is at x0+(nx-1)dx. If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a YZ plane would have nx=1.

/RNGY={y0,dy,ny} Specifies the range along the Y-axis. The interpolated values start at y0. There are ny equally spaced interpolated values where the last value is at y0+(ny-1)dy. If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a XZ plane would have ny=1.
InverseErf

/\text{RNGZ}=[z_0,dz,nz] \quad \text{Specifies the range along the Z-axis. The interpolated values start at } z_0. \text{ There are } nz \text{ equally spaced interpolated values where the last value is at } z_0+(nz-1)dz. \text{ If you would like to interpolate the data for a single plane you can set the appropriate number of values to 1. For example, a XY plane would have } nz=1.\

/\text{Z} \quad \text{No error reporting.}

Details
The triangulation wave defines a set of tetrahedra that spans the convex source domain. If the requested range consists of points outside the domain, the interpolated values will be set to NaN. The interpolation process for points inside the convex domain consists of first finding the tetrahedron in which the point resides and then linearly interpolating the scalar value using the barycentric coordinate of the interpolated point.

In some cases the interpolation may result in NaN values for points that are clearly inside the convex domain. This may happen when the preceding Triangulate3D results in tetrahedra that are too thin. You can try using Triangulate3D with the flag /OUT=4 to get more specific information about the triangulation. Alternatively you can introduce a slight random perturbation to the input source wave before the triangulation.

Example
Function Interpolate3DDemo()
Make/O/N=(50,4) ddd=gnoise(20) // First 3 columns store XYZ coordinates
ddd[3]=ddd[p][2] // Fourth column stores a scalar which is set to z
Triangulate3D ddd // Perform the triangulation
Wave M_3dVertexList
Interpolate3D /RNGX={-30,1,80}/RNGY={-40,1,80}/RNGZ={-40,1,80}
/DEST=W_Interp triangulationWave=M_3dVertexList,srcWave=ddd
End

References

InverseErf

inverseErf(x)
The inverseErf function returns the inverse of the error function.

Details
The function is calculated using rational approximations in several regions followed by one iteration of Halley’s algorithm.

See Also
The erf, erfc, dawson, and inverseErfc functions.

InverseErfc

inverseErfc(x)
The inverseErfc function returns the inverse of the complementary error function.

Details
The function is calculated using rational approximations in several regions followed by one iteration of Halley’s algorithm.

See Also
The erf, erfc, erfcw, dawson, and inverseErf functions.
**ItemsInList**

\[ \text{ItemsInList}(listStr \ [, listSepStr]) \]

The ItemsInList function returns the number of items in listStr. listStr should contain items separated by listSepStr which typically is ";".

Use ItemsInList to count the number of items in a string containing a list of items separated by a string (usually a single ASCII character), such as those returned by functions like TraceNameList or AnnotationList, or a line from a delimited text file.

If listStr is "" then 0 is returned.

listSepStr is optional. If missing, listSepStr defaults to ",".

**Details**

listStr is searched for item strings bound by listSepStr on the left and right.

An item can be empty. The lists "abc;def;;ghi" and ";abc;def;;ghi;" have four items (the third item is ";").

listStr is treated as if it ends with a listSepStr even if it doesn’t. The search is case-sensitive.

In Igor6, only the first byte of listSepStr was used. In Igor7 and later, all bytes are used.

**Examples**

Print ItemsInList("wave0;wave1;wave1#1;") // prints 3
Print ItemsInList("key1=val1,key2=val2", ",") // prints 2
Print ItemsInList("1 \t 2 \t", ",\t") // prints 2
Print ItemsInList(";") // prints 1
Print ItemsInList(";e;") // prints 2
Print ItemsInList(";a;") // prints 2
Print ItemsInList(";e;") // prints 3

**See Also**

The AddListItem, StringFromList, FindListItem, RemoveListItem, RemoveFromList, WaveList, TraceNameList, StringList, VariableList, and FunctionList functions.

**j**

The j function returns the loop index of the 2nd innermost iterate loop in a macro. Not to be used in a function. Iterate loops are archaic and should not be used.

**JCAMPLoadWave**

\[ \text{JCAMPLoadWave} \ [flags] [fileNameStr] \]

The JCAMPLoadWave operation loads data from the named JCAMP-DX file into waves.

**Parameters**

If fileNameStr is omitted or is "", or if the /I flag is used, JCAMPLoadWave presents an Open File dialog from which you can choose the file to load.

If you use a full or partial path for fileNameStr, see Path Separators on page III-429 for details on forming the path.
JCAMPLoadWave

Flags

/A   Automatically assigns arbitrary wave names using "wave" as the base name. Skips names already in use.
/A=baseName   Same as /A but it automatically assigns wave names of the form baseName0, baseName1.
/D   Creates double-precision waves. If omitted, JCAMPLoadWave creates single-precision waves.
/H   Reads header information from JCAMP file. If you include /W, this information is stored in the wave note. If you include /V, it is stored in header variables.
/I   Forces JCAMPLoadWave to display an Open File dialog even if the file is fully specified via /P and fileNameStr.
/N   Same as /A except that, instead of choosing names that are not in use, it overwrites existing waves.
/N=baseName   Same as /N except that it automatically assigns wave names of the form baseName0, baseName1.
/O   Overwrite existing waves in case of a name conflict.
/P=pathName   Specifies the folder to look in for fileNameStr. pathName is the name of an existing symbolic path.
/Q   Suppresses the normal messages in the history area.
/R   Reads data from file and creates Igor waves.
/V   Set variables from header information if /H is also present
/W   Stores header information in the wave note if /R and /H are also present.

Details
The /N flag instructs Igor to automatically name new waves "wave", or baseName if /N=baseName is used, plus a number. The number starts from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten.
The /A flag is like /N except that Igor skips names already in use.

Output Variables
JCAMPLoadWave sets the following output variables:

V_flag   Number of waves loaded or -1 if an error occurs during the file load.
S_fileName   Name of the file being loaded.
S_path   File system path to the folder containing the file.
S_waveNames   Semicolon-separated list of the names of loaded waves.

S_path uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon.
When JCAMPLoadWave presents an Open File dialog and the user cancels, V_flag is set to 0 and S_fileName is set to "".
In addition, if the /V flag is used, variables are created corresponding to JCAMP-DX labels in the header. See Variables Set By JCAMPLoadWave on page II-153 for details.

Example
Function LoadJCAMP(pathName, fileName)
    String pathName     // Name of Igor symbolic path or ""
    String fileName     // Full path, partial path or simple file name

    JCAMPLoadWave/P=$pathName fileName
if (V_Flag == 0)
    Print "No waves were loaded"
return -1
endif

NVAR VJC_NPOINTS
Printf "Number of points: %d\r", VJC_NPOINTS

SVAR SJC_YUNITS
Printf "Y Units: %s\r", SJC_YUNITS

return 0
End

See Also
Loading JCAMP Files on page II-152

JacobiCn

JacobiCn(x, k)

jlim

jlim
The jlim function returns the ending loop count for the 2nd inner most iterate loop. Not to be used in a function. Iterate loops are archaic and should not be used.

JointHistogram

JointHistogram [flags] wave1, wave2 [, wave3, wave4]
The JointHistogram computes 2D, 3D and 4D joint histograms of data provided in the input waves. The input waves must be 1D real numeric waves having the same number of points. The result of the operation is stored in the multidimensional wave M_JointHistogram in the current data folder or in the wave specified via the /DEST flag.

This operation was added in Igor Pro 7.00.
JointHistogram

**Flags**

/BINS={nx, ny, nz, nt} Specifies the number of bins along each axis. Set the number of bins for unused axes to zero. If the number of bins is non-zero, then the flags /XBMT, /YBMT, /ZBMT, and /TBMT are overridden.

/C Sets the output wave scaling so that the values in each axis are centered in the bins. By default, wave scaling of the output wave is set with values at the left bin edges. This flag has no effect on axes where bins are specified by using /XBWV, /YBWV, /ZBWV or /TBWV.

/E Excludes outliers. This flag is relevant only if there are one or more bin waves specified by using /XBWV, /YBWV, /ZBWV or /TBWV. By default values that might fall below the first bin or above the last bin are folded into the first and last bin respectively. These values (outliers) are excluded from the joint histogram when you use /E. See /P below for the way outliers affect the probability calculation.

/DEST=destWave Specifies the output wave created by the operation. If you omit /DEST then the output wave is M_JointHistogram in the current data folder.

It is an error to specify a destination which is the same as one of the input waves. When used in a user-defined function, the JointHistogram operation by default creates a real wave reference for the destination wave. See Automatic Creation of WAVE References on page IV-71 for details.

/P=mode Normalizes the histogram to a probability density. Use mode=0 to count all points, including possible outliers but excluding non-finite values, in the probability calculation. This is the default setting. Use mode=1 if you want to completely exclude outliers from the normalization. When outliers are excluded the output wave sums to 1. When they are included the sum of the output wave is smaller by the ratio of the number of outliers to the total number of points in the histogram.

/W=weightWave Creates a weighted histogram. Instead of adding a single count to the appropriate bin, the corresponding value from weightWave is added to the bin. weightWave may be any real number type.

/XBMT=method These flags specify which method is used to set the bins. By default method=0. These flags are overridden by /BINS if a non-zero value is specified for a given axis and by /XBWV, /YBWV, /ZBWV and /TBWV.

/YBMT=method

/ZBMT=method

/TBMT=method See JointHistogram Binning Methods below for details.

/XBWV=xBinWave Specifies the exact bins for a corresponding axis.

/YBWV=yBinWave The wave must be 1D real numeric wave with monotonically increasing finite values and must contain a minimum of 3 data points.

/ZBWV=zBinWave

/TBWV=tBinWave

/Z [=zval] Suppresses error reporting. /Z is equivalent to /Z=1 and /Z=0 is equivalent to not using the /Z flag at all.

**Details**
The input waves must be 1D real numeric waves. If one or more waves contain a non-finite value (a NaN or INF) the corresponding row of all waves are not counted in the joint histogram.
The optional waves that define user-specified bins must be real numeric waves and contain a monotonically increasing values. Using non-finite values in user-specified bin waves may lead to unpredictable results.

**JointHistogram Binning Methods**

The `/XBMT`, `/YBMT`, `/ZBMT` and `/TBMT` flags set the binning method for the X, Y, Z and T dimensions respectively.

These flags are overridden by `/BINS` if a non-zero value is specified for a given axis and by `/XBWV`, `/YBWV`, `/ZBWV` and `/TBWV`.

The `method` parameter is defined as follows:

- **method=0**: 128 equally spaced bins between the minimum and maximum of the input data. This is the default setting.
- **method=1**: The number of bins is computed using Sturges’ method where
  \[ \text{numBins} = 1 + \log_2(N) \]
  N is the number of data points in each wave. The bins are distributed so that they include the minimum and maximum values.
- **method=2**: The number of bins is computed using Scott’s method where the optimal bin width is given by
  \[ \text{binWidth} = 3.49 \times \sigma \times N^{-1/3} \]
  \( \sigma \) is the standard deviation of the distribution and N is the number of points. The bins are distributed so that they include the minimum and maximum values.
- **method=3**: Freedman-Diaconis method where
  \[ \text{binWidth} = 2 \times \text{IQR} \times N^{-1/3} \]
  \( \text{IQR} \) is the interquartile distance (see `StatsQuantiles`) and the bins are evenly distributed between the minimum and maximum values.

**Example: 2D Joint Histogram**

```
Make/O/N=(1000) xwave=gnoise(10), ywave=gnoise(5)
JointHistogram/BINS={20,30} xwave,ywave
NewImage M_JointHistogram
```

**Example: 2D Joint Histogram using one bins wave**

```
Make/O/N=(1000) xwave=gnoise(10), ywave=gnoise(5)
Make/O/N=3 xBinsWave={-8,0,14}
JointHistogram/BINS={0,30}/XBWV=xBinsWave/E xwave,ywave
Display; AppendImage/T M_JointHistogram vs {xBinsWave,*}
```

**Example: 3D Joint Histogram**

```
Make/O/N=(1000) xwave=gnoise(10), ywave=gnoise(5), zwave=enoise(4)
JointHistogram/BINS={15,15,20,0} xwave,ywave,zwave
NewImage M_JointHistogram
ModifyImage M_JointHistogram plane=10
```

**See Also**

Histogram, ImageHistogram

**JulianToDate**

```
JulianToDate(julianDay, format)
```

The JulianToDate function returns a date string containing the day, month, and year. The input `julianDay` is truncated to an integer.

**Parameters**

- `julianDay` is the Julian day to be converted.
- `format` specifies the format of the returned date string.
KillBackground

<table>
<thead>
<tr>
<th>format</th>
<th>Date String</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>mm/dd/year</td>
</tr>
<tr>
<td>1</td>
<td>dd/mm/year</td>

<td>Tuesday November 15, 2002</td>
</tr>
<tr>
<td>3</td>
<td>year mm dd</td>
</tr>
<tr>
<td>4</td>
<td>year/mm/dd</td>
</tr>
</tbody>
</table>

See Also
The `dateToJulian` function.
For more information about the Julian calendar see: <http://www.tondering.dk/claus/calendar.html>.

KillBackground

The `KillBackground` operation kills the unnamed background task.

KillBackground works only with the unnamed background task. New code should use named background tasks instead. See Background Tasks on page IV-307 for details.

Details
You can not call `KillBackground` from within the background function itself. However, if you return 1 from the background function, instead of the normal 0, Igor will terminate the background task.

See Also
The `BackgroundInfo`, `CtrlBackground`, `CtrlNamedBackground`, `setBackground`, and `SetProcessSleep` operations; and Background Tasks on page IV-307.

KillControl

`KillControl [/W=winName] controlName`

The `KillControl` operation kills the named control in the top or specified graph or panel window or subwindow.

If the named control does not exist, `KillControl` does not complain.

Flags

`/W=winName` Looks for the control in the named graph or panel window or subwindow. If `/W` is omitted, `KillControl` looks in the top graph or panel window or subwindow.

When identifying a subwindow with `winName`, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

See Also
Chapter III-14, Controls and Control Panels, for details about control panels and controls.
KillDataFolder

KillDataFolder [/Z] dataFolderSpec

The KillDataFolder operation kills the specified data folder and everything in it including other data folders. However, if dataFolderSpec is the name of a data folder reference variable that refers to a free data folder, the variable is cleared and the data folder is killed only if this is the last reference to that free data folder.

Flags

/Z No error reporting (except for setting V_flag). Does not halt function execution.

Parameters
dataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

Details

If specified data folder is the current data folder or contains the current data folder then Igor makes its parent the new current data folder.

For legacy reasons, a null data folder is taken to be the current data folder. This can happen when using a $ expression where the string might possibly evaluate to "".

It is legal to kill the root data folder. In this case the root data folder itself is not killed but everything in it is killed.

KillDataFolder generates an error if any of the waves involved are in use. In this case, nothing is killed.

Execution ceases unless /Z is specified.

The variable V_flag is set to 0 when there is no error, otherwise it is an error code.

Examples

KillDataFolder foo // Kills foo in the current data folder.
KillDataFolder :bar:foo // Kills foo in bar in current data folder.
String str = "root:foo"
KillDataFolder $str // Kills foo in the root data folder.

See Also
Chapter II-8, Data Folders and the KillStrings, KillVariables, and KillWaves operations.

KillFIFO

KillFIFO FIFOName

The KillFIFO operation discards the named FIFO.

Details

FIFOs are used for data acquisition.

If there is an output or review file associated with the FIFO, KillFIFO closes the file. If the FIFO is used by an XOP, you should call the XOP to release the FIFO before killing it.

See Also
See FIFOs and Charts on page IV-301 for information about FIFOs and data acquisition.

KillFreeAxis

KillFreeAxis [/W=winName] axisName

The KillFreeAxis operation removes a free axis specified by axisName from a graph window or subwindow.
KillPath

Flags
/W=winName  Kills the free axis in the named graph window or subwindow. If /W is omitted, it acts on the top graph window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details
Only an axis created by NewFreeAxis can be killed and only if no traces or images are attached to the axis.

See Also
The NewFreeAxis operation.

KillPath

KillPath [/A/Z] pathName
The KillPath operation removes a path from the list of symbolic paths. KillPath is a newer name for the RemovePath operation.

Flags
/A  Kills all symbolic paths in the experiment except for the built-in paths. Omit pathName if you use /A.
/Z  Does not generate an error if a path to be killed is a built-in path or does not exist. To kill all paths in the experiment, use KillPath/A/Z.

Details
You can’t kill the built-in paths “home” and “Igor”.

See Also
The NewPath operation.

KillPICTs

KillPICTs [/A/Z] [PICTName [, PICTName]...]
The KillPICTs operation removes one or more named pictures from the current Igor experiment.

Flags
/A  Kills all pictures in the experiment.
/Z  Does not generate an error if a picture to be killed is in use or does not exist. To kill all pictures in the experiment, use KillPICTs/A/Z.

Details
You can not kill a picture that is used in a graph or page layout.

Warning: You can kill a picture that is referenced from a graph or layout recreation macro. If you do, the graph or layout can not be completely recreated. Use the Find dialog (Edit menu) to locate references in the procedure window to a named picture you want to kill.

See Also
See Pictures on page III-481 for general information on how Igor handles pictures.
KillStrings

**KillStrings** [/A/Z] [stringName [, stringName]...]
The KillStrings operation discards the named global strings.

**Flags**
- `/A` Kills all global strings in the current data folder. If you use /A, omit stringName.
- `/Z` Does not generate an error if a global string to be killed does not exist. To kill all global strings in the current data folder, use KillStrings/A/Z.

KillVariables

**KillVariables** [/A/Z] [variableName [, variableName]...]
The KillVariables operation discards the named global numeric variables.

**Flags**
- `/A` Kills all global variables in the current data folder. If you use /A, omit variableName.
- `/Z` Does not generate an error if a global variable to be killed does not exist. To kill all global variables in the current data folder, use KillVariables/A/Z.

KillWaves

**KillWaves** [flags] waveName [, waveName]...
The KillWaves operation destroys the named waves.

**Flags**
- `/A` Kills all waves in the current data folder. If you use /A, omit waveNames.
- `/F` Deletes the Igor binary wave file from which waveName was loaded.
- `/Z` Does not generate an error if a wave to be killed is in use or does not exist.

**Details**
The memory the waves occupied becomes available for other uses. You can’t kill a wave used in a graph or table or which is reserved by an XOP.

XOPs reserve a wave by sending the OBJINUSE message.

For functions compiled with the obsolete rtGlobals=0 setting, you also can’t kill a wave referenced from a user-defined function.

**Examples**
KillWaves/A/Z  // kill waves not in use in current data folder

KillWindow

**KillWindow** [flags] winName
The KillWindow operation kills or closes a specified window or subwindow without saving a recreation macro.

**Parameters**
- `winName` is the name of an existing window or subwindow.

When identifying a subwindow with `winName`, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Flags**
- `/Z` Does not generate an error if the specified window does not exist.

**See Also**
The DoWindow operation.
KMeans

The KMeans operation analyzes the clustering of data in populationWave using an iterative algorithm. The result of KMeans is a specification of the classes which is saved in the wave M_KMClasses in the current data folder. Optional results include the distribution of class members (W_KMMembers) and the inter-class distances. populationWave is a 2D wave in which columns correspond to members of the population and rows contain the dimensional information.

Flags

/CAN
Analyze the clustering by computing Euclidean distances between the means of the resulting classes. The resulting distances are stored in an NxN square matrix where N is the number of classes. Self distances (along the diagonal) or distances involving classes that did not survive the iterations are filled with NaN. Also saves the wave W_KMDispersion, which contains the sum of the distances between the center of each class and its members. Distances are evaluated using the method specified by /DIST.

/DEAD=method
Specifies how the algorithm should handle “dead” classes, which are those that lose all members in a given iteration.
- method=1: Remove the class if it loses all members.
- method=2: Default; keeps the last value of the mean vector in case the class might get new members in a subsequent iteration.
- method=3: Assigns the class a random mean vector.

/DIST=mode
Specifies how the class distances are evaluated.
- mode=1: Distance is evaluated as the sum of the absolute values (also known as Manhattan distance).
- mode=2: Default; distance is evaluated as Euclidean distance.

/INIT=method
Specifies the initialization method.
- method=1: Random assignment of members of the population to a class.
- method=2: User-specified mean values (/INW).
- method=3: Default; initialize classes using values of a random selection from the population.

/INW=iWave
Sets the initial classes. The number of rows of iWave equals the dimensionality of the class and the number of columns of iWave is the number of classes. For example, if we want to initialize 5 classes in a problem that involves position in two dimensions then iWave must have 2 rows and 5 columns. The number of rows must also match the number of rows in populationWave.

/NCLS=num
Sets the number of classes in the data. If the initialization method uses specific means (/INIT=2) then the number of columns of iWave (see /INW) must match num. The default number of classes is 2.
KMeans uses an iterative algorithm to analyze the clustering of data. The algorithm is not guaranteed to find a global optimum (maximum likelihood solution) so the operation provides various flags to control when the iterations terminate. You can determine if the operation iterates a fixed number of times or loops until at most a specified maximum number of elements change class membership in a single iteration. If you are computing KMeans in more than one dimension you should pay attention to the relative magnitudes of the data in each dimension. For example, if your data is distributed on the interval \([0,1]\) in the first dimension and on the interval \([0,1e7]\) in the second dimension, the operation will be biased by the much larger magnitude of values in the second dimension.

**Examples**

Create data with 3 classes:

```
Make/O/N=(1,128) jack=4+gnoise(1)
jack[0][15,50]+=10
jack[0][60,]=+20
```

Perform KMeans looking for 5 classes:

```
KMeans/init=1/out=1/ter=1/dead=1/tern=1000/ncls=5 jack
Print M_KMClasses
```

```
M_KMClasses[0][0] = {24.1439, 68}
M_KMClasses[0][1] = {14.1026, 36}
M_KMClasses[0][2] = {4.01537, 24}
```

**See Also**

The FPCLustering function.

---

**Details**

The `KMeans` function uses an iterative algorithm to analyze the clustering of data. The algorithm is not guaranteed to find a global optimum (maximum likelihood solution) so the operation provides various flags to control when the iterations terminate. You can determine if the operation iterates a fixed number of times or loops until at most a specified maximum number of elements change class membership in a single iteration. If you are computing `KMeans` in more than one dimension, you should pay attention to the relative magnitudes of the data in each dimension. For example, if your data is distributed on the interval \([0,1]\) in the first dimension and on the interval \([0,1e7]\) in the second dimension, the operation will be biased by the much larger magnitude of values in the second dimension.

**Examples**

Create data with 3 classes:

```
Make/O/N=(1,128) jack=4+gnoise(1)
jack[0][15,50]+=10
jack[0][60,]=+20
```

Perform `KMeans` looking for 5 classes:

```
KMeans/init=1/out=1/ter=1/dead=1/tern=1000/ncls=5 jack
Print M_KMClasses
```

```
M_KMClasses[0][0] = {24.1439, 68}
M_KMClasses[0][1] = {14.1026, 36}
M_KMClasses[0][2] = {4.01537, 24}
```

**See Also**

The `FPCLustering` function.
Label

Label \[/W=winName/Z\] axisName, labelStr
The Label operation labels the named axis with labelStr.

Parameters
axisName is the name of an existing axis in the top graph. It is usually one of “left”, “right”, “top” or “bottom”, though it may also be the name of a free axis such as “VertCrossing”.

labelStr contains the text that labels the axis.

Flags

/W=winName Adds axis label in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/Z No errors generated if the named axis doesn’t exist. Used for style macros.

Details
labelStr can contain escape codes which affect subsequent characters in the text. An escape code is introduced by a backslash character. In a literal string, you must enter two backslashes to produce one. See Backslashes in Annotation Escape Sequences on page III-59 for details.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See Annotation Escape Codes on page III-54 for details.

Some escape codes insert text based on axis properties. See Axis Label Escape Codes on page III-58 for details.

The characters “<??>” in an axis label indicate that you specified an invalid escape code or used a font that is not available.

See Also
See Annotation Escape Codes on page III-54. See the Legend operation about wave symbols.

Trace Names on page II-222, Programming With Trace Names on page IV-86.

laguerre

laguerre \((n, x)\)
The laguerre function returns the Laguerre polynomial of degree \(n\) (positive integer) and argument \(x\). The polynomials satisfy the recurrence relation:

\[(n + 1)\text{Laguerre}(n + 1,x) = (2n + 1 - x)\text{Laguerre}(n,x) - n \text{Laguerre}(n - 1,x),\]

with the initial conditions

Laguerre\((0,x) = 1\)

and

Laguerre\((1,x) = 1 - x.\)

See Also
The laguerreA, laguerreGauss, chebyshev, chebyshevU, hermite, hermiteGauss, and legendreA functions.
laguerreA

\[ \text{laguerreA}(n, k, x) \]

The \text{laguerreA} function returns the associated Laguerre polynomial of degree \( n \) (positive integer), index \( k \) (non-negative integer) and argument \( x \). The associated Laguerre polynomials are defined by

\[ L_n^k(x) = (-1)^k \frac{d^k}{dx^k} \left[ L_{n+k}(x) \right], \]

where \( L_{n+k}(x) \) is the Laguerre polynomial.

See Also
The \text{laguerre} and \text{laguerreGauss} functions.

References

laguerreGauss

\[ \text{laguerreGauss}(p, m, r) \]

The \text{laguerreGauss} function returns the normalized product of the associated Laguerre polynomials and a Gaussian. This function is typically encountered in solutions to physical problems where it represents the radial solution with an additional factor \( \exp(i m \phi) \) which is not included in this case. The LaguerreGauss is given by

\[ U_{pm}(r) = \frac{2 p!}{\pi (m+p)!} \left( r \sqrt{2} \right)^m L_p^m \left( 2 r^2 \right) \exp(-r^2). \]

See Also
The \text{laguerre}, \text{laguerreA}, and \text{hermiteGauss} functions.

LambertW

\[ \text{LambertW}(z, \text{branch}) \]

The \text{LambertW} function returns the complex value of Lambert's W function for complex \( z \) and integer index \( \text{branch} \). The function can be defined through its inverse,

\[ z = w \cdot e^w. \]

Since \( w \) is multivalued, the branch parameter is used to differentiate between solutions for the equation. The \text{LambertW} function was added in Igor Pro 7.00.

Details
IGOR's \text{LambertW} uses complex input and output. You can use \text{LambertW} in real expressions but you must make sure that you are not calling the function in a range where its imaginary part is non-zero.

The average accuracy of the function defined by \( \text{cabs}(z-w \cdot \text{exp}(w)) \) in the region \( |\text{real}(z)| < 10, |\text{imag}(z)| < 10 \) is 5e-14. In general the accuracy decreases with increasing \( |\text{branch}| \) and with increasing distance from the origin in the z-plane.

IGOR uses a hybrid algorithm to compute the function which requires longer computation times in the presence of numerical instabilities.

References
Layout

Layout [flags] [objectSpec [, objectSpec]...] [as titleStr]
The Layout operation creates a page layout.

Note: The Layout operation is antiquated and cannot be used in user-defined functions. For new programming, use the NewLayout operation instead.

Parameters
All of the parameters are optional.

Each objectSpec parameter identifies a graph, table, textbox or picture to be added to the layout. An object specification can also specify the location and size of the object, whether the object should have a frame or not, whether it should be transparent or opaque, and whether it should be displayed in high fidelity or not. See Details.

titleStr is a string expression containing the layout’s title. If not specified, Igor will provide one which identifies the objects displayed in the graph.

Flags

/A=(rows,cols) Specifies rows and columns for tiling or stacking.

/B=(r,g,b) Specifies the background color for the layout. r, g, and b are integers from 0 to 65535. Defaults to white (65535,65535, 65535).

/C=colorOnScreen Obsolete. In ancient times, this flag switched the screen display of the layout between black and white and color. It is still accepted but has no effect.

/G=g Specifies grout, the spacing between tiled objects. Units are points unless /I, /M, or /R are specified.

/HIDE=H Hides (H = 1) or shows (H = 0, default) the window.

/I Specifies that coordinates are in inches. This affects subsequent /G, /W, and objectSpec coordinates. Coordinates are relative to the top/left corner of the paper.

/K=k Specifies window behavior when the user attempts to close it.
    k=0: Normal with dialog (default).
    k=1: Kills with no dialog.
    k=2: Disables killing.
    k=3: Hides the window.

If you use /K=2 or /K=3, you can still kill the window using the KillWindow operation.

/M Specifies that coordinates are in centimeters. This affects subsequent /G, /W, and objectSpec coordinates. Coordinates are relative to the top/left corner of the paper.

/P=orientation orientation is either Portrait or Landscape (e.g., Layout/P= Landscape). This controls the orientation of the page in the layout. See Details.

If you use the /P flag, you should make it the first flag in the Layout operation. This is necessary because the orientation of the page affects the behavior of other flags, such as /T and /G.

/R Specifies that coordinates are in percent. This affects subsequent /G, /W, and objectSpec coordinates. For /W, coordinates are as a percent of the main screen. For /G and objectSpec, coordinates are relative to the top/left corner of the printing part of the page.

/S Stacks objects.

/T Tiles objects.

/W=(left, top, right, bottom)
Details
When you create a new page layout window, if preferences are enabled, the page size is determined by the preferred page size as set via the Capture Layout Prefs dialog. If preferences are disabled, as is usually the case when executing a procedure, the page is set to the factory default size.

If you use the /P flag, you should make it the first flag in the Layout operation. This is necessary because the orientation of the page affects the behavior of other flags, such as /T and /G.

The form of an objectSpec is:

\[ \text{objectName} \left[ \left( \text{objLeft}, \text{objTop}, \text{objRight}, \text{objBottom} \right) \right] \left[ /O=\text{objType} \right] \left[ /F=\text{frame} \right] \left[ /T=\text{trans} \right] \left[ /D=\text{fidelity} \right] \]

objectName can be the name of an existing graph, table or picture. It can also be the name of an object that does not yet exist. In this case it is called a “dummy object”.

objectSpec can be specified using a string by using the $ operator, but the entire objectSpec must be in the string.

Here are some examples of valid usage:

```
Layout Graph0
Layout/I Graph0(1, 1, 6, 5)/F=1
String s = "Graph0"
Layout/I $s
String s = "Graph0(1, 1, 6, 5)/F=1"
Layout/I $s // Entire object spec is in string.
```

The object’s coordinates are determined as follows:

- If objectName is followed by a coordinates specification in (objLeft, objTop, objRight, objBottom) form then this sets the object’s coordinates. The units for the coordinates are points unless the /I or /M flag was present in which case the units are inches or centimeters respectively.
- If the object coordinates are not specified explicitly but the Layout/S flag was present then the object is stacked. If the Layout/T flag was present then the object is tiled, and if the Layout/A=(rows,cols) flag is present, tiling is performed using that number of rows and columns.
- If the object’s coordinates are not determined by these rules then the object is set to a default size and is stacked.

Each object has a type (graph, table, textbox or picture) determined as follows:

- If the objectName/O=objType flag is present then it determines the object’s type:
  - objType=1: Graph.
  - objType=2: Table.
  - objType=8: Picture.
  - objType=32: Textbox.

If there is no /O flag and objectName is the name of an existing graph, table or picture, then the object type is graph, table or picture.

If the object’s type is not determined by the above rules and objectName contains “Table”, “PICT”, or “TextBox”, then the object type is table, picture or textbox.

If the object’s type is not specified by any of the above rules, it is taken to be a graph type object.

The remaining flags have the following meanings:

- /D=fidelity Controls the drawing of the layout object:
  - fidelity=0: Low fidelity display.
  - fidelity=1: High fidelity display (default).
Layout

The **Layout** operation is a procedure subtype keyword that identifies a macro as being a page layout recreation macro. It is automatically used when Igor creates a window recreation macro for a layout. See **Procedure Subtypes** on page IV-199 and **Killing and Recreating a Layout** on page II-410 for details.

### See Also

The **NewLayout** and **LayoutInfo** operations. See Chapter II-17, **Page Layouts**.

---

**LayoutInfo**

**LayoutInfo**(*winNameStr, itemNameStr*)

The **LayoutInfo** function returns a string containing a semicolon-separated list of keywords and values that describe an object in the active page of a page layout or overall properties of the layout. The main purpose of **LayoutInfo** is to allow an advanced Igor programmer to write a procedure which formats or arranges objects.

*winNameStr* is the name of an existing page layout window or "" to refer to the top layout.

*itemNameStr* is a string expression containing one of the following:

- The name (e.g., "Graph0") of a layout object in the active page to get information about that object.
- An object instance (e.g., "Graph0#0" or "Graph0#1") to get information about a particular instance of an object in the active page. This is of use only in the unusual situation when the same object appears in the active page multiple times. "Graph0#0" is equivalent to "Graph0". "Graph0#1" is the second occurrence of Graph0 in the active page.
- An integer object index starting from zero to get information about an object referenced by its position in the active page in the layout. Zero refers to the first object going from back to front in the page.
- The word "Layout" to get overall information about the layout.

### Details

In cases 1, 2 and 3 above, where *itemNameStr* references an object, the returned string contains the following keywords, with a semicolon after each keyword-value pair.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIDELITY</td>
<td>Object fidelity expressed as a code usable in a ModifyLayout fidelity command.</td>
</tr>
<tr>
<td>FRAME</td>
<td>Object frame expressed as a code usable in a ModifyLayout frame command.</td>
</tr>
<tr>
<td>HEIGHT</td>
<td>Object height in points.</td>
</tr>
</tbody>
</table>
In case 4 above, where `itemNameStr` is "Layout", the returned string contains the following keywords, with a semicolon after each keyword-value pair.

### Keyword | Information Following Keyword
--- | ---
INDEX | Object position in back-to-front order in the active page of the layout, starting from zero.
LEFT | Object left position in points.
NAME | The name of the object.
SELECTED | Zero if the object is not selected or nonzero if it is selected.
TOP | Object top position in points.
TRANS | Object transparency expressed as a code usable in a `ModifyLayout` trans command.
TYPE | Object type which is one of: Graph, Table, Picture, or Textbox.
WIDTH | Object width in points.

In case 4 above, where `itemNameStr` is "Layout", the returned string contains the following keywords, with a semicolon after each keyword-value pair.

### Keyword | Information Following Keyword
--- | ---
BGRGB | Layout background color expressed as `<red>`, `<green>`, `<blue>` where each color is a value from 0 to 65535.
MAG | Layout magnification: 0.25, 0.5, 1.0, or 2.0.
NUMOBJECTS | Total number of objects in the active page of the layout.
NUMSELECTED | Number of selected objects in the active page of the layout.
PAGE | A rectangle defining the part of the paper that is inside the margins, expressed in points. The format is `<left>`, `<top>`, `<right>`, `<bottom>`.
CURRENTPAGENUM | One-based page number of the currently active page. Added in Igor Pro 7.00.
NUMPAGES | Total number of pages in the layout. Added in Igor Pro 7.00.
PAPER | A rectangle defining the bounds of the paper, expressed in points. The format is `<left>`, `<top>`, `<right>`, `<bottom>`.
SELECTED | A comma-separated list of the names of selected objects in the active page of the layout.
UNITS | Units used to display object locations and sizes. This will be one of the following: 0 for points, 1 for inches, 2 for centimeters.

LayoutInfo returns "" in the following situations:
- `winNameStr` is "" and there are no layout windows.
- `winNameStr` is a name but there are no layout windows with that name.
- `itemNameStr` is not "Layout" and is not the name or index of an existing object.

### Examples

This example sets the background color of all selected graphs in the active page of a particular page layout to the color specified by `red`, `green`, and `blue`, which are numbers from 0 to 65535.

```plaintext
Function SetLayoutGraphsBackgroundColor(layoutName, red, green, blue)
    String layoutName // Name of layout or "" for top layout.
    Variable red, green, blue
    Variable index
    String info
    Variable selected
    String indexStr
    String objectTypeStr
    String graphNameStr
```
```
index = 0
do
    sprintf indexStr, "%d", index
    info = LayoutInfo(layoutName, indexStr)
    if (strlen(info) == 0)
        break   // No more objects
    endif
    selected = NumberByKey("SELECTED", info)
    if (selected)
        objectTypeStr = StringByKey("TYPE", info)
        if (CmpStr(objectTypeStr,"Graph") == 0)// This is a graph?
            graphNameStr = StringByKey("NAME", info)
            ModifyGraph/W=$graphNameStr wbRGB=(red,green,blue)
        endif
    endif
    index += 1
while(1)
End
```

The Layout operation. See Chapter II-17, Page Layouts.

LayoutMarquee

LayoutMarquee is a procedure subtype keyword that puts the name of the procedure in the layout Marquee menu. See Marquee Menu as Input Device on page IV-157 for details.

See Also
See Chapter II-17, Page Layouts.

LayoutPageAction

```
LayoutPageAction [/W=winName] [keyword = value [, keyword = value ...]]
```
The LayoutPageAction operation adds, deletes, reorders, or adjusts the sizes of layout pages.
The LayoutPageAction operation was added in Igor Pro 7.00.

Parameters

appendPage
   Appends a new page.
insertPage=page
   Inserts a new page before page.
   Page numbers start from 1. Pass 0 for page to insert before the first page.
page=page
   Makes page the active page.
   Page numbers start from 1.
deletePage=page
   Deletes page. This action cannot be undone.
   Page numbers start from 1.
reorderPages={anchorPage, page1, ...}
   Reorders the pages so that page1 and any others appear before anchorPage, in the same order as their appearance in the command.
   Page numbers start from 1.
size=(width, height)
   Sets the global page dimensions for the layout to width and height, specified in units of points.
size(page)=(width, height)
Sets the dimensions of *page* to *width* and *height*, specified in units of points.
Using this keyword with *page* set to -1 modifies the global page dimensions for the layout.

```
margins=(leftMargin, topMargin, rightMargin, bottomMargin)
```
Sets the global page margins for the layout to the specified values, expressed in units of points.

```
margins(page)=(leftMargin, topMargin, rightMargin, bottomMargin)
```
Sets the margins of specified page to these values, expressed in units of points.
Page numbers start from 1.
Passing -1 for *page* sets the global margins for the layout.

**Flags**

```
/W=winName
```
Modifies the named layout. When omitted, the actions affect the top layout.

**Details**

Page numbers start from 1. Use *page*=0 to refer to the active page.
The layout as a whole has a size and margins. These are called "global" dimensions and govern all pages by default. You can set the global dimensions using the size and margins keyword without specifying a particular page.
You can override the dimensions for a given page using size(*page*) and margins(*page*) to specify custom dimensions.
Use size(*page*)=(0,0) to revert the specified page to the global layout dimensions. This reverts both the page size and its margins.

**See Also**

Page Layouts on page II-407, NewLayout, ModifyLayout

**LayoutSlideShow**

```
LayoutSlideShow [/W=winName] [keyword = value [, keyword = value ...]]
```
The LayoutSlideShow operation starts, stops, or modifies a slideshow that displays the pages of a page layout.
The LayoutSlideShow operation was added in Igor Pro 7.00.

**Parameters**

```
autoMode=\a
```
Controls whether the presentation will advance between slides automatically (*a*=1) or manually (*a*=0). Use the delay keyword to control the delay between automatic transitions.

```
delay=d
```
*d* is the number of seconds to wait between slide transitions when running in auto mode.

```
otherScreenContents=\o
```
Controls what is displayed on any additional screens that may be connected.
```
\o=0: Other screens show the presentation.
\o=1: Other screens show a presenter's view with additional information.
Use the presentersView keyword to control the contents of this view.
\o=2: Other screens show a presenter's view with additional information.
Use the presentersView keyword to control the contents of this view.
```

```
page=p
```
Causes the slideshow to start from page *p*. *p* is a page number starting from 1. This keyword has no effect unless the start keyword is also present.
LayoutSlideShow

**presenterView=p** Controls what is displayed on the screens that show the presenter's view.

*p* is a bitfield of flags:

- Bit 0: Show the next page.
- Bit 1: Show the current time.
- Bit 2: Show the elapsed time.

**Setting Bit Parameters** on page IV-13 for details about bit settings.

**scaleMode=s** Specifies how the pages are scaled to fit the screen.

- s=0: No scaling. Pages are drawn at actual size even if they are much larger or smaller than the screen size.
- s=1: All pages are individually scaled to the screen size.
- s=2: All pages are scaled by the same factor so that the largest page fits on the screen. This preserves the relative sizes of the pages.

**screen=s** Specifies the screen to be used for the main presentation. Use *s=1* to use the primary screen. Use *IgorInfo* to determine the number of available screens.

**start** Starts the slideshow.

**stop** Stops the slideshow. You can also stop it by pressing the escape key.

**wrapMode=w** Controls what happens when the presentation reaches the last page in the slideshow.

- w=0: Advancing to the next page has no effect.
- w=1: Advancing to the next page causes the slideshow to wrap around to the first page.
- w=2: Advancing to the next page causes the slideshow to stop.

**Flags**

/W=winName  
*winName* is the name of the desired layout window. If /W is omitted or if *winName* is "$"", the top layout window is used.

**Details**

A layout slide show can be used to present an Igor experiment to others, or to run an information kiosk. Any changes to the layout window during a slide show are automatically reflected in the slides. For example you could use a background task to update a graph so that the slides always show the latest data.

You can control a running slide show by right-clicking on the slideshow. Alternatively, use the arrow keys or a mouse click to advance to the next slide.

Press the space bar to toggle between automatic and manual advancing of the slides. Press escape to end the slideshow.

**Example**

Function DemoSlideshow()  // Press escape to end the slideshow

NewLayout

TextBox/C/N=text0/F=0/A=LB/X=33.57/Y=70.81 "\\Z961"
LayoutPageAction appendpage

TextBox/C/N=text0/F=0/A=LB/X=33.57/Y=70.81 "\\Z962"
LayoutPageAction appendpage

TextBox/C/N=text0/F=0/A=LB/X=33.57/Y=70.81 "\\Z963"
LayoutSlideShow autoMode=1,delay=1,page=1,wrapMode=1,start

End

**See Also**

Page Layouts on page II-407, NewLayout, LayoutPageAction
LayoutStyle

LayoutStyle

LayoutStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Layout dialog and in the Layout Macros menu. See Page Layout Style Macros on page II-429 for details.

See Also

See Chapter II-17, Page Layouts and Page Layout Style Macros on page II-429.

leftx

leftx(waveName)

The leftx function returns the X value of point 0 (the first point) of the named 1D wave. The leftx function is not multidimensional aware. The multidimensional equivalent of this function is DimOffset.

Details

Point 0 contains a wave’s first value, which is usually the leftmost point when displayed in a graph. Leftx returns the value elsewhere called x0. The function DimOffset returns any of x0, y0, z0, or t0, for dimensions 0, 1, 2, or 3.

See Also

The deltax and rightx functions.

For multidimensional waves, see DimDelta, DimOffset, and DimSize.

For an explanation of waves and X scaling, see Changing Dimension and Data Scaling on page II-63.

Legend

Legend [flags] [legendStr]

The Legend operation puts a legend on a graph or page layout.

Parameters

legendStr contains the text that is printed in the legend.

If legendStr is missing or is an empty string (""), the text needed for a default legend is automatically generated. Legends are automatically updated when waves are appended to or removed from the graph or when you rename a wave in the graph.

legendStr can contain escape codes which affect subsequent characters in the text. An escape code is introduced by a backslash character. In a literal string, you must enter two backslashes to produce one. See Backslashes in Annotation Escape Sequences on page III-59 for details.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See Annotation Escape Codes on page III-54 for details. However normally you leave it to Igor to automatically manage the legend.

See Legend Text on page III-43 for a discussion of what legendStr may contain.

Flags

/H=legendSymbolWidth

Sets the width in points of the area in which to draw the wave symbols. A value of 0 means “default”. This results in a width that is based on the text size in effect when the symbol is drawn. A value of 36 gives a 0.5 inch (36 points) width which is nice in most cases.

/H={legendSymbolWidth, minThickness, maxThickness}
This is an additional form of the /H flag. The legendSymbolWidth parameter works the same as described above.

The minThickness and maxThickness parameters allow you to create a legend whose line and marker thicknesses are different from the thicknesses of the associated traces in the graph. This can be handy to make the legend more readable when you use very thin lines or markers for the traces.

minThickness and maxThickness are values from 0.0 to 10.0. Also, setting minThickness to 0.0 and maxThickness to 0.0 (default) uses the same thicknesses for the legend symbols as for the traces.

/J Disables the default legend mechanism so that a default legend is not created even if legendStr is an empty string (""") or omitted.

Window recreation macros use /J in case legendStr is too long to fit on the same command line as the Legend operation itself. In this case, an AppendText command appears after the Legend command to append legendStr to the empty legend. For really long values of legendStr, there may be multiple AppendText commands.

/M[=sameSize] /M or /M=1 specifies that legend markers should be the same size as the marker in the graph.

/M=0 turns same-size mode off so that the size of the marker in the legend is based on text size.

See the TextBox operation for documentation for all other flags.

Examples
The command Legend (with no parameters) creates a default legend. A default legend in a layout contains a line for each wave in each of the graphs in the layout, starting from the bottom graph and working toward the front.

The command:
Legend/C/M=name ""
changes the named existing legend to a default legend.

You can put a legend in a page layout with a command such as:
Legend "\s(Graph0.wave0) this is wave0"
This creates a legend in the layout that shows the symbol for wave0 in Graph0. The graph named in the command is usually in the layout but it doesn’t have to be.

TextBox, Tag, ColorScale, AnnotationInfo, AnnotationList.
Annotation Escape Codes on page III-54.
Legend Text on page III-43.
Trace Names on page II-222, Programming With Trace Names on page IV-86.
Color as f(z) Legend Example on page II-236 for a discussion of creating a legend whose symbols match the markers in a graph that uses color as f(z).

legendreA
legendreA(n, m, x)
The legendreA function returns the associated Legendre polynomial:

\[ P_n^m(x) \]
where \( n \) and \( m \) are integers such that \( 0 \leq m \leq n \) and \( |x| \leq 1 \).

References

V-448
The `limit` function returns `num`, limited to the range from `low` to `high`:

- `num` if `low <= num <= high`.
- `low` if `num < low`.
- `high` if `num > high`.

Since all comparisons with NaN return false, limit will not work as expected with NaNs. If a parameter may be NaN, use `numtype` to test it before calling `limit`.

**See Also**
- `SelectNumber`, `min`, `max`

### LinearFeedbackShiftRegister

The `LinearFeedbackShiftRegister` operation implements a, well, linear feedback shift register, or LFSR. A LFSR is a way to produce a sequence of very bad pseudorandom numbers, or a random bit stream (that is, a random sequence of zeroes of ones that over time are nearly equal in number).

If it produces bad random numbers, why would I want to use a LFSR? A properly-configured LFSR will create a “maximal-length sequence”: a LFSR of `N` bits will produce $2^N-1$ numbers in a quasi-random sequence without repeating. That is, it will produce all the `N`-bit numbers except zero. This gives the sequence good spectral properties for certain applications, and, taking the least-significant bit as the output, it creates a pseudorandom bit stream with nearly equal numbers of zeroes and ones (*nearly* means one more one than zeroes).

The `LinearFeedbackShiftRegister` operation generates either a wave full of the sequential states of the shift register or a wave full of ones and zeroes representing the least significant bit of the shift register.

### Linear Feedback Shift Registers

A LFSR is a shift register with taps. The tap bits are XOR’ed together and the result, after the register is shifted, becomes the new most significant bit. Here is a diagram of a 7-bit LFSR:

![Diagram of 7-bit LFSR](image)

Each successive number is generated by shifting the contents of the register (boxes 1-7) to the right, while shifting in the output of the XOR node. The XOR node samples specified bits of the register contents, generating its output ready to be shifted in. Thus, the inputs of the XOR are bits sampled before a shift; the output of the XOR becomes the leading bit in the register after a shift.

In many applications the output of interest is the stream of bits that appear in the last position. This stream of bits is a pseudorandom sequence of ones and zeroes (or ones and minus ones, or whatever other binary sequence you need).

The bits fed into the XOR node are referred to as *taps*. The taps illustrated here would be specified with the tap list 7,6,4,1. As implemented in Igor Pro, the output tap (tap 7 in the illustration) is the least significant bit, so an alternate way to express the tap list is as the binary number $1001011_2$ ($77_{10}$).

With the right taps, a LFSR produces a maximal-length sequence. The list of sequential states in a maximal-length sequence has length $2^N-1$ without repeating a state. That means that every possible `N`-bit nonzero number appears exactly once in the maximal-length sequence.

Maximal-length tap lists always have an even number of taps.

If you have a tap list that gives a maximal-length sequence, you can generate another tap list from it. If your tap list is `(n, A, B, C)` the new tap list is `(n, n-C, n-B, n-A)`. This new tap list will generate a bit stream that is the mirror image in time of the bit stream produced by the first tap list.
Flags

/DEST=wavename Specifies a wave to receive the generated sequence. With /MODE=0, the number type of the wave must have at least \( nbits \) bits for an integer wave, or at least an \( nbit \) mantissa if it is a floating-point wave. That is, /N=25 requires a double-precision wave or a 32-bit integer wave. /N=18 requires any floating-point wave or a 16- or 32-bit integer wave. If you use an integer wave, we recommend an unsigned integer wave for /N=8, 16, or 32.

If /MODE=1 is used, any number type is acceptable. See the Details for what happens if you don’t use /DEST.

If wavename doesn’t exist, a suitable integer wave will be made.

If wavename already exists, LinearFeedbackShiftRegister will use it as-is. The sequence length will be taken from the wave. If the number type of the wave is not suitable, an error is issued. If the sequence length is less than the number of points in your wave, it will be truncated to match.

/FREE In a user-defined function, makes a free wave. See Free Waves on page IV-89 for details.

/INIT=initialValue Sets the initial value of the shift register to initialValue. This will also be the first value in the output for /MODE=0, or the least-significant bit of initialValue will be the first output for /MODE=1. You can use this initial value to restart a very long sequence from the last state of a previous run.

Default is a single 1 bit in the first position (bit \( nbits-1 \) for /N=\( nbits \)).

/LEN=length Sets the length of sequence to generate. If the sequence repeats before length states are generated, the sequence is terminated early. If length is larger than the number of states in a maximal-length sequence, you will get a maximal-length sequence, or a shorter sequence if the initial value is seen again (that is, your sequence is not a maximal-length sequence).

You can specify length greater than the maximal-length sequence length, but it will be truncated to the maximal length.

/MAX=index An internal table of tap lists gives maximal-length sequences. This table has up to 32 tap lists for each value of \( nbits \). You select a tap list by setting index to a number from 0 to 31. For values of \( nbits \) that do not have 32 maximal-length tap lists, the table repeats. Most \( nbits \) values have many more than 32 possible maximal-length sequences. For each tap list in the table, another tap list can be accessed using the /MROR flag.

/MODE=doBitStream Sets the output stream format.

doBitStream=0: Succession of bit register states (default).
doBitStream=1: Stream of ones and zeroes.

/MROR [=doMirror] Transforms the tap list into its complementary tap list, creating a mirror-image bit stream, when you use /MROR or doMirror=1. Specify the tap list using /TAPS, /TAPB, or /MAX.

/N=\( nbits \) Determines the number of bits in the shift register. A maximal-length sequence will have \( 2^{nbits}-1 \) states. \( nbits \) must be in the range of 1-32. Note that \( nbits = 1 \) or 2 is not very interesting.

/STOP=stopValue Terminates the sequence when stopValue is the next shift register value. You can use this flag to generate long sequences using multiple calls to LinearFeedbackShiftRegister by storing the initial value of the first call, and setting stopValue to that initial value in subsequent calls.

/TAPB=tapbits An alternate way to express the tap list. tapbits is a number in which each bit represents a tap, with bit 0 representing the tap with tap number \( nbits \).

/TAPS={t1, t2, …} Specifies the tap list. Tap numbers are in the range from 1 to \( nbits \).
Details
If the /TAPS, /TAPB, or /MAX flags are absent, the maximal-length sequence corresponding to /MAX=0 is generated.

In you omit the /DEST flag, a wave named W_LFSR will be generated for you. W_LFSR is an unsigned integer wave with number type set to the minimum size for the shift register size and /MODE setting. Thus, if you set /N=10/MODE=0, W_LFSR will be an unsigned 16-bit integer wave.

Because W_LFSR is an unsigned integer wave, you will need to redimension the wave to a floating-point wave for many purposes. Use the Redimension operation or the Redimension Waves item in the Data menu.

Up to /N=18, W_LFSR will initially be created large enough to hold a maximal-length sequence, unless you request a shorter sequence using the /LEN flag. If the initial value is seen again before a maximal-length sequence is generated, it means that the tap list specified was not one that generates a maximal-length sequence, and generation is terminated. The wave is shortened to the generated sequence length.

If you set a register size greater than /N=18 and you do not use /LEN, the generated sequence will stop after $2^{18}-1$ (2,621,43) states. Note that beyond some $N$, it will be impossible to create a wave large enough to hold a maximal-length sequence.

Some tap lists do not generate maximal-length sequences but also do not repeat the initial value. In that case, the generated sequence will be of maximal length but will contain repeated subsequences. The $V_{\text{flag}}$ variable will be set to 0 if the sequence was not a maximal-length sequence, or 1 if it was. If /LEN=length values were generated, $V_{\text{flag}}$ is set to 2.

If you specify your own wave using /DEST, the sequence length will be the same as the length of your wave. Your wave will be resized if a shorter sequence is generated.

Generating Long Sequences in Smaller Segments
Very long maximal-length sequences will not fit in the largest wave you can make. It may also be more convenient to make multiple, small fragments of a longer sequence. You can do this using the /INIT, /STOP, and /LEN flags, along with the $V_{\text{nextValue}}$ variable. Here is an example of making 1000-point subsequences from a 16-bit maximal-length sequence:

```
// Start with the first 1000 states, with initial value of 1
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=1
// /STOP=1 sets the stopping value to the first initial value
// Restart using the $V_{\text{nextValue}}$ variable to continue the sequence
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=(V_{\text{nextValue}})/STOP=1
// Continue...
LinearFeedbackShiftRegister/N=16/LEN=1000/INIT=(V_{\text{nextValue}})/STOP=1
```

Variables
The LinearFeedbackShiftRegister operation returns information in the following variables:

- $V_{\text{flag}}$: Set to zero when a nonmaximal-length sequence was detected. This occurs if the initial value is seen again before a maximal-length sequence was generated, or if a maximal-length sequence was generated but the final state was not the same as the initial state.
  - Set to 1 when a maximal-length sequence was generated.
  - Set to 2 when the sequence was limited by /LEN=length or by the default limit of $2^{18}-1$ (2,621,43) states.

- $V_{\text{tapValue}}$: Set to the binary representation of the tap sequence used. That is, you can generate the same sequence using /TAPB=$V_{\text{tapValue}}$. If you use /MROR=1, $V_{\text{tapValue}}$ reflects that setting. It will also give the actual tap value used when you specify the a maximal-length sequence using the /MAX flag.

- $V_{\text{nextValue}}$: Set to the next value beyond the last generated register state. This can be used to restart a truncated sequence.

Examples
Generate a 16-bit maximal-length sequence and reprocess the output values to be centered on zero and normalized to a maximum value of 1:

```
LinearFeedbackShiftRegister/N=16
Redimension/D W_LFSR
```
Another way to do the same thing that avoids the Redimension operation, which could lead to fragmentation of memory:

Make/D/N=(2^16-1) LFSR_output
LinearFeedbackShiftRegister/N=16/DEST=LFSR_output
LFSR_output -= 2^15
LFSR_output /= 2^15-1

Make a bit stream with random +1 and -1 instead of 0 and 1:
LinearFeedbackShiftRegister/N=16/MODE=1
Redimension/B W_LFSR
W_LFSR = W_LFSR*2-1

See Also
If you really need random numbers, we provide high-quality RNG's that return random deviates from a number of distributions. See enoise, gnoise, and others.

References
A discussion of LFSR's can be found in “Generation of Random Bits” (Section 7.4) in Press, William H., *et al.*, *Numerical Recipes in C*, 2nd ed., 994 pp., Cambridge University Press, New York, 1992. They refer to “primitive polynomials modulo 2” and do not use the name Linear Feedback Shift Register, but it is the same thing. We use an implementation equivalent to their Method I.

**ListBox**

```
ListBox [/Z] ctrlName [keyword = value [, keyword = value ...]]
```

The ListBox operation creates or modifies the named control that displays, in the target window, a list from which the user can select any number of items.

For information about the state or status of the control, use the `ControlInfo` operation.

**Parameters**

`ctrlName` is the name of the ListBox control to be created or changed.

The following keyword=value parameters are supported:

- **align=alignment**
  Sets the alignment mode of the control. The alignment mode controls the interpretation of the `leftOrRight` parameter to the `pos` keyword. The `align` keyword was added in Igor Pro 8.00.
  - If `alignment=0` (default), `leftOrRight` specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.
  - If `alignment=1`, `leftOrRight` specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

- **appearance={kind [, platform]}**
  Sets the appearance of the control. `platform` is optional. Both parameters are names, not strings.
  - `kind` can be one of `default`, `native`, or `os9`.
  - `platform` can be one of `Mac`, `Win`, or `All`.

See `Button` and `DefaultGUIControls` for more appearance details.

- **clickEventModifiers=modifierSelector**
Selects modifier keys to ignore when processing clicks to start editing a cell or when toggling a checkbox. That is, use this keyword if you want to prevent a shift-click (for instance) from toggling checkbox cells. Allows the action procedure to receive mousedown events with those modifiers without interfering actions on the part of the listbox control.

 modifierSelector is a bit pattern with a bit for each modifier key; sum these values to get the desired combination of modifiers:

 modifierSelector=1: Control key (Macintosh only)
 modifierSelector=2: Option (Macintosh) or Alt (Windows)
 modifierSelector=4: Context click (right click on Windows, control-click on Macintosh)
 modifierSelector=8: Shift key
 modifierSelector=16: Cmd key (Macintosh) or Ctrl key (Windows)
 modifierSelector=32: Caps lock key

See Setting Bit Parameters on page IV-13 for details about bit settings.

**col=c**
Sets the left-most visible column (user scrolling will change this). The list is scrolled horizontally as far as possible. Sometimes this won’t be far enough to actually make column c the first column, but it will at least be visible. Use c =1 to put the left edge of column 1 (the second column) at the left edge of the list.

colorWave=cw
Specifies a 3-column (RGB) or 4-column (RGBA) numeric wave. Used in conjunction with planes in selWave to define foreground and background colors for individual cells. Values range from 65535 (full on) to 0.

disable=d
Sets user editability of the control.

  d=0: Normal.
  d=1: Hide.
  d=2: Draw in gray state; disable control action.

editStyle=e
Sets the style for cells designated as editable (see selWave, bit 1).

  e=0: Uses a light blue background (default).
  e=1: Draws a frame around the cell with a white background.
  e=2: Combines the frame with the blue background. The background in all cases can be overridden using the colorWave parameter.

focusRing=fr
Enables or disables the drawing of a rectangle indicating keyboard focus:

  fr=0: Focus rectangle will not be drawn.
  fr=1: Focus rectangle will be drawn (default).

On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.

font="fontName"
Sets the font used for the list box items, e.g., font="Helvetica".

frame=f
Specifies the list box frame style.

  f=0: No frame.
  f=1: Simple rectangle.
  f=2: 3D well.
  f=3: 3D raised.
  f=4: Text well style.

fsizes
Sets list box font size.
ListBox

fstyle=fs  

fs is a bitwise parameter with each bit controlling one aspect of the font style as follows:

Bit 0:  Bold
Bit 1:  Italic
Bit 2:  Underline
Bit 4:  Strikethrough

See Setting Bit Parameters on page IV-13 for details about bit settings.

hScroll=h  

Scrolls the list to the right by h pixels (user scrolling will change this). h is the total amount of horizontal scrolling, not an increment from the current scroll position: h will be the value returned in the V_horizScroll variable by ControlInfo.

def=

helpWave=w  

Text wave containing text for tooltips for individual listbox cells. See ListBox Help below. Added in Igor Pro 8.00.

keySelectCol=col  

Sets scan column number col when doing keyboard selection. Default is to scan column zero.

listWave=w  

A 1D or 2D text wave containing the list contents.

mode=m  

List selection mode specifying how many list selections can be made at a time.

m=0:  No selection allowed.
m=1:  One or zero selection allowed.
m=2:  One and only one selection allowed.
m=3:  Multiple, but not disjoint, selections allowed.
m=4:  Multiple and disjoint selections allowed.

When multiple columns are used, you can enable individual cells to be selected using modes 5, 6, 7, and 8 in analogy to m=1-4. When using m=3 or 4 with multiple columns, only the first column of the selWave is used to indicate selections. Checkboxes and editing mode, however, use all cells even in modes 0-4.

Modes 9 and 10 are the same as modes 4 and 8 except they use different selection rules and require testing bit 3 as well as bit 0 in selWave. In modes 4 and 8, a shift click toggles individual cells or rows, but in modes 9 and 10, the Command (Macintosh) or Ctrl (Windows) key toggles individual cells or rows whereas Shift defines a rectangular selection. To determine if a cell is selected, perform a bitwise AND with 0x09.

m=0:  No selection allowed.
m=1:  One or zero selection allowed.
m=2:  One and only one selection allowed.
m=3:  Multiple, but not disjoint, selections allowed.

proc=p  

Set name of user function proc to be called upon certain events. See discussion below.

pos=leftOrRight,top  

Sets the position in pixels of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

pos+=dx,dy  

Offsets the position of the list box in pixels.

row=r  

r is desired top row (user scrolling will change this). Use a value of -1 to scroll to the first selected cell (if any). Combine with selRow to select a row and to ensure it is visible (modes 1 and 2).

selCol=c  

Defines the selected column when mode is 5 or 6 and no selWave is used. To read this value, use ControlInfo and the V_selCol variable.

selRow=s  

Defines the selected row when mode is 1 or 2; when no selWave is used, it is defined by modes 5 or 6. Use -1 for no selection.

To read this value, use ControlInfo and the V_value variable.
**ListBox**

`selWave = sw`  

*sw* is a numeric wave with the same dimensions as `listWave`. It is optional for modes 0-2, 5 and 6 and required in all other modes.

In modes greater than 2, *sw* indicates which cells are selected. In modes 1 and 2 use `ControlInfo` to find out which row is selected.

In all modes *sw* defines which cells are editable or function as checkboxes or disclosure controls.

Numeric values are treated as integers with individual bits defined as follows:

- **Bit 0 (0x01):** Cell is selected.
- **Bit 1 (0x02):** Cell is editable.
- **Bit 2 (0x04):** Cell editing requires a double click.
- **Bit 3 (0x08):** Current shift selection.
- **Bit 4 (0x10):** Current state of a checkbox cell.
- **Bit 5 (0x20):** Cell is a checkbox.
- **Bit 6 (0x40):** Cell is a disclosure cell. Drawn as a disclosure triangle (*Macintosh*) or a treeview expansion node (*Windows*).
- **Bit 7 (0x80):** Cell is disabled. Clicks on the cell are ignored and it is drawn with a grayed appearance. Added in Igor Pro 8.00. Because of technical issues, this bit currently does not prevent the selection of the cell using the arrow keys.

In modes 3 and 4 bit 0 is set only in column zero of a multicolumn listbox.

Other bits are reserved. Additional dimensions are used for color info. See the discussion for `colorWave`. `selWave` is not required for modes 5 and 6.

`setEditCell = [row, col, selStart, selEnd]`  

Initiates edit mode for the cell at *row*, *col*. An error is reported if *row* or *col* is less than zero. Nothing happens and no error is reported if *row*, *col* is beyond the limits of the listbox, or if the cell has not been made editable by setting bit 1 of `selWave`.

*selStart* and *selEnd* set the range of bytes that are selected when editing is initiated; 0 is the start of the text. If there are N bytes in the listbox cell, setting *selStart* or *selEnd* to N or greater moves the start or end of the selection to the point after the last character. Setting *selStart* and *selEnd* to the same value selects no characters and the insertion point is set to *selStart*. Setting *selStart* to -1 always causes all characters to be selected.

`size = [width, height]`  

Sets list box size in pixels.

`special = [kind, height, style]`
ListBox

Specifies special cell formatting or contents.

**kind=0:** Normal text but with specified height (if nonzero). Use a style of 1 to autocalculate widths based on the entire list contents. In this case, user widths are taken to be minimums and the last is not repeated.

**kind=1:** Text taken to be the names of graphs or tables. Images of the graphs or tables are displayed in the cells. Use a style of 0 to display just the presentation portion of the graph or 1 to display it entirely. For tables, only the presentation portion is displayed.

**kind=2:** Text taken to be the names of pictures. Images are displayed in the cells.

**kind=3:** Displays a PNG, TIFF, or JPEG image. You can obtain binary picture data using SavePICT.

**kind=4:** Displays raw text without any escape code processing. Added in Igor Pro 8.00 to allow display of LaTeX expressions which make heavy use of backslashes.

For **kind=1** or 2, height may be zero to auto-set cell height to same as width or a specific value.

**titleWave=** Specifies a text wave containing titles for the listbox columns, instead of using the list wave dimension labels. Each row is the title for one column; if you have N columns you must have a wave with N rows.

**userColumnResize=** Enables resizing the list columns using the mouse.

- **u=0:** Columns are not resizable (default). The widths parameter still works, though.
- **u=1:** User can resize columns by dragging the column dividers.
  - When resizing a column without Option, Alt, or Shift modifiers (a “normal” resizing), any width added to the column is subtracted from the following column (if any).
  - When resizing while pressing Option (Macintosh) or Alt (Windows), only columns following the dragged divider will move (the same way table columns are resized).
  - When pressing Shift, all columns are set to the same width as the column being resized. If the total widths of all columns is less than the width of the listbox, then each column expands to fill the available width.

**userdata=** Sets the unnamed user data to **UDStr**.

**userdata(UDName)=** Sets the named user data, **UDName**, to **UDStr**.

**userdata+=** Appends **UDStr** to the current unnamed user data.

**userdata(UDName)+=** Appends **UDStr** to the current named user data, **UDName**.

**widths={}** Optional list of minimum column widths in screen pixels. If more columns than widths, the last is repeated. If total of widths is greater than list box width then a horizontal scroll bar will appear. If total is less than available width then each expands proportionally.
**ListBox**

**widths+=\{w1,w2,…\}** Additional column widths. Because only 2500 bytes fit on a command line, lists with many columns may require multiple widths+= parameters to define all the column widths. However if all the widths are the same, widths+= is not needed; just use:

```
ListBox ctrlName widths={sameWidth}
```

**win=winName** Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

**Flags**

**/Z** No error reporting.

**Details**

If the list wave has column dimension labels (see SetDimLabel), then those will be used as column titles. Note that a 1D wave is subtly different from a 1 column 2D wave. The former does not have any columns and therefore no column dimension labels.

Alternately, use a text wave with the titleWave keyword to specify column titles.

Using escape codes you can change the font, size, style, and color of the title. See Annotation Escape Codes on page III-54 or details.

For instance, to make a title bold use the \f01 escape sequence:

```
SetDimLabel 1, columnNum, "$\f01My Label\", textWave
```

If you can’t fit title text within the 255 byte limit (styled text can be especially long), use the titleWave keyword with a text wave. The wave must have as many rows as the list wave has columns. When using a title wave, there are no restrictions on the number of bytes or on what characters you can use.

This example uses a title wave to add a red up-arrow graph marker to the end of a centered title:

```
Make/O/T/H=(numColumns) columnTitles
columnTitles[colnNum]="\JCThis is the title\K(65535,0,0)\k(65535,0,0)\W523"
ListBox list0 titleWave=columnTitles
```

That’s a 51-byte title that results in 19 characters or symbols that you actually see. \JC requests centered text, \K sets the text color (which colors the inside of the graph marker), \k sets the marker stroke color, and \W523 inserts a down-pointing triangular graph marker.

When using modes that allow multiple selections, use Shift to extend or add to the selection.

You can specify individual cells as being editable by setting bit 1 (counting from zero on the right) in selWave. The user can start editing a cell by either clicking in it or, if the cell is selected, by pressing Enter (or Return). When finished, the user can press Enter to accept the changes or can press Escape to reject changes. The user may also press Up or Down Arrow to accept changes and begin editing the next editable cell in a column. Likewise, Tab and Shift-Tab moves to the next or previous column in a row. If bit 2 of selWave is set then a double click will be required rather than a single click. **Note:** in edit mode, Tab and Shift-Tab are used to move left and right because the Left and Right Arrow keys are used to move the text entry cursor left and right.

When the listbox has keyboard focus (either by tabbing to the list box or by clicking in the box), the keyboard arrow keys move a cell selection (or row depending on mode). When not in cell edit mode, Tab and Shift-Tab move the keyboard focus to other objects in the window. The Home, End, Page Up, and Page Down keys affect the vertical scroll bar.

When the listbox has focus, the user may type the first few chars of an entry in the list to select that entry. Only the first column is used. If a match is not found then nothing is done. The search is case insensitive.

**ListBox Help**

You can provide a text wave with help strings to show a tool tip for individual cells or rows of a listbox in place of the generic help string provided by the help keyword. In general, the string in helpWave[\{listbox row\}][\{listbox column\}] is used. If your help wave is a 1D wave, then the listbox column is ignored, and helpWave[\{listbox row\}] is used in all columns.
Note that a 1D wave (Make/N=rows) is not the same as a 2D wave with one column (Make/N=(rows,1)). A 2D wave with one column provides help for column 0 only and the generic help string is shown for column 1 and beyond. A 1D wave provides help for all columns.

If the help wave has an empty string for a given row and column then the generic help string is shown for the corresponding listbox cell. If the help wave has too few rows or columns, then the generic help string is shown for the cells outside the range of the help wave.

Listbox Action Procedure

The action procedure for a ListBox control takes a predefined structure WMListboxAction as a parameter to the function:

```plaintext
Function ActionProcName(LB_Struct) : ListboxControl
    STRUCT WMListboxAction &LB_Struct
    ...
    return 0
End
```

The “: ListboxControl” designation tells Igor to include this procedure in the Procedure pop-up menu in the List Box Control dialog.

See WMListboxAction for details on the WMListboxAction structure.

Although the return value is not currently used, action procedures should always return zero.

You may see an old format listbox action procedure in old code:

```plaintext
Function MyListboxProc(ctrlName,row,col,event) : ListboxControl
    String ctrlName // name of this control
    Variable row // row if click in interior, -1 if click in title
    Variable col // column number
    Variable event // event code
    ...
    return 0 // other return values reserved
End
```

This old format should not be used in new code.

Specifying Cell Color

The background and foreground (text) color of individual cells may be defined by providing colorWave in conjunction with specific planes in selWave. The planes in selWave are taken to be integer indexes into colorWave. The planes are defined by specific dimension labels and not by specific plane numbers. To provide foreground colors, define a plane labeled “foreColors” that contains the desired index values. Likewise define and fill a plane labeled “backColors” for background colors. The value 0 is special and indicates that the default colors should be used. Note that if you have a one column list for which you want to supply colors, the selWave needs to be three dimensional but with just one column. Here is an example:

```plaintext
Make/T/N=(5,1) tw= "row "+num2str(p) // 5 row, 1 col text wave (2D)
Make/B/U/N=(5,1,2) sw // 5 row, 1 col, 2 plane byte wave
Make/O/W/U myColors={{{0,0,0},{65535,0,0},{0,65535,0},{0,0,65535},{0,65535,65535}}}
MatrixTranspose myColors // above was easier to enter as 3 rows, 5 cols
NewPanel
ListBox lb,mode=3,listWave= tw,selWave= sw,size={200,100},colorWave=myColors
sw[][[1]]= p // arbitrary index values into plane 1
```

Now, execute the following commands one at a time and observe the results:

```plaintext
SetDimLabel 2,1,backColors,sw // define plane 1 as background colors
SetDimLabel 2,1,foreColors,sw // redefine plane 1 s foreground colors
sw[])[fcolor]= 4-p // change the color index values
```

In the above example, the selWave was defined as unsigned byte. If you need more than 254 colors, you will have to use a larger number size.

The color wave may have four columns instead of three, with the fourth specifying transparency (65535=opaque, 0=transparent). Transparency of the background color is of limited utility as it just shows the white background color through the cell color, resulting in pastel shades. Transparency of the foreground color permits the cell background color to show through the text color.
Checkboxes in Cells
You can cause a cell to contain a checkbox by setting bit 5 in selWave. The title (if any) is taken from listWave and the results (selected/deselected) is bit 4 of selWave. If a checkbox cell is selected then the space bar will toggle the checkbox. (Clicking a checkbox cell does not select it — use the arrow keys.)

Errors
Your listbox may be drawn with a red X and an error code. The error codes are:

<table>
<thead>
<tr>
<th>Error</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>E1</td>
<td>The listbox is too small</td>
</tr>
<tr>
<td>E2</td>
<td>The listWave is invalid (missing, not text or no rows)</td>
</tr>
<tr>
<td>E3</td>
<td>The listWave and selWave do not match in dimensions</td>
</tr>
<tr>
<td>E4</td>
<td>Mode is greater than 2 but no selWave was specified</td>
</tr>
<tr>
<td>E5</td>
<td>The number of rows in titleWave does not match the number of columns in listWave</td>
</tr>
<tr>
<td>E6</td>
<td>The titleWave is not a textWave</td>
</tr>
</tbody>
</table>

Event Queue
It is possible for a single user action to produce more than one event. For instance, pressing the up arrow key while editing to select a cell that is not visible generates event codes 4, 8, and 6. Igor calls your action procedure separately for each code.

If your code tests for a nonzero value in eventCode2, and uses it only if it is nonzero, then the event queue method will not break your code. If you have determined empirically when you need to use eventCode2 and you do not test, your code will break.

Scroll Event Warnings
Events 8, 9, and 10 report to you that the listbox has been scrolled vertically or horizontally. These events are envisioned as allowing you to keep two listboxes synchronized (you may find other uses for these events). You might use an action procedure like this one to keep two listboxes (named list0 and list1) in sync:

```plaintext
Function ListBoxProc2(LB_Struct) : ListBoxControl

  STRUCT WMListboxAction &LB_Struct
    if (LB_Struct.eventCode == 8)
      String listname
      if (CmpStr(LB_Struct.ctrlName, "list1") == 0)
        listname = "list0"
      else
        listname = "list1"
      endif
      ControlInfo $listname
      if (V_startRow != LB_Struct.row)
        listbox $listname,row=LB_Struct.row
        ControlUpdate $listname
      endif
    endif
  endif
  return 0
End
```

It is very easy to create an infinite cascade of events feeding back between the two listboxes, especially if you use event 10. When this happens, you will see your listboxes jigging up and down endlessly. The test using ControlInfo is intended to make this unlikely.

The slow response of the old-style, nonstructure action procedure can defeat the ControlInfo test by delaying the action procedure execution. If you use events 8, 9, or 10, we recommended that you use the new-style action procedure.

Note on Keystroke Event
In a keystroke event passed to a listbox action procedure the eventCode is 12. A character code is stored in the row field of the WMListboxAction structure. This works only for ASCII characters and a few special
characters such as delete (8), forward delete (127) and escape (27). It does not work for non-ASCII characters such as accented characters which are represented as UTF-8 and require multiple bytes.

As explained below, many keystroke events are not sent to the listbox action procedure because they are consumed by the internal listbox code in Igor. For this reason the keystroke event for a listbox is of limited use.

The architecture of Igor controls is such that events are passed to an action procedure only after the control has used them. In the case of a keystroke event, that means that other uses of the keystroke may consume the event before the action procedure gets a chance at it. In particular, a listbox editable cell that is actively being edited consumes keystroke events, and the action procedure is not called. The only editing-related events your action procedure will get are event codes 6 and 7.

If an arrow key is pressed, and this results in the selected row or cell changing, your action procedure will not get a keystroke event. Instead, your action procedure will receive event code 4 or 5. If the arrow key causes scrolling to occur, the action procedure will also get event code 8 or 9.

Examples

Here is a simple Listbox example:

```
Make/O/T/N=30 tjack="this is row "+num2str(p)
Make/O/B/N=30 sjack=0
NewPanel /W=(19,61,319,261)
ListBox lb1,pos={42,9},size={137,94},listWave=tjack,selWave=sjack,mode=3
Edit/W=(367,61,724,306) tjack,sjack
ModifyTable width(tjack)=148
```

Make selections in the list and note changes in the table and vice versa. Edit one of the list text values in the table and note update of the list.

Here is an example using a titleWave and styled text in the title cells. Note that the last title isn’t very long when rendered, but requires a 63 byte specification.

```
Make/O/T/N=(4,3) ListWave="row "+num2str(p)+" col "+num2str(q)
Make/O/T/N=3 titles // three rows to match 3-column ListWave
titles[0] = "\f01Bold Title"
titles[1] = "title with semicolon;"
titles[2] = "Marker in Gray: \K(40000,40000,40000)\k(40000,40000,40000)\W517"
NewPanel /W=(515,542,1011,794)
ListBox list0,pos={1,2},size={391,120},listWave=ListWave
ListBox list0,titleWave=titles
```

An example experiment that lets you easily experiment with ListBox settings is available in “Examples:Feature Demos 2:ListBox Demo.pxp”.

Setting Bit Parameters on page IV-13 for further details about bit settings.

The `GetUserData` operation for retrieving named user data.

**ListBoxControl**

ListBoxControl

ListBoxControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined listbox control. See `Procedure Subtypes` on page IV-199 for details. See `ListBox` for details on creating a listbox control.

**ListMatch**

```
ListMatch(listStr, matchStr [, listSepStr])
```

The ListMatch function returns each list item in `listStr` that matches `matchStr`.

`ListItem` should contain items separated by `listSepStr` which typically is ";".

You may include asterisks in `matchStr` as a wildcard character. Note that matching is case-insensitive. See `StringMatch` for wildcard details.

`ListSepStr` is optional. If omitted it defaults to ";".

V-460
See Also
The GrepList, StringMatch, StringFromList, and WhichListItem functions.

ListToTextWave

ListToTextWave(listStr, separatorStr)
The ListToTextWave function returns a free text wave containing the individual list items in listStr.

See Free Waves on page IV-89 for details on free waves.
The ListToTextWave function was added in Igor Pro 7.00.

Parameters
listStr is an string that contains any number of substrings separated by a common string separator.
separatorStr is the separator string that separates one item in the list from the next. It is usually a single semicolon character but can by any string.

Details
The ListToTextWave function returns a free wave so it can't be used on the command line or in a macro. If you need to convert the free wave to a global wave use MoveWave.

For lists with a large number of items, using ListToWave and then retrieving the substrings sequentially from the returned text wave is much faster than retrieving the substrings using StringFromList. This is because StringFromList must search from the start of the list to the desired substring each time it is called.

The reverse operation, converting the contents of a text wave into a string list, can be accomplished using wfprintf like this:

```
WAVE/T tw
String list
wfprintf list, "%s\r", tw // Carriage-return separated list
```

Example

Function Test(num, separator)
  Variable num
  String separator // Usually ";"

  // Build a string list using separator
  String list = ""
  Variable i
  for(i=0; i<num; i+=1)
    list += "item_" + num2str(i) + separator
  endfor

  // Convert to a text wave and print its elements
  Wave/T w = ListToTextWave(list, separator)
  Print numpnts(w)
  for(i=0; i<num; i+=1)
    Print i, w[i]
  endfor
End

ListToWaveRefWave, WaveRefWaveToList, wfprintf

Using Strings as Lists on page IV-167, StringFromList, MoveWave, Free Waves on page IV-89

ListToWaveRefWave

ListToWaveRefWave(stringList [, options])
The ListToWaveRefWave function returns a free wave containing a wave reference for each entry in stringList that corresponds to an existing wave.

The ListToWaveRefWave function was added in Igor Pro 7.00.

Parameters
stringList is a semicolon-separated string list of waves specified using full paths or partial paths relative to the current data folder.
options is a bit field that is 0 by default. Set bit 0 to if you want the function to generate an error (see GetRTError) if any of the list elements does not specify an existing wave. Other bits are reserved for future use and must be cleared.

Example

```plaintext
Function Test()
    NewDataFolder/O/S root:TestDF // Create empty data folder as current DF
    Make/O aaa // aaa will be the first wave in list
    Make/O bbb
    String strList = WaveList("**", ";", ")
    Wave/WAVE wr = ListToWaveRefWave(strList, 0) // Returns a free wave
    Wave w = wr[0]
    Print GetWavesDataFolder(w, 2)
    Wave w = wr[1]
    Print GetWavesDataFolder(w, 2)
End
```

See Also
WaveRefWaveToList, ListToTextWave, Wave References on page IV-70

**In**

\[ \ln(num) \]

The \( \ln \) function returns the natural logarithm of \( num \), -INF if \( num \) is 0, or NaN if \( num \) is less than 0. In complex expressions, \( num \) is complex, and \( \ln(num) \) returns a complex value.

To compute a logarithm base \( n \) use the formula:

\[
\log_n(x) = \frac{\log(x)}{\log(n)}.
\]

See Also
The \( \log \) function.

**LoadData**

```
LoadData [flags] fileOrFolderNameStr
```

The LoadData operation loads data from the named file or folder. “Data” means Igor waves, numeric and string variables and data folders containing them. The specified file or folder must be an Igor packed experiment file or a folder containing Igor binary data, such as an Igor unpacked experiment folder or a folder in which you have stored Igor binary wave files.

LoadData loads data objects into memory and they become part of the current Igor experiment, disassociated from the file from which they were loaded.

If loading from a file-system folder, the data (waves, variables, strings) in the folder, including any subfolders if /R is specified, is loaded into the current Igor data folder.

If loading from a packed Igor experiment file, the data in the file, including any packed sub-data folders if /R is specified, is loaded into the current Igor data folder.

Use LoadData to load experiment data using Igor procedures. To load experiment data interactively, use the Data Browser (Data menu).

**Parameters**

If you use a full or partial path for `fileOrFolderNameStr`, see Path Separators on page III-429 for details on forming the path.

If `fileOrFolderNameStr` is omitted you get to locate the file (if /D is omitted) or the folder (if /D is present) via a dialog.

**Flags**

/D If present, loads from a file-system folder (a directory). If omitted, LoadData loads from an Igor packed experiment file.
LoadData

/GREP={regExpStr, grepMode, objectTypeMask, grepFlags}

Applies a regular expression to determine what objects are loaded. /GREP was added in Igor Pro 8.00.

See Using Regular Expressions With LoadData on page V-465 for details.

/I

Interactive. Forces LoadData to present a dialog.

/I=objectNamesStr

Loads only the objects named in the semicolon-separated list of object names.

/L=loadFlags

Controls what kind of data objects are loaded with a bit for each data type:

<table>
<thead>
<tr>
<th>loadFlags</th>
<th>Bit Number</th>
<th>Loads this Object Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>Waves</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>Numeric Variables</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>String Variables</td>
</tr>
</tbody>
</table>

To load multiple data types, sum the values shown in the table. For example, /L=1 loads waves only, /L=2 loads numeric variables only, and /L=3 loads both waves and numeric variables. See Setting Bit Parameters on page IV-13 for further details about bit settings.

If no /L is specified, all object types are loaded. This is equivalent to /L=7. All other bits are reserved and should be set to zero.

/O=[overwriteMode]

If /O alone is used, overwrites existing data objects in case of a name conflict.

overwriteMode is defined as follows:

0: No overwrite, as if there were no /O.
1: Normal overwrite. In the event of a name conflict, objects in the incoming file replace the conflicting objects in memory. Incoming data folders completely replace any conflicting data folders in memory.
2: Mix-in overwrite. In the event of a name conflict, objects in the incoming file replace the conflicting objects in memory but nonconflicting objects in memory are left untouched.

See Details for more about overwriting.

/P=pathName

Specifies folder to look in for the specified file or folder. pathName is the name of an existing Igor symbolic path. See Symbolic Paths on page II-21 for details.

/Q

Suppresses the normal messages in the history area.

/R

Recursively loads sub-data folders.

/S=subDataFolderStr

Specifies a sub-data folder within a packed experiment file to be loaded. See Loading a Specific Data Folder from a Packed Experiment on page V-464 for details.

/T=[topLevelName]

If /T=[topLevelName] is specified, it creates a new data folder in the current data folder with the specified name and places the loaded data in the new data folder.

If just /T is specified, it creates a new data folder in the current data folder with a name derived from the name of the unpacked experiment folder, packed experiment file or packed sub-data folder being loaded.

Details

If /T is present, LoadData loads the top level data folder and its contents. If /T is omitted, it loads just the contents of the top level data folder and not the data folder itself. This distinction has an analogy in the desktop. You can drag the contents of disk folder A into folder B or you can drag folder A itself into folder B.
LoadData

Because LoadData can load from a complex packed Igor experiment file or from a complex hierarchy of file-system folders, it does not set the variables normally set by a file loader: S_path, S_fileName, and S_waveNames. The variable V_flag is set to the total number of objects loaded, or to -1 if the user cancelled the open file dialog. To find what objects were created by LoadData, you can use the CountObjects and GetIndexedObjName functions.

Overwriting Existing Data

If you do a load of a data folder, overwriting an existing data folder of the same name, the behavior of LoadData depends on whether you use /J. If you do not use /J, the entire data folder and all of its contents are replaced. If you do use /J, just the specified objects in the data folder are replaced, leaving any other preexisting objects in the data folder unchanged.

If you do not use the /O (overwrite) flag or if you use /O=0 and there is a conflict between objects or data folders in the current data folder and objects or data folders in the file or folder being loaded, LoadData presents a dialog to ask you if you want to replace the existing data. However, LoadData can not replace an object with an object of a different type and will refuse to do so.

You can overwrite an object that is in use, such as a wave that is displayed in a graph or table. You can also overwrite a data folder that contains objects that are in use. This is a powerful feature. Imagine that you define a data structure consisting of waves, variables and possibly sub-data folders. You can display the data in graphs and tables and you can display these in a layout. You can then overwrite the data with an analogous data structure from a packed experiment file and Igor will automatically update any graphs, tables or layouts that need to be updated.

Controlling Which Objects Are Loaded

LoadData provides several ways to control whether a given object is loaded or is skipped. These method, which are described in the following sections, include:

- Using /L to control whether waves, numeric variables, and string variables are loaded
- Specifying a sub-data folder using /S
- Specifying object names using /J
- Applying a regular expression using /GREP. /GREP requires Igor Pro 8.00 or later.

You can use more than one of these flags. For example, if you use /S and /J, then LoadData loads only objects in the data folder specified by /S with names listed using /J. In most cases, if you use /GREP, you will not need to combine it with /S or /J.

Loading a Specific Data Folder from a Packed Experiment

If present, /S=subDataFolderStr specifies the sub-data folder within the packed experiment file from which the load is to start. For example:

```
LoadData/P=Path1/S="root:Folder A:Folder B" "aPackedExpFile.pxp"
```

This starts loading from data folder "root:Folder A:Folder B" in the packed experiment file. subDataFolderStr is the full data folder path to the desired data folder. A trailing semicolon is allowed but not required. Since this parameter is specified as a string, you must not use single quotes to quote liberal names.

Prior to Igor Pro 7.00, the "root:" part of the data folder path was implicit and you had to omit it from subDataFolderStr. Now you can provide the full path including "root:" and this is recommended for clarity. For backward compatibility, if subDataFolderStr does not start with "root:", LoadData automatically prepends it.

/S has no effect if you are loading from an unpacked file system folder rather than from a packed experiment file.

Specifying /S="" acts like no /S at all.

Loading Specific Objects Based on Object Name

If /J=objectNamesStr is used, then only the objects named in objectNamesStr are loaded into the current experiment. For example, /J="wave0;wave1;" will load only the two named waves, ignoring any other data in the file or folder being loaded.

Assume that you have an experiment that contains 5 runs where each run, stored in a separate data folder in a packed experiment file, consists of data acquired from four channels from an ADC card. Using the /J flag, you can load just one specific channel from each run. You can use this to compare that channel's data from all runs without loading the other channels.
The list of object names used with /J must be semicolon-separated. A semicolon after the last object name in the list recommended but optional. Since objectNamesStr is specified as a string, you must not use single quotes to quote liberal names.

objectNamesStr is limited to 2000 bytes.

Specifying /J=“” acts like no /J at all.

If you load a hierarchy of data folders, using the /R flag, with /J in effect, LoadData will create each data folder in the hierarchy even if it contains none of the named objects. This behavior is necessary to avoid loading a sub-data folder without loading its parent, as well as other such complications.

Using Regular Expressions With LoadData

If you include the /GREP={regExpStr,grepMode,objectTypeMask,grepFlags} flag, LoadData applies a regular expression (see Regular Expressions on page IV-170) to determine if a given object is to be loaded.

Before we get into the details, here are some simple examples. These examples assume that we are loading a packed experiment file named "Packed.pxp" and have an Igor symbolic path named Data.

// Load waves named wave1 from all data folders
LoadData/P=Data/Q/R/L=1/GREP={"(?i)^wave1$",1,1,0} "Packed.pxp"

// Load root:DataFolder0B and all objects in it
LoadData/P=Data/Q/R/L=7/GREP={"(?i)^root:DataFolder0B::$",3,8,0} "Packed.pxp"

// Load all data folders whose paths are of the form root:DataFolder<suffix>
LoadData/P=Data/Q/R/L=7/GREP={"(?i)^root:DataFolder.+.*$",3,8,0} "Packed.pxp"

See the Examples on page V-466 for more examples.

regExpStr is the regular expression.

GREP is by default case-sensitive but Igor names are case-insensitive. For this reason, we recommend that you start regExpStr with "(?i)" which turns GREP's case-sensitivity off.

When looking for the appropriate value for regExpStr, you may find it helpful to test if a given name or path is matched by a given regular expression using GrepString. For example:

Print GrepString("root:DataFolder0A:str0", "(?i).*0$") // Prints 1 if path is matched

The grepMode parameter selects one of three modes of using the regular expression.

If grepMode is 1, LoadData matches the name of each object of types specified by objectTypeMask against the specified regular expression. If there is a match, the object passes this test.

If grepMode is 2, LoadData matches the full data folder path to the object's parent data folder for objects of types specified by objectTypeMask against the regular expression. The full data folder path starts from "root:" and includes a trailing colon. If there is a match, the object passes this test. By definition, the parent of the root: data folder is "" (empty string) which can be expressed using the regular expression "^$".

If grepMode is 3, LoadData matches the full data folder path to the object against the regular expression. The full data folder path starts from "root:" and includes a trailing colon for data folder objects only. If there is a match, the object passes this test.

When loading unpacked data, modes 2 and 3 are not supported and are ignored. They apply when loading data from a packed experiment file only.

objectTypeMask is a bitwise parameter with each bit controlling whether the regular expression is applied to a given object type. Bits 0, 1, 2, and 3 control whether the regular expression is applied against waves, numeric variables, string variables and data folders respectively. You can apply a given regular expression to more than one type of object by setting more than one bit in objectTypeMask. See Setting Bit Parameters on page IV-13 for details about bit settings.

grepFlags is a bitwise parameter. Currently only bit 0 is used so its value must be 0 or 1. Normally, when grepFlags=0, objects that do not match the regular expression are skipped by LoadData. If grepFlags=1, the meaning of a match is reversed and objects that do match the regular expression are skipped by LoadData. For example:

// Load all objects whose name ends with "2"
LoadData/P=Data/Q/R/L=7/GREP={"(?i)[2]$",1,7,0} "Packed.pxp" // Normal mode

// Load all objects except those whose name ends with "2"
LoadData/P=Data/Q/R/L=7/GREP={"(?i)[2]!$",1,7,1} "Packed.pxp" // Reverse mode
It is often not necessary, but you can use /GREP more than once in a given LoadData command, each time with a different combination of grepMode, object type, and reverse mode. A given object is loaded only if it passes all tests as well as any tests specified by /L, /J, and /S. For example:

```
// Load root:DataFolder0B and all objects in it, except objects whose name ends with "2"
LoadData/P=Data/Q/R/L=7/GREP={"(?i)\root:DataFolder0B:\$",3,8,0}/GREP={"(?i)\[2\]\$",1,7,1} "Packed.pxp"
```

In this example, the first /GREP flag restricts which data folders are loaded and the second /GREP flag restricts which waves and variables are loaded.

If no test is applied to a particular kind of object then all objects of that type are loaded. For example, this command

```
LoadData/P=<pathName>/GREP={"(?i)^wave1\$",1,1,0} <file name>
```

specifies that only waves named "wave1" should be loaded but it says nothing about numeric variables, string variables, or data folders so they are all loaded regardless of name. If you want to exclude all numeric and string variables, add the /L flag:

```
LoadData/P=<pathName>/L=1/GREP={"(?i)^wave1\$",1,1,0} <file name>
```

As LoadData progresses through the data folders of the source, it has to create each data folder before it applies regular expression tests to objects in that data folder and its descendants. Consequently, it would be possible to end up with empty data folders because no data objects were loaded into them or their descendants. To eliminate the clutter that this would create, if you use /GREP, after loading all of the data, LoadData deletes any empty data folders that it created along the way. Data folders that existed before LoadData ran are not deleted even if they are empty. For backward compatibility, this pruning of empty data folders is done only if you use /GREP.

For each combination of grepMode, object type, and reverse mode, only one regular expression is applied. If you specify, for example, /GREP={"(?i)first",1,1,0} /GREP={"(?i)second",1,1,0}, the second /GREP flag overrides the first because they both apply a name test (grepMode=1) to wave objects (objectTypeMask=1) using normal mode (grepFlags=0). By contrast, /GREP={"(?i)first",1,1,0} /GREP={"(?i)second",1,2,0} results in no overriding because the first /GREP flag applies to waves (objectTypeMask=1) while the second applies to numeric variables (objectTypeMask=2). Similarly, /GREP={"(?i)first",1,1,0} /GREP={"(?i)second",1,1,1} results in no overriding because the first /GREP flag uses normal mode (grepFlags=0) while the second uses reverse mode (grepFlags=1).

**Examples**

These examples assume that we are loading a packed experiment file named "Packed.pxp" and have an Igor symbolic path named Data. The file contains this data hierarchy:

```
root:
  wave0, wave1, wave2, var0, var1, var2, str0, str1, str2
DataFolder0A
  wave0, wave1, wave2, var0, var1, var2, str0, str1, str2
DataFolder0B
  wave0, wave1, wave2, var0, var1, var2, str0, str1, str2
```

```
// Load everything
LoadData/P=Data/Q/R "Packed.pxp"

// Load all objects named wave1
LoadData/P=Data/Q/R/J="wave1: " "Packed.pxp"

// Load all objects whose name ends with "2"
LoadData/P=Data/Q/R/L=7/GREP={"(?i)\[2\]\$",1,7,0} "Packed.pxp"

// Load all numeric variables whose name starts with "var"
LoadData/P=Data/Q/R/L=2/GREP={"(?i)^\var\",1,2,0} "Packed.pxp"

// Load all string variables whose name starts with "str" and ends with "2"
LoadData/P=Data/Q/R/L=4/GREP={"(?i)^str.*2\$",1,4,0} "Packed.pxp"

// Load all objects whose path contains "DataFolder", case-insensitive
LoadData/P=Data/Q/R/L=7/GREP={"(?i)DataFolder\",2,7,0} "Packed.pxp"

// Load root:DataFolder0B and all objects in it using /S
LoadData/P=Data/Q/R/L=7/S="root:DataFolder0B"/T "Packed.pxp"

// Load root:DataFolder0B and all objects in it using /GREP
LoadData/P=Data/Q/R/L=7/GREP={"(?i)\root:DataFolder0B:\$",3,8,0} "Packed.pxp"

// Load all objects whose path contains "DataFolder" and whose name ends with "1"
LoadData/P=Data/Q/R/L=7/GREP={"(?i)DataFolder\",2,7,0}/GREP={"(?i).*1\$",1,7,0} "Packed.pxp"
LoadPackagePreferences

LoadPackagePreferences ([/MIS=\text{mis\_match} /P=\text{path\_Name}] \text{package\_Name}, \text{prefs\_FileName}, \text{record\_ID}, \text{prefs\_Struct})

The LoadPackagePreferences operation loads preference data previously stored on disk by the SavePackagePreferences operation. The data is loaded into the specified structure.

\textbf{Note:} The package preferences structure must not use fields of type Variable, String, WAVE, NVAR, SVAR or FUNCREF because these fields refer to data that may not exist when LoadPackagePreferences is called.

The structure can use fields of type char, uchar, int16, uint16, int32, uint32, int64, uint64, float and double as well as fixed-size arrays of these types and substructures with fields of these types.

If the \text{/P} flag is present then the location on disk of the preference file is determined by \text{path\_Name} and \text{prefs\_FileName}. However in the usual case the \text{/P} flag will be omitted and the preference file is located in a file named \text{prefs\_FileName} in a directory named \text{package\_Name} in the Packages directory in Igor’s preferences directory.

\textbf{Note:} You must choose a very distinctive name for \text{package\_Name} as this is the only thing preventing collisions between your package and someone else’s package. If you use a name longer than 31 bytes, your package will require Igor Pro 8.00 or later.

See Saving Package Preferences on page IV-244 for background information and examples.

\textbf{Parameters}

\text{package\_Name} is the name of your package of Igor procedures. It is limited to 255 bytes and must be a legal name for a directory on disk. This name must be very distinctive as this is the only thing preventing collisions between your package and someone else’s package. If you use a name longer than 31 bytes, your package will require Igor Pro 8.00 or later.

\text{prefs\_FileName} is the name of a preference file to be loaded by LoadPackagePreferences. It should include an extension, typically ".\text{bin}".

\text{prefs\_Struct} is the structure into which data from disk, if it exists, will be loaded.

\text{record\_ID} is a unique positive integer that you assign to each record that you store in the preferences file. If you store more than one structure in the file, you would use distinct \text{record\_IDs} to identify which structure you want to load. In the simple case you will store just one structure in the preference file and you can use 0 (or any positive integer of your choice) as the \text{record\_ID}.

\textbf{Flags}

\text{/MIS=\text{mis\_match}} Controls what happens if the number of bytes in the file does not match the size of the structure:

0: Returns an error. Default behavior if /MIS is omitted.
1: Returns the smaller of the size of the structure and the number of bytes in the file. Does not return an error. Use this if you want to read and update old versions of a preferences structure.

\text{/P=\text{path\_Name}} Specifies the directory to look in for the file specified by \text{prefs\_FileName}.

\text{path\_Name} is the name of an existing symbolic path. See Symbolic Paths on page II-21 for details.

\text{/P=$<\text{empty \ string \ variable}>} acts as if the /P flag were omitted.
LoadPICT

Details
LoadPackagePreferences sets the following output variables:

- **V_flag**: Set to 0 if no error occurred or to a nonzero error code.
  - If the preference file does not exist, V_flag is set to zero so you must use V_bytesRead to detect that case.

- **V_bytesRead**: Set to the number of bytes read from the file. This will be zero if the preference file does not exist.

- **V_structSize**: Set to the size in bytes of prefsStruct. This may be useful in handling structure version changes.

After calling LoadPackagePreferences if V_flag is nonzero or V_bytesRead is zero then you need to create default preferences as illustrated by the example referenced below.

V_bytesRead, in conjunction with the /MIS flag, makes it possible to check for and deal with old versions of a preferences structure as it loads the version field (typically the first field) of an older or newer version structure. However in most cases it is sufficient to omit the /MIS flag and treat incompatible preference data the same as missing preference data.

Example
See the example under *Saving Package Preferences in a Special-Format Binary File* on page IV-245.

See Also
SavePackagePreferences.

LoadPICT

**LoadPICT** [flags] [fileNameStr], pictName]

The LoadPICT operation loads a picture from a file or from the Clipboard into Igor. Once you have loaded a picture, you can append it to graphs and page layouts.

Parameters
The file to be loaded is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see *Path Separators* on page III-429 for details on forming the path.

If you want to force a dialog to select the file, omit the fileNameStr parameter.

If fileNameStr is “Clipboard” and /P=pathName is omitted, LoadPICT loads its data from the Clipboard rather than from a file.

pictName is the name that you want to give to the newly loaded picture. You can refer to the picture by its name to append it to graphs and page layouts. LoadPICT generates an error if the name conflicts with some other type of object (e.g., wave or variable) or if the name conflicts with a built-in name (e.g., the name of an operation or function).

If you omit pictName, LoadPICT automatically names the picture as explained in Details.

Flags

- **/I=resIndex**: Specifies the resource to load by resource index, starting from 1 (*Macintosh only*).

- **/M=promptStr**: Specifies a prompt to use if LoadPICT needs to put up a dialog to find the file.

- **/N=resNameStr**: A string that specifies the resource to load by resource name (*Macintosh only*).

- **/O**: Overwrites an existing picture with the same name.

  If /O is omitted and there is an existing picture with the same name, LoadPICT displays a dialog in which you can resolve the name conflict.
LoadPICT

/P=pathname
Specifies the folder to look in for the file. pathname is the name of an existing symbolic path.

/Q
Quiet: suppresses the insertion of picture info into the history area.

/R=resourceID
Specifies the resource to load by resource ID (Macintosh only).

/Z
Doesn't load the picture, just checks for its existence.

Details
If the picture file is not fully specified then LoadPICT presents a dialog from which you can select the file. “Fully specified” means that LoadPICT can determine the name of the file (from the fileNameStr parameter) and the folder containing the file (from the flag /P=pathName flag or from the fileNameStr parameter). If you want to force a dialog, omit the fileNameStr parameter.

If you use /P=pathname, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See Symbolic Paths on page II-21 for details.

On Macintosh, LoadPICT can load picture data from the file’s data or resource fork. Most graphics programs store a picture in the data fork. Some programs may store one or more pictures as resources. If you use /R, /I, or /N, it loads the picture from the specified resource in the file. Otherwise, it loads the picture from the file’s data fork.

If you omit pictName, LoadPICT automatically names the picture as follows:

On Macintosh, if the picture was loaded from the resource fork of a file (you used /R, /I, or /N) and the resource had a nonempty name, it uses the resource name. If necessary, the name is made legal by replacing illegal characters or shortening it.

If the picture was loaded from a file, LoadPICT uses the file name. If necessary, it makes it into a legal name by replacing illegal characters or shortening it.

Otherwise, LoadPICT uses a name of the form “PICT_n”.

If the resulting name is in conflict with an existing picture name, Igor puts up a name conflict resolution dialog. LoadPICT sets the variable V_flag to 1 if the picture exists and fits in available memory or to 0 otherwise.

It also sets the string variable S_info to a semicolon-separated list of values:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>Name of the loaded PICT, often “PICT_0”, etc.</td>
</tr>
<tr>
<td>SOURCE</td>
<td>One of “data fork”, “resource fork” or “Clipboard”.</td>
</tr>
<tr>
<td>RESOURCENAME</td>
<td>Name of the resource the picture was loaded from, or “” if the source was not the file’s resource fork.</td>
</tr>
<tr>
<td>RESOURCEID</td>
<td>Resource ID the picture was loaded from, or 0 if the source was not the file’s resource fork.</td>
</tr>
</tbody>
</table>
LoadWave

See Also
See Pictures on page III-481 for general information on how Igor handles pictures.
The ImageLoad operation for loading PICT and other image file types into waves, and the PICTInfo function.

LoadWave

LoadWave  [flags]  [fileNameStr]
The LoadWave operation loads data from the named Igor binary, Igor text, delimited text, fixed field text, or general text file into waves. LoadWave can load 1D and 2D data from delimited text, fixed field text and general text files, or data of any dimensionality from Igor binary and Igor text files.

Parameters
The file to be loaded is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If LoadWave can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-429 for details on forming the path.

If fileNameStr is “Clipboard” and /P=pathName is omitted, LoadWave takes its data from the Clipboard rather than from a file. This is not implemented for binary loads.

If fileNameStr is omitted or is “”, or if the /I flag is used, LoadWave presents an Open File dialog from which you can choose the file to load.
Flags

/A  “Auto-name and go” option (used with /G, /F or /J).
This skips the dialog in which you normally enter wave names. Instead it automatically assigns names of the form wave0, wave1, choosing names that are not already in use. When used with /W, it reads wave names from the file instead of automatically assigning names and /A just skips the wave name dialog. The /B flag can also override names specified by /A.

/A=baseName  Same as /A but it automatically assigns wave names of the form baseName0, baseName1.

/B=columnInfoStr  Specifies the name, format, numeric type, and field width for columns in the file. See Specifying Characteristics of Individual Columns.

/C  This is used in experiment recreation commands generated by Igor to force experiment recreation to continue if an error occurs in loading a wave.

/D  Creates double precision waves. (Used with /G, /F or /J.) The /B flag can override the numeric precision specified by the /D flag.

/E=editCmd  Controls table creation:
  editCmd=1:  Makes a new table containing the loaded waves.
  editCmd=2:  Appends the loaded waves to the top table. If no table exists, a new table is created.
  editCmd=0:  Same as if /E had not been specified (loaded waves are not put in any table).

/ENC=encoding  
/ENC={textEncoding, tecOptions}
Specifies the text encoding of the plain text file being loaded.
This flag was added in Igor Pro 7.00.
This flag is ignored when loading an Igor binary wave file.

See Text Encoding Names and Codes on page III-463 for a list of accepted values for textEncoding.

For most purposes the default value for tecOptions, 3, is fine and you can use /ENCG=textEncoding instead of /ENCG={textEncoding, tecOptions}.

tecOptions is an optional bitwise parameter that controls text encoding conversion. See Setting Bit Parameters on page IV-13 for details about bit settings.

 tecOptions is defined as follows:
Bit 0: If cleared, the presence of null bytes causes LoadWave to consider the text invalid in all byte-oriented text encodings. This makes it easier for LoadWave to identify UTF-16 and UTF-32 text which usually contains null bytes.
If set (default), null bytes are allowed in byte-oriented text encodings.

Bit 1: If cleared LoadWave does not validate text if the specified text encoding is UTF-8.
If set (default), LoadWave validates text even if the text encoding is UTF-8.

Bit 2: If cleared (default) LoadWave validates the text in the specified text encoding except that validation for UTF-8 is skipped if bit 1 is cleared.
If set, LoadWave assumes that the text is valid in the specified text encoding and does not validate it. Setting this bit makes LoadWave slightly faster but it is usually inconsequential.

Bit 3: If cleared (default), LoadWave presents the Choose Text Encoding dialog if the specified text encoding is not valid for the text in the file.
If set, LoadWave does not present the Choose Text Encoding dialog if the text is not valid in the specified text encoding and instead returns an error. Set this bit if you are running an automated procedure and do not want it interrupted by a dialog.

See LoadWave Text Encoding Issues on page V-480 for further discussion.

/F={numColumns, defaultFieldWidth, flags}
Indicates that the file uses the fixed field file format. Most FORTRAN programs generate files in this format.
numColumns is the number of columns of data in the file.
defaultFieldWidth is the default number of bytes in each column. If the columns do not all have the same number of bytes, you need to use the /B flag to provide more information to LoadWave.
flags is a bitwise parameter that controls the conversion of text to values. The bits are defined as follows:

Bit 0: If set, any field that consists entirely of the digit “9” is taken to be blank. A field that consists entirely of the digit “9” except for a leading “+” or “-” is also taken to be blank.

All other bits are reserved and must be cleared.

/G Indicates that the file uses the general text format.
LoadWave

/H Loads the wave into the current experiment and severs the connection between the wave and the file. When the experiment is saved, the wave copy will be saved as part of the experiment. For a packed experiment this means it is saved in the packed experiment file. For an unpacked experiment this means it is saved in the experiment's home folder.

See Sharing Versus Copying Igor Binary Wave Files on page II-141.

/I Forces LoadWave to display an Open File dialog even if the file is fully specified via /P and fileNameStr.

/J Indicates that the file uses the delimited text format.

/K=k Controls how to determine whether a column in the file is numeric or text (only for delimited text and fixed field text files).

- \( k=0 \): Deduces the nature of the column automatically.
- \( k=1 \): Treats all columns as numeric.
- \( k=2 \): Treats all columns as text.

This flag as well as the ability to load text data into text waves were added in Igor Pro 3.0. The default for the LoadWave operation is \( /K=1 \), meaning that it will treat all columns as numeric. We did this so that existing procedures would behave the same in Igor Pro 3.0 as before. Use \( /K=0 \) when you want to load text columns into text waves. \( /K=2 \) may have use in a text-processing application.

For finer control, the /B flag specifies the format of each column in the file individually.

/L=\{nameLine, firstLine, numLines, firstColumn, numColumns\}

Affects loading delimited text, fixed field text, and general text files only (/J, /F or /G). /L is accepted no matter what the load type but is ignored for Igor binary and Igor text loads. Line and column numbers start from 0.

- nameLine is the number of the line containing column names. For general text loads, 0 means auto. See Loading General Text Files on page II-132 for details.
- firstLine is the number of the first line to load into a wave. For general text loads, 0 means auto. See Loading General Text Files on page II-132 for details.
- numLines is the number of lines that should be treated as data. 0 means auto which loads until the end of the file or until the end of the block of data in general text files. The numLines parameter can also be used to make loading very large files more efficient. See Loading Very Large Files.
- firstColumn is the number of the first column to load into a wave. This is useful for skipping columns.
- numColumns is the number of columns to load into a wave. 0 means auto, which loads all columns.

/M Loads data as matrix wave. If /M is used then it ignores the /W flag (read wave names) and follows the /U flags instead.

The wave is autonamed unless you provide a specific wave name using the /B flag.

The type of the wave (numeric or text) is determined by an assessment of the type of the first loaded column unless you override this using the /K flag or the /B flag.

See The Load Waves Dialog for Delimited Text — 2D on page II-128 for further information.

/N Same as /A except that, instead of choosing names that are not in use, it overwrites existing waves.

/N=baseName Same as /N except that it automatically assigns wave names of the form baseName0, baseName1.
Overwrite existing waves in case of a name conflict.

Specifies the folder to look in for `fileNameStr`. `pathName` is the name of an existing symbolic path.

Suppresses the normal messages in the history area.

Specifies a custom date format for dates in the file. If the `/R` flag is used, it overrides the date setting that is part of the `/V` flag.

`languageName` controls the language used for the alphabetic date components, namely the month and the day-of-week. `languageName` is one of the following:

- Default
- Chinese
- ChineseSimplified
- Danish
- Dutch
- English
- Finnish
- French
- German
- Italian
- Japanese
- Korean
- Norwegian
- Portuguese
- Russian
- Spanish
- Swedish

Default means the system language on Macintosh or the user default language on Windows.

`yearFormat` is one of the following codes:

- 1: Two digit year.
- 2: Four digit year.

`monthFormat` is one of the following codes:

- 1: Numeric, no leading zero.
- 2: Numeric with leading zero.
- 3: Abbreviated alphabetic (e.g., Jan).
- 4: Full alphabetic (e.g., January).

`dayOfMonthFormat` is one of the following codes:

- 1: Numeric, no leading zero.
- 2: Numeric with leading zero.

`dayOfWeekFormat` is one of the following codes:

- 1: Abbreviated alphabetic (e.g., Mon).
- 2: Full alphabetic (e.g., Monday).

`layoutStr` describes which components appear in the date in what order and what separators are used. `layoutStr` is constructed as follows (but with no line break):

```
"<component keyword><separator>
<component keyword><separator>
<component keyword><separator>
<component keyword>"
```

where `<component keyword>` is one of the following:

- Year
- Month
- DayOfMonth
- DayOfWeek

and `<separator>` is a string of zero to 15 bytes.
Starting from the end, parts of the layout string must be omitted if they are not used. Extraneous spaces are not allowed in \textit{layoutStr}. Each separator must be no longer than 15 bytes. No component can be used more than once. Some components may be used zero times.

\textit{pivotYear} determines how LoadWave interprets two-digit years. If the year is specified using two digits, \textit{yy}, and is less than \textit{pivotYear} then the date is assumed to be 20\textit{yy}. If the two digit year is greater than or equal to \textit{pivotYear} then the year is assumed to be 19\textit{yy}. \textit{pivotYear} must be between 4 and 40.

See \textbf{Loading Custom Date Formats} on page V-476 for further discussion of date formats.

\textit{/T} Indicates that the file uses the Igor text format.

Although LoadWave is generally thread-safe, it is not thread-safe to load an Igor text file containing an Igor command (e.g., "X <command>").

\textit{/U=\{readRowLabels, rowPositionAction, readColLabels, colPositionAction\}}

These parameters affect loading a matrix (/M) from a delimited text (/J) or a fixed field text (/F) file. They are accepted no matter what the load type is but are ignored when they don’t apply.

If \textit{readRowLabels} is nonzero, it reads the first column of data in the file as the row labels for the matrix wave.

\textit{rowPositionAction} has one of the following values:

0: The file has no row position column.
1: Uses the row position column to set the row scaling of the matrix wave.
2: Creates a 1D wave containing the values in the row position column. The name of the 1D wave will be the same as the matrix wave but with the prefix “RP_”.

The \textit{readColumnLabels} and \textit{columnPositionAction} parameters have analogous meanings. The prefix used for the column position wave is “CP_”.

See Chapter II-9, \textbf{Importing and Exporting Data} for further details.

\textit{/V=\{delimsStr, skipCharsStr, numConversionFlags, loadFlags\}}

These parameters affect loading delimited text (/J) and fixed field text (/F) data and column names. They do not affect loading general text (/G). They are accepted no matter what the load type is but are ignored when they don’t apply. These parameters should rarely be needed.

\textit{delimsStr} is a string expression containing the characters that should act as delimiters for delimited file loads. (When loading data as general text, the delimiters are always tab, comma and space.) The default is “\textbackslash t,” for tab and comma. You can specify the space character as a delimiter, but it is always given the lowest priority behind any other delimiters contained in \textit{delimsStr}. The low priority means that if a line of text contains any other delimiter besides the space character, then that delimiter is used rather than the space character.

\textit{skipCharsStr} is a string expression containing characters that should always be treated as garbage and skipped when they appear before a number. The default is “$” for space and dollar sign. This parameter should rarely be needed.
LoadWave

$numConversionFlags$ is a bitwise parameter that controls the conversion of text to numbers. The bits are defined as follows:

- **Bit 0:** If set: dates are dd/mm/yy.
  If cleared: dates are mm/dd/yy.
- **Bit 1:** If set: decimal character is comma.
  If cleared: it is period.
- **Bit 2:** If set: thousands separators in numbers are ignored when loading delimited text only (LoadWave/J).
  The thousands separator is the comma in 1,234 or, if comma is the decimal character, the dot in 1.234.
  Most numeric data files do not use thousands separators and searching for them slows loading down so this bit should usually be 0.
  This bit has no effect if the thousands separator (e.g., comma) is also a delimiter character as specified by delimsStr.

All other bits are reserved and must be cleared.

See Setting Bit Parameters on page IV-13 for details about bit settings.

If the /R flag is used to specify the date format, this overrides the setting of bit 0.

$loadFlags$ is a bitwise parameter that controls the overall load. The bits are defined as follows:

- **Bit 0:** If set, ignores blanks at the end of a column. This is appropriate if the file contains columns of unequal length. Set $loadFlags = 1$ to set bit 0.
- **Bit 1:** If set, when the /W flag is specified and the line containing column labels starts with one or more space characters, the spaces are taken to be a blank column name. The resulting column will be named Blank. Use this if both the line containing column labels and the lines containing data start with leading spaces in a space-delimited file. Set $loadFlags = 2$ to set bit 1.
- **Bit 2:** If set: Disables pre-counting of lines of data. See Loading Very Large Files below.
- **Bit 3:** If set: Disables unescaping of backslash characters in text columns. See Escape Sequences below.
- **Bit 4:** If set: Disables support for quoted strings.

Setting this bit improves compatibility with Igor7. It applies to delimited text only and should rarely be needed. See Quoted Strings in Delimited Text Files on page II-129 and Delimited Text Compatibility With Igor7 on page II-130 for background information.

/W

Looks for wave names in a file. (With /G, /F, and /J.)

LoadWave cleans up column names to create standard, not liberal, wave names. See Object Names on page III-475 and CleanupName for details.

Use /W/A to read wave names from the file and then continue the load without displaying the normal wave name dialog.

**Details**

Without the /G, /F, /J, or /T flags, LoadWave loads Igor binary wave files.

If you use /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See Symbolic Paths on page II-21 for details.

When loading a general text file, the delimiters are always tab, comma and space.

**Loading Custom Date Formats**

Here are some examples showing custom date formats and how you would specify them using the /R flag:
When loading data as delimited text, if you use a date format containing a comma, such as “October 11, 1999”, you must use the /V flag to make sure that LoadWave will not treat the comma as a delimiter.

When loading a date format that consists entirely of digits, such as 991011, you must use the LoadWave/B to specify that the data is a date. Otherwise, LoadWave will treat it as a regular number.

Loading Very Large Files
The number of waves (columns) or points (rows) that LoadWave can handle when loading a text file is limited only by available memory.

You can improve the speed and efficiency of loading very large files (i.e., more than 50,000 lines of data) using the numLines parameter of the /L flag. Normally this parameter is used to load a section of the file instead of the whole file. However, in delimited, general text and fixed field text loads, the numLines parameter also specifies how many rows the waves should initially have. Thus all of the required memory is allocated at the start of the load, rather than increasing the number of wave rows over and over as more lines of data are loaded. When loading very large files, if you know the exact number of lines of data in the file, use the numLines parameter of the /L flag. If you don’t know the exact number of lines, you can provide a number that is guaranteed to be larger.

If you omit the /L flag or if the numLines parameter is zero, and if you are loading a file greater than 500,000 bytes, and if you are running on Windows, LoadWave will automatically count the lines of data in the file so that the entire wave can be allocated before data loading starts. This acts as if you used /L and set numLines to the exact correct value. For very large files on Windows, this can speed the loading process considerably. For small files on Windows and for files of any size on Macintosh, it actually makes the load slower. That’s why this feature takes effect only on Windows and only for files of greater than 500,000 bytes. You can disable this feature by using the /V flag and setting bit 2 to 1.

Escape Sequences
An escape sequence is a two-character sequence used to represent special characters in plain text. Escape sequences are introduced by a backslash character.

By default, in a text column, LoadWave interprets the following escape sequences: \t (tab), \n (linefeed), \r (carriage-return), \\ (backslash), \" (double-quote) and \' (single-quote). This works well with Igor’s Save operation which uses escape sequences to encode the first four of these characters.

If you are loading a file that does not use escape sequences but which does contain backslashes, you can disable interpretation of these escape sequences by setting bit 3 of the loadFlags parameter of the /V flag. This is mainly of use for loading a text file that contains unescaped Windows file system paths.

Generating Wave Names
The /N flag automatically names new waves “wave” (or baseName if =baseName is used) plus a digit. The digit starts from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten.

The /A flag is like /N except that it skips names already in use.
Specifying Characteristics of Individual Columns

The /B=columnInfoStr flag provides information to LoadWave for each column in a delimited text (/J), fixed field text (/F) or general text (/G) file. The flag overrides LoadWave's normal behavior. In most cases, you will not need to use it.

columnInfoStr is constructed as follows:
"<column info>;<column info>; ... ;<column info>;

where <column info> consists of one or more of the following:

- **C=<number>**  The number of columns controlled by this column info specification. <number> is an integer greater than or equal to one.

- **F=<format>**  A code that specifies the data type of the column or columns. <format> is an integer from -2 to 10. The meaning of the <format> is:
  - -2: Text. The column will be loaded into a text wave.
  - -1: Format unknown. It will deduce the format.
  - 0 to 5: Numeric.
  - 6: Date.
  - 7: Time.
  - 8: Date/Time.
  - 9: Octal number.
  - 10: Hexadecimal number.

The F= flag is used for delimited text and fixed field text files only. It is ignored for general text files.

- **N=<name>**  A name to use for the column. <name> can be a standard name (e.g., wave0) or a quoted liberal name (e.g., 'Heart Rate'). If <name> is '_skip_' (including single quotation marks) then LoadWave will skip the column.

The N= flag works for delimited text, fixed field text and general text files.

- **T=<numtype>**  A number that specifies what the numeric type for the column should be. This flag overrides the LoadWave/D flag. It has no effect on columns whose format is text. <numtype> must be one of the following:
  - 2: 32-bit float.
  - 4: 64-bit float.
  - 8: 8-bit signed integer.
  - 16: 16-bit signed integer.
  - 32: 32-bit signed integer.
  - 72: 8-bit unsigned integer.
  - 80: 16-bit unsigned integer.

The T= flag is used for delimited text, fixed field text and general text files.

- **W=<width>**  The column field width for fixed field files. <width> is an integer greater than or equal to one. Fixed width files are FORTRAN-style files in which a fixed number of bytes is allocated for each column and spaces are used as padding.

The W= flag is used for fixed field text only.

Here is an example of the /B=columnInfoStr flag:

```
/B="C=1,F=-2,T=2,W=20,N=Factory; C=1,F=6,W=16,T=4,N=MfgDate;
C=1,F=0,W=16,T=2,N=TotalUnits; C=1,F=0,W=16,T=2,N=DefectiveUnits;"
```

This example is shown on two lines but in a real command it would be on a single line. In a procedure, it could be written as:

```
String columnInfoStr = ""
columnInfoStr += "C=1,F=-2,T=2,W=20,N=Factory;"
columnInfoStr += "C=1,F=6,T=4,W=16,N=MfgDate;"
```
columnInfoStr += "C=1,F=0,T=2,W=16,N=TotalUnits;"
columnInfoStr += "C=1,F=0,T=2,W=16,N=DefectiveUnits;"

Note that each flag inside the quoted string ends with either a comma or a semicolon. The comma separates one flag from the next within a particular column info specification. The semicolon marks the end of a column info specification. The trailing semicolon is required. Spaces and tabs are permitted within the string.

This example provides information about a file containing four columns.

The first column info specification is “C=1;F=-2,T=2,W=20,N=Factory;”. This indicates that the specification applies to one column, that the column format is text, that the numeric format is single-precision floating point (but this has no effect on text columns), that the column data is in a fixed field width of 20 bytes, and that the wave created for this column is to be named Factory.

The second column info specification is “C=1;F=6,T=4,W=16,N=MfgDate;”. This indicates that the specification applies to one column, that the column format is date, that the numeric format is double-precision floating point (double precision should always be used for dates), that the column data is in a fixed field width of 16 bytes, and that the wave created for this column is to be named MfgDate.

The third column info specification is “C=1;F=0,T=2,W=16,N=TotalUnits;”. This indicates that the specification applies to one column, that the column format is numeric, that the numeric format is single-precision floating point, that the column data is in a fixed field width of 16 bytes, and that the wave created for this column is to be named TotalUnits.

The fourth column info specification is the same as the third except that the wave name is DefectiveUnits.

All of the items in a column specification are optional. The default value for each item in the column info specification is as follows:

- **C=<number>** C=1. Specifies that the column info describes one column.
- **F=<format>** F=1. Determines the format as dictated by the /K flag. If /K=0 is used, LoadWave will automatically determine the column format.
- **N=<name>** N=_auto_. Generates the wave name as it would if the /B flag were omitted.
- **T=<numtype>** Defaults to T=4 (double precision) if the LoadWave/D flag is used or to T=2 (single precision) if the /D flag is omitted.
- **W=<width>** W=0. For a fixed width file, LoadWave will use the default field width specified by the /F flag unless you provide an explicit field width greater than 0 using W=<width>.

Taking advantage of the default values, we could abbreviate the example as follows:

```
/B="F=-2,W=20,N=Factory; F=6,T=4,W=16,N=MfgDate;
W=16,N=TotalUnits; W=16,N=DefectiveUnits;"
```

If the file were not a fixed field text file, we would omit the W= flag and the example would become:

```
/B="F=-2,N=Factory;F=6,T=4,N=MfgDate;N=TotalUnits;N=DefectiveUnits;"
```

Here are some more examples and discussion that illustrate the use of the /B=columnInfoStr flag.

In this example, the /B flag is used solely to specify the name to use for the waves created from the columns in the file:

```
/B= "N=WaveLength; N=Absorbance;"
```

The wave names in the previous example are standard names. If you want to use liberal names, such as names containing spaces or dots, you must use single quotes. For example:

```
/B= "N='Wave Number'; N='Reflection Angle';"
```

The name that you specify via N= can not be used if overwrite is off and there is already a wave with this name or if the name conflicts with a macro, function or operation or variable. In these cases, LoadWave generates a unique name by adding one or more digits to the name specified by the N= flag for the column in question. You can avoid the problem of a conflict with another wave name by using the overwrite (/O) flag or by loading your data into a newly-created data folder. You can minimize the likelihood of a name conflict with a function, operation or variable by avoiding vague names.

If you specify the same name in two N= flags, LoadWave will generate an error, so make sure that the names are unique.

Except if the specified name is '_skip_', the N= flag generates a name for one column only, even if the C= flag is used to specify multiple columns. Consider this example:
This ostensibly uses the name Test for 10 columns. However, wave names must be unique, so LoadWave will not do this. It will use the name Test for just the first column and the other columns will receive default names.

You can load a subset of the columns in the file using the /L flag. Even if you do this, the column info specifications that you provide via the /B flag start from the first column in the file, not from the first column to be loaded. For example, if you are using /L to skip columns 0 and 1, you must skip columns 0 and 1 in the column info specification, like this:

// Skip column 0 and 1 and name the successive columns
/L=[0,0,0,2,0] /B="C=2;N=Column2;N=Column3;"

The "C=2;" part accepts default specifications for columns 0 and 1 and the subsequent specifications apply to subsequent columns.

You can achieve the same thing using /B without /L, like this:

/B="C=2,N='_skip_';N=Column2;N=Column3;"

Also, when loading data into a matrix wave, LoadWave uses only one name. If you specify more than one name, only the first is used. If you are loading data into a matrix and also skipping columns, the explanation above about skipping applies.

In this example, the /B flag solely specifies the format of each column in the file. The file in question starts with a text column, followed by a date column, followed by 3 numeric columns.

/B="F=-2; F=6; C=3,F=0"

In most cases, it is not necessary to use the F= flag because LoadWave can automatically deduce the formats. The flag is useful for those cases where it deduces the column formats incorrectly. It is also useful to force LoadWave to interpret a column as octal or hexadecimal because LoadWave can not automatically deduce these formats.

The numeric codes (0…10) used by the F= flag are the same as the codes used by the ModifyTable operation. If you create a table using the /E flag, the F= flag controls the numeric format of table columns.

The code -1 is not a real column format code. If you use F=-1 for a particular column, LoadWave will deduce the format for that column from the column text.

In this example, the /B flag is used solely to specify the width of each column in a fixed field file. This file contains a 20 byte column followed by ten 16 byte columns followed by three 24 byte columns.

/B="C=1,W=20; C=10,W=16; C=3,W=24"

The field widths specified via W= override the default field width specified by the /F flag. If all of the columns in the file have the same field width then you can use just the /F flag.

You can load a subset of the columns in the file using the /L flag. Even if you do this, the column info specifications that you provide via the /B flag start from the first column in the file, not from the first column to be loaded.

LoadWave Text Encoding Issues

This section discusses text encoding issues of interest to advanced users. It assumes that you are familiar with the general topic of text encodings as explained under Text Encodings on page III-437.

Since Igor stores all text internally as UTF-8, it must convert text read from a file from the source text encoding to UTF-8. In order to do this it needs to know the source text encoding.

When loading an Igor binary wave file LoadWave ignores the /ENCG=textEncoding flag. The loaded wave's text encoding is determined as described under LoadWave Text Encodings for Igor Binary Wave Files on page III-453. The rest of this section applies to loading data from plain text files, not from Igor binary wave files.

When loading a text data file you can use the /ENCG=textEncoding flag to tell Igor what that text encoding is. See Text Encoding Names and Codes on page III-463 for a list of accepted values for textEncoding.

LoadWave uses the text encoding specified by /ENCG and the rules described under Determining the Text Encoding for a Plain Text File on page III-446 to determine the source text encoding for conversion of the text file's data to UTF-8. If you omit /ENCG or specify /ENCG=0, the specified text encoding is unknown and does not factor into the determination of the source text encoding. If following the rules does not identify a text encoding that works for converting the file's text to UTF-8, Igor displays the Choose Text Encoding dialog.
If the file contains nothing but ASCII characters, as is often the case, then any byte-oriented text encoding will work and there is no need to use the /ENCG flag.

When you are loading a huge file (e.g., hundreds of megabytes), finding a valid source text encoding may add a noticeable amount to the time it takes to load the file. If you know that the file is either all ASCII or is valid UTF-8, you can tell LoadWave to skip text encoding conversion altogether using an optional parameter, like this:

/ENCG={1,4}

"1" tells LoadWave that the text is valid as UTF-8, meaning that it is all ASCII or, if it contains non-ASCII characters, they are properly encoded as UTF-8.

"4" tells LoadWave to assume that the text is valid as UTF-8 and skip all validation and conversion.

In testing with a 200 MB delimited text file containing 1 million rows and 20 columns, we found that using /ENCG=[1,4] saved about 10% of the time.

**NOTE:** If you use this flag but the file is not valid UTF-8 and you are loading data into text wave, the text waves will wind up with invalid data which will result in errors when you use the waves later.

As noted above, if following the rules does not identify a text encoding that works for converting the file’s text to UTF-8, Igor displays the Choose Text encoding dialog. If you are loading many files using an unattended, automated procedure, displaying this dialog will cause your procedure to grind to a halt. You can prevent this by using another optional flag, like this:

/ENCG={1,8}

If you use this flag and LoadWave can not determine the source text encoding for a file, it will return an error. If you want your procedure to continue with other files you must check for and handle the error using GetRTError on page V-290.

**Output Variables**

LoadWave sets the following variables:

- `V_flag`: Number of waves loaded.
- `S_fileName`: Name of the file being loaded.
- `S_path`: File system path to the folder containing the file.
- `S_waveNames`: Semicolon-separated list of the names of loaded waves.

`S_path` uses Macintosh path syntax (e.g., `"hd:FolderA:FolderB:"`), even on Windows. It includes a trailing colon. If LoadWave is loading from the Clipboard, `S_path` is set to "".

When LoadWave presents an Open File dialog and the user cancels, `V_flag` is set to 0 and `S_fileName` is set to "".

**See Also**

The ImageLoad operation.

See Importing Data on page II-120 for further information on loading waves, including loading multidimensional data from HDF, PICT, TIFF and other graphics files. Check the “More Extensions:File Loaders” folder other file-loader extensions.

**Setting Bit Parameters** on page IV-13 for further details about bit settings.

### Loess

**Loess** `[flags] srcWave = srcWaveName [, factors = factorWaveName1 [, factorWaveName2 ...]]`

The Loess operation smooths `srcWaveName` using locally-weighted regression smoothing. This algorithm is sometimes classified as a “nonparametric regression” procedure. The regression can be constant, linear, or quadratic. A robust option that ignores outliers is available. See Basic Algorithm, Robust Algorithm, and References for additional details and terminology.

This implementation works with waveforms, XY pairs of waves, false-color images, matrix surfaces, and multivariate data (one dependent data wave with multiple independent variable data waves).

Unlike the FilterFIR operation, Loess discards any NaN input values and will not generate a result that is wholly NaN.
**Loess**

**Parameters**

srcWaveName is the input data to be smoothed. It may be a one-dimensional or a two-dimensional wave, and it may contain NaNs.

When no /DEST flag is specified, Loess will overwrite srcWaveName with the smoothed result.

If srcWaveName is one-dimensional and no factors are provided, X values are derived from the X scaling of srcWaveName.

If srcWaveName is two-dimensional, the factors keyword is not permitted and the X and Y values are derived from the X and Y scaling of srcWaveName.

Higher dimensions of srcWaveName are not supported.

The optional factors parameter(s) provide the independent variable value(s) that correspond to the observed value in srcWaveName.

Note: Cleveland et al. (1992) use the term “multiple factors” instead of “multivariate”, hence the keyword name “factors” is used to denote these waves.

Use one factors wave when srcWaveName is the one-dimensional Y wave of an XY data pair:

srcWaveName[i] = someFunction(factorWaveName1[i])

Use multiple factors waves when srcWaveName contains the values of a multivariate function. “Multivariate” means that srcWaveName contains the observed results of a process that combines multiple independent input variables:

srcWaveName[i] = someFunction(factorWaveName1[i], factorWaveName2[i],...)

A maximum of 10 factors waves is supported.

All factors wave(s) must be numeric, noncomplex, one-dimensional and have the same number points as srcWaveName.

Any NaN values in srcWaveName[i], factorWaveName1[i], factorWaveName2[i], ... cause all corresponding values to be ignored. Factors waves may contain NaN values only when /DFCT is specified.

Loess does not support NaNs in any of destFactorWaveName1, destFactorWaveName2,... and the results are undefined.

**Flags**

/CONF={confInt, ciPlusWaveName [,ciMinusWaveName]}

confInt specifies the confidence interval (a probability value from 0 to 1).

ciPlusWaveName and the optional ciMinusWaveName are the names of new or overwritten output waves to hold the fitted value ± the confidence interval.

Note: /CONF uses large memory allocations, approximately N*N*8 bytes, where N is the number of points in srcWaveName (see Memory Details).

/DEST=destWaveName

Specifies the name of the wave to hold the smoothed data. It creates destWaveName if it does not already exist or overwrites it if it does. The x (and possibly y) scaling of destWave determines the independent (factor) coordinates unless /DFCT={destFactorWaveName1 [,destFactorWaveName2...]} is also specified.

/DFCT

Specifies that the /DEST wave's x (and possibly y) scaling determines the independent (factor) coordinates at which to compute the smoothed data.

/DFCT={destFactorWaveName1 [,destFactorWaveName2...]}
Specifies the names of one-dimensional waves providing the independent coordinates at which to compute the smoothed data.

If /DFCT={...} is used, the same number of waves must be specified for /DFCT and for factors = {factorWaveName1 [, factorWaveName2 ...]}, though their lengths may (and usually will) be different. The length of destFactorWaveName waves must be the same as that of the destWaveName wave.

All destination factor waves must be numeric, noncomplex, and one-dimensional. The number of destination factor waves must match the number of source factor waves (if specified), or match the dimensionality of srcWaveName (one destination factor wave if srcWaveName is one-dimensional, two destination factors waves if srcWaveName is two-dimensional.)

The values in the destination factor waves may not be NaN.

/E=extrapolate

Set extrapolate to nonzero to use a slower fitting method that computes values beyond the domain defined by the source factors. This is the “surface” parameter named “direct” in Cleveland et al. (1992). The default is extrapolate = 0, which uses the “interpolate” surface parameter, instead.

/N=neighbors

Specifies the number of values in the smoothing window.

If neighbors is even, the next larger odd number is used. When neighbors is less than two, no smoothing is done.

The default is 0.5*numpnts(srcWaveName) rounded up to the next odd integer or 3, whichever is larger.

Use either /N or /SMTH, but not both.

/NORM [=norm]

Set norm to 0 when specifying multiple factors and they all have the same scale and meaning, for example multiple factors all in units of meters.

The default is norm = 1, which normalizes each factor independently when computing the weighting function. This is appropriate when the factors are not dimensionally related, for example one factor measures wavelength and another measures temperature.

/OR=order

Specifies the regression (fitting) order, the d parameter in Cleveland (1977):

order=0: Fits a constant to the locally-weighted neighbors around each point.

order=1: Fits a line to the locally-weighted neighbors around each point (Lowess smoothing).

order=2: Default; fits a quadratic (Loess smoothing).

/PASS=passes

The number of iterations of local weighting and regression fitting performed. The minimum is 1 and the default is 4. In Cleveland (1977), passes corresponds to r.

/R [=robust]

Set robust to nonzero to use a robust fitting method that uses a bisquare weight function instead of the normal tricube weight function. This corresponds to the “symmetric” family in Cleveland et al. (1992). The robust method is less affected by outliers. The default is robust = 0, which is the “gaussian” family in Cleveland et al. (1992).

/SMTH=sf

Another way to express the number of values in the smoothing window, 0 ≤ sf ≤ 1. The default is 0.5.

To compute neighbors from sf, use:

neighbors = 1+floor(sf*numpnts(srcWaveName)).

Use either /N or /SMTH, but not both.
Loess

Basic Algorithm
The basic locally-weighted regression algorithm fits a constant, line, or quadratic to each point of the source data, using data that falls within the given span of neighbors over the factor data. Data outside of the span is ignored (given a weight of zero), and data inside the span is given a weight that depends on the distance of the data from the point being evaluated: data closer to the point being evaluated have higher weights and have a greater affect on the fit.

The basic algorithm uses the “tricube” weighting function to emphasize near values and deemphasize far values. For the one-factor case (simple XY data), the weighting function can be expressed as:

\[ w_i = \left( 1 - \frac{x - x_i}{\max_q (x - x_j)} \right)^3 \]

where \( \max_q (x - x_j) \) is the maximum Euclidean distance of the q factor values within the given span from the factor point \( x \) whose observation \( y \) value is being evaluated.

The weights are applied to the factor values in the span to compute the constant, linear, or quadratic regression at \( x \).

When multiple factors are used, the Euclidean distance is computed using one dimension per factor. The default is to normalize each factor’s range by the standard deviation of that factor’s values before computing the Euclidean distances. When factors are dimensionally equal, use the \(/NORM=0\) option to skip this normalization. (See \(/NORM\), about “dimensionally equal”.)

Robust Algorithm
The robust algorithm adds to the basic algorithm a method to identify and remove outliers by rejecting values that exceed a threshold related to the “median absolute deviation” of the basic regression’s residuals. The remaining values are used to compute robust “bisquare” weighting values:

\[ /TIME=\text{secs} \]

\( \text{ secs is the number of seconds allowed to complete the calculation before either warning (default) or stopping.} \)

If the stop bit (4) of \(/V=\text{verbose}\) is set, the calculation stops after the allotted time. If the diagnostic bit of \(/V=\text{verbose}\) is also set, warnings about the calculation exceeding the allotted time are printed to the history area.

As an example, use \(/TIME=30/V=6\) to abort calculations longer than 30 seconds and print the warning to the history area.

\( /V = \text{verbose} \)

Controls how much information to print to the history area. \text{ verbose} is a bitwise parameter with each bit controlling one aspect:

\( \text{ verbose}=0: \) Prints nothing to the history area (default).

\( \text{ verbose}=1: \) Prints the number of observations, equivalent number of parameters, and residual standard error.

\( \text{ verbose}=2: \) Prints diagnostic information and error messages.

\( \text{ verbose}=4 \) Use with \(/TIME\). If this bit is set, calculations that exceed \text{ secs} seconds are aborted.

Set \text{ verbose} to 6 to both limit the time and print diagnostic and error messages.

\(/V\) alone is the same as \(/V=3\), which prints all information.

\text{ S_info} contains all the informational messages regardless of the value of \text{ verbose}.

\( /Z = z \)

Set \text{ z} to nonzero to prevent an error from stopping execution. Use the \text{ V_flag} variable to see if the smoothing succeeded.
where $e_i$ is the difference between the observed value and the regression’s fitted value, and $\text{median}(|e_i|)$ is evaluated for all the observed values.

These robust weighting values are multiplied with the original weighting values and a new regression (with new residuals) is computed. This process repeats 4 times by default. Use the /PASS flag to specify a different number of repetitions.

Details
Loess sets the variable V_flag to 0 if the smoothing was successful, or to an error code if not. Unlike other operations, the /Z flag allows execution to continue even if input parameters are in error.

Information printed to the history area when /V is set is always stored in the S_info string, even if /V=0 (the default). S_Info also contains the error message text if V_flag is an error code.

The error messages are described in Cleveland et al. (1992). They are often more dire than they seem.

The error message “Span too small. Fewer data values than degrees of freedom” usually means that the /SMTH or /N values are too small. The error code returned in V_Flag for this case is 1106.

The “Extrapolation not allowed with blending” (V_Flag = 1115) error usually means that the destination factors are trying to compute observations outside of the source factors domain without specifying /E=1. This happens if the /DEST destWaveName already exists and has X scaling that extends beyond the X scaling of srcWaveName. The solution is either kill the /DEST wave, limit the X scaling to the domain of the source wave, or use /E=1.

Memory Details
Loess requires a lot of memory, especially with the /CONF flag. Even without /CONF, the memory allocations exceed this approximation:

Number of bytes allocated = number of points in srcWaveName * 216

With /CONF, Loess can allocate large amounts of memory, approximately N*N*8 bytes, where N is the number of points in srcWaveName. The 2GB memory limit of 32-bit addressing limits srcWaveName to approximately 10,000 points when using /CONF.

More precisely, the memory allocation may be approximated by this function:

```
Function ComputeLoessMemory(srcPoints, numFactorsWaves, doConfidence)
Variable srcPoints // number of points in srcWave, aka N
Variable numFactorsWaves// 1 or number of factors (independent variables)
Variable doConfidence // true if /CONF is specified
Variable doubles= 9 * srcPoints // 9 allocated double arrays
    doubles += 5 * numFactorsWaves * srcPoints // 5 more arrays
    doubles += (1+numFactorsWaves) * srcPoints // another array
    doubles += (4+5) * srcPoints // two more arrays
if( doConfidence )
    doubles += srcPoints*srcPoints // one HUGE array
endif
Variable bytes= doubles * 8
return bytes
End
```

log

\[ \log(n) = \log(x) \]

The log function returns the log base 10 of num.
It returns -INF if num is 0, and returns NaN if num is less than 0.
To compute a logarithm base n use the formula:

\[ \log_n(x) = \frac{\log(x)}{\log(n)}. \]

See Also
The ln function.

logNormalNoise

\[ \log\text{NormalNoise}(m, s) \]

The logNormalNoise function returns a pseudo-random value from the lognormal distribution function whose probability distribution function is

\[ f(x, m, s) = \frac{1}{xs\sqrt{2\pi}} \exp \left\{ -\frac{[\ln(x) - m]^2}{2s^2} \right\}, \]

with a mean \( \exp \left( m + \frac{1}{2}s^2 \right) \),
and variance \( \exp \left( 2m^2 + s^2 \right) \left[ \exp(s^2) - 1 \right] \).

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use SetRandomSeed. The algorithm uses the Mersenne Twister random number generator.

See Also
The SetRandomSeed operation.
Noise Functions on page III-372.
Chapter III-12, Statistics for a function and operation overview.
The LombPeriodogram is used in spectral analysis of signal amplitudes specified by srcAmpWave which are sampled at possibly random sampling times given by srcTimeWave. The only assumption about the sampling times is that they are ordered from small to large time values. The periodogram is calculated for either a set of frequencies specified by srcFreqWave (slow method) or by the flags /FR and /NF (fast method). Unless you specify otherwise, the results of the operation are stored by default in W_LombPeriodogram and W_LombProb in the current data folder.

Flags

/DESP=dataFolderAndName

Saves the computed P-values in a wave specified by dataFolderAndName. The destination wave will be created or overwritten if it already exists. dataFolderAndName can include a full or partial path with the wave name.

Creates by default a wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-71 for details.

If this flag is not specified, the operation saves the P-values in the wave W_LombProb in the current data folder.

/DEST=dataFolderAndName

Saves the computed periodogram in a wave specified by dataFolderAndName. The destination wave will be created or overwritten if it already exists. dataFolderAndName can include a full or partial path with the wave name (/DEST=root:bar:destWave).

Creates by default a wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-71 for details.

If this wave is not specified the operation saves the resulting periodogram in the wave W_LombPeriodogram in the current data folder.

/FR=fRes

Use /FR to specify the frequency resolution of the output. This flag is used together with /NF to specify the range of frequencies for which the periodogram is computed. Note that fRes is also the lowest frequency in the output.

/NF=numFreq

Use /NF to specify the number of frequencies at which the periodogram is computed. The range of frequencies of the periodogram is then [fRes, (numFreq-1)*fRes].

/Q

Quiet mode; suppresses printing results in the history area.

/Z

Do not report any errors.

Details

The LombPeriodogram (sometimes referred to as "Lomb-Scargle" periodogram) is useful in detection of periodicities in data. The main advantage of this approach over Fourier analysis is that the data are not required to be sampled at equal intervals. For an input consisting of N points this benefit comes at a cost of an O(N^2) computations which becomes prohibitive for large data sets. The operation provides the option of computing the periodogram at equally spaced (output) frequencies using /FR and /NF or at completely arbitrary set of frequencies specified by srcFreqWave. It turns out that when you use equally spaced output frequencies the calculation is more efficient because certain parts of the calculation can be factored.

The Lomb periodogram is given by
lorentzianNoise

lorentzianNoise(a, b)
The function returns a pseudo-random value from a Lorentzian distribution

\[ f(x) = \frac{1}{\pi} \frac{(b / 2)}{(x - a)^2 + (b / 2)^2} . \]
Here \( a \) is the center and \( b \) is the full line width at half maximum (FWHM).

SetRandomSeed, enoise, gnoise.
Noise Functions on page III-372.
Chapter III-12, Statistics for a function and operation overview.

LowerStr

LowerStr(\( str \))
The LowerStr function returns a string expression identical to \( str \) except that all upper-case ASCII characters are converted to lower-case.

See Also
The UpperStr function.

Macro

Macro macroName([parameters]) [:macro type]
The Macro keyword introduces a macro. The macro will appear in the Macros menu unless the procedure file has an explicit Macros menu definition. See Chapter IV-4, Macros and Macro Syntax on page IV-116 for further information.

MacroList

MacroList(matchStr, separatorStr, optionsStr)
The MacroList function returns a string containing a list of the names of user-defined procedures that start with the Proc, Macro, or Window keywords that also satisfy certain criteria. Note that if the procedures need to be compiled, then MacroList may not list all of the procedures.

Parameters
Only macros having names that match \( matchStr \) string are listed. See WaveList for examples.
\( separatorStr \) is appended to each macro name as the output string is generated. \( separatorStr \) is usually ";" for list processing (See Processing Lists of Waves on page IV-193 for details on list processing).
\( optionsStr \) is used to further qualify the macros. It is a string containing keyword-value pairs separated by commas. Available options are:

KIND:\( nk \) Determines the kind of procedure returned.
\( nk=1 \): List Proc procedures.
\( nk=2 \): List Macro procedures.
\( nk=4 \): List Window procedures.
\( nk \) can be the sum of these values to match multiple procedure kinds. For example, use 3 to list both Proc and Macro procedures.

NPARAMS:\( np \) Restricts the list to macros having exactly \( np \) parameters. Omitting this option lists macros having any number of parameters.

SUBTYPE:\( typeStr \) Lists macros that have the type \( typeStr \). That is, you could use ButtonControl as \( typeStr \) to list only macros that are action procedures for buttons.

WIN:\( windowNameStr \) Lists macros that are defined in the named procedure window. “Procedure” is the name of the built-in procedure window.

Note: Because \( optionsStr \) keyword-value pairs are comma separated and procedure window names can have commas in them, the WIN: keyword must be the last one specified.
Examples
To list all Macros with three parameters:
Print MacroList("**",";","KIND:2,NPARAMS:3")
To list all Macro, Proc, and Window procedures in the main procedure window whose names start with b:
Print MacroList("b*",";","WIN:Procedure")

See Also
The DisplayProcedure operation and the FunctionList, OperationList, StringFromList, and WinList functions.
For details on procedure subtypes, see Procedure Subtypes on page IV-199, as well as Button, CheckBox, SetVariable, and PopupMenu.

magsqr
magsqr (z)
The magsqr function returns the sum of the squares of the real and imaginary parts of the complex number z, that is, the magnitude squared.

Examples
Assume waveCmplx is complex and waveReal is real.
waveReal = sqrt(magsqr(waveCmplx))
sets each point of waveReal to the magnitude of the complex points in waveCmplx.
You may get unexpected results if the number of points in waveCmplx differs from the number of points in waveReal because of interpolation. See Mismatched Waves on page II-77 for details.

See Also
The cabs function.
WaveMetrics provides Igor Technical Note 006, "DSP Support Macros" which uses the magsqr function to compute the magnitude of FFT data, and Power Spectral Density with options such as windowing and segmenting. See the Technical Notes folder. Some of the techniques discussed there are available as Igor procedure files in the "WaveMetrics Procedures:Analysis:" folder.

Make
Make [flags] waveName [, waveName]...
Make [flags] waveName = {n0,n1,...}...
Make [flags] waveName = {{n0,n1,...},{n0,n1,...},...}...
The Make operation creates the named waves. Use braces to assign data values when creating the wave.

Flags
/B Makes 8-bit signed integer waves or unsigned waves if /U is present.
/C Makes complex waves.
/D Makes double precision waves.
/DF Wave holds data folder references.
See Data Folder References on page IV-77 for more discussion.
/FREE Creates a free wave. Allowed only in functions and only if a simple name or wave reference structure field is specified.
See Free Waves on page IV-89 for more discussion.
/I Makes 32-bit signed integer waves or unsigned waves if /U is present.
/L Makes 64-bit signed integer waves or unsigned waves if /U is present. Requires Igor Pro 7.00 or later.
/N=n n is the number of points each wave will have. If n is an expression, it must be enclosed in parentheses: Make/N=(myVar+1) aNewWave
Make

/N=(n1, n2, n3, n4)

n1, n2, n3, n4 specify the number of rows, columns, layers and chunks each wave will have. Trailing zeros can be omitted (e.g., /N=(n1, n2, 0, 0) can be abbreviated as /N=(n1, n2)).

/O Overwrites existing waves in case of a name conflict. After an overwrite, you cannot rely on the contents of the waves and you will need to reinitialize them or to assign appropriate values.

/R Makes real value waves (default).

/T Makes text waves.

/T=size Makes text waves with pre-allocated storage.
size is the number of bytes preallocated by Igor for each element in each text wave. The waves are not initialized - it is up to you to initialize them.
Preallocation can dramatically speed up text wave assignment when the wave has a very large number of points but only when all strings assigned to the wave are exactly the same size as the preallocation size.

/U Makes unsigned Integer waves.

/W Makes 16-bit signed integer waves or unsigned waves if /U is present.

/WAVE Wave holds wave references.
See Wave References on page IV-70 for more discussion.

/Y=type See Wave Data Types below.

Wave Data Types
You can use /Y=(numType) to set the data type instead of the /B, /C, /D, /I, /L, /R, /T, /U, and /W data type flags. See WaveType function for numType values. The /Y flag overrides other type flags. You still need to use the explicit data type flags to control the automatic wave reference created by the compiler if you use the wave in an assignment statement in the same function; see WAVE Reference Types on page IV-72 for details.

Details
Unless overridden by the flags, the created waves have the default length, type, precision, units and scaling. The factory defaults are:

Note: The preferred precision set by the Miscellaneous Settings dialog only presets the Make Waves dialog checkbox and determines the precision of imported waves. It does not affect the Make operation.

The SetScale, Duplicate, and Redimension operations.

MakeIndex

MakeIndex [/A/C/R] sortKeyWaves, indexWaveName

The MakeIndex operation sets the data values of indexWaveName such that they give the ordering of sortKeyWaves.

For simple sorting problems, MakeIndex is not needed. Just use the Sort operation.

Parameters
sortKeyWaves is either the name of a single wave, to use a single sort key, or the name of multiple waves in braces, to use multiple sort keys.
indexWaveName must specify a numeric wave.

All waves must be of the same length and must not be complex.

Flags
/A Alphanumeric. When sortKeyWaves includes text waves, the normal sorting places “wave1” and “wave10” before “wave9”. Use /A to sort the number portion numerically, so that “wave9” is sorted before “wave10”.
/C Case-sensitive. When sortKeyWaves includes text waves, the ordering is case-insensitive unless you use the /C flag which makes it case-sensitive.
/LOC Performs a locale-aware sort.
When sortKeyWaves includes text waves, the text encoding of the text waves’ data is taken into account and sorting is done according to the sorting conventions of the current system locale. This flag is ignored if the text waves’ data encoding is unknown, binary, Symbol, or Dingbats. This flag cannot be used with the /A flag. See Details for more information.
/R Reverse the index so that ordering is from largest to smallest.

Details
MakeIndex is used in preparation for a subsequent IndexSort operation. If /R is used the ordering is from largest to smallest. Otherwise it is from smallest to largest.

When the /LOC flag is used, the bytes stored in the text wave at each point are converted into a Unicode string using the text encoding of the text wave data. These Unicode strings are then compared using OS specific text comparison routines based on the locale set in the operating system. This means that the order of sorted items may differ when the same sort is done with the same data under different operating systems or different system locales.

When /LOC is omitted the sort is done on the raw text without regard to the waves’ text encoding.

See Also
MakeIndex and IndexSort Operations on page III-133.

MandelbrotPoint

MandelbrotPoint(x, y, maxIterations, algorithm)

The MandelbrotPoint function returns a value between 0 and maxIterations based on the Mandelbrot set complex quadratic recurrence relation \( z[n] = z[n-1]^2 + c \) where \( x \) is the real component of \( c \), \( y \) is the imaginary component of \( c \) and \( z[0] = 0 \).

The returned value is the number of iterations the equation was evaluated before \( |z[n]| > 2 \) (the escape radius of the Mandelbrot set), or maxIterations, whichever is less.
MarcumQ

Parameters

- algorithm=0  The "Escape Time" algorithm returns the integer n which is the number of iterations until \(|z[n]| > 2\).
- algorithm=1  The "Renormalized Iteration Count Algorithm" algorithm returns a floating point value which is a refinement of the number of iterations n by adding the quantity:
  \[
  5 - \ln\left( \ln\left( |z[n+4]| \right) \right) / \ln(2)
  \]
  (which requires four more iterations of the recurrence relation). The returned value is clipped to maxIterations.

See Also
The “MultiThread Mandelbrot Demo” experiment.

References
http://en.wikipedia.org/wiki/Mandelbrot_set
http://linas.org/art-gallery/escape/escape.html

MarcumQ

MarcumQ(m, a, b)
The MarcumQ function returns the generalized Q-function defined by the integral

\[
Q_m(a, b) = \int_b^\infty \left( \frac{u}{a} \right)^{m-1} \exp\left( -\frac{(a^2 + u^2)}{2} \right) I_{m-1}(au) du
\]

where \(I_k\) is the modified Bessel function of the first kind and order \(k\).

Its applications have been primarily in the fields of communication and detection theory. However, an interesting interpretation of its result with \(m=1\) and appropriate parameter scaling is the fractional power of a two-dimensional circular Gaussian function within a displaced circular aperture.

Depending on the input arguments, the MarcumQ function may be computationally intensive but you can abort the calculation at any time.

References

MarkPerfTestTime

MarkPerfTestTime idval
Use the MarkPerfTestTime operation for performance testing of user-defined functions in conjunction with SetIgorOption DebugTimer. When used between SetIgorOption DebugTimer, Start and SetIgorOption DebugTimer, Stop, MarkPerfTestTime stores the ID value and the time of the call in a buffer. When SetIgorOption DebugTimer, Stop is called the contents of the buffer are dumped to a pair of waves: W_DebugTimerIDs will contain the ID values and W_DebugTimerVals will contain the corresponding times of the calls relative to the very first call. The timings use the same high precision mechanism as the StartMSTimer and StopMSTimer calls.

By default, SetIgorOption DebugTimer, Start allocates a buffer for up to 10000 entries. You can allocate a different sized buffer using SetIgorOption DebugTimer, Start=bufsize.

See Also
SetIgorOption, StartMSTimer, and StopMSTimer.

Additional documentation can be found in an example experiment, PerformanceTesting.pxp, and a WaveMetrics procedure file, PerformanceTestReport.ipf.
MatrixCondition

MatrixCondition(wave2D, mode)

MatrixCondition returns the estimated reciprocal of the condition number of a 2D square matrix wave2D.

The condition number is the product of the norm of the matrix with the norm of the inverse of the matrix (see details below). The type of norm is determined by the value of the mode parameter. 1-norm is used if mode is 1 and infinity-norm is used otherwise.

The MatrixCondition function was added in Igor Pro 7.00.

Details

The function uses LAPACK routines to estimate the reciprocal condition number by first obtaining the norm of the input matrix and then using LU decomposition to obtain the norm of the inverse of the matrix. The estimate returned is

\[ \text{reciprocalCon} = \frac{1}{\|\text{wave2D}\| \|\text{wave2D}^{-1}\|}, \]

where the norms are selected by the choice of the mode parameter. The 1-norm of matrix A with elements \(a_{ij}\) is defined as

\[ \|A\|_1 = \max_{1 \leq j \leq n} \sum_{i=1}^{m} |a_{ij}|, \]

and the infinity-norm is defined by

\[ \|A\|_{\infty} = \max_{1 \leq i \leq m} \sum_{j=1}^{n} |a_{ij}|. \]

The function returns a NaN if there is any error in the input parameters.

References

http://en.wikipedia.org/wiki/Matrix_norm

See Also

MatrixSVD provides a condition number for L2 norm using the ratio of singular values.

The MatrixOp operation for more efficient matrix operations.

Matrix Math Operations on page III-137 for more about Igor’s matrix routines.

MatrixConvolve

MatrixConvolve [ /R=roiWave] coefMatrix, dataMatrix

The MatrixConvolve operation convolves a small coefficient matrix coefMatrix into the destination dataMatrix.

Flags

/ R=roiWave  
Modifies only data contained inside the region of interest. The ROI wave should be 8-bit unsigned with the same dimensions as dataMatrix. The interior of the ROI is defined by zeros and the exterior is any nonzero value.

Details

On input coefMatrix contains an NxM matrix of coefficients where N and M should be odd. Generally N and M will be equal. If N and M are greater than 13, it is more efficient to perform the using the Fourier transform (see FFT).

The convolution is performed in place on the data matrix and is acausal, i.e., the output data is not shifted.
MatrixCorr

Edges are handled by replication of edge data.

When `dataMatrix` is an integer type, the results are clipped to limits of the given number type. For example, unsigned byte is clipped to 0 to 255.

MatrixConvolve works also when both `coefMatrix` and `dataMatrix` are 3D waves. In this case the convolution result is placed in the wave `M_Convolution` in the current data folder, and the optional `/R=roiWave` is required to be an unsigned byte wave that has the same dimensions as `dataMatrix`.

This operation does not support complex waves.

See Also
MatrixFilter and ImageFilter for filter convolutions.

Matrix Math Operations on page III-137 for more about Igor’s matrix routines.

The Loess operation.

MatrixCorr

```
MatrixCorr [/COV] [/DEGC] waveA [, waveB]
```

The MatrixCorr operation computes the correlation or covariance or degree of correlation matrix for the input 1D wave(s).

If we denote elements of `waveA` by \{x_i\} and elements of `waveB` by \{y_i\} then the correlation matrix for these waves is the vector product of the form:

\[
\begin{bmatrix}
  x_1 \\
  x_2 \\
  x_3 \\
  \vdots \\
  x_n
\end{bmatrix}
\begin{bmatrix}
  y_1 & y_2 & y_3 & \ldots & y_n
\end{bmatrix}^* =
\begin{bmatrix}
  x_1y_1^* & x_1y_2^* & x_1y_3^* & \ldots & x_1y_n^* \\
  x_2y_1^* & x_2y_2^* & x_2y_3^* & \ldots & x_2y_n^* \\
  x_3y_1^* & x_3y_2^* & x_3y_3^* & \ldots & x_3y_n^* \\
  \vdots & \vdots & \vdots & \ddots & \vdots \\
  x ny_1^* & x ny_2^* & x ny_3^* & \ldots & x ny_n^*
\end{bmatrix}
\]

where * denotes complex conjugation. If you use the optional `waveB` then the matrix is the cross correlation matrix. `waveB` must have the same length of `waveA` but it does not have to be the same number type.

Flags
The flags are mutually exclusive; only one matrix can be generated at a time.

/COV Calculates the covariance matrix.

The covariance matrix for the same input is formed in a similar way after subtracting from each vector its mean value and then dividing the resulting matrix elements by \((n-1)\) where \(n\) is the number of elements of `waveA`.

Results are stored in the M_Corr or M_Covar waves in the current data folder.

/DEGC Calculates the complex degree of correlation. The degree of correlation is defined by:

\[
deg C = \frac{M_{-Covar}}{\sqrt{Var(waveA) \cdot Var(waveB)}},
\]

where `M_Covar` is the covariance matrix and `Var(wave)` is the variance of the wave.

The complex degree of correlation should satisfy: \(0 \leq |deg C| \leq 1\).

Examples
The covariance matrix calculation is equivalent to:

```
Variable N=1/(DimSize(waveA,0)-1)
Variable ma=mean(waveA,-inf,inf)
Variable mb=mean(waveB,-inf,inf)
waveA-=ma
waveB-=mb
MatrixTranspose/H waveB
MatrixMultiply waveA,waveB
M_product*=N

Matrix Math Operations on page III-137 for more about Igor’s matrix routines.

References

MatrixDet

**matrixDet(dataMatrix)**

The MatrixDet function returns the determinant of dataMatrix. The matrix wave must be a real, square matrix or else the returned value will be NaN.

Details
The function calculates the determinant using LU decomposition. If, following the decomposition, any one of the diagonal elements is either identically zero or equal to $10^{-100}$, the return value of the function will be zero.

See Also
The MatrixOp operation for more efficient matrix operations.
Matrix Math Operations on page III-137 for more about Igor’s matrix routines.

MatrixDot

**MatrixDot(waveA, waveB)**

The MatrixDot function calculates the inner (scalar) product for two 1D waves. A 1D wave A represents a vector in the sense:

$$A = \sum \alpha_i \hat{e}_i, \quad \hat{e}_i \text{ is a unit vector.}$$

Given two such waves A and B, the inner product is defined as

$$ip = \sum \alpha_i \beta_i.$$  

When both waveA and waveB are complex and the result is assigned to a complex-valued number MatrixDot returns:

$$ipc = \sum \alpha_i^* \beta_i.$$  

If the result is assigned to a real number, MatrixDot returns:

$$ip = \left|\sum \alpha_i^* \beta_i\right|.$$  

If either waveA or waveB is complex and the result is assigned to a real-valued number, MatrixDot returns:

$$ip = \left|\sum \alpha_i \beta_i\right|.$$  

When the result is assigned to a complex-valued number MatrixDot returns:

$$ipc = \sum \alpha_i \beta_i.$$
MatrixEigenV

See Also
The MatrixOp operation for more efficient matrix operations.
Matrix Math Operations on page III-137 for more about Igor’s matrix routines.

MatrixEigenV

MatrixEigenV [flags] matrixA [, matrixB]
MatrixEigenV computes the eigenvalues and eigenvectors of a square matrix using LAPACK routines.

Flags for General Matrices

/C
Creates complex valued output for real valued input waves. This is equivalent to converting the input to complex, with zero imaginary component, prior to computing the eigenvalues and eigenvectors. The main benefit of this format is that the output has simple packing of eigenvalues and eigenvectors. See the example in the Details for General Matrices section below.

The /C flag was added in Igor Pro 7.00.

/B=balance
Determines how the input matrix should be scaled and or permuted to improve the conditioning of the eigenvalues.

balance=0 (default), 1, 2, or 3, corresponding respectively to N, P, S, or B in the LAPACK routines. Applicable only with the /X flag.

0: Do not scale or permute.
1: Permute.
2: Do diagonal scaling.
3: Scale and permute.

/L
 Calculates for left eigenvectors.

/O
Overwrites matrixWave, requiring less memory.

/R
Calculates for right eigenvectors.

/S=sense
Determines which reciprocal condition numbers are calculated.

sense=0 (default), 1, 2, or 3, corresponding respectively to N, E, V, or B in the LAPACK routines. Applicable only with the /X flag.

0: None.
1: Eigenvalues only.
2: Right eigenvectors.
3: Eigenvalues and right eigenvectors.

If sense is 1 or 3 you must compute both left and right eigenvectors.

NOTE: /S is applicable only with the /X flag or for the generalized eigenvalue problem.

/X
Uses LAPACK expert routines, which require additional parameters (see /B and /S flags). The operation creates additional waves:

The W_MatrixOpInfo wave contains in element 0 the ILO, in element 1 the IHI, and in element 2 the ABNRM from the LAPACK routines.

The wave W_MatrixRCONDE contains the reciprocal condition numbers for the eigenvalues.

The wave W_MatrixRCONDV contains the reciprocal condition number for the eigenvectors.
MatrixEigenV

Flags for Symmetric Matrices

/SYM Computes the eigenvalues of an NxN symmetric matrix and stores them in the wave W_eigenValues. You must specify this flag if you want to use the special routines for symmetric matrices. The number of eigenvalues is stored in the variable V_npnts. Because W_eigenValues has N points, only the first V_npnts will contain relevant eigenvalues.

When using this flag with complex input the matrix is assumed to be Hermitian.

/EVEC Computes eigenvectors in addition to eigenvalues. Eigenvectors will be stored in the wave M_eigenVectors, which is of dimension NxN. The first V_npnts columns of the wave will contain the V_npnts eigenvectors corresponding to the eigenvalues in W_eigenValues. /EVEC must be preceded by /SYM.

/RNG={method,low,high} Determines what is computed:

method=0: Computes all the eigenvalues or eigenvectors (default).
method=1: Computes eigenvalues for low and high double precision range.
method=2: Computes eigenvalues for low and high integer indices (1 based). For example, to compute the first 3 eigenvalues use: /RNG={2,1,3}.

/RNG must be preceded by /SYM.

Flags for Generalized Eigenvalue Problem
These are the same flags as for general (non-symmetric) matrices above except for /O and /X which are not supported for the generalized eigenvalue solution.

Common Flags

/Z No error reporting (except for setting V_flag).

Details

There are three mutually exclusive branches for the operation. The first is designed for a square matrix input matrixA. The operation computes the solution to the problem

\[ Ax = \lambda x, \]

where \( A \) is the input matrix, \( x \) is an eigenvector and \( \lambda \) is an eigenvalue.

The second branch is designed for symmetric matrices \( A \), i.e., when \( A = A^T \), where the superscript \( T \) denotes a transpose.

The third branch of the operation is designed to solve the generalized eigenvalue problem,

\[ Ax = \lambda Bx, \]

where \( A \) and \( B \) are square matrices, \( x \) is an eigenvector and \( \lambda \) is an eigenvalue.

Each branch of the operation supports its own set of flags as shown above. All branches support input of single and double precision in real or complex waves. If you specify both matrix\( A \) and matrix\( B \) then they must have the same number type.

Details for General Matrices

The eigenvalues are returned in the 1D complex wave W_eigenValues. The eigenvectors are returned in the 2D wave M_R_eigenVectors or M_L_eigenVectors.

The calculated eigenvectors are normalized to unit length.

Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.
If the $j$th eigenvalue is real, then the corresponding eigenvector $u(j) = M[[j]]$ is the $j$th column of $M_L_{eigenVectors}$ or $M_R_{eigenVectors}$. If the $j$th and $(j+1)$th eigenvalues form a complex conjugate pair, then $u(j) = M[[j]] + iM[[j+1]]$ and $u((j+1)) = M[[j]] - iM[[j+1]]$.

**Example**

Function TestMatrixEigenVReal()
Make/D/N=(2,2)/O eee={{0,1},{-1,0}}
MatrixEigenV/R eee
Wave W_eigenvalues, M_R_{eigenVectors}
MatrixOP/O firstEV=cmplx(col(M_R_{eigenVectors},0),col(M_R_{eigenVectors},1))
MatrixOP/O aa=eee x firstEV - W_eigenvalues[0]*firstEV
Print aa
End

Function TestMatrixEigenVComplex()
Make/D/N=(2,2)/O eee={{0,1},{-1,0}}
MatrixEigenV/R/C eee
Wave W_eigenvalues, M_R_{eigenVectors}
MatrixOP/O aa=eee x col(M_R_{eigenVectors},0) - W_eigenValues[0]*col(M_R_{eigenVectors},0)
Print aa
End

**Details for Symmetric Matrices**
The LAPACK routines that compute the eigenvalues and eigenvectors of symmetric matrices claim to use the Relatively Robust Representation whenever possible. If your matrix is symmetric you should use this branch of the operation (/SYM) for improved accuracy.

**Details for Generalized Eigenvalue Problem**
Here the right eigenvectors (/R) are solutions to the equation

$$Ax = \lambda Bx,$$

and the left eigenvectors (/L) are solutions to

$$x^H A = \lambda x^H B,$$

where the superscript $H$ denotes the conjugate transpose.

When both $matrixA$ and $matrixB$ are real valued, the operation creates the following waves in the current data folder:

- $W_{alphaValues}$ Contains the complex alpha values.
- $W_{betaValues}$ Contains the real-valued denominator such that the eigenvalues are given by $\lambda_j = \frac{\alpha_j}{\beta_j}$.
- $M_{leftEigenVectors}$ and $M_{rightEigenVectors}$ Real valued waves where columns correspond to eigenvectors of the equation.

Every point in the wave $W_{alphaValues}$ corresponds to an eigenvalue. When the imaginary part of $W_{alphaValues}[j]$ is zero, the eigenvalue is real and the corresponding eigenvector is also real e.g., $M_{rightEigenVectors}[[j]]$. When the imaginary part is positive then there are two eigenvalues that are complex-conjugates of each other with corresponding complex eigenvectors given by\[\text{cmplx}(M_{rightEigenVectors}[][j],M_{rightEigenVectors}[][j+1])\]and\[\text{cmplx}(M_{rightEigenVectors}[][j],-M_{rightEigenVectors}[][j+1])\]

When both $matrixA$ and $matrixB$ are complex the operation creates the complex waves:

- $W_{alphaValues}$, $W_{betaValues}$, $M_{leftEigenVectors}$, $M_{rightEigenVectors}$

with the ratio $W_{alphaValues}[j]/W_{betaValues}[j]$ expressing the generalized eigenvalue. The corresponding $M_{leftEigenVectors}[[j]]$ and $M_{rightEigenVectors}[[j]]$ are the respective left and right eigenvectors.
The simplicity of the complex case suggests that when \textit{matrixA} and \textit{matrixB} are real it is best to convert them to complex waves prior to executing \texttt{matrixEigenV}.

Depending on the choice of /S the operation also calculates the reciprocal condition number for the eigenvalues (stored in \texttt{W.reciprocalConditionE}) and the reciprocal condition number of the eigenvectors (stored in \texttt{W.reciprocalConditionV}). Note that a zero entry in \texttt{W.reciprocalConditionV} implies that the eigenvalues could not be ordered.

\textbf{See Also}
\textbf{Matrix Math Operations} on page III-137 for more about Igor's matrix routines and for background references with details about the LAPACK libraries.

Symmetric matrices can also be decomposed using the \texttt{MatrixSchur} operation and using \texttt{MatrixOp chol}.

\textbf{MatrixFilter}

\texttt{MatrixFilter \{flags\} Method dataMatrix}

The MatrixFilter operation performs one of several standard image filter type operations on the destination \texttt{dataMatrix}.

\textbf{Parameters}

\textit{Method} selects the filter type. \textit{Method} is one of the following names:

- \texttt{avg} \textit{n}x\textit{n} average filter.
- \texttt{FindEdges} 3x3 edge finding filter.
- \texttt{gauss} \textit{n}x\textit{n} gaussian filter.
- \texttt{gradN, gradNW, gradW, gradSW, gradS, gradSE, gradE, gradNE} 3x3 North, NorthWest, West, ... pointing gradient filter.
- \texttt{median} \textit{n}x\textit{n} median filter. You can assign values other than the median by specifying the desired rank using the /M flag.
- \texttt{min} \textit{n}x\textit{n} minimum rank filter.
- \texttt{max} \textit{n}x\textit{n} maximum rank filter.
- \texttt{NanZapMedian} \textit{n}x\textit{n} filter that only affects data points that are NaN. Replaces them with the median of the \textit{n}x\textit{n} surrounding points. Unless /P is used, automatically cycles through matrix until all NaNs are gone or until \textit{cols*rows} iterations.
- \texttt{point} 3x3 point finding filter \texttt{8*center-outer}.
- \texttt{sharpen} 3x3 sharpening \texttt{filter=(12*center-outer)/4}.
- \texttt{sharpenmore} 3x3 sharpening \texttt{filter=(9*center-outer)}.

\textbf{Note}: The thin keyword to MatrixFilter will be removed someday. The functionality will be available — just not as a part of MatrixFilter. The /R flag does not apply to the lame duck thin keyword.
MatrixGaussJ

**Flags**

/B=b  
Specifies value that is considered background. Used with thin. If object is black on white background, use 255. If object is white on a black background, use 0.

/F=value  
Specifies the value in the ROI wave that marks excluded pixels. value is either 0 or 1.  
This flag was added in Igor Pro 7.00.  
By default, and for compatibility with Igor Pro 6, value=0. Use /F=1 if your ROI wave contains 1 for pixels to be excluded.

/M=rank  
Assigns a pixel value other than the median when used with the median filter. Valid rank values are between 0 and n^2-1 (for the default median rank=int(n^2/2)).

/N=n  
For any method described above as “n x n”, you can specify that the filtering kernel will be a square matrix of size n. In the absence of the /N flag, the default size is 3.

/P=p  
Filter passes over the data p times. The default is one pass.

/R=roiWave  
Only the data outside the region of interest will be modified. roiWave should be an 8-bit unsigned wave with the same dimensions as the data matrix. The exterior of the ROI is defined by zeros and the interior is any nonzero value.

/T  
Applies the thinning algorithm of Zhang and Suen with the thin parameter. The wave M_MatrixFilter contains the results; the input wave is not overwritten.

**Details**

This operation does not support complex waves.

**See Also**

ImageFilter operation for additional options. Matrix Math Operations on page III-137 for more about Igor’s matrix routines. The Loess operation.

**References**

MatrixGaussJ

**MatrixGaussJ**  
**matrixA**, **vectorsB**  
The MatrixGaussJ operation solves matrix expression A*x=b for column vector x given matrix A and column vector b. The operation can also be used to calculate the inverse of a matrix.

**Parameters**

*matrixA* is a NxN matrix of coefficients and *vectorsB* is a NxM set of right-hand side vectors.

**Details**

On output, the array of solution vectors x is placed in M_x and the inverse of A is placed in M_Inverse.

If the result is a singular matrix, V_flag is set to 1 to indicate the error. All other errors result in an alert, and abort any calling procedure.

All output objects are created in the current data folder.

An error is generated if the dimensioning of the input arrays is invalid.

This routine is provided for completeness only and is not recommended for general work (use LU decomposition — see MatrixLUD). MatrixGaussJ does calculate the inverse matrix but that is not generally needed either.

**See Also**

Matrix Math Operations on page III-137 for more about Igor’s matrix routines. The MatrixLUD operation.
MatrixGLM

MatrixGLM [/Z] matrixA, matrixB, waveD
The MatrixGLM operation solves the general Gauss-Markov Linear Model problem (GLM) which minimizes the 2-norm of a vector \( y \)

\[
\min \|y\|_2 \quad \text{subject to} \quad d = Ax + By.
\]

A is matrixA (an NxM wave), B is matrixB (an NxP wave), and d is provided by waveD which is a 1D wave of N rows. The vectors x and y are the results of the calculation; they are stored in output waves Mat_X and Mat_Y in the current data folder.

Flags

/Z In the event of an error, MatrixGLM will not return the error to Igor, which would cause procedure execute to abort. Your code should use the V_flag output variable to detect and handle errors.

Details

All input waves must have the same numeric type. Supported types are single-precision and double-precision floating point, both real and complex. The output waves Mat_X and Mat_Y have the same numeric type as the input.

The LAPACK algorithm assumes that \( M \leq N \leq M+P \) and

\[
\text{rank}(A) = M,
\]

\[
\text{rank}(AB) = N.
\]

Under these assumptions there is a unique solution x and a minimal 2-norm solution y, which are obtained using a generalized QR factorization of A and B. If the operation completes successfully the variable V_Flag is set to zero. Otherwise it contains a LAPACK error code.

Output Variables

V_flag Set to 0 if MatrixGLM succeeds or to a LAPACK error code.

See Also

Matrix Math Operations on page III-137 for more about Igor's matrix routines and for background references with details about the LAPACK libraries.

MatrixInverse

MatrixInverse [flags] srcWave
The MatrixInverse operation calculates the inverse or the pseudo-inverse of a square matrix. srcWave may be real or complex.

MatrixInverse saves the result in the wave M_Inverse in the current data folder.
MatrixLinearSolve

Flags

/D  Creates the wave W_W that contains eigenvalues of the singular value decomposition (SVD) for the pseudo-inverse calculation. If one or more of the eigenvalues are small, the matrix may be close to singular.

/G  Calculates only the direct inverse; does not affect calculation of pseudo-inverse. By default, it calculates the inverse of the matrix using LU decomposition. The inverse is calculated using Gauss-Jordan method. The only advantage in using Gauss-Jordan is that it is more likely to flag singular matrices than the LU method.

/O  Overwrites the source with the result.

/P  Calculates the pseudo-inverse of a square matrix using the SVD algorithm. The calculated pseudo-inverse is a unique minimal solution to the problem:

$$\min_{X} \|AX - I_n\|_F,$$

Example

Make/N=(2,2) mat0={2,3},1,7}  // Creates wave M_inverse
MatrixInverse mat0  // Check the results
MatrixOp/O mat1=M_inverse x mat0  // Verify that you got the identity matrix

See Also

The MatrixOp operation for more efficient matrix operations.

Matrix Math Operations on page III-137 for more about Igor's matrix routines.

References

See sec. 5.5.4 of:

MatrixLinearSolve

MatrixLinearSolve [flags] matrixA matrixB

The MatrixLinearSolve operation solves the linear system $matrixA \cdot X = matrixB$ where $matrixA$ is an N-by-N matrix and $matrixB$ is an N-by-NRHS matrix of the same data type.
MatrixLinearSolveTD

Flags

/M=method  Determines the solution method which best suites input matrixA.

method=1:  Uses simple LU decomposition (default). See also LAPACK documentation for SGESV, CGESV, DGESV, and ZGESV.

Creates the wave W_IPIV that contains the pivot indices that define the permutation matrix P. Row (i) if the matrix was interchanged with row ipiv(i).

method=2:  If matrixA is band diagonal, you also have to specify /D. See also LAPACK documentation for SGBSV, CGBSV, DGBSV, and ZGBSV.

Creates the wave W_IPIV, which contains the pivot indices that define the permutation matrix P. Row (i) if the matrix was interchanged with row ipiv(i). Also note that if you are using the /O flag, the overwritten waves may have a different dimensions.

method=4:  For tridiagonal matrix; still expecting full matrix in matrixA, but it will ignore the data in the elements outside the 3 diagonals. See also LAPACK documentation for SGTSV, CGTSV, DGTSV, and ZGTSV.

method=8:  Symmetric/hermitian. See also LAPACK documentation for SPOSV, CPOSV, DPOSV, and ZPOSV.

method=16:  Complex symmetric (complex only). See also LAPACK documentation for CSYSV and ZSYSV.

/D={sub,super}  Specifies a band diagonal matrix. The subdiagonal (sub) and superdiagonal (super) size must be positive integers.

/L  Uses the lower triangle of matrixA. /L and /U are mutually exclusive flags.

/U  Uses the upper triangle of matrixA. /U is the default.

/O  Overwrites matrixA and matrixB with the results of the operation. This will save on the amount of memory needed.

/Z  No error reporting.

Details

If /O is not specified, the operation also creates the n-by-n wave M_A and the n-by-nrhs solution wave M_B. The variable V_flag is created by the operation. If the operation completes successfully, V_flag is set to zero, otherwise it is set to the LAPACK error code.

See Also

Matrix Math Operations on page III-137 for more about Igor’s matrix routines and for background references with details about the LAPACK libraries.

MatrixLinearSolveTD

MatrixLinearSolveTD [/Z] upperW, mainW, lowerW, matrixB

The MatrixLinearSolveTD operation solves the linear system TDMatrix*X = matrixB. In the matrix product on the left hand side, TDMatrix is a tridiagonal matrix with upper diagonal upperW, main diagonal mainW, and lower diagonal lowerW. It solves for vector(s) X depending on the number of columns (NRHS) in matrixB.

Flags

/Z  No error reporting.

Details

The input waves can be single or double precision (real or complex). Results are returned in the wave M_TDLinearSolution in the current data folder. The wave mainW determines the size of the main diagonal
MatrixLLS

(N). All other waves must match it in size with upperW and mainW containing one less point and matrixB consisting of N-by-NRHS elements of the same data type.

MatrixLinearSolveTD should be more efficient than MatrixLinearSolve with respect to storage requirements.

MatrixLinearSolveTD creates the variable V_flag, which is zero when it finishes successfully.

See Also
Matrix Math Operations on page III-137; the MatrixLinearSolve and MatrixOp operations.

MatrixLLS

MatrixLLS [/O/Z/M=method] matrixA matrixB

The MatrixLLS operation solves overdetermined or underdetermined linear systems involving MxN matrixA, using either QR/LQ or SV decompositions. Both matrixA and matrixB must have the same number type. Supported types are real or complex single precision and double precision numbers.

Flags

/M=method Specifies the decomposition method.

method=0: Decomposition is to QR or LQ (default). Creates the 2D wave M_A, which contains details of the QR/LQ factorization.

method=1: Singular value decomposition. Creates the 2D wave MA, which contains the right singular vectors stored row-wise in the first \( \min(m, n) \) rows. Creates the 1D wave M_SV, which contains the singular values of matrixA arranged in decreasing order.

/O Overwrites matrixA with its decomposition and matrixB with the solution vectors. This requires less memory.

/Z No error reporting.

Details

When the /O flag is not specified, the solution vectors are stored in the wave M_B, otherwise the solution vectors are stored in matrixB. Let matrixA be \( m \times n \) columns and matrixB be an \( m \times NRHS \) (if NRHS=1 it can be omitted). If \( m \geq n \), MatrixLLS solves the least squares solution to an overdetermined system:

\[
\min ||matrixB - matrixA \times X||.
\]

Here the first \( n \) rows of M_B contain the least squares solution vectors while the remaining rows can be squared and summed to obtain the residual sum of the squares. If you are not interested in the residual you can resize the wave using, for example:

Redimension/N=(n,NRHS) M_B

If \( m < n \), MatrixLLS finds the minimum norm solution of the underdetermined system:

\[
matrixA \times X = matrixB.
\]

In this case, the first \( m \) rows of M_B contain the minimum norm solution vectors while the remaining rows can be squared and summed to obtain the residual sum of the squares for the solution. If you are not interested in the residual you can resize the wave using, for example:

Redimension/N=(m,NRHS) M_B

Note: Here matrixB consists of one or more column vectors B corresponding to one or more solution vectors X that are computed simultaneously. If matrixB consists of a single column, M_B is a 2D matrix wave that contains a single solution column.

The variable V_flag is set to 0 when there is no error; otherwise it contains the LAPACK error code.

See Also
Matrix Math Operations on page III-137 for more about Igor’s matrix routines and for background references with details about the LAPACK libraries.
MatrixLUBkSub

MatrixLUBkSub matrixL, matrixU, index, vectorB
The MatrixLUBkSub operation provides back substitution for LU decomposition.

Details
This operation is used to solve the matrix equation \( Ax = b \) after you have performed LU decomposition (see MatrixLUD). Feed this routine \( M_{\text{Lower}}, M_{\text{Upper}} \) and \( W_{\text{LUPermutation}} \) from MatrixLUD along with your right-hand-side vector \( b \). The solution vector \( x \) is returned as \( M_x \). The array \( b \) can be a matrix containing a number of \( b \) vectors and the \( M_x \) will contain a corresponding set of solution vectors.

Generates an error if the dimensions of the input matrices are not appropriate.

See Also
Matrix Math Operations on page III-137 for more about Igor’s matrix routines.

MatrixLUD

MatrixLUD [flags] matrixA
The MatrixLUD operation computes the LU factorization of a matrix. The general form of the factorization/decomposition is expressed in terms of matrix products:
\[
M_{\text{Pt}} \times \text{srcWave} = M_{\text{Lower}} \times M_{\text{Upper}}
\]

\( M_{\text{Pt}}, M_{\text{Lower}} \) and \( M_{\text{Upper}} \) are outputs created by MatrixLUD.
\( M_{\text{Pt}} \) is the transpose of the permutation matrix, \( M_{\text{Lower}} \) is a lower triangular matrix with 1’s on the main diagonal and \( M_{\text{Upper}} \) is an upper triangular (or trapezoidal) matrix.

The MatrixLUD operation was substantially changed in Igor Pro 7.00. See the /B flag for information about backward compatibility.

Flags

/B This flag is provided for backward compatibility only; it is not compatible with any other flag. /B makes MatrixLUD behave as it did in Igor Pro 6. This flag is deprecated and will be removed in a future version of Igor.

The input is restricted to a 2D real valued, single or double precision square matrix. The outputs (all double precision) are stored in the waves \( M_{\text{Upper}}, M_{\text{Lower}} \) and \( W_{\text{LUPermutation}} \) in the current data folder.

The \( W_{\text{LUPermutation}} \) output wave was needed for solving a linear system of equations using the back substitution routine, MatrixLUBkSub. For better computation methods see MatrixLinearSolve, MatrixLinearSolveTD and MatrixLLS.

/CMF Uses Combined Matrix Format where the upper and lower matrix factors are combined into a single matrix saved in the wave \( M_{\text{LUFactors}} \) in the current data folder. The upper matrix factor is constructed from the main and from the upper diagonals of \( M_{\text{LUFactors}} \). The lower matrix factor is constructed from the lower diagonals of \( M_{\text{LUFactors}} \) and setting the main diagonal to 1.

/MIND Finds the minimum magnitude diagonal element of \( M_{\text{Upper}} \) and store it in \( V_{\text{min}} \). This is useful for investigating the behavior of the determinant of the matrix when it is close to being singular.

/PMAT Saves the transpose of the permutation matrix in a double precision wave \( M_{\text{Pt}} \) in the current data folder. Note that the permutation matrix is orthogonal and so the inverse of the matrix is equal to its transpose.

/SUMP Computes the sum of the phases of the elements on the main diagonal of \( M_{\text{Upper}} \) and store in the variable \( V_{\text{Sum}} \). \( V_{\text{Sum}} \) is initialized to NaN and is set only if /SUMP is specified and \( M_{\text{Upper}} \) is complex.
MatrixLUDTD

Details
The input matrix srcWave is an MxN real or complex wave of single or double precision. Use MatrixLUDTD if your input is tri-diagonal.

The main results of the factorization are stored in the waves M_Lower, M_Upper and M_Pt. Alternatively the lower and upper factors can be combined and stored in the wave M_LUFactors (see /CMF). The waves M_Lower, M_Upper and M_LUFactors have the same data type as the input wave. M_Pt is always double precision.

When the input matrix srcWave is square (NxN), the resulting matrices have the same dimensions (NxN). You can reconstruct the input using the MatrixOp expression:

MatrixOp rA = (M_Pt^t) x (M_Lower x M_Upper)

If the input matrix is rectangular (NxM) the reconstruction depends on the size of N and M. If N<M:

MatrixOp rA = (M_Pt^t) x (subRange(M_lower,0,N-1,0,N-1) x M_Upper)

If N>M:

MatrixOp rA = (M_Pt^t) x M_lower x subRange(M_Upper,0,M-1,0,M-1)

The variable V_flag is set to zero if the operation succeeds and to 1 otherwise (e.g., if the input is singular). When you use the /B flag the polarity of the matrix is returned in the variable V_LUPolarity. The variables V_Sum and V_min are also set by some of the flag options above.

See Also
MatrixLUDTD, MatrixLUBkSub, MatrixLinearSolve, MatrixLinearSolveTD, MatrixLLS, MatrixOp

Matrix Math Operations on page III-137 for more about Igor’s matrix routines.

MatrixLUDTD

MatrixLUDTD [flags] srcMain, srcUpper, srcLower
The MatrixLUDTD operation computes the LU factorization of a tri-diagonal matrix. The general form of the factorization/decomposition is expressed in terms of matrix products:

M_Pt x triDiagonalMat = M_Lower x M_Upper

triDiagonalMat is the matrix defined by the main diagonal specified by srcMain, the upper diagonal specified by srcUpper, and the lower diagonal specified by srcLower.

M_Pt is an output wave created when the /PMAT flag is present. M_Lower and M_Upper are output waves created when the /FM flag is present. M_Pt is the transpose of the permutation matrix, M_lower is a lower triangular matrix with 1’s on the main diagonal and M_Upper is an upper triangular (or trapezoidal) matrix.

Flags

/MIND Finds the minimum magnitude diagonal element of M_Upper and stores it in V_min. This feature is useful if you want to investigate the behaviour of the determinant of the matrix when it is close to being singular.

/PMAT Saves the transpose of the permutation matrix in the wave M_Pt in the current data folder. Note that the permutation matrix is orthogonal and so the inverse of the matrix is equal to its transpose.

/SUMP Computes the sum of the phases of the elements on the main diagonal of M_Upper and store in the variable V_Sum. Note that the variable is initialized to NaN and that it is not set unless this flag is specified and M_Upper is complex.

/FM The full matrix output is stored in the waves M_Lower and M_Upper in the current data folder.

Details
You specify the tridiagonal matrix using three 1D waves of the same data type (single or double precision real or complex).

If /FM is present the output of the operation consists of two 2D waves and one 1D wave:

M_Lower is a lower triangular matrix with 1’s on the main diagonal.
M_Upper is an upper triangular (or trapezoidal) matrix.  
W_PIV is 1D wave containing pivot indices.  
See code example below for implementation details.  

If /FM is omitted the output of the operation consists of five 1D waves:  
W_Diagonal is the main diagonal of matrixU.  
W_UDiagonal is the first upper diagonal of M_Upper.  
W_U2Diagonal is the second diagonal of M_Upper.  
W_LDiagonal is the first lower diagonal of M_Lower.  
W_PIV is a vector of pivot indices.  

In this case M_Lower can be constructed (see below) from W_LDiagonal and the pivot index wave W_PIV.  
If you are working with tridiagonal matrices you can take advantage of MatrixOp functionality to 
reconstruct your outputs. For example:  

MatrixOp/O M_Upper=Diagonal(W_diagonal)  
MatrixOp/O M_Upper=setOffDiag(M_Upper,1,W_UDiagonal)  
MatrixOp/O M_Upper=setOffDiag(M_Upper,2,W_U2Diagonal)  

These commands can be combined into a single command line.  
The construction of M_Lower is a bit more complicated and can be accomplished for real data using the 
following code:  

Function MakeLTMatrix(W_diagonal,W_LDiagonal,W_PIV)  
Wave W_diagonal,W_LDiagonal,W_PIV  
Variable i,N=DimSize(W_diagonal,0)  
MatrixOp/O M_Lower=setOffDiag(ZeroMat(N,N,4),-1,W_LDiagonal)  
M_Lower=p==q'-1?M_Lower[p][q] // Set the main diagonal to 1's  
MatrixOp/O index=W_PIV-1 // Convert from 1-based array  
for(i=1;i<=N-2;i+=1)  
  if(index[i]!=i)  
    variable j,tmp  
    for(j=0;j<=i-1;j+=1)  
      tmp=M_Lower[i][j]  
      M_Lower[i][j]=M_Lower[i+1][j]  
      M_Lower[i+1][j]=tmp  
  endif  
endfor  
End  

This code is provided for illustration only. In practice you could use the /FM flag so that the operation 
creates the full lower and upper matrices for you.  
The variable V_flag is set to zero if the operation succeeds and to 1 otherwise (e.g., if the input is singular).  
The variables V_Sum and V_min are also set by some of the flag options above.  

See Also  
MatrixLUD, MatrixOp, Matrix Math Operations on page III-137 for more about Igor’s matrix routines.

MatrixMultiply

MatrixMultiply matrixA [/T], matrixB [/T] [, additional matrices]  
The MatrixMultiply operation calculates matrix expression matrixA*matrixB and puts the result in a matrix 
wave named M_product generated in the current data folder. The /T flag can be included to indicate that 
the transpose of the specified matrix should be used.  
If any of the source matrices are complex, then the result is complex.  

Parameters  
If matrixA is an NxP matrix then matrixB must be a PxM matrix and the product is an NxM matrix. Up to 10 
matrices can be specified although it is unlikely you will need more than three. The inner dimensions must 
be the same. Multiplication is performed from right to left.  
It is legal for M_product to be one of the input matrices. Thus MatrixMultiply A, B, C could also be done as:
MatrixOp

MatrixMultiply B,C
MatrixMultiply A,M_product

Details
Supports multiplication of complex matrices.
An error is generated if the dimensioning of the input arrays is invalid.

See Also
The MatrixOp operation for more efficient matrix operations.
Matrix Math Operations on page III-137 for more about Igor’s matrix routines.

MatrixOp

MatrixOp [/C /FREE /NTHR=n /O /S] destwave = expression
The MatrixOp operation evaluates expression and stores the result in destWave.

expression may include literal numbers, numeric variables, numeric waves, and the set of operators and
functions described below. MatrixOp does not support text waves, strings or structures.
MatrixOp is faster and in some case more readable than standard Igor waveform assignments and matrix
operations.

Parameters

destWave
Specifies a destination wave for the assignment expression. destWave is created at
runtime. If it already exists, you must use the /O flag to overwrite it or the operation
returns an error.

When the operation is completed, destWave has the dimensions and data type implied
by expression. In particular, it may be complex if expression evaluates to a complex
quantity. If expression evaluates to a scalar, destWave is a 1x1 wave.

If you include the /FREE flag then destWave is created as a free wave.

By default the data type of destWave depends on the data types of the operands and
the nature of the operations on the right-hand side of the assignment. If expression
references integer waves only, destWave may be an integer wave too but most
operations with a scalars convert destWave into a double precision wave. See
MatrixOp Data Promotion Policy on page III-144 for further discussion.

Even if destWave exists before the operation, MatrixOp may change its data type and
dimensionality as implied by expression.

You can force the number type using MatrixOp functions such as uint16 and fp32.

expression
expression is a mathematical expression referencing waves, local variables, global
variables and literal numbers together with MatrixOp functions and MatrixOp
operators as listed in the following sections.

You can use any combination of data types for operands. In particular, you can mix
real and complex types in expression. MatrixOp determines data types of inputs and
the appropriate output data type at runtime without regard to any type declaration
such as Wave/C.
Operators

+  Addition between scalars, matrix addition or addition of a scalar (real or complex) to each element of a matrix.

-  Subtraction of one scalar from another, matrix subtraction, or subtracting a scalar from each element of a matrix. Subtraction of a matrix from a scalar is not defined.

*  Multiplication between two scalars, multiplication of a matrix by a scalar, or element-by-element multiplication of two waves of the same dimensions.

/  Division of two scalars, division of a matrix by a scalar, or element-by-element division between two waves of the same dimensions.

Division of a scalar by a matrix is not supported but you can use the rec function with multiplication instead.

x  Matrix multiplication (lower case x symbol only).

This operator must be preceded and followed by a space. Matrix multiplication requires that the number of columns in the matrix on the left side be equal to the number of rows in the matrix on the right.

.  Generalized form of a dot product. In an expression a.b it is expected that a and b have the same number of points although they may be of arbitrary numeric type. The operator returns the sum of the products of the sequential elements as if both a and b were 1D arrays.

^t  Matrix transpose. This is a postfix operator meaning that ^t appears after the name of a matrix wave.

^h  Hermitian transpose. This is a postfix operator meaning that ^h appears after the name of a matrix wave.

&& Logical AND operator supports all real data types and results in a signed byte numeric token with the value of either 0 or 1. The operation acts on an element by element basis and is performed for each element of the operand waves.

|| Logical OR operator supports all real data types and results in a signed byte numeric token with the value of either 0 or 1. The operation acts on an element by element basis and is performed for each element of the operand waves.

MatrixOp does not support operator combinations such as + =.

This table shows the precedence of MatrixOp operators:

<table>
<thead>
<tr>
<th>MatrixOp Operator</th>
<th>Precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>^h</td>
<td>^t</td>
</tr>
<tr>
<td>x</td>
<td>.</td>
</tr>
<tr>
<td>*</td>
<td>/</td>
</tr>
<tr>
<td>+</td>
<td>-</td>
</tr>
<tr>
<td>&amp;&amp;</td>
<td></td>
</tr>
</tbody>
</table>

You can use parentheses to force evaluation order.

Operators that have the same precedence associate from right to left. This means that a * b / c is equivalent to a * (b / c).

Functions

These functions are available for use with MatrixOp.

abs (w)  Absolute value of a real number or the magnitude of a complex number.

acos (w)  Arc cosine of w.
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Added In Igor Pro 7.00</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\text{acosh}(w))</td>
<td>Inverse hyperbolic cosine of (w). Added in Igor Pro 7.00.</td>
<td></td>
</tr>
<tr>
<td>(\text{asin}(w))</td>
<td>Arc sine of (w).</td>
<td></td>
</tr>
<tr>
<td>(\text{asinh}(w))</td>
<td>Inverse hyperbolic sine of (w). Added in Igor Pro 7.00.</td>
<td></td>
</tr>
<tr>
<td>(\text{asyncCorrelation}(w))</td>
<td>Asynchronous spectrum correlation matrix for a real valued input matrix wave (w). See (\text{syncCorrelation}) for details.</td>
<td></td>
</tr>
<tr>
<td>(\text{atan}(w))</td>
<td>Arc tangent (inverse tangent) of (w).</td>
<td></td>
</tr>
<tr>
<td>(\text{atan2}(y, x))</td>
<td>Arc tangent (inverse tangent) of real (y/x).</td>
<td></td>
</tr>
<tr>
<td>(\text{atanh}(w))</td>
<td>Inverse hyperbolic tangent of (w). Added in Igor Pro 7.00.</td>
<td></td>
</tr>
<tr>
<td>(\text{averageCols}(w))</td>
<td>Returns a ((1 \times \text{columns})) wave containing the averages of the columns of matrix (w). This is equivalent to (\text{sumCols}(w)/\text{numRows}(w)). Added in Igor Pro 7.00.</td>
<td></td>
</tr>
<tr>
<td>(\text{axisToQuat}(ax))</td>
<td>See \textit{Functions Using Quaternions} on page V-528.</td>
<td></td>
</tr>
<tr>
<td>(\text{backwardSub}(U, c))</td>
<td>Returns a column vector solution for the matrix equation (Ux=c), where (U) is an ((N \times N)) wave representing an upper triangular matrix and (c) is a column vector of (N) rows. If (c) has additional columns they are ignored. Ideally, (U) and (c) should be either SP or DP waves (real or complex). Other numeric data types are supported with a slight performance penalty. This function is typically used in solving linear equations following a matrix decomposition into lower and upper triangular matrices (e.g., Cholesky), with an expression of the form: (\text{MatrixOp/O solVector=backwardSub}(U, \text{forwardSub}(L, b))) where (U) and (L) are the upper and lower triangular factors. Added in Igor Pro 7.00.</td>
<td></td>
</tr>
<tr>
<td>(\text{beam}(w, row, col))</td>
<td>When (w) is a 3D wave the beam function returns a 1D array corresponding to the data in the beam defined by (w[\text{row}][\text{col}]). In other words, it returns a 1D array consisting of all elements in the specified row and column from all layers. See also \textit{ImageTransform getBeam}. When (w) is a 4D wave it returns a 2D array containing (w[\text{row}][\text{col}][\text{chunk}]). In other words, it returns a matrix consisting of all elements in the specified row and column from all layers and all chunks. The beam function belongs to a special class in that it does not operate on a layer by layer basis. It therefore does not permit compound expressions in place of any of its parameters. The beam function has the highest precedence.</td>
<td></td>
</tr>
<tr>
<td>(\text{bitAnd}(w1, w2))</td>
<td>Returns an array of the same dimensions and number type as (w1) where each element corresponds to the bitwise AND operation between (w1) and (w2). (w2) can be either a single number or a matrix of the same dimensions as (w1). Both (w1) and (w2) must be real integer numeric types. Added in Igor Pro 7.00.</td>
<td></td>
</tr>
<tr>
<td>(\text{bitOr}(w1, w2))</td>
<td>Returns an array of the same dimensions and number type as (w1) where each element corresponds to the bitwise OR operation between (w1) and (w2). (w2) can be either a single number or a matrix of the same dimensions as (w1). Both (w1) and (w2) must be real integer numeric types. Added in Igor Pro 7.00.</td>
<td></td>
</tr>
</tbody>
</table>
bitShift(w1, w2) Returns an array of the same dimensions and number type as w1 shifted by the amount specified in w2. When w2 is positive the shifting is to the left. When it is negative the shifting is to the right. w2 can be either a single number or a matrix of the same dimensions as w1. Both w1 and w2 must be real integer numeric types. Added in Igor Pro 7.00.

bitXor(w1, w2) Returns an array of the same dimensions and number type as w1 where each element corresponds to the bitwise XOR operation between w1 and w2. w2 can be either a single number or a matrix of the same dimensions as w1. Both w1 and w2 must be real integer numeric types. Added in Igor Pro 7.00.

bitNot(w) Returns an array of the same dimensions and number type as w where each each element is the bitwise complement of the corresponding element in w. Added in Igor Pro 7.00.

catCols(w1, w2) Concatenates the columns of w2 to those of w1. w1 and w2 must have the same number of rows and the same number type. Added in Igor Pro 7.00.

catRows(w1, w2) Concatenates the rows of w2 to those of w1. w1 and w2 must have the same number of columns and the same number type. Added in Igor Pro 7.00.

cbrt(w) Returns the cube root of the elements of w. When w is complex cbrt returns the principal cube root (the root with a positive imaginary number). Added in Igor Pro 8.00.

ceil(z) Smallest integer larger than z.

chirpZ(data, A, W, M) Chirp Z Transform of the 1D wave data calculated for the contour defined by

\[ z_k = AW^{-k}, \]
\[ k = 0, 1, \ldots, M - 1. \]

Here both A and W are complex and the standard z transform for a sequence \( x(n) \) is defined by

\[ X(z) = \sum_{k=0}^{N-1} x(n)z^{-k}. \]

The phase of the output is inverted to match the result of the ChirpZ transform on the unit circle with that of the FFT.

chirpZf(data, f1, f2, df) Chirp Z Transform except that the transform parameters are specified by real-valued starting frequency f1, end frequency f2 and frequency resolution df. The transform is confined to the unit circle because both A and W have unit magnitude.

chol(w) Returns the Cholesky decomposition U of a positive definite symmetric matrix w such that w=U^t \times U. Note that only the upper triangle of w is actually used in the computation.

chunk(w, n) Returns chunk n from 4D wave w. Added in Igor Pro 7.00.
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>clip(w, low, high)</code></td>
<td>Returns the values in the wave <code>w</code> clipped between the <code>low</code> and the <code>high</code> parameters. If <code>w</code> contains NaN or INF values, they are not modified. The result retains the same number type as the input wave <code>w</code> irrespective of the range of the <code>low</code> and <code>high</code> input parameters.</td>
</tr>
<tr>
<td><code>cmplx(re, im)</code></td>
<td>Returns a complex token from two real tokens. <code>re</code> and <code>im</code> must have the same dimensionality. Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td><code>col(w, c)</code></td>
<td>Returns column <code>c</code> from matrix wave <code>w</code>.</td>
</tr>
<tr>
<td><code>colRepeat(w, n)</code></td>
<td>Returns a matrix that consists of <code>n</code> identical columns containing the data in the wave <code>w</code>. If <code>w</code> is a 2D wave, it is treated as if it were a single column containing all the data. Higher dimensions are supported on a layer-by-layer basis. MatrixOp returns an error if <code>n&lt;2</code>. Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td><code>conj(matrixWave)</code></td>
<td>Complex conjugate of the input expression.</td>
</tr>
<tr>
<td><code>const(r, c, val)</code></td>
<td>Returns an <code>(r x c)</code> matrix where all elements are equal to <code>val</code>. The data type of the returned matrix is the same as that of <code>val</code>. See also <code>zeromat</code> below. Added in Igor Pro 7.00.</td>
</tr>
<tr>
<td><code>convolve(w1, w2, opt)</code></td>
<td>Convolution of <code>w1</code> with <code>w2</code> subject to options <code>opt</code>. The dimensions of the result are determined by the largest dimensions of <code>w1</code> and <code>w2</code> with the number of rows padded (if necessary) so that they are even. Supported options include <code>opt=0</code> for circular convolution and <code>opt=4</code> for acausal convolution. For fast 2D convolutions where <code>w1</code> is an image and <code>w2</code> is a square kernel of the same numeric type, you can use <code>opt=-1</code> or <code>opt=-2</code>. When <code>opt=-1</code> the convolution at the boundaries is evaluated using zero padding. When <code>opt=-2</code> the padding is a reflection of <code>w1</code> about the boundaries. When working with integer waves the kernel is internally normalized by the sum of its elements. The kernel for floating point waves remain unchanged. To convolve an image in <code>w1</code> with a smaller point spread function in <code>w2</code> you can use: <code>opt=-1</code> if you want to pad the image boundaries with zeros or <code>opt=-2</code> if you want to pad the boundaries by reflecting image values about each boundary. The negative options are designed for a very optimized convolution calculation which requires that <code>w1</code> and <code>w2</code> have the same numeric type. If the size of the point spread function is larger than about 13x13 it may become more efficient to compute the convolution using the positive options.</td>
</tr>
<tr>
<td><code>correlate(w1, w2, opt)</code></td>
<td>Correlation of <code>w1</code> with <code>w2</code> subject to options <code>opt</code>. The dimensions of the result are determined by the largest dimensions of <code>w1</code> and <code>w2</code> with the number of rows padded (if necessary) so that they are even. Supported options include <code>opt=0</code> for circular correlation and <code>opt=4</code> for acausal correlation.</td>
</tr>
<tr>
<td><code>cos(w)</code></td>
<td>Cosine of <code>w</code>.</td>
</tr>
<tr>
<td><code>cosh(w)</code></td>
<td>Hyperbolic cosine of <code>w</code>. Added in Igor Pro 7.00.</td>
</tr>
</tbody>
</table>
covariance(w) Returns the sample covariance matrix. Added in Igor Pro 8.00. If \( w \) is a rows x cols real matrix then the returned value is the cols x cols matrix Q with elements

\[
q_{ij} = \frac{1}{\text{ROWS} - 1} \sum_{k=0}^{\text{ROWS}-1} \left( w_{ij} - \overline{w}_i \right) \left( w_{ik} - \overline{w}_k \right),
\]

where

\[
\overline{w}_k = \frac{1}{\text{ROWS}} \sum_{i=0}^{\text{ROWS}-1} w_{ik}.
\]

crossCovar(w1, w2, opt) Returns the cross-covariance for 1D waves \( w1 \) and \( w2 \). The options parameter opt can be set to 0 for the raw cross-covariance or to 1 if you want the results to be normalized to 1 at zero offset. If \( w1 \) has \( N \) rows and \( w2 \) has \( M \) rows then the returned vector is of length \( N+M-1 \). The cross-covariance is computed by subtracting the mean of each input followed by correlation and optional normalization. See also Correlate with the /NODC flag.

det(w) Returns a scalar corresponding to the determinant of matrix \( w \), which must be real.

diagonal(w) Creates a square matrix that has the same number of rows as \( w \). All elements are zero except for the diagonal elements which are taken from the first column in \( w \). Use DiagRC if the input is not an existing wave (such as a result from another function).

diagRC(w, rows, cols) 2D matrix of dimensions \( \text{rows} \) by \( \text{cols} \). All matrix elements are set to zero except those of the diagonal which are filled sequentially from elements of \( w \). The dimensionality of \( w \) is unimportant. If the total number of elements in \( w \) is less than the number of elements on the diagonal then all elements will be used and the remaining diagonal elements will be set to zero.

e Returns the base of the natural logarithm.

equal(a, b) Returns unsigned byte result with 1 for equality and zero otherwise. The dimensionality of the result matches the dimensionality of the largest parameter. Either or both \( a \) or \( b \) can be constants (i.e., one row by one column). If \( a \) and \( b \) are not constants, they must have the same dimensions. Both parameters can be either real or complex. A comparison of a real with a complex parameter returns zero.

erf(w) Returns the error function (see erf) for real values in \( w \). Added in Igor Pro 7.00.

erfc(w) Returns the complementary error function (see erfc) for real values in \( w \). Added in Igor Pro 7.00.

exp(w) Exponential function for \( w \) which can be real or complex, scalar or a matrix.

FCT(w, dir) See Trignometric Transform Functions on page V-526.

fft(w, options) FFT of \( w \). \( w \) must have an even number of rows.

\( \text{options} \) contains a binary field flag. Set bit 1 to 1 if you want to disable the zero centering (see /Z flag in the FFT operation). Other bits are reserved.

MatrixOp does not support wave scaling and therefore it does not produce the same wave scaling changes as the FFT operation.
MatrixOp

floor(w)  Largest integer smaller than w. If w is complex the function is separately
applied to the real and imaginary parts.

forwardSub(L,b)  Returns a column vector solution for the matrix equation Lx=b, where L is an
(NxN) wave representing a lower triangular matrix and b is a column vector
of N rows. If b has additional columns they are ignored.
Ideally, L and b should be either SP or DP waves (real or complex). Other
numeric data types are supported with a slight performance penalty.
This function is typically used in solving linear equations following a matrix
decomposition into lower and upper triangular matrices (e.g., Cholesky),
with an expression of the form:
MatrixOp/O solVector=backwardSub(U,forwardSub(L,b))
where U and L are the upper and lower triangular factors.

Added in Igor Pro 7.00.

fp32(w)  Converts w to 32-bit single precision floating point representation. See also
the /NPRM flag below for more information.

Added in Igor Pro 7.00.

fp64(w)  Converts w to 64-bit single precision floating point representation. See also
the /NPRM flag below for more information.

Added in Igor Pro 7.00.

Frobenius(w)  Returns the Frobenius norm of a matrix defined as the square root of the sum
of the squared absolute values of all elements.

FST(w,dir)  See Trignometric Transform Functions on page V-526.

FSST(w,dir)  See Trignometric Transform Functions on page V-526.

FSCT(w,dir)  See Trignometric Transform Functions on page V-526.

FSCT2(w,dir)  See Trignometric Transform Functions on page V-526.

getDiag(w2d,d)  Returns a 1D wave that contains diagonal d of w2d. d=0 is the main diagonal,
d>0 correspond to upper diagonals and d<0 to lower diagonals.

Added in Igor Pro 7.00.

greater(a,b)  Returns an unsigned byte for the truth of a > b. Both a and b must be real but
one or both can be constants (see equal() above). The dimensionality of the
result matches the dimensionality of the largest parameter.

hypot(w1,w2)  Returns the square root of the sum of the squares of w1 and w2.

Added in Igor Pro 7.00.

ifft(w,options)  IFFT of w.

options is a bitwise parameter defined as follows:
Bit 0: Forces the result to be real, like the IFFT operation /C flag.
Bit 1: Disables center-zero.
Bit 2: Swaps the results.

See Setting Bit Parameters on page IV-13 for details about bit settings.
MatrixOp does not support wave scaling and therefore it does not produce
the same wave scaling changes as the IFFT operation.
MatrixOp

identity\((n,m)\)  
Creates a computational object that is an identity matrix. If you use a single argument \(n\), the identity created is an \((nxn)\) square matrix with 1’s for diagonal elements (the remaining elements are set to zero). If you use both arguments, the function creates an \((nxm)\) zero matrix and fills its diagonal elements with 1’s. Note that the identity is created at runtime and persists only for the purpose of the specific operation.

identity\((n)\)  

imag\((w)\)  
Imaginary part of \(w\).

indexCols\((w)\)  
Returns a token of the same dimensions as \(w\) where each element is equal to its column index. This is the MatrixOp equivalent of q used on righthand side of a standard wave assignment statement. The returned token is an unsigned 32-bit integer if the number of columns in \(w\) is less than \(2^{32}\) or double-precision floating point otherwise.
Added in Igor Pro 8.00.

indexRows\((w)\)  
Returns a token of the same dimensions as \(w\) where each element is equal to its row index. This is the MatrixOp equivalent of p used on righthand side of a standard wave assignment statement. The returned token is an unsigned 32-bit integer if the number of rows in \(w\) is less than \(2^{32}\) or double-precision floating point otherwise.
Added in Igor Pro 8.00.

inf()  
Returns INF.
Added in Igor Pro 7.00.

int8\((w)\)  
Converts \(w\) to 8-bit signed integer representation. See also the /NPRM flag below for more information.
Added in Igor Pro 7.00.

int16\((w)\)  
Converts \(w\) to 16-bit signed integer representation. See also the /NPRM flag below for more information.
Added in Igor Pro 7.00.

int32\((w)\)  
Converts \(w\) to 32-bit signed integer representation. See also the /NPRM flag below for more information.
Added in Igor Pro 7.00.

integrate\((w, opt)\)  
Returns a running sum of \(w\).
If \(opt=0\) the sum runs over the entire input wave treating the columns of 2D waves as if they were part of one big column.
If \(opt=1\) the running sum is computed separately for each column of a 2D wave.
Added in Igor Pro 7.00.

intMatrix\((w)\)  
Returns a double-precision matrix of the same dimensions as \(w\).
Each element of the returned matrix is the sum of all the corresponding elements of \(w\) that are above and to the left of it, i.e.,

\[
out_{ij} = \sum_{m=0}^{i} \sum_{n=0}^{j} w_{mn}.
\]

The utility of this function is apparent in the following relationship:
\[
\sum_{i=x_1}^{x_2} \sum_{j=y_1}^{y_2} w_{ij} = out[x_2, y_2] - out[x_2, y_1 - 1] - out[x_1 - 1, y_2] + out[x_1 - 1, y_1 - 1].
\]

intMatrix was added in Igor Pro 7.00.

\(\text{inv}(w)\)
Returns the inverse of the square matrix \(w\).
If \(w\) is not invertible, the operation returns a matrix of the same dimensions where all elements are set to NaN.

\(\text{inverseErf}(w)\)
Returns the inverse error function (see \text{inverseErf}) for the real values in \(w\).
Added in Igor Pro 7.00.

\(\text{inverseErfc}(w)\)
Returns the inverse complementary error function (see \text{inverseErfc}) for the real values in \(w\).
Added in Igor Pro 7.00.

\(\text{layer}(w)\)
Returns layer \(n\) from the 3D wave \(w\). \(w\) can not be a compound expression.
Added in Igor Pro 7.00.

\(\text{limitProduct}(w_1, w_2)\)
Returns a partial element-by-element multiplication of waves \(w_1\) and \(w_2\).
It is assumed that the dimensions of \(w_1\) are greater or equal to that of \(w_2\). If \(w_2\) is of dimensions NxM then the function returns a matrix of the same dimensions as \(w_1\) with the first NxM elements contain the product of the corresponding elements in \(w_1\) and \(w_2\) and the remaining elements set to zero.
The function is designed to be used in filtering applications where the size of the kernel \(w_2\) is much smaller than the size of the input \(w_1\).
Added in Igor Pro 7.00.

\(\text{log}(w)\)
Log base 10 of a token \(w\) which can be real or complex, scalar or a matrix.

\(\text{ln}(w)\)
Natural logarithm of a token \(w\) which can be real or complex, scalar or a matrix.

\(\text{mag}(w)\)
Returns a real valued wave containing the magnitude of each element of \(w\). This is equivalent to the \text{abs} function.

\(\text{magSqr}(w)\)
Returns a real value wave containing the square of a real \(w\) or the squared magnitude of complex \(w\).

\(\text{maxAB}(a, b)\)
Returns the larger of the two real numbers \(a\) and \(b\).
\text{maxAB} does not support NaN or complex inputs.
Added in Igor Pro 7.00.

\(\text{maxCols}(w)\)
Returns a 1D wave containing the maximum value of each column in the wave \(w\). If \(w\) is complex the output contains the maximum magnitude of each column of \(w\).
\text{maxCols} does not support NaN.
Added in Igor Pro 7.00.

\(\text{maxRows}(w)\)
Returns a 1D wave containing the maximum value of each row in the wave \(w\). If \(w\) is complex the output contains the maximum magnitude of each row of \(w\).
\text{maxRows} does not support NaN.
Added in Igor Pro 8.00.
MatrixOp

maxVal(w) Returns the maximum value of the wave w. If w is complex it returns the maximum magnitude of w.

When w is real, the returned number type is the same as w's.

When w is complex, the result is real and represents the maximum of the magnitudes of the elements of w. If w is double precision, then the result is double precision; otherwise it is single precision.

When w is a 3D or 4D wave, maxVal returns a (1 x 1 x layers x chunks) data token.

maxVal does not support NaN values.

mean(w) Returns the mean value w.

minCols(w) Returns a 1D wave containing the minimum value of each column in the wave w. If w is complex the output contains the minimum magnitude of each column of w.

minCols does not support NaN.

Added in Igor Pro 8.00.

minRows(w) Returns a 1D wave containing the minimum value of each row in the wave w. If w is complex the output contains the minimum magnitude of each row of w.

minRows does not support NaN.

Added in Igor Pro 8.00.

minVal(w) Returns the minimum value of the wave w. If w is complex the function returns the minimum magnitude of w.

When w is real, the returned number type is the same as w’s.

When w is complex, the result is real and represents the minimum of the magnitudes of the elements of w. If w is double precision, then the result is double precision; otherwise it is single precision.

When w is a 3D or 4D wave, minVal returns a (1 x 1 x layers x chunks) data token.

minVal does not support NaN values.

mod(w, b) Returns the remainder after dividing w by b. b can be a scalar or a matrix of the same dimensions as w.

Added in Igor Pro 7.00.

nan() Returns NaN.

Added in Igor Pro 7.00.

normalize(w) Normalized version of a vector or a matrix. Normalization is such that the returned token should have a unity magnitude except if all elements are zero, in which case output is unchanged.

normalizeCols(w) Divides each column of the real wave w by the square root of the sum of the squares of all elements of the column.

normalizeRows(w) Divides each row of the real wave w by the square root of the sum of the squares of all the elements in that row.

numCols(w) Returns the number of columns in the wave w. When w is 1D the function returns 1.

numPoints(w) Returns the number of points in a layer of w.

numRows(w) Returns the number of rows in w.
MatrixOp

**numType(w)**  
Number the number type of \( w \):
- 0: \( w \) is a normal number
- 1: \( w \) is +/-INF
- 2: \( w \) is NaN

**outerProduct(w1, w2)**  
For a 1D wave \( w_1 \) containing \( M \) points and a 1D wave \( w_2 \) containing \( N \) points, outerProduct returns an \( M \) by \( N \) matrix where the \((i,j)\) element is:
\[
\text{out}[i,j] = w_1[i] \times \text{conj}(w_2[j])
\]

Added in Igor Pro 8.00.

**p2Rect(w)**  
Converts each element of \( w \) from polar to rectangular representation.

**phase(w)**  
Returns a real valued wave containing the phase of each element of \( w \) calculated using \( \text{phase} = \text{atan2}(y, x) \).

**Pi**  
Returns \( \pi \).

**powC(w1, w2)**  
Complex valued \( w_1 w_2 \) where \( w_1 \) and \( w_2 \) can be real or complex.

**powR(x, y)**  
Returns \( x^y \) for real \( x \) and \( y \).

**productCol(w, c)**  
Returns the a \((1 \times 1)\) wave containing the product of the elements in column \( c \) of wave \( w \). The output is double precision real or complex.

Added in Igor Pro 7.00.

**productCols(w)**  
Returns a \((1 \times \text{cols})\) wave where each entry is the product of all the elements in the corresponding column. The output is double precision real or complex.

Added in Igor Pro 7.00.

**productDiagonal(w, d)**  
Returns a \((1 \times 1)\) wave containing the product of the elements on the specified diagonal of wave \( w \). \( d=0 \) is the main diagonal, \( d>0 \) correspond to upper diagonals and \( d<0 \) to lower diagonals. The output is double precision real or complex.

Added in Igor Pro 7.00.

**productRow(w, r)**  
Returns the a \((1 \times 1)\) wave containing the product of the elements in row \( r \) of wave \( w \). The output is double precision real or complex.

Added in Igor Pro 7.00.

**productRows(w)**  
Returns a \((1 \times \text{rows})\) wave where each entry is the product of all the elements in the corresponding row. The output is double precision real or complex.

Added in Igor Pro 7.00.

**quat(arg)**  
See Functions Using Quaternions on page V-528.

**quatToAxis(qIn)**  
See Functions Using Quaternions on page V-528.

**quatToEuler(qIn, mode)**  
See Functions Using Quaternions on page V-528.

**quatToMatrix(qIn)**  
See Functions Using Quaternions on page V-528.

**r2Polar(w)**  
Performs the equivalent of the \( \text{r2polar} \) function on each element of \( w \), i.e., each complex number \((x+iy)\) is converted into the polar representation \( r, \theta \) with \( x+iy=r \exp(i \theta) \).

**real(w)**  
Real part of \( w \).

**rec(w)**  
Reciprocal of each element in \( w \).

**redimension(w, nr, nc)**
MatrixOp

Returns an \((nr \times nc)\) matrix from the data in the wave \(w\). The data in \(w\) are moved contiguously (column by column regardless of dimensionality) into the output. If the output size is larger than \(w\) the remaining points are set to zero. If \(w\) contains more than one layer the new dimensions apply on a layer by layer basis. For example:

\[
\text{Make/N=(10,20,30)} \quad ddd = p + 10*q + 100*r
\]

\[
\text{MatrixOp/O aa = redimension(ddd,25,1)}
\]

creates a wave \(aa\) with dimensions \((25,1,30)\).

Added in Igor Pro 7.00.

\[
\text{replace(w,findVal,replacementVal)}
\]

Replace in wave \(w\) every occurrence of \(\text{findVal}\) with \(\text{replacementVal}\). The wave \(w\) retains its dimensionality and number type. \(\text{replacementVal}\) is converted to the same number type as \(w\) which may cause truncation.

\[
\text{replaceNaNs(w,replacementVal)}
\]

Replaces every occurrence of NaN in the wave \(w\) with \(\text{replacementVal}\). The wave \(w\) retains its dimensionality. \(\text{replacementVal}\) is converted to the same number type as \(w\) which may cause truncation.

\[
\text{reverseCol(w,c)}
\]

Returns array \(w\) with column \(c\) in reverse order.

Added in Igor Pro 7.00.

\[
\text{reverseCols(w)}
\]

Returns array \(w\) with all columns in reverse order.

Added in Igor Pro 7.00.

\[
\text{reverseRow(w,r)}
\]

Returns array \(w\) with row \(r\) in reverse order.

Added in Igor Pro 7.00.

\[
\text{reverseRows(w)}
\]

Returns array \(w\) with all rows in reverse order.

Added in Igor Pro 7.00.

\[
\text{rotateChunks(w,n)}
\]

Returns a matrix where the last \(n\) chunks of \(w\) are moved to chunks \([0, n-1]\). If \(n\) is negative then the first \(\text{abs}(n)\) chunks are moved to the end of the data. It is an error to pass NaN for \(n\).

Added in Igor Pro 7.00.

\[
\text{rotateCols(w,nc)}
\]

Rotates the columns of a 2D wave \(w\) so that the last \(nc\) columns are moved to columns \([0,nc -1]\) of the data. If \(nc\) is negative the first \(\text{abs}(nc)\) columns are moved to columns \([n-1-nc ,n-1]\). Here \(n\) is the total number of columns. It is an error to pass NaN for \(nc\). If \(nc\) is greater than the number of columns then the effective rotation is \(\text{mod}(nc ,\text{actualCols})\).

\[
\text{rotateLayers(w,n)}
\]

Returns a matrix where the last \(n\) layers of \(w\) are moved to layers \([0, n-1]\). If \(n\) is negative then the first \(\text{abs}(n)\) layers are moved to the end of the data. It is an error to pass NaN for \(n\).

Added in Igor Pro 7.00.

\[
\text{rotateRows(w,nr)}
\]

Rotates the rows of a 2D wave \(w\) so that the last \(nr\) rows are moved to rows \([0,nr -1]\) of the data. If \(nr\) is negative the first \(\text{abs}(nr)\) rows are moved to rows \([n-1-nr ,n-1]\) where \(n\) is the total number of rows. It is an error to pass NaN for \(nr\). If \(nr\) is greater than the number of rows then the effective rotation is \(\text{mod}(nr ,\text{actualRows})\).

\[
\text{round}(z)
\]

Rounds \(z\) to the nearest integer. The rounding method is “away from zero”.

\[
\text{row(w,r)}
\]

Returns row \(r\) from matrix wave \(w\). The returned row is a \((1xC)\) wave where \(C\) is the number of columns in \(w\). To convert it to a 1D wave use \text{Redimension/N=}(C). See also \text{ImageTransform} \text{getRow}.
MatrixOp

**rowRepeat**(w, n)
Returns a matrix that consists of n identical rows containing the data in the wave w. If w is a 2D wave, it is treated as if it were a single column containing all the data. Higher dimensions are supported on a layer-by-layer basis. MatrixOp returns an error if n<2.

Added in Igor Pro 7.00.

**scale**(w, low, high)
Returns the values in the wave w scaled between the low and the high parameters. If w contains NaN or INF values, they are not modified. The result retains the same number type as that of w irrespective of the range of the low and high input parameters.

**scaleCols**(w1, w2)
Returns a matrix of the same dimensions as w1 where each column of w1 is scaled by the value in the corresponding row of the 1D wave w2. The number of rows in w2 must equal the number of columns in w1.

Added in Igor Pro 7.00.

**scaleRows**(w1, w2)
Returns a matrix of the same dimensions as w1 where each row of w1 is scaled by the value in the corresponding row of the 1D wave w2. The number of rows in w2 must equal the number of rows in w1.

Added in Igor Pro 7.00.

**setCol**(w2d, c, w1d)
Returns the data in the w2d with the contents of w1d stored in column c.
w1d must have at least as many elements as the number of rows of w2d. w2d and w1d must be either both real or both complex.

Added in Igor Pro 7.00.

**setNaNs**(w, mask)
Returns the data in the wave w with NaNs stored where the mask wave is non-zero. The wave w can be of any numeric type.

mask must have the same dimensions as w and must be real. It is usually the result of another expression. For example, to set all values in the destination to NaN where w is greater than 5:

```
MatrixOp/o ou = setNaNs(w, greater(w, 5))
```

Added in Igor Pro 7.00.

**setOffDiag**(w, d, w1)
Returns the data in the w with the contents of w1 stored in diagonal d.
d=0 is the main diagonal of w, d>0 correspond to upper diagonals and d<0 to lower diagonals. w and w1 can either be both real or both complex.

Added in Igor Pro 7.00.

**setRow**(w2d, r, w1d)
Returns the data in the w2d with the contents of w1d stored in row r.
w1d must have at least as many elements as the number of columns in w2d. w2d and w1d must be either both real or both complex.

Added in Igor Pro 7.00.

**sgn**(w)
Returns the sign of each element in w. It returns -1 for negative numbers and 1 otherwise. It does not accept complex numbers.

**shiftVector**(w, n, val)
Shifts the element of a 1D row-vector w by n elements and fills the displaced elements with val, which must match the data type of w and should be expressed as cmplx(a, b) for complex w.

**sin**(z)
Sine of z.

**sinh**(z)
Hyperbolic sine of z. Added in Igor Pro 7.00.

**slerp**(qIn1, qIn2, frac)
See Functions Using Quaternions on page V-528.

**sqrt**(z)
Square root of z.

**subRange**(w, rs, re, cs, ce)

Returns a contiguous subset of the wave $w$ from starting row $rs$ through ending row $re$ and from starting column $cs$ through ending column $ce$. This is similar to Duplicate/R except that dimension scaling and labels not preserved.

Added in Igor Pro 7.00.

`subtractMean(w, opt)` Computes the mean of the real wave $w$ and returns the values of the wave minus the mean value ($opt=0$). Computes the mean of each column and subtracts it from that column ($opt=1$). Subtracts the mean of each row from row values ($opt=2$).

`subWaveC(w, r, c, count[, stride])` Returns a subset of the data that is sampled along columns of the wave $w$, containing count elements starting with the element at row $r$ and column $c$. By default $stride=1$ and the sampling is continuous.

You can specify a negative stride to sample backwards from the starting element.

The operation returns an error if the sampling would exceed the array bounds in either direction.

For example:

```
Make/O/N=(22,33) ddd=x
MatrixOP/O/P=1 aa=subWaveC(ddd,4,5,10,2)
   // aa={4,6,8,10,12,14,16,18,20,0}
MatrixOP/O/P=1 aa=subWaveC(ddd,4,5,5,-4)
   // aa={4,0,18,14,10}
```

`subWaveR(w, r, c, count[, stride])` Returns a subset of the data that is sampled along rows of the wave $w$, containing count elements starting with the element at row $r$ and column $c$. By default $stride=1$ and the sampling is continuous.

You can specify a negative stride to sample backwards from the starting element.

The operation returns an error if the sampling would exceed the array bounds in either direction.

Examples:

```
Make/O/N=(10,20) ddd=y
   // Forward sampling across right boundary
MatrixOP/O/P=1 aa=subWaveR(ddd,4,15,6,2)
   // aa={15,17,19,1,3,5}
   // Reverse sampling across left boundary
MatrixOP/O/P=1 aa=subWaveR(ddd,2,3,5,-1)
   // aa={3,2,1,0,19}
```

`sum(z)` Returns the sum of all the elements in expression $z$. 
MatrixOp

sumBeams \( (w) \) Returns an \((n \times m)\) matrix containing the sum over all layers of all the beams of the 3D wave \( w \):

\[
out_{ij} = \sum_{k=0}^{nLayers-1} W_{ijk}.
\]

A beam is a 1D array in the Z-direction.

sumBeams is a non-layered function which requires that \( w \) be a proper 3D wave and not the result of another expression.

sumCols \( (w) \) Returns a \((1 \times m)\) matrix containing the sums of the \( m \) columns in the \( n \times m \) input wave \( w \):

\[
out_i = \sum_{j=0}^{nRows-1} W_{ij}.
\]

sumRows \( (w) \) Returns an \((n \times 1)\) matrix containing the sums of the \( n \) rows in the \( n \times m \) input wave \( w \):

\[
out_j = \sum_{i=0}^{nCols-1} W_{ij}.
\]

sumSqr \( (w) \) Sum of the squares of all elements in \( w \).

syncCorrelation \( (w) \) Synchronous spectrum correlation matrix for a real valued input matrix wave \( w \). See also asyncCorrelation.

The correlation matrix is computed by subtracting from each column of \( w \) its mean value, multiplying the resulting matrix by its transpose, and finally dividing all elements by \((nrows-1)\) where nrows is the number of rows in \( w \).

tan \( (w) \) Tangent of \( w \).

tanh \( (w) \) Hyperbolic tangent of \( w \). Added in Igor Pro 7.00.

tensorProduct \( (w1, w2) \) Returns a 2D matrix that is the tensor product of the 2D matrices \( w1 \) and \( w2 \). For example, the tensor product of two \((2 \times 2)\) matrices is given by:

\[
\begin{pmatrix}
  a_{11} & a_{12} \\
  a_{21} & a_{22}
\end{pmatrix} \otimes \begin{pmatrix}
  b_{11} & b_{12} \\
  b_{21} & b_{22}
\end{pmatrix} = \begin{pmatrix}
  a_{11}b_{11} & a_{11}b_{12} & a_{12}b_{11} & a_{12}b_{12} \\
  a_{11}b_{21} & a_{11}b_{22} & a_{12}b_{21} & a_{12}b_{22} \\
  a_{21}b_{11} & a_{21}b_{12} & a_{22}b_{11} & a_{22}b_{12} \\
  a_{21}b_{21} & a_{21}b_{22} & a_{22}b_{21} & a_{22}b_{22}
\end{pmatrix}
\]

Added in Igor Pro 7.00.

Trace \( (w) \) Returns a real or complex scalar which is the sum of the diagonal elements of \( w \). If \( w \) is not a square matrix, the sum is over the elements for which the row and column indices are the same.
MatrixOp

transposeVol(w, mode) For 3D wave w, transposeVol returns a transposed 3D wave depending on the value of the mode parameter:
- mode=1: output=w[p][r][q]
- mode=2: output=w[r][p][q]
- mode=3: output=w[r][q][p]
- mode=4: output=w[q][r][p]
- mode=5: output=w[q][p][r]

transposeVol is a non-layered function which requires that w be a proper 3D wave and not the result of another expression.

triDiag(w1, w2, w3) Returns a tri-diagonal matrix where w1 is the upper diagonal, w2 the main diagonal and w3 the lower diagonal. If w2 has n points then w1 and w3 are expected to have n-1 points. The waves can be of any numeric type and the returned wave has a numeric type that accommodates the input.

uint8(w) Converts w to 8-bit unsigned integer representation. See also the /NPRM flag below for more information. Added in Igor Pro 7.00.

uint16(w) Converts w to 16-bit unsigned integer representation. See also the /NPRM flag below for more information. Added in Igor Pro 7.00.

uint32(w) Converts w to 32-bit unsigned integer representation. See also the /NPRM flag below for more information. Added in Igor Pro 7.00.

varCols(w) Returns a (1 x cols) wave where each element contains the variance of the corresponding column in w.

waveIndexSet(w1, w2, w3) Returns a matrix of the same dimensions as w1 with values taken either from w1 or from w3 depending on values in w2 using:

\[
out[i][j] = \begin{cases} 
  w1[i][j] & \text{if } w2[i][j] < 0 \\
  w3[w2[i][j]] & \text{otherwise}
\end{cases}
\]

w1 and w2 must have the same number of rows and columns. w1 and w3 must match in number type. w2 cannot be unsigned.

Values from w2 are used as point number indices into w3 which is treated like a 1D wave regardless of its actual dimensionality.

An index value from w2 is out-of-bounds if it is greater than or equal to the number of points in w3. In this case, the output value is taken from w1 as if the index value were negative.

waveMap(w1, w2) Returns an array of the same dimensions as w2 containing the values w1[w2[i][j]]. The data type of the output is the same as that of w1. Values of w2 are taken as 1D integer indices into the w1 array. See also IndexSort.

waveChunks(w) Returns the number of chunks in the wave w. Added in Igor Pro 7.00.

waveLayers(w) Returns the number of layers in the wave w. Added in Igor Pro 7.00.

wavePoints(w) Returns the number of points in the wave w. Added in Igor Pro 7.00.

within(w, low, high) Returns an array of the same dimensions as w with the value 1 where the corresponding element of w is between low and high (low <= w[i][j] < high). Added in Igor Pro 7.00.

All parameters must be real. It is an error to pass a NaN as either low or high. It is also an error if low >= high. If w contains NaNs, the corresponding outputs are 0.
MatrixOp

zeroMat(r, c, nt)  Returns an (r x c) matrix of number type nt where all entries are set to zero. See WaveType for supported types. See also const above. Added in Igor Pro 7.00.

Trigonometric Transform Functions

FCT(w, dir)  Computes the fast, real to real cosine transform on 1D wave w.
            Added in Igor Pro 8.00.
            The forward transform (dir=1) is defined by:

            \[ F(k) = \frac{1}{n} \left[ f(0) + f(n) \cos(k\pi) \right] + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \left( \frac{ik\pi}{n} \right), \quad k = 0, \ldots, n \]

            The number of intervals is \( n = \text{numpnts}(w) - 1 \).
            The inverse transform (dir=-1) is defined by:

            \[ f(i) = \frac{1}{2} \left[ F(0) + F(n) \cos(i\pi) \right] + \sum_{k=1}^{n-1} F(k) \cos \left( \frac{ik\pi}{n} \right), \quad i = 0, \ldots, n \]

            See Trigonometric Transforms on page V-531 below for more information.

FST(w, dir)  Computes the fast, real to real sine transform on 1D wave w.
            Added in Igor Pro 8.00.
            The forward transform (dir=1) is defined by:

            \[ F(k) = \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \left( \frac{ik\pi}{n} \right), \quad k = 1, \ldots, n - 1 \]

            The number of intervals is \( n = \text{numpnts}(w) - 1 \).
            The inverse transform (dir=-1) is defined by:

            \[ f(i) = \sum_{k=1}^{n-1} F(k) \sin \left( \frac{ik\pi}{n} \right), \quad i = 1, \ldots, n - 1 \]

            See Trigonometric Transforms on page V-531 below for more information.
MatrixOp

**FSST(\(w, \text{dir}\))** Computes the fast, real to real staggered sine transform on 1D wave \(w\).

Added in Igor Pro 8.00.

The forward direction \((\text{dir}=1)\) is defined by:

\[
F(k) = \frac{1}{n} \sin \left( \frac{(2k-1)\pi}{2} \right) f(n) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \left( \frac{i(2k-1)\pi}{2n} \right), \quad k = 1, \ldots, n
\]

Here the number of intervals is \(n = \text{numpnts}(w) - 1\).

The inverse transform \((\text{dir}=-1)\) is defined by:

\[
f(i) = \sum_{k=1}^{n} F(k) \sin \left( \frac{i(2k-1)\pi}{2n} \right), \quad i = 1, \ldots, n
\]

See Trigonometric Transforms on page V-531 below for more information.

**FSCT(\(w, \text{dir}\))** Computes the fast, real to real, staggered cosine transform on 1D wave \(w\).

Added in Igor Pro 8.00.

The forward direction \((\text{dir}=1)\) is defined by:

\[
F(k) = \frac{1}{n} f(0) + \frac{2}{n} \sum_{j=1}^{n-1} f(j) \cos \left( \frac{j\pi(2k+1)}{2n} \right), \quad k = 0, \ldots, n-1
\]

The inverse transform \((\text{dir}=-1)\) is defined by:

\[
f(i) = \sum_{k=0}^{n-1} F(k) \cos \left( \frac{(2k+1)i\pi}{2n} \right), \quad i = 0, \ldots, n-1
\]

See Trigonometric Transforms on page V-531 below for more information.

**FSST2(\(w, \text{dir}\))** Computes the fast, real to real, staggered2 sine transform on 1D wave \(w\).

Added in Igor Pro 8.00.

The forward direction \((\text{dir}=1)\) is defined by:

\[
F(k) = \frac{2}{n} \sum_{i=1}^{n} f(i) \sin \left( \frac{(2k-1)(2i-1)\pi}{4n} \right), \quad k = 1, \ldots, n
\]

The inverse transform \((\text{dir}=-1)\) is defined by:

\[
f(i) = \sum_{k=1}^{n} F(k) \cos \left( \frac{(2k-1)(2i-1)\pi}{4n} \right), \quad i = 1, \ldots, n
\]

See Trigonometric Transforms on page V-531 below for more information.
Functions Using Quaternions
These functions create and manipulate quaternion tokens or return quaternion results. They were added in Igor Pro 8.00. See MatrixOp Quaternion Data Tokens on page III-145 for background information on quaternions in MatrixOp.

**quat(arg)**
Converts arg into a quaternion token.

arg can be:
- A scalar which is converted to a real quaternion
- A 1x3 or 3x1 wave which is converted to a pure imaginary quaternion
- The output from another quat call

Arithmetic on quaternion tokens obeys quaternion arithmetic rules.

arg must not be complex. The resulting quaternion token is not normalized by the quat function.

See MatrixOp Quaternion Data Tokens on page III-145 for details.

**quatToMatrix(qIn)**
Converts qIn into a quaternion token, if not already a quaternion token, normalizes it, and returns the equivalent 4x4 homogeneous rotation matrix.

**quatToAxis(qIn)**
Converts qIn into a quaternion token, if not already a quaternion token, normalizes it, and returns the equivalent axis of rotation and rotation angle. The result is a 4-element wave in which the first three elements define the rotation axis and the last element is the rotation angle in radians.

**quatToEuler(qIn, mode)**
Converts qIn into a quaternion token, if not already a quaternion token, and returns a 3x1 wave containing equivalent Euler angles expressed in radians.

The returned Euler angles are phi (rotation about the X axis), theta (rotation about the Y axis), and psi (rotation about the Z axis).

The mode parameter defines the rotation sequence. The supported modes are: 121, 123, 131, 132, 212, 213, 231, 232, 312, 313, 321 and 323. 1 designates the X axis, 2 the Y axis and 3 the Z axis. See, for example: https://www.euclideanspace.com/maths/geometry/rotations/conversions/quatToEuler/quat_2_euler_paper_ver2-1.pdf
MatrixOp was designed to work with 2D waves (matrices) but also works with 1D, 3D and 4D waves. A 1D wave is treated like a 1-column matrix. 3D and 4D waves are treated on a layer-by-layer basis, as if each layer were a matrix.

You can reference subsets of waves in expression. Only two types of subsets are supported: those that evaluate to a single element, which are treated as scalars, and those that evaluate to one or more layers. For example:

```
wave1d[a]       Scalar
wave2d[a][b]    Scalar
wave3d[a][b][c] Scalar
wave3d[][](a)   Layer a from 3D wave
wave3d[][](a,b) Layers a through b from 3D wave
wave3d[][](a,b,c) Layers a through b stepping by c from 3D wave
```

You can pass waves of any dimensions as parameters to MatrixOp functions. For example:

```
Make/O/N=128 wave1d = x
MatrixOp/O outWave = powR(wave1d,2)
```

MatrixOp does not allow using the same 3D wave on both sides of the assignment:

```
MatrixOp/O wave3D = wave3D + 3   // Not allowed
```

See MatrixOp Wave Data Tokens on page III-140 for further discussion.

Flags

/C Provides a complex wave reference for destWave. If omitted, MatrixOp creates a real wave reference for destWave. The wave reference allows you to refer to the output wave in a subsequent statement of a user-defined function.

/FREE Creates destWave as a free wave. Allowed only in functions and only if a simple name or wave reference structure field is specified.

Requires Igor Pro 6.1 or later. For advanced programmers only.

See Free Waves on page IV-89 for more discussion.

/NTHR=n Sets the number of threads used to compute the results for 3D waves. Each thread computes the results for a single layer of the input.

By default (/NTHR omitted) the calculations are performed by the main thread only.

If n=0 the operation uses as many threads you have processors on your computer.

If n>0, n specifies the number of threads to use. More threads may or may not improve performance.
MatrixOp

/\text{NPRM} \quad \text{Use /NPRM to restrict the automatic promotion of numeric data types in MatrixOp expressions.}

By default, MatrixOp promotes numeric data types so that operations result in reasonable accuracy. In some situations you may want to keep the results as a particular data type even at the risk of truncation or overflow. If you include the /NPRM flag, MatrixOp creates the destination wave using the highest precision data type in the expression. For example, an expression A=B+C where B is 16-bit wave and C is an 8-bit wave results in a 16-bit wave A. Unsigned number types can result only when all operands are unsigned.

/NPRM is ignored when data promotion is required. For example:

\begin{verbatim}
Make/B/U wave2
MatrixOp/O/NPRM wave1 = -wave2
\end{verbatim}

You can use MatrixOp functions such as int8, int16, etc., to precisely control the number type of any token.

/O \quad \text{Overwrites destWave if it already exists.}

/P=\text{printMode} \quad \text{Controls printing of the result of the MatrixOp evaluation. /P was added in Igor Pro 8.00.}

/P is ignored if MatrixOp is not running in the main thread.

\text{printMode} is a value between 0 and 2:

0: \quad \text{No printing is done (default).}

1: \quad \text{Prints the result from evaluating expression in layer-by-layer order to the history area of the command window and stores the result in the destination wave.}

2: \quad \text{Prints the result from evaluating expression in layer-by-layer order to the history area of the command window but does not create or store the resulting values in the destination wave. If the destination wave may already exist, you must include the /O flag, even though the destination wave is not changed by the operation.}

Use /P=1 if you want MatrixOp to work normally and then to print the destination wave.

Use /P=2 if you want MatrixOp to print its result without creating or affecting any waves.

Values are printed sequentially using 16-digit precision. Output is not formatted to represent rows and columns.

When the operation's result is a 3D or 4D wave, the results are printed on a layer-by-layer basis.

See \text{MatrixOp Printing Examples} on page V-532 below.

/S \quad \text{Preserves the dimension scaling, units and wave note of a pre-existing destination wave in a MatrixOp/O command.}

\textbf{Details}

MatrixOp has the general form:

\texttt{MatrixOp [flags] destWave = expression}

destWave specifies the wave created by MatrixOp or overwritten by MatrixOp/O.

From the command line, destWave can be a simple wave name, a partial data folder path or a full data folder path. In a user-defined function it can be a simple wave name or, if /O is present, a wave reference pointing to an existing wave.

expression is a mathematical expression that consists of one or more data tokens combined with the built-in MatrixOp functions and MatrixOp operators listed above. MatrixOp does not support the p, q, r, s, or x, y, z, t symbols that are used in waveform assignment statements.

Data tokens include waves, variables and literal numbers.
You can use any combination of data types for operands. In particular, you can mix real and complex types in expression. MatrixOp determines data types of inputs and the appropriate output data type at runtime without regard to any type declaration such as Wave/C.

**Trigonometric Transforms**

The trigonometrics transform functions were added in Igor Pro 8.00.

FST, FCT, FSST, FSCT, FSST2 and FSCT2 are implemented using INTEL MKL library functions. The transforms may automatically execute in multiple threads.

In MatrixOP's implementation, all input and output arrays are zero based. This is illustrated by the following example for the staggered2 cosine:

```plaintext
Function DoStaggered2Cosine(inWave)
    Wave inWave
    Variable n = dimsize(inWave,0)
    Make/O/N=(n)/D outStaggered2CosTransform=0
    Variable i, k, theSum, frontFactor=2/n
    for(k=1; k<=n; k+=1)
        theSum=0
        for(i=1; i<=n; i+=1)
            theSum += inWave[i-1] * cos((2*k-1) * (2*i-1) * pi/(4*n))
        endfor
        outStaggered2CosTransform[k-1] = frontFactor * theSum
    endfor
End
```

**Examples**

In addition to these examples, see MatrixOp Optimization Examples on page III-147.

The following matrices are used in these examples:

Make/O/N=(3,3) r1=x, r2=y

Matrix addition and matrix multiplication by a scalar:

MatrixOp/O outWave = r1+r2-3*r1

Using the matrix Identity function:

MatrixOp/O outWave = Identity(3) x r1

Create a persisting identity matrix for another calculation:

MatrixOp/O id4 = Identity(4)

Using the Trace function:

MatrixOp/O outWave = (Trace(r1)*identity(3) x r1)-3*r1

Using matrix inverse function Inv() with matrix multiplication:

MatrixOp/O outWave = Inv(r2) x r2

Using the determinant function Det():

MatrixOp/O outWave = Det(r1)+Det(r2)

Using the Transpose postfix operator:

MatrixOp/O outWave = r1^t+(r2-r1)^t-r2^t

Using a mix of real and complex data:

Variable/C complexVar = cmplx(1,2)
MatrixOp/O outWave = complexVar*r2 - Cmplx(2,4)*r1

Hermitian transpose operator:

MatrixOp/O outWave = Trace(complexVar*r2)^h -Trace(cmplx(2,4)*r1)^h

In-place operation and conversion to complex:

MatrixOp/O r1 = r1*cmplx(1,2)

Image filtering using 2D spatial filter filterWave:

MatrixOp/O filteredImage=IFFT(FFT(srcImage,2)*filterWave,3)
Positive shift:
Make/O w={0,1,2,3,4,5,6}
MatrixOp/O w=shiftVector(w,2,77)
Print w
// w[0]= {77,77,0,1,2,3,4}

Negative shift:
Make/O w={0,1,2,3,4,5,6}
MatrixOp/O w=shiftVector(w,(-2),77)
Print w
// w[0]= {2,3,4,5,6,77,77}

MatrixOp Printing Examples
// Print a single-valued result
Make/O/N=(10,5) m2D=(p+1)*(q+1)
MatrixOp/O/P=1 aa=sum(m2D)
aa={825}

// Print a real 2D result
Make/O/N=(1,4) ddd=enoise(3)
MatrixOp/O/P=1 aa=ddd
aa={-2.273916482925415,-2.327789783477783,1.286988377571106,-0.8658701777458191}

// Print higher-dimension result layer-by-layer
Make/O/N=(3,4,3) ddd=z+1
MatrixOp/O/P=1 aa=mean(ddd)
aa={1} // Each layer results in a 1x1 value
aa={2}
aa={3}

FastOp

MatrixRank

```matlab
matrixRank(matrixWaveA [, conditionNumberA])
```

The matrixRank function returns the rank of `matrixWaveA` subject to the specified condition number.

The matrix is not considered to have full rank if its condition number exceeds the specified `conditionNumberA`.

If the optional parameter `conditionNumberA` is not specified, Igor Pro uses the value $10^{20}$.

`matrixRank` supports real and complex single precision and double precision numeric wave data types.

The value of `conditionNumberA` should be large enough but taking into account the accuracy of the numerical representation given the numeric data type.

If there are any errors the function returns NaN.

See Also
Matrix Math Operations on page III-137 for more about Igor’s matrix routines.
MatrixSchur

MatrixSchur [/Z] srcMatrix
The MatrixSchur operation computes for an NxN nonsymmetric srcMatrix, the eigenvalues, the real Schur form A and the matrix of Schur vectors V.

The Schur factorization has the form: S = V x A x (V^T), where V^T is the transpose (use V^H if S is complex) and x denotes matrix multiplication.

Flags
/Z No error reporting.

Details
The operation creates:

M_A Upper triangular matrix containing the Schur form A.
M_V Unitary matrix containing the orthogonal matrix V of the Schur vectors.
W_REigenValues Waves containing the real and imaginary parts of the eigenvalues when srcMatrix is a real wave. If srcMatrix is complex, the eigenvalues are stored in W_eigenValues.

The variable V_flag is set to 0 when there is no error; otherwise it contains the LAPACK error code.

Examples
You can test this operation for an N-by-N source matrix:
Make/D/C/H=(5,5) M_S=cmplx(enoise(1),enoise(1))
MatrixSchur M_S
MatrixOp/O unitary=(M_V^h) x M_V // Check unitary
MatrixOp/O diff=abs(M_S-M_V x M_A x (M_V^H)) // Check decomposition

See Also
Matrix Math Operations on page III-137 for more about Igor’s matrix routines and for background references with details about the LAPACK libraries.

MatrixSolve

MatrixSolve method, matrixA, vectorB
The MatrixSolve operation was superseded by MatrixLLS and is included for backward compatibility only.

Used to solve matrix equation Ax=b using the method of your choice. Choices for method are:

method Solution Method
GJ Gauss Jordan.
LU LU decomposition.
SV Singular Value decomposition.

Details
The array b can be a matrix containing a number of b vectors and the output matrix M_x will contain a corresponding set of solution vectors.

V_flag is set to zero if success, 1 if singular matrix using GJ or LU and 1 if SV fails to converge.

For normal problems you should use LU. GJ is provided only for completeness and has no practical use.

When using SV, singular values smaller than 10^-6 times the largest singular value are set to zero before back substitution.

Generates an error if the dimensions of the input matrices are not appropriate.

See Also
The MatrixLLS operation. Matrix Math Operations on page III-137 for more about Igor’s matrix routines.
MatrixSVBkSub

MatrixSVBkSub matrixU, vectorW, matrixV, vectorB
The MatrixSVBkSub operation does back substitution for SV decomposition.

Details
Used to solve matrix equation Ax=b after you have performed an SV decomposition.
Feed this routine the M_U, W_W and M_V waves from MatrixSVD along with your right-hand-side vector b. The solution vector x is returned as M_x.
The array b can be a matrix containing a number of b vectors and the M_x will contain a corresponding set of solution vectors.
Generates an error if the dimensions of the input matrices are not appropriate.

See Also
Matrix Math Operations on page III-137 for more about Igor’s matrix routines.

MatrixSVD

MatrixSVD [flags] matrixWave
The MatrixSVD operation uses the singular value decomposition algorithm to decompose an MxN matrixWave into a product of three matrices. The default decomposition is into MxM wave M_U, min(M,N) wave W_W and Nxn wave M_VT.

Flags
/B Use this flag for backwards compatibility with Igor Pro 3. This option applies only to real valued input waves. Note that no other flag can be combined with /B. Here the decomposition is such that:

U*W*V^T = matrixWave
U: MxN column-orthonormal matrix.
W: Nxn diagonal matrix of positive singular values.
V: Nxn orthonormal matrix.

/DACA Replaces the standard LAPACK algorithm with one that is based on a divide and conquer approach. For a typical 1000x1000 matrix this provides a 6x speed improvement.
Added in Igor Pro 7.00.

/INVW Saves the inverse of the elements in W_W. The results are then stored in wave W_InvW.

/O Overwrites matrixWave with the first columns of U. Use this flag to if you need to conserve memory. See also related settings of /U and /V.

/PART = nVals Performs a partial SVD computing only nVals singular values (stored in W_W) and the associated vectors in the matrix M_U and M_V. If you use this flag the operation ignores all other flags except /PDEL. The partial SVD is computed using the Power method of Nash and Shlien.
The /PART flag was added in Igor Pro 7.00.

/PDEL = del Sets the convergence threshold which defaults to 1e-6. Larger positive values result in faster execution but may lead to less accurate results.
The /PDEL flag was added in Igor Pro 7.00.
MatrixTrace

/U = UMatrixOptions

UMatrixOptions can have the following values:
0: All columns of U are returned in the wave M_U (default).
1: The first min(m,n) columns of U are returned in the wave M_U.
2: The first min(m,n) columns of U overwrite matrixWave (/O must be specified).
3: No columns of U are computed.

/V = VMatrixOptions

VMatrixOptions can have the following values:
0: All rows of V^T are returned in the wave M_VT (default).
1: The first min(m,n) rows of V^T are returned in the wave M_VT.
2: The first min(m,n) rows of V^T are overwritten on matrixWave (/O must be specified).
3: No rows of V^T are computed.

/Z

No error reporting.

Details
The singular value decomposition is computed using LAPACK routines. The diagonal elements of matrix W are returned as a 1D wave named W_W. If /B is used W_W will have N elements. Otherwise the number of elements in W_W is min(M,N).

The matrix V is returned in a matrix wave named M_V if /B is used otherwise the transpose V^T is returned in the wave M_VT.

All output objects are created in the current data folder.

The variable V_flag is set to zero if the operation succeeds. It is set to 1 if the algorithm fails to converge.

The variable V_SVConditionNumber is set to the condition number of the input matrix. The condition number is the ratio of the largest singular value to the smallest.

Example
Make/O/D/N=(10,20) A=gnoise(10)
MatrixSVD A
MatrixOp/O diff=abs(A-(M_U x DiagRC(W_W,10,20) x M_VT))
Print sum(diff,-inf,inf)

References

See Also
The MatrixOp operation for more efficient matrix operations.
Matrix Math Operations on page III-137 for more about Igor's matrix routines and for background references with details about the LAPACK libraries.

MatrixTrace

matrixTrace(dataMatrix)

The matrixTrace function calculates the trace (sum of diagonal elements) of a square matrix. dataMatrix can be of any numeric data type.

If the matrix is complex, it returns the sum of the magnitudes of the diagonal elements.

See Also
Matrix Math Operations on page III-137 for more about Igor's matrix routines.
MatrixTranspose

**MatrixTranspose**

MatrixTranspose [/H] matrix

The MatrixTranspose operation Swaps rows and columns in matrix.

Does not take complex conjugate if data are complex. You can do that as a follow-on step.

Swaps row and column labels, units and scaling.

This works with text as well as numeric waves. If the matrix has zero data points, it just swaps the row and column scaling.

**Flags**

/H Computes the Hermitian conjugate of a complex wave.

**See Also**

The MatrixOp operation for more efficient matrix operations.

**Matrix Math Operations** on page III-137 for more about Igor’s matrix routines.

**max**

max(num1, num2 [, num3, ... num200])

The max function returns the greatest value of num1, num2, ... num200.

If any parameter is NaN, the result is NaN.

**Details**

In Igor7 or later, you can pass up to 200 parameters. Previously max was limited to two parameters.

**See Also**

min, limit, WaveMin, WaveMax

**mean**

mean(waveName [, x1, x2])

The mean function returns the arithmetic mean of the wave for points from x=x1 to x=x2.

**Details**

If x1 and x2 are not specified, they default to -∞ and +∞, respectively.

The wave values from x1 to x2 are summed, and the result divided by the number of points in the range.

The X scaling of the wave is used only to locate the points nearest to x=x1 and x=x2. To use point indexing, replace x1 with pnt2x(waveName, pointNumber1), and a similar expression for x2.

If the points nearest to x1 or x2 are not within the point range of 0 to numpnts(waveName)-1, mean limits them to the nearest of point 0 or point numpnts(waveName)-1.

If any values in the point range are NaN, mean returns NaN.

The function returns NaN if the input wave has zero points.

Unlike the area function, reversing the order of x1 and x2 does not change the sign of the returned value.

**Examples**

Make/O/N=100 data; SetScale/I x 0,Pi,data
data=sin(x)
Print mean(data,0,Pi) // the entire point range, and no more
Print mean(data) // same as -infinity to +infinity
Print mean(data,Inf,-Inf) // +infinity to -infinity

The following is printed to the history area:

Print mean(data,0,Pi) // the entire point range, and no more
0.630201
Print mean(data) // same as -infinity to +infinity
0.630201
Print mean(data,Inf,-Inf) // +infinity to -infinity
0.630201

max
See Also
Variance, WaveStats, median, APMath

The figure “Comparison of area, faverage and mean functions over interval (12.75,13.32)”, in the Details section of the faverage function.

median
median(waveName [, x1, x2])
The median function returns the median value of the wave for points from \(x=x1\) to \(x=x2\).
The median function was added in Igor Pro 7.00.

Details
If you omit \(x1\) and \(x2\), they default to -INF and +INF, respectively.
The X scaling of the wave is used only to locate the points nearest to \(x=x1\) and \(x=x1\). To use point indexing, replace \(x1\) with "pnt2x(waveName,pointNumber1 )", and a similar expression for \(x2\).
If the points nearest to \(x1\) or \(x2\) are outside the point range of 0 to numpnts(waveName)-1, median limits them to the nearest of point 0 or point numpnts(waveName)-1.
If the wave contains NaNs they are skipped.
The function returns NaN if the input wave has zero non-NaN points.

See Also
mean, Variance, StatsMedian, StatsQuantiles, WaveStats

MeasureStyledText
MeasureStyledText [/W=winName /A=axisName /F=fontName /SIZE=fontSize /STYL=fontStyle] styledTextStr
The MeasureStyledText operation takes as input a string optionally containing style codes such as are used in graph annotations. It sets various variables with information about the dimensions of the string.

Flags
/W=winName Takes default text information from the window \(winName\).
/A=axisName Takes default text information from the axis named \(axisName\). If the /W flag is used, the axis should be in that window (the window should also be a graph). If the /W flag is not used, MeasureStyledText looks at the top graph window.
/F=fontNameStr The name of the default font.
/SIZE=size Sets default font size.
/STYL=fontStyle Sets default font style:
  Bit 0: Bold
  Bit 1: Italic
  Bit 2: Underline
  Bit 4: Strikethrough

See Setting Bit Parameters on page IV-13 for details about bit settings.
Parameters

- \textit{styledTextStr} The text to be measured.
  The text can contain escape codes to set the font, size, style, color and other properties.
  See \textit{Annotation Escape Codes} on page III-54 for details.

Details

In the absence of formatting codes within the text that set the font, font size and font style, some mechanism must be provided that sets them. The /W flag tells MeasureStyledText to look at a particular window and get defaults from that window.

The /A flag specifies that the defaults should come from a graph’s axis of the given name. MeasureStyledText will look for the axis in the window named by /W, or in the top graph window in the absence of the /W flag.

The /F, /SIZE and /STYL flags set defaults that override any defaults from a window or axis. If you don’t use any flags, the defaults are Igor’s overall defaults.

Variables

The MeasureStyledText operation returns information in the following variables:

- \textit{V\_width} The width in points of the text.
- \textit{V\_height} The height in points of the text.

See Also

\textit{Annotation Escape Codes} on page III-54 for a list of text formatting codes.

Menu

\texttt{Menu \textit{menuNameStr} [, hideable, dynamic, contextualmenu]}

The Menu keyword introduces a menu definition. You can use this to create your own menu, or to add items to a built-in Igor menu.

Use the optional \textit{hideable} keyword to make the menu hideable using \texttt{HideIgorMenus}.

Use the optional \textit{dynamic} keyword to cause Igor to re-evaluate the menu definition when the menu is used. This is helpful when the menu item text is provided by a user-defined function. See \textit{Dynamic Menu Items} on page IV-126.

Use the optional \textit{contextualmenu} keyword for menus invoked by \texttt{PopupContextualMenu/N}.

See Chapter IV-5, \textit{User-Defined Menus} for further information.

\textit{min}

\texttt{min(num1, num2 [, num3, ... num200])}

The min function returns the least value of \textit{num1}, \textit{num2}, ... \textit{num200}.

If any parameter is NaN, the result is NaN.

Details

In Igor7 or later, you can pass up to 200 parameters. Previously min was limited to two parameters.

See Also

\textit{max}, \textit{limit}, \textit{WaveMin}, \textit{WaveMax}

\textit{MLLoadWave}

\texttt{MLLoadWave [flags] fileNameStr}

The MLLoadWave operation loads data from the named Matlab MAT file into single 1D waves (vectors), multidimensional waves (matrices), numeric variables or string variables.

For background information, including configuration instructions, see \textit{Loading Matlab MAT Files} on page II-148.
Parameters
The file to be loaded is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If LoadWave can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-429 for details on forming the path.

If fileNameStr is omitted or is "" or the /I flag is used, MLLoadWave displays an Open File dialog in which you locate the file to be loaded.

Flags
/A[]=name  Assign wave names using "wave" or name, if present, as the name or base name. Skips names already in use.
/B  This flag is obsolete and is ignored. Previously it was required to tell MLLoadWave the byte order of the data in the file. MLLoadWave now determines the byte order automatically.
/C  Loads columns from a Matlab matrix into an Igor 1D wave. Use /R to load rows.
/E  Skips empty Matlab matrices.
/G  Tells Igor to make numeric and string variables global when called from a macro. When called from a user-defined function or from the command line, variables are always created as globals.
/I  Interactive. Displays the Open File dialog to get the path to the file.
/M=m  m=1: Loads an entire Matlab matrix into an Igor 1D wave. This is the default if you omit /M.
     m=2: Loads an entire Matlab matrix into an Igor multidimensional wave.
     m=3: Loads an entire Matlab matrix into a transposed Igor multidimensional wave.
     /M by itself is equivalent to /M=1.
     Starting with Igor Pro 8.00, after loading a matrix that results in an Mx1 2D wave, MLLoadWave automatically redimensions the wave as an M-row 1D wave.
/N[]=name  Assign wave names using "wave" or name, if present, as the name or base name. Overwrites existing waves if the name is already in use.
/O  Overwrites existing waves and variables in case of a name conflict. If /O is omitted, MLLoadWave chooses names that don’t conflict with existing objects.
/P=pathName  Specifies the folder to look in for the specified file or folder. pathName is the name of an existing Igor symbolic path.
/Q  Be quiet. Suppresses normal diagnostic messages.
/R  Loads rows from a Matlab matrix into an Igor 1D wave. Use /C to load columns.
/S=s  Controls how Matlab string data is loaded:
     s=1  Skips Matlab string matrices.
     s=2  Loads Matlab string matrices into Igor string variables. This is the default if /S is omitted.
     s=3  Loads Matlab string matrices into Igor text waves.
     /S by itself is equivalent to /S=1.
/T  Displays the loaded waves in a new table.
/V  Skips Matlab numeric variables (numeric matrices with one element).
MLLoadWave Wave Naming
If neither /A, /A=name, /N, or N=name is used then the waves names are taken from the matrix name, as stored in the Matlab file.

When loading 1D waves, the /N flag instructs MLLoadWave to automatically name new waves "wave" (or baseName if /N=baseName is used) plus a number. The number starts from zero and increments by one for each wave loaded from the file. When loading multidimensional waves, name is used without an appended number.

The /A flag is like /N except that MLLoadWave skips names already in use.

If you specify /M=2 (load matrix into matrix) or /M=3 (load matrix into transposed matrix), MLLoadWave uses the name without appending any digits. For example, if you have a 5x3 matrix in a file and you tell MLLoadWave to load it as a matrix using the name "mat", MLLoadWave will name the matrix "mat".

However, if you tell MLLoadWave to load the matrix as 3 1D waves, it will use "mat0", "mat1" and "mat2".

If the name that MLLoadWave would use when creating a wave or variable is in use for an object of the same type and if you use the overwrite flag, then it will overwrite the existing object. If you do not tell MLLoadWave to overwrite, it will choose a non-conflicting name. If the conflict is with an object of a different type or with an operation or function, MLLoadWave will also choose a non-conflicting name.

Loading Strings from Matlab Files
When loading Matlab strings into Igor, you can tell MLLoadWave to create Igor string variables or Igor text waves. For example, if you have a 2x8 string matrix, MLLoadWave can create two string variables (/S=2) or one text wave (/S=3) containing two elements.

When loading Matlab string data into an Igor wave, the Igor wave will be of dimension one less than the Matlab data set. This is because each element in a Matlab string data set is a single byte whereas each element in an Igor string wave is a string (any number of bytes).

Loading Numeric Variables from Matlab Files
MLLoadWave loads numeric matrices with one element into Igor numeric variables. It loads all other numeric matrices into Igor waves.

When called from a macro, MLLoadWave creates local numeric and string variables unless you use the /G flag which tells it to create global variables. When called from the command line or from a user-defined function, MLLoadWave always creates global variables. Macros should be avoided in new programming.

Automatic Redimensioning from 2D to 1D
Starting with Igor Pro 8.00, after loading a matrix that results in an Mx1 2D wave, MLLoadWave automatically redimensions the wave as an M-row 1D wave.

This automatic redimensioning not affect the naming of the wave. It is still named using the 2D rules explained above under MLLoadWave Wave Naming.

Loading 3D and 4D Data from Matlab Files
For a discussion of how MLLoadWave handles 3D and 4D Matlab data, see Numeric Data Loading Modes.

/Y=y
Specifies the number type of the numeric waves to be created. The allowed codes for y are:

2: Single-precision floating point
4: Double-precision floating point
32: 32-bit signed integer
16: 16-bit signed integer
8: 8-bit signed integer
96: 32-bit signed integer
80: 16-bit signed integer
72: 8-bit signed integer

/Z
Interactive load. Displays a dialog presenting options for each Matlab matrix in the file.
Specifying Loading Options for Each Matlab Matrix

The /Z flag instructs MLLoadWave to load each Matlab object (matrix, vector, variable, string) step by step. MLLoadWave presents a dialog for each Matlab object in the file. You can choose to load or skip the object. If you omit the /Z flag, MLLoadWave will load all objects in the file without presenting any dialogs.

Output Variables

MLLoadWave sets the following output variables:

- **S_path**: File system path to the folder containing the file. This is a system file path (e.g., "hd:FolderA:FolderB:"), not an Igor symbolic path. The path uses Macintosh path syntax, even on Windows, and has a trailing colon.
- **S_fileName**: Name of the loaded file.
- **V_flag**: Number of waves created.
- **V_flag1**: Number of Matlab data sets (2D, 3D, or 4D) loaded.
- **V_flag2**: Number of waves created.
- **V_flag3**: Number of numeric variables created.
- **V_flag4**: Number of string variables created.
- **S_waveNames**: Semicolon-separated list of the names of loaded waves.

Prior to MLLoadWave 5.50, the variables V_Flag1, V_Flag2, V_Flag3 and V_Flag4 were named V1_Flag, V2_Flag, V3_Flag and V4_Flag.

See Also

- Symbolic Paths on page II-21
- See Loading Matlab MAT Files on page II-148 for background information, including configuration instructions.

\[ \text{mod} \]

\[ \text{mod}(\text{num}, \text{div}) \]

The mod function returns the remainder when \( \text{num} \) is divided by \( \text{div} \).

The mod function may give unexpected results when \( \text{num} \) or \( \text{div} \) is fractional because most fractional numbers can not be precisely represented by a finite-precision floating point value.

See Also
- trunc, gcd

\[ \text{ModDate} \]

\[ \text{ModDate}(\text{waveName}) \]

The ModDate function returns the modification date/time of the wave.

Details

The returned value is a double precision Igor date/time value, which is the number of seconds from 1/1/1904. It returns zero for waves created by versions of Igor prior to 1.2, for which no modification date/time is available.

See Also
- WaveModCount, Secs2Date, Secs2Time
Modify

Modify

We recommend that you use ModifyGraph, ModifyTable, ModifyLayout, or ModifyPanel rather than Modify. When interpreting a command, Igor treats the Modify operation as ModifyGraph, ModifyTable, ModifyLayout or ModifyPanel, depending on the target window. This does not work when executing a user-defined function.

ModifyBoxPlot

ModifyBoxPlot [/W=winName] [keyword=value, keyword=value, ...]

The ModifyBoxPlot operation modifies a box plot trace in the target or named graph. To create a box plot trace, see AppendBoxPlot. For a detailed discussion of box plots and the parts of a box plot, see Box Plots on page II-266.

ModifyBoxPlot was added in Igor Pro 8.00.

Parameters

trace=traceName Specifies the name of a box plot trace to be modified. An error results if the named trace is not a box plot trace. Without the trace keyword, ModifyBoxPlot uses the first trace in the graph, whether it is a box plot trace or not. But, see the instance keyword for an exception.

instance=instanceNum The combination of trace and instance works the same as (traceName#instanceNum) for a ModifyGraph keyword.

The instance keyword without trace keyword accesses the instanceNum'th trace in the graph, just like [traceNum] used with a ModifyGraph keyword. See Trace Names on page II-222 and Object Indexing on page IV-21.

medianIsMarker[]=v If v is omitted or is non-zero, the median is shown using a marker instead of with a line across the box part of the box plot.

notched[]=n If n omitted or is non-zero, a notched box plot is drawn. The notches represent the 95 percent confidence limits of the median value.

quartileMethod=m Selects the method to be used in computing the quartiles (top and bottom of the boxes):

m=0: Tukey's method (default)
m=1: Minitab method
m=2: Moore and McCabe method
m=3: Mendenhall and Sincich method

See the discussion of StatsQuantiles /QM flag for details.

showData=whatData Selects a subset of the raw data for each box plot in a trace to be displayed using markers. The value of whatData is a name:

All: Show all data points (default)
None: Show no data points
Outliers: Show only outliers and far outliers
FarOutliers: Show only far outliers

See Box Plots on page II-266 for more information about outliers.

By default, the marker for normal data points is a hollow circle 0.7 times the size of a normal trace marker, outliers are shown by a full-size filled circle, and far outliers are shown using a full-size filled box.

showFences[]=v If v is omitted or non-zero, the fences are shown as dotted lines the same width as the boxes. See Box Plots on page II-266 for a discussion of fences. v defaults to 0.
showMean\[=v\] If \( v \) is omitted or non-zero, the mean of the data is shown as a marker. \( v \) defaults to 0.

whiskerMethod=\( m \) The whiskers are drawn from the quartiles (top or bottom of the box) to some extreme value, as determined by whiskerMethod:

\( m=0: \) The extreme data values (default)
\( m=1: \) The inner fences
\( m=2: \) The “adjacent” points - the last data points inside the inner fences
\( m=3: \) One standard deviation away from the mean value
\( m=6: \) The 9th and 91st percentiles
\( m=5: \) The 2nd and 98th percentiles

See Box Plots on page II-266 for a discussion of fences and percentiles.

Appearance Parameters

boxWidth=\( w \) For a non-category X axis, boxWidth sets the width of the box showing the quartiles. If \( w \) is between zero and one, it is taken to be a fraction of the width of the plot rectangle. If \( w \) is greater than one, it is in points.

If the box plot is displayed using a category X axis, boxWidth is ignored. The box width is set the same as a category plot box and is affected by ModifyGraph barGap and catGap.

A new non-category box plot has box width set as boxWidth=1/(2\( n \)) where \( n \) is the number of data sets (the number of boxes) on the trace.

capWidth=\( w \) The whiskers may optionally be terminated with a horizontal line of width controlled by the capWidth keyword. If \( w \) is between zero and one, it is a fraction of the box width. If \( w \) is greater than one, it is in points. If \( w \) is zero (default), no cap is drawn.

jitter=\( j \) Applies a random horizontal offset to each displayed data point in order to make it easier to see dense data sets. \( j \) controls the maximum offset applied to any data point, expressed as a fraction of the box width. The value of \( j \) may be greater than 1, but in general values less than 1 look better. The default is 0.7.

lineStyles=\{boxStyle, whiskerStyle, medianStyle[, capStyle]\} Set the line style used to draw the box, the whiskers, the median line, and optionally the whisker caps. See Dashed Lines on page III-470 for a description of line styles.

A line style of -1 uses the line style set by ModifyGraph lstyle.

All parameters default to -1.

lineThickness=\{boxThickness, whiskerThickness, medianThickness[, capThickness]\} Sets the line thickness used to draw the box, the whiskers, the median line, and optionally the whisker caps. A thickness less than zero uses the thickness set by the ModifyGraph lsize keyword. A zero thickness hides the corresponding element of the box plot.

All parameters default to -1.

markers=\{dataMarker, outlierMarker, farOutlierMarker[, medianMarker, meanMarker]\}
Color Parameters

All colors are specified as \((r, g, b, a)\) which represent red, green, blue, and optionally alpha (transparency) expressed as integers from 0 to 65535. If you omit \(a\), it defaults to 65535 which represents fully opaque. \(a=0\) represents fully transparent. Specify \(color=(0,0,0)\) to use the color set by \texttt{ModifyGraph rgb}.

- \texttt{boxColor=(r,g,b,a)}
  - Sets the outline color of the box part. Default is black.
- \texttt{boxFill=(r,g,b,a)}
  - Sets the fill color of the box.
- \texttt{capColor=(r,g,b,a)}
  - Sets the color of the cap line, if present. Default is black.
- \texttt{dataColor=(r,g,b,a)}
  - Sets the color of non-outlier data points. Default is black.
- \texttt{farOutlierColor=(r,g,b,a)}
  - Sets the color of far outlier points. Default is trace color.
- \texttt{meanColor=(r,g,b,a)}
  - Sets the color of the mean marker. Default is trace color.
- \texttt{medianLineColor=(r,g,b,a)}
  - Sets the color of the median line. You can see the effect only if \texttt{medianIsMarker} is not set. Default is black.
- \texttt{medianMarkerColor=(r,g,b,a)}
  - Sets the color of the median marker. You can see the effect only if \texttt{medianIsMarker} is set. Default is trace color.
- \texttt{outlierColor=(r,g,b,a)}
  - Sets the color of the markers for normal outliers. Default is trace color.
- \texttt{whiskerColor=(r,g,b,a)}
  - Sets the color the whisker lines. Default is black.

Example

\begin{verbatim}
Make/O/N=(25,3) multicol          // A three-column wave with 25 rows
SetRandomSeed(.4)                 // For reproducible "randomness"
multicol = gnoise(1)              // Three normally-distributed data sets
multicol[20][1] = 5               // A "far" outlier
multicol[13][2] = -4              // An outlier
Display; AppendBoxPlot multicol
ModifyGraph lSize=2
ModifyBoxPlot markers={8,19,19}
ModifyBoxPlot markerSizes={3,5,9}
ModifyBoxPlot capWidth=0.5
ModifyBoxPlot boxColor=(0,0,65535)
ModifyBoxPlot medianLineColor=(0,0,65535)
ModifyBoxPlot whiskerColor=(40000,40000,65535)
ModifyBoxPlot capColor=(40000,40000,65535)
ModifyBoxPlot boxFill=(0,0,65535,20000)
ModifyBoxPlot dataColor=(0,0,0)
ModifyBoxPlot outlierColor=(0,0,0)
ModifyBoxPlot farOutlierColor=(0,0,0)
ModifyBoxPlot jitter=0.75
\end{verbatim}

Box Plots on page II-266

ModifyBrowser

ModifyBrowser [/M] [keyword = value [, keyword = value ...]]
The ModifyBrowser operation modifies the state of the Data Browser according to the specified keywords.
Documentation for the ModifyBrowser operation is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "ModifyBrowser"

ModifyCamera

ModifyCamera [flags] [keywords]
The ModifyCamera operation modifies the properties of a camera window.
Documentation for the ModifyCamera operation is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "ModifyCamera"

ModifyContour

ModifyContour [/W=winName] contourInstanceName, keyword=value
[ , keyword=value...]
The ModifyContour operation modifies the number, Z value and appearance of the contour level traces associated with contourInstanceName.

contourInstanceName is a name derived from the name of the wave that provides the Z data values. It is usually just the name of the wave, but may have #1, #2, etc. added to it in the unlikely event that the same Z wave is contoured more than once in the same graph.

contourInstanceName can also take the form of a null name and instance number to affect the instance of a contour plot. That is,

ModifyContour '"#1'
modifies the appearance of the second contour plot in the top graph, no matter what the contour plot names are. Note: Two single quotes, not a double quote.

The number of contour level traces and their Z values are set by the autoLevels, manLevels, and moreLevels keywords, described in the Parameters section. Normally, you will use either autoLevels or manLevels, and then optionally generate additional levels using moreLevels.

Parameters
Each parameter has the syntax

keyword = value

and is applied to all of the contour level traces associated with contourInstanceName.
To modify an individual contour level trace, use **ModifyGraph**.

```plaintext
autoLevels= [minLevel, maxLevel, numLevels]
```

Controls automatic determination of contour levels.

If `numLevels` is zero, no automatic levels are generated. If it is nonzero, it specifies the desired number of automatic contour levels.

`minLevel` specifies the minimum contour level and `maxLevel` specifies the maximum contour level. The values that you specify are an approximate guide for Igor to use in determining the actual levels.

However, if `minLevel` or `maxLevel` is * (asterisk symbol), Igor uses the minimum or maximum value of the Z data for the corresponding contour level.

Using the `autoLevels` keyword cancels the effect of any previous `autoLevels` or `manLevels` keyword.

When you first append a contour plot to a graph, default contour levels are generated by the default setting `autoLevels=[*,*,11]`.

```plaintext
boundary=b
```

Draws an outline around the XY domain of the contour data. For a matrix, this draws a rectangle showing the minimum and maximum X and Y values. For XYZ triples, the outline is a polygon enclosing the outside edges of the Delaunay Triangulation. Like the contour lines, the boundary is drawn using a graph trace, whose name is usually something like `"contourInstanceName = boundary"`.

- `b=0`: Hides the data boundary (default).
- `b=1`: Shows the data boundary.

```plaintext
cIndexFill= matrixWave
```

Sets contour fills to use a color index wave when automatic fill is on (see the fill keyword).

cIndexFill works the same as the cIndexLines keyword which controls the colors of the contour level traces.

See **Contour Fills** on page II-304 for more information.

cIndexFill was added in Igor Pro 7.00.

```plaintext
cIndexLines= matrixWave
```

Sets the Z value mapping mode such that contour line colors are determined by doing a lookup in the specified matrix wave.

`matrixWave` is a 3 column wave that contains red, green, and blue values from 0 to 65535. (The matrix can actually have more than three columns. Any extra columns are ignored.)

The color for a the contour line at Z=z is determined by finding the RGB values in the row of `matrixWave` whose scaled X index is z. In other words, the red value is `matrixWave(z)[0]`, the green value is `matrixWave(z)[1]` and the blue value is `matrixWave(z)[2]`.

If `matrixWave` has default X scaling, where the scaled X index equals the point number, then row 0 contains the color for Z=0, row 1 contains the color for Z=1, etc.

If you use `cIndexLines`, you must not use `ctabLines` or `rgbLines` in the same command.

```plaintext
cTabFill= [zMin, zMax, ctName, mode]
```
Sets contour fills to use a color table when automatic fill is on (see the fill keyword).

cTabFill works the same as the ctabLines keyword which controls the colors of the contour level traces.

See Contour Fills on page II-304 for more information.

cTabFill was added in Igor Pro 7.00.

cTabFill = [zMin, zMax, ctName, mode]

Sets the Z value mapping mode such that contour line colors are determined by doing a lookup in the specified color table. \( z_{\text{Min}} \) is mapped to the first color in the color table. \( z_{\text{Max}} \) is mapped to the last color. Z values between the min and max are linearly mapped to the colors between the first and last in the color table.

You can enter * (an asterisk) for \( z_{\text{Min}} \) and \( z_{\text{Max}} \), which uses the minimum and maximum Z values of the data. The default is \(*,*,\text{Rainbow}\).

Set parameter mode to 1 to reverse the color table; zero or missing does not reverse the color table.

tName can be any color table name returned by the CTabList function, such as Grays or Rainbow (see Image Color Tables on page II-323) or the name of a 3 column or 4 column color table wave (see Color Table Waves on page II-329).

A color table wave name supplied to ctabLines must not be the name of a built-in color table (see CTabList). A 3 column or 4 column color table wave must have values that range between 0 and 65535. Column 0 is red, 1 is green, and 2 is blue. In column 3 a value of 65535 is opaque, and 0 is fully transparent.

If you use cTabFill, you must not use cIndexLines or rgbLines in the same command.

equalVoronoiDistances = e

Normally the x range and y range of the data are each normalized to a 0-1 range separately to generate the Voronoi triangulation. Voronoi triangulation is a distance-based ("nearest neighbor") algorithm that may benefit from scaling the X and Y ranges together to avoid numerical problems that occur when the triangles become very thin because of widely differing x and y ranges.

e=0: The x and y ranges are scaled individually to the 0-1 range (default).
e=1: The x and y ranges are scaled so that that maximum range of x or y is scaled to the 0-1 range, and the other is proportionally smaller. For example, if yMax-yMin = 1000 and xMax-xMin = 5, then the y range is scaled to 0-1 and the y range is scaled to 5/1000 = 0.005.

The equalVoronoiDistances keyword is allowed only for XYZ contour plots.

fill = f

Controls the automatic filling of contour levels.

f=0: Turns automatic fill off. Default.
f=1: Turns automatic fill on.

See Contour Fills on page II-304 for more information.

fill was added in Igor Pro 7.00.
XYZ contours can be interpolated to increase the apparent resolution, resulting in smoother contour lines.

This keyword is allowed only for XYZ contours, created by **AppendXYZContour**.

- **interpolate** = \(i\)
  - \(i=0\): Linear interpolation (default). This means that only the original Delaunay triangulation generates contour lines.
  - \(i=1\): Four times the resolution generates a smoother set of contour lines. As expected, this takes longer than Linear interpolation.
  - \(i=2\): Sixteen times the resolution generates a much smoother set of contour lines. This is rather slow.

The interpolate parameter can be up to 8. Each time you increase \(i\) by one, you quadruple the apparent resolution and get smoother contour lines at the expense of computation time. Values of \(i\) greater than two are impractical because of the computation time required.

- **labelBkg** = \((r, g, b)\)
  - Sets the background color for all contour level labels to the specified color. \(r, g,\) and \(b\) are values from 0 to 65535.

- **labelBkg** = \(b\)
  - Controls the background color of contour labels.
    - \(b=0\): Uses each label’s individual background color, as set via the Modify Annotation dialog.
    - \(b=1\): Makes all contour level labels transparent.
    - \(b=2\): Uses the plot area background color as the label background color (default).
    - \(b=3\): Uses the window background color as the label background color.

- **labelDigits** = \(d\)
  - \(d\) is the number of digits after the decimal point when using labelFormat = 3 or labelFormat = 5.

- **labelFont** = \(fontName\)
  - Default; specifies the font to use for contour level labels. If you pass "" for \(fontName\), it will use the graph font (set via the Modify Graph dialog) for contour labels.

- **labelFormat** = \(l\)
  - Controls the formatting of contour labels. See the **printf** operation for a discussion of formatting.
    - \(l=0\): Uses general format that is suitable for most data. This is equivalent to "\%<sigDigits>g".
    - \(l=1\): Uses integer format, equivalent to "\%<sigDigits>d". This rounds fractional values.
    - \(l=3\): Uses fixed point format, equivalent to "\%<decimalDigits>f".
    - \(l=5\): Uses exponential format, equivalent to "\%<decimalDigits>e".

- **labelFSize** = \(s\)
  - Specifies the font size of contour labels in points. For example, use labelSize = 12 for 12 point type. The default value is 0, which chooses the size automatically based on the size of the graph.

- **labelFStyle** = \(n\)
  - \(n\) is a bitwise parameter with each bit controlling one aspect of the font style for the contour level labels. The default is 0, plain text.
    - Bit 0: Bold
    - Bit 1: Italic
    - Bit 2: Underline
    - Bit 4: Strikethrough

See **Setting Bit Parameters** on page IV-13 for details about bit settings.
**ModifyContour**

**labelHV=**<i>hv</i>  
Specifies the contour label orientation.

- If <i>hv</i> is 3, 4, 5, or 6, the contour label's text rotates whenever it is redrawn, usually when the underlying contour data changes, the graph is resized, or the label is reattached to a new contour trace point.
  - <i>hv</i>=0: Horizontal contour level labels.
  - <i>hv</i>=1: Vertical contour level labels.
  - <i>hv</i>=2: Horizontal or vertical contour level labels, depending on the slope of the contour line.
  - <i>hv</i>=3: Tangent to the contour line.
  - <i>hv</i>=4: Tangent to the contour line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal (default).
  - <i>hv</i>=5: Perpendicular to the contour line.
  - <i>hv</i>=6: Perpendicular to the contour line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal.

**labelRGB=**(<i>r</i>, <i>g</i>, <i>b</i>)  
Sets the text color for all contour level labels. <i>r</i>, <i>g</i>, and <i>b</i> are values from 0 to 65535. The default is black, labelRGB=(0,0,0).

**labels=**<i>l</i>  
Controls the display of contour labels.
- <i>l</i>=0: Hides contour level labels.
- <i>l</i>=1: Leaves any contour level labels in place but stops updating them and stops generation of new labels.
- <i>l</i>=2: Generates or updates labels for the existing contour levels and window size when the command executes, but disables further updating of labels when window size or contour plot changes. This is the recommended setting if updating the labels takes long enough to annoy you.
- <i>l</i>=3: Default; generates labels for all contour levels whenever the contoured data changes but not when the window size changes. If you resize the graph, the labels may overlap or be too sparse.
- <i>l</i>=4: Generates labels for all contour levels whenever the contoured data, contour levels, axis range, or the graph size changes. (Actually, there are too many causes to list here. If all this update annoys you, use labels=2 “update once, now”.)

**labelSigDigits=**<i>d</i>  
<i>d</i> is the number of significant digits when labelFormat=0 is used.

**logLines=**<i>1</i> or <i>0</i>  
0 sets the default linearly-spaced contour line colors.
1 turns on logarithmically-spaced line colors. This requires that the contour levels values be greater than 0 to display correctly.

Affects line color only when the cIndexLines or ctabLines parameter is used.

logLines does not affect the contour levels. To assign logarithmically-spaced contour levels, use the moreLevels parameter and disable autoLevels, for example:

```plaintext
ModifyContour ' #0, autoLevels={*,*,0} // No auto levels
ModifyContour ' #0, moreLevels=0
ModifyContour ' #0, moreLevels={1e-07,1e-06,1e-05,1e-04}
```

**manLevels=**<i>{firstLevel, increment, numLevels}</i>  
Explicitly specifies contour levels. ModifyContour will generate <i>numLevels</i> contour levels, evenly spaced starting from <i>firstLevel</i> and stepping by <i>increment</i>.

**manLevels=**<i>manLevelsWave</i>
ModifyContour

Explicitly specifies contour levels. ModifyContour will generate contour levels at the values in manLevelsWave.

manLevels cancels the effect of any previous manLevels or autoLevels settings.

moreLevels= \{level, level \ldots\}

Explicitly specifies contour levels. ModifyContour will generate a contour trace for each of the listed levels. The maximum number of levels that you can specify in a single command is the 50. However, you can concatenate any number of ModifyContour moreLevels commands. moreLevels adds levels in addition to any specified by manLevels or autoLevels. It does not override other parameters.

moreLevels=0: Removes all levels generated by previous moreLevels settings.

nullValue= zValue

This keyword only affects the behavior of the ContourZ function. It is allowed only for XYZ contours, created by AppendXYZContour.

By default, ContourZ treats data outside the domain of the contour as NaN and so returns NaN if you ask for a contour value outside that domain.

The nullValue keyword allows you to change the default behavior to make ContourZ treat values outside the domain as the specified zValue.

nullValueAuto

This keyword only affects the behavior of the ContourZ function. It is allowed only for XYZ contours, created by AppendXYZContour.

nullValueAuto acts like nullValue= zValue with zValue automatically set to the minimum value in the Z wave minus 1.

See the nullValue keyword for details.

To turn nullValueAuto off and return the contour to the default state, execute:

ModifyContour <contourInstanceName>, nullValue= NaN

perturbation= p

Enable or disable perturbation (alteration) of the x and y values by a miniscule amount to improve the natural neighbor triangulation of XYZ contours.

p=0: Disables perturbation, preserving the original x and y values unchanged.

p=1: Enables x/y perturbation (default). The values are shifted by random values less than +/-0.000005 times the x and y domain extents.

You can observe the perturbed x/y coordinates in the triangulation trace added by ModifyContour triangulation=1.

The perturbation keyword is allowed only for XYZ contour plots.

rgbFill= (r, g, b)

Specifies red, green, and blue values for all contour fills. r, g, and b are values from 0 to 65535.

If you use rgbFill, you must not use cIndexFill or ctabFill in the same command.

rgbLines= (r, g, b)

Specifies red, green, and blue values for all contour lines. r, g, and b are values from 0 to 65535.

If you use rgbLines, you must not use cIndexLines or ctabLines in the same command.

triangulation= t

Draws the Delaunay Triangulation. As part of the XYZ contouring algorithm, the XY domain is subdivided into triangles in a process called Delaunay Triangulation. Like the contour lines, the triangulation is drawn using a graph trace, whose name is usually something like “contourInstanceName = triangulation”.

The triangulation keyword is allowed only for XYZ contours, created by AppendXYZContour.

\( t=0 \): Hides the Delaunay triangulation (default).

\( t=1 \): Shows the Delaunay triangulation.
ModifyControl

ModifyControl \[/Z\] \textit{ctrlName} \[ \textit{keyword} = \textit{value} \[, \textit{keyword} = \textit{value} \ldots\] \]

The ModifyControl operation modifies the named control. ModifyControl works on any kind of existing control. To modify multiple controls, use MODIFYCONTROLLIST.

Parameters

\textit{ctrlName} specifies the name of the control to be created or changed. The control must exist.

Keywords

The following keyword=value parameters are supported:

activate      align      appearance   bodywidth   disable   fColor
focusRing     font       fSize       fStyle      help      labelBack
noproc        pos        proc        rename      size       title
userdata      valueBackColor valueColor  win

For details on these keywords, see the documentation for \textit{SetVariable} on page V-776.

The following keywords are not supported:

Flags

\textit{update=}, \textit{update=u} Sets the type of updating of contour traces when the data or contour settings change.

\textit{u=0}: Turns off dynamic updates, which might be advisable if updates take a long time.

\textit{u=1}: Updates the contours only once, or until you next execute an update=1 command.

\textit{u=2}: Updates are automatic (default).

\textit{u=3} Marks the contour plot as having been updated once \((u=1)\) already. This option is used in recreation macros to prevent an extra redraw of a graph saved with \(u=1\) update mode in effect.

If you use it in a command, the result is similar to \(u=0\), but the Modify Contour Appearance dialog will automatically select “update once, now” from the Update Contours pop-up menu.

\textit{xymarkers=x} Controls the visibility of XY markers.

\textit{x=0}: Hides markers showing XY coordinates of the Z data (default).

\textit{x=1}: Displays markers showing XY coordinates of Z data. Initially, this uses marker number zero. You can change this using the Modify Trace Appearance dialog.

References

ModifyControl

**Flags**

/Z No error reporting.

**Details**

Use `ModifyControl` to move, hide, disable, or change the appearance of a control without regard to its kind.

**Example**

Here is a TabControl procedure that shows and hides all controls in the tabs appropriately, without knowing what kind of controls they are.

The “trick” here is that all controls that are to be shown within particular tab \( n \) have been assigned names that end with “\( \_tab n \)” such as “\( \_tab0 \)” and “\( \_tab1 \)”:

```plaintext
Function TabProc(ctrlName, tabNum) : TabControl
    String ctrlName
    Variable tabNum

    String curTabMatch= "\_tab"+num2istr(tabNum)
    String controls= ControlNameList("*")
    Variable i, n= ItemsInList(controls)
    for(i=0; i<n; i+=1)
        String control= StringFromList(i, controls)
        Variable isInATab= stringmatch(control,"\_tab\*")
        if( isInATab )
            Variable show= stringmatch(control,curTabMatch)
            ControlInfo $control // gets V_disable
            if( show )
                V_disable= V_disable & ~0x1 // clear the hide bit
            else
                V_disable= V_disable | 0x1 // set the hide bit
            endif
            ModifyControl $control disable=V_disable
        endif
    endfor
    return 0
End
```

// Action procedures which enable or disable the buttons

```plaintext
Function Tab1CheckProc(ctrlName, enableButton) : CheckBoxControl
    String ctrlName
    Variable enableButton

    ModifyControl button_tab1, disable=(enableButton ? 0 : 2 )
End

Function Tab0CheckProc(ctrlName, enableButton) : CheckBoxControl
    String ctrlName
    Variable enableButton

    ModifyControl button_tab0, disable=(enableButton ? 0 : 2 )
End
```

// Panel macro that creates a TabControl using TabProc

```plaintext
Window TabbedPanel() : Panel
    PauseUpdate; Silent 1 // building window...
    NewPanel /W=(381,121,614,237) as "Tab Demo"
    TabControl tab, pos={12,9},size={205,91},proc=TabProc,tabLabel(0)="Tab 0"
    TabControl tab, tabLabel(1)="Tab 1",value= 0
    Button button_tab0, pos={54,39},size={110,20},disable=2
    Button button_tab1, title="Button in Tab 0"
    Button button_tab0, title="Button in Tab 0"
    Button button_tab1, pos={54,63},size={110,20},disable=1
    Button button_tab0, title="Button in Tab 1"
    CheckBox check1_tab1, pos={51,41}, size={117,14}, disable=1, value= 1
    CheckBox check1_tab1, proc=Tab1CheckProc, title="Enable Button in Tab 1"
    CheckBox check0_tab0, pos={51,73}, size={117,14}, proc=Tab0CheckProc
    CheckBox check0_tab0, value= 0, title="Enable Button in Tab 0"
EndMacro
```

Run TabbedPanel to create the panel. Then click on “Tab 0” and “Tab 1” to run TabProc.
ModifyControlList

ModifyControlList [/Z] listStr [, keyword = value]...

The ModifyControlList operation modifies the controls named in the listStr string expression. ModifyControlList works on any kind of existing control.

Parameters
listStr is a semicolon-separated list of names in a string expression. The expression can be an explicit list of control names such as "button0;checkbox1;" or it can be any string expression such as a call to the ControlNameList string function:

ModifyControlList ControlNameList("","","*_tab0") disable=1

The controls must exist.

Keywords

The following keyword=value parameters are supported:

activate align appearance bodywidth disable fColor
focusRing font fSize fStyle help labelBack
noproc pos proc rename size title
userdata valueBackColor valueColor win

For details on these keywords, see the documentation for SetVariable on page V-776.

The following keywords are not supported:

mod popmatch popvalue value variable

Flags

/Z No error reporting.

Details
Use ModifyControlList to move, hide, disable, or change the appearance of multiple controls without regard to their kind.

If listStr contains the name of a nonexistent control, an error is generated.

If listStr is "" (or any list element in listStr is ""), it is ignored and no error is generated.

Example
Here is the TabControl procedure example from ModifyControl rewritten to use ModifyControlList. It shows and hides all controls in the tabs appropriately, without knowing what kind of controls they are, but the code is simpler. This method does not, however, preserve the enable bit when a control is hidden.

The “trick” here is that all controls that are to be shown within particular tab n have been assigned names that end with "_tabn" such as "_tab0" and "_tab1":

// Action procedure
Function TabProc2(ctrlName,tabNum) : TabControl
    String ctrlName
    Variable tabNum
    String controlsInATab= ControlNameList("","","*_tab")
    String curTabMatch= "*_tab"+num2istr(tabNum)
    String controlsInCurTab= ListMatch(controlsInATab, curTabMatch)
    String controlsInOtherTabs=ListMatch(controlsInATab,"!"+curTabMatch)
ModifyFreeAxis

ModifyControlList controlsInOtherTabs disable=1 // hide
ModifyControlList controlsInCurTab disable=0 // show
return 0
End

// Panel macro that creates a TabControl using TabProc2():
Window TabbedPanel2() : Panel
  PauseUpdate; Silent 1 // building window...
  NewPanel /W=(35,208,266,374) as "Tab Demo"
  TabControl tab,pos={12,9},size={205,140},proc=TabProc2
  TabControl tab,tabLabel(0)="Tab 0"
  TabControl tab,tabLabel(1)="Tab 1",value= 0
  Button button_tab0,pos={26,43},size={110,20},title="Button in Tab0"
  Button button2_tab0,pos={26,74},size={110,20},title="Button in Tab0"
  Button button3_tab0,pos={26,106},size={110,20},title="Button in Tab0"
  Button button_tab1,pos={85,43},size={110,20},title="Button in Tab1"
  Button button2_tab1,pos={85,75},size={110,20},title="Button in Tab1"
  Button button3_tab1,pos={84,108},size={110,20},title="Button in Tab1"
  ModifyControlList ControlNameList("",";","*_tab1") disable=1
EndMacro

Run TabbedPanel2 and then click on "Tab 0" and "Tab 1" to run TabProc2.

The Button, Chart, CheckBox, GroupBox, ListBox, PopupMenu, SetVariable, Slider, TabControl, TitleBox, and ValDisplay controls.

ModifyFreeAxis

ModifyFreeAxis [/W=winName] axisName, master=mastName
  [, hook=funcName]

The ModifyFreeAxis operation designates the free axis (created with NewFreeAxis) to follow a controlling axis from which it gets axis range and units information. The free axis updates whenever the controlling axis changes. The axis limits and units can be modified by a user hook function.

Parameters
axisName is the name of the free axis (which must have been created by NewFreeAxis).
masterName is the name of the master axis controlling axisName.

funcName is the name of the user function that modifies the limits and units properties of the axis. If funcName is $"", the named hook function is removed.

Flags
/W=winName Modifies axisName in the named graph window or subwindow. If /W is omitted the command affects the top graph window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details
The free axis can also be designated to call a user-defined hook function that can modify limits and units properties of the axis. The hook function must be of the following form:

Function MyAxisHook(info)
  STRUCT WMAxisHookStruct &info
  <code to modify graph units or limits>
  return 0
End

/554
where WMAxisHookStruct is a built-in structure with the following members:

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>char win[MAX_WIN_PATH+1]</td>
<td>Host (sub)window.</td>
</tr>
<tr>
<td>char axName[MAX_OBJ_NAME+1]</td>
<td>Name of the axis.</td>
</tr>
<tr>
<td>char mastName[MAX_OBJ_NAME+1]</td>
<td>Name of controlling axis or nil.</td>
</tr>
<tr>
<td>char units[MAX_UNITS+1]</td>
<td>Axis units. User modifiable.</td>
</tr>
<tr>
<td>double min, max</td>
<td>Axis range minimum and maximum values. User modifiable.</td>
</tr>
</tbody>
</table>

The constants used to size the char arrays are internal to Igor and are subject to change in future versions.

The hook function is called when refreshing axis range information (generally early in the update of a graph). Your hook must never kill a graph or an axis.

**Example**

This example demonstrates how to program a free axis hook function, whose most important task is to change the values of info.min and info.max to alter the axis range of the free axis. The example free axis displays Fahrenheit values for data in Celsius.

Function CentigradeAndFahrenheit()

`Make/O/N=20 temperatures = -2+p/3+gnoise(0.5) // sample data`
`Display temperatures// default left axis will indicate data's centigrade range`
`String graphName = S_name`
`Label/W=$graphName left "°C"`
`ModifyGraph/W=$graphName zero(left)=1`

// make a right axis whose range will be Fahrenheit
`NewFreeAxis/R/O/W=$graphName fahrenheit`
`ModifyGraph/W=$graphName freePos(fahrenheit)={0,kwFraction},lblPos(fahrenheit)=43`
`Label/W=$graphName fahrenheit "°F"`
`ModifyFreeAxis/W=$graphName fahrenheit, master=left, hook=CtoF_FreeAxisHook`

// NOTE master=left part which makes the "free" axis
// actually a "slave" to the left ("master") axis.
End

Function CtoF_FreeAxisHook(info)

```pascal
STRUCT WMAxisHookStruct &info
    GetAxis/Q/W=$info.win $info.mastName // get master axis range in V_min, V_Max
    Variable minF = V_min*9/5+32
    Variable maxF = V_max*9/5+32
    // SetAxis/W=$info.win $info.axName, minF, maxF
    // SetAxis here is fruitless. These values get overwritten by Igor
    // after reading info.min and info.max, which we now set:
    info.min = minF // new min for free axis
    info.max= maxF // new max for free axis
    return 0
End
```

**See Also**

The SetAxis, KillFreeAxis, and NewFreeAxis operations.

The ModifyGraph (axes) operation for changing other aspects of a free axis.
ModifyGizmo

ModifyGizmo [flags] keyword [=value]
The ModifyGizmo operation changes Gizmo properties.

Documentation for the ModifyGizmo operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "ModifyGizmo"

ModifyGraph  (general)

ModifyGraph [/W=winName/Z] key=value [, key=value]...
The ModifyGraph operation modifies the target or named graph. This section of ModifyGraph relates to
general graph window settings.

Parameters

expand=e Specifies the onscreen expansion (or magnification) factor of a graph. e may be zero or 0.125 to 8 times expansion.

Graph magnification affects only base graphs (not subwindowed graphs), and it affects only the onscreen display; it has no effect on graph exporting or printing.

When magnification changes, the graph window will automatically resize except for negative values, which are used in recreation macros where the size is already correct.

frameInset= i Specifies the number of pixels by which to inset the frame of the graph subwindow.

frameStyle= f Specifies the frame style for a graph subwindow.

f=0: None.
f=1: Single.
f=2: Double.
f=3: Triple.
f=4: Shadow.
f=5: Indented.
f=6: Raised.
f=7: Text well.

The last three styles are fake 3D and will look good only if the background color of the enclosing space and the graph itself is a light shade of gray.

gfMult=f Multiplies font and marker size by f percent. Clipped to between 25% and 400%; it is applied after all other font and marker size calculations.

gFont=fontStr Specifies the name of the default font for the graph, overriding the normal default font. The normal default font for a subgraph is obtained from its parent while a base graph uses the value set by the DefaultFont operation.

gfSize=gfs Sets the default size for text in the graph. Normally, the default size for text is proportional to the graph size; gfSize will override that calculation as will the gfRelSize method. Use a value of -1 to make a subgraph get its default font size from its parent.

gfRelSize=pct Specifies the percentage of the graph size to use in calculating a default size for text in the graph. This overrides the normal method for setting default font size as a function of graph size. When used, the default marker size is set to one third the font size. Use a value of 0 to revert to the default method.

gmSize=gms Sets the default size for markers in the graph. Use a value of -1 to make a subgraph get its default marker size from its parent.

height=heightSpec Sets the height for the graph area. See the Examples.
Modifying the Graph Interface

**swapXY=s**
Sets the orientation of the X and Y axes.
- **s=0:** Normal orientation of X and Y axes.
- **s=1:** Swap X and Y values to plot Y coordinates versus the horizontal axes and X coordinates versus the vertical axes. The effect is similar to mirroring the graph about the lower-left to upper-right diagonal.

**useComma=uc**
Controls the decimal separator used in tick mark labels.
- **uc=0:** Use period as decimal separator and comma as thousands separator (default) when displaying numbers in graph labels and annotations.
- **uc=1:** Use comma as decimal separator and period as the thousands separator. This does not alter the presentation of numbers in `{expression}` constructs in annotations.

**UIControl=f**
Disables certain aspects of the user interface for graphs. The UIControl keyword, added in Igor Pro 7.00, is for use by advanced Igor programmers who want to disable user actions.

This is a bitwise setting. **Setting Bit Parameters** on page IV-13 for details about bit settings.

- **f** is defined as follows:
  - **Bit 0:** Disable axis click. Prevents moving or otherwise modifying an axis.
  - **Bit 1:** Disable cursor click. Prevents moving a graph cursor.
  - **Bit 2:** Disable trace drag. Prohibits the click-and-hold action to offset a trace on the graph.
  - **Bit 3:** Disable marquee. When set, you can’t make a marquee on the graph, which in turn prevents changing the range of the graph using the marquee.
  - **Bit 4:** Disable draw mode.
  - **Bit 5:** Disable double click. Prohibits any double-click action. In general, double-clics in a graph bring up dialogs to modify the graph’s appearance.
  - **Bit 6:** Disable clicks on annotations. Prevents modification of annotations.
  - **Bit 7:** Disable tool tips.
  - **Bit 8:** Disable contextual menus.
  - **Bit 9:** Disable marquee menu. With this set, you can still have a marquee and use it for, i.e., selecting some portion of the graph, but you can’t use the marquee menu to change the graph’s range. Note that if bit 3 is set, this bit is moot.
  - **Bit 10:** Disable mouse wheel events. This will prevent axis scaling using the mouse wheel.
  - **Bit 11:** Disable option-drag. Prevents offsetting the graph by holding down the option (Macintosh) or Alt (Windows) key and then dragging in the plot area.

To disable items in the Graph menu use **SetIgorMenuMode**.

**useLongMinus=m**
Uses a normal (**m=0**; default) or long dash (**m=1**) for the minus sign.

**width=widthSpec**
Sets the width of the graph area. See the examples.
ModifyGraph (traces)

Flags

/N=winName  Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/Z  Does not generate an error if the indexed trace, named wave, or named axis does not exist in a style macro.

Examples

The following code creates a graph where all the text expands and contracts directly in relation to the window size:

Make jack=sin(x/8);display jack
ModifyGraph mode=4,marker=8,gfRelSize=5.0
TextBox/N=text0/A=MC "Some \Zr200big\]0 and \Zr050small\]0\rtex\"

The widthSpec and heightSpecs set the width and height mode for the top graph. The following examples illustrate how to specify the various modes.

ModifyGraph width=0, height=0

Set to auto height, width mode. The width, height of horizontal and vertical axes are automatically determined based on the overall size of the graph and other factors such as axis offset setting and effect of exterior textboxes. This is the normal, default mode.

Variable n=72*5

ModifyGraph width=n

Five inches as points absolute width mode, horizontal axis width constrained to n points.

ModifyGraph height=n

Absolute height mode, n is in points. The height of the vertical axes is constrained to n points.

Variable n=2

ModifyGraph width={perUnit,n,bottom}

Per unit width mode. The width of the horizontal axes is n points times the range of the bottom axis.

ModifyGraph height={Aspect,n}

Aspect height mode, n = aspect ratio. The height of the vertical axes is n times the width of the horizontal axes.

ModifyGraph width={Plan,n,bottom,left}

Plan width mode. The width of the horizontal axes is n times the height of the vertical axes times range of the bottom axis divided by the range of the left axis.

ModifyGraph  (traces)

ModifyGraph /[W=winName/Z]  key [{(traceName)}] = value
    [, key [{(traceName)}] = value]...

This section of ModifyGraph relates to modifying the appearance of wave “traces” in a graph. A trace is a representation of the data in a wave, usually connected line segments.

Parameters

Each key parameter may take an optional traceName enclosed in parentheses. Usually traceName is simply the name of a wave displayed in the graph, as in “mode (myWave) =4”. If “(traceName)” is omitted, all traces in the graph are affected. For instance, “ModifyGraph 1Size=0.5” sets the lines size of all traces to 0.5 points.

For multiple trace instances, traceName is followed by the “#” character and instance number. For example, “mode (myWave#1) =4”. See Instance Notation on page IV-20.

A string containing a trace name can be used with the $ operator to specify traceName. For example, String MyTrace="myWave#1"; mode ($MyTrace)=4.

Though not shown in the syntax, the optional “(traceName)” may be replaced with “[traceIndex]”, where traceIndex is zero or a positive integer denoting the trace to be modified. “[0]” denotes the first trace appended to the graph, “[1]” denotes the second trace, etc. This syntax is used for style macros, in conjunction with the /Z flag.
For certain modes and certain properties, you can set the conditions at a specific point on a trace by appending the point number in square brackets after the trace name. For more information, see the **Customize at Point** on page V-569.

The parameter descriptions below omit the optional "(traceName)". When using ModifyGraph from a user-defined function, be careful not to pass wave references to ModifyGraph. ModifyGraph expects trace names, not wave references. See **Trace Name Parameters** on page IV-87 for details.

```
arrowMarker=0
arrowMarker={aWave, lineThick, headLen, headFat, posMode [], barbSharp=b, barbSide=s, frameThick=f}[

Draws arrows instead of conventional markers at each data point in a wave. Arrows are not clipped to the plot area and will be drawn wherever a data point is within the plot area.

*aWave* contains arrow information for each data point. It is a two (or more) column wave containing arrow line lengths (in points) in column 0 and angles (in radians measured counterclockwise) in column 1. Zero angle is a horizontal arrow pointing to the right. If an arrow is below the minimum length of 4 points, a default marker is drawn.

You can change arrow markers into standard meteorological wind barbs by adding a column to *aWave* and giving it a column label of windBarb. Values are integers from 0 to 40 representing wind speeds up to 4 flags. Use positive integers for clockwise barbs and negative for the reverse. Use NaN to suppress the drawing. See **Wind Barb Plots** on page II-264 for an example.

Additional columns may be supplied in *aWave* to control parameters on a point by point basis. These optional columns are specified by dimension label and not by specific column numbers. The labels are *lineThick*, *headLen*, and *headFat* that correspond to the same parameters listed above.

*lineThick* is the line thickness in points.

*headLen* is the arrow head length in points.

*headFat* controls the arrow fatness. It is the width of the arrow head divided by the length.

*posMode* specifies the arrow location relative to the data point.

- **posMode=0**: Start at point.
- **posMode=1**: Middle on point.
- **posMode=2**: End at point.

In addition to the wave specification, *aWave* can also be the literal **inline** to draw lines and arrows between points on the trace (see **Examples**). If *aWave* is **inline**, *posMode* values are:

- **posMode=0**: Arrow at start.
- **posMode=1**: Arrow in middle.
- **posMode=2**: Arrow at end.
- **posMode=3**: Arrow in middle pointing backwards.

You can also enable inline mode even if *aWave* is not **inline** by setting *posMode* to values between 4 and 7. These are the same as modes 0-3 above.

Optional parameters must be specified using **keyword = value** syntax and can only be appended after *posMode* in any order.

*barbSharp* is the continuously variable barb sharpness between -1.0 and 1.0:

- **barbSharp=1**: No barb; lines only.
- **barbSharp=0**: Blunt (default).
- **barbSharp=-1**: Diamond.
**barbSide** specifies which side of the line has barbs relative to a right-facing arrow:
- **barbSide=0**: None.
- **barbSide=1**: Top.
- **barbSide=2**: Bottom.
- **barbSide=3**: Both (default).

**frameThick** specifies the stroke outline thickness of the arrow in points. The default is **frameThick = 0** for solid fill.

**aWave** can contain columns with data for each optional parameter using matching column names.

**barStrokeRGB=(r,g,b)**

Specifies a separate color for bar strokes (outlines) if **useBarStrokeRGB** is 1. **r**, **g**, and **b** specify the amount of red, green and blue in the color of the stroked lines as an integer from 0 to 65535. The default is black (0,0,0).

Applies only to Histogram Bars drawing mode (mode=5).

The bar fill color continues to be set with the **rgb=(r,g,b)**, **zColor={...}**, **usePlusRGB**, **plusRGB=(r,g,b)**, **useNegRGB**, and **negRGB=(r,g,b)** parameters.

Use **barStrokeRGB** and **useBarStrokeRGB** to put a differently-colored outline around Histogram Bars:

![useBarStrokeRGB=0](image1)

![useBarStrokeRGB=1](image2)

**cmplxMode=c**

Display method for complex waves.
- **cmplxMode=0**: Default mode displays both real and imaginary parts (imaginary part offset by dx/2).
- **cmplxMode=1**: Real part only.
- **cmplxMode=2**: Imaginary part only.
- **cmplxMode=3**: Magnitude.
- **cmplxMode=4**: Phase (radians).

**cmplxMode=0** does not work when the trace is a subrange of a multidimensional wave.

**column=n**

Changes the displayed column from a matrix. Out of bounds values are clipped.

**gaps=g**

Controls treatment of NaNs:
- **gaps=0**: No gaps (ignores NaNs).
- **gaps=1**: Gaps (shows NaNs as gaps).

**gradient**

See **Gradient Fills** on page III-472 for details.

**gradientExtra**

See **Gradient Fills** on page III-472 for details.

**hBarNegFill=n**

Fill kind for negative areas if **useNegPat** is true. **n** is the same as for the **hbFill** keyword.
hbFill=n

Sets the fill pattern.

n=0: No fill.
n=1: Erase.
n=2: Solid black.
n=3: 75% gray.
n=4: 50% gray.
n=5: 25% gray.
n>=6: See Fill Patterns on page III-472.

hideTrace=h

Removes a trace from the graph display.

h=0: Shows the trace if it is hidden.
h=1: Hides the trace and removes it from autoscale calculations.
h=2: Hides the trace.

When using h=1 to hide a graph trace, the hidden trace symbol and following text in annotations are also hidden. The amount of hidden text is the lesser of: the remaining text on the same line or the text up to but not including another trace symbol "\s(traceName) ".

lHair=lh

Sets the hairline factor for traces printed on a PostScript® printer.

lineJoin={j, ml}

Sets the line join style and miter limit.

Line join:

j=0      Miter joins
j=1      Round joins
j=2      Bevel joins (default)

Miter limit (applies when j=0):

ml >= 1      Sets miter limit to ml
ml = INF      Sets miter limit to unlimited
ml = 0       Leaves miter limit unchanged
ml = -1      Sets miter limit to default (10)

See Line Join and End Cap Styles on page III-470 for further information.

The lineJoin keyword was added in Igor Pro 8.00.

live=lv

lv is a bitwise parameter defined as follows:

Bit 0: Live mode (see Live Mode below)
Bit 1: Fast line drawing (see Fast Line Drawing)

See Setting Bit Parameters on page IV-13 for details about bit settings.

logZColor=lzc

Controls the interpretation of the zColor parameter.

lzc=0: Sets the default linearly-spaced zColors.
lzc=1: Turns on logarithmically-spaced zColors. This requires that the zWave values be greater than 0 to display correctly.

Affects trace line color only when the zColor parameter is used with a color table or color index wave - it has no effect if rgb=(r,g,b) parameter or zColor={...,directRGB} are used.
ModifyGraph (traces)

- **lOptions=cap**
  - Sets the line end cap style:
    - \( cap=0 \): Flat caps
    - \( cap=1 \): Round caps
    - \( cap=2 \): Square caps (default)
  
  See **Line Join and End Cap Styles** on page III-470 for further information.

- **lSize=l**
  - Sets the line thickness, which can be fractional or zero, which hides the line.

- **lSmooth=ls**
  - Sets the smoothing factor for traces printed on a PostScript® printer.

- **lStyle=s**
  - Sets trace line style or dash pattern.
    - \( s=0 \) for solid lines. \( s=1 \) to \( s=17 \) for various dashed line styles.

- **marker=n**
  - \( n =0 \) to \( n =62 \) designates various markers if \( mode=3 \) or \( 4 \).
    - You can also create custom markers. See the **SetWindow** markerHook keyword.
    - See **Markers** on page II-229 for a table of marker values.

- **mask={maskwave,mode,value} or 0**
  - Specifies individual points for display by comparing values in maskWave with value as specified by mode.
    - \( mode=0 \): Exclude if equal.
    - \( mode=1 \): Include if equal.
    - \( mode=2 \): Include if bitwise AND is true.
    - \( mode=3 \): Include if bitwise AND is false.

  maskwave can be specified using subrange notation. The length of maskwave (or subrange) must match the size of specified trace’s wave (or subrange.) Bitwise modes should be used with integer waves with the intent of using one mask wave with multiple traces. See **Examples**.

- **mode=m**
  - Sets trace display mode.
    - \( m=0 \): Lines between points.
    - \( m=1 \): Sticks to zero.
    - \( m=2 \): Dots at points.
    - \( m=3 \): Markers.
    - \( m=4 \): Lines and markers.
    - \( m=5 \): Histogram bars.
    - \( m=6 \): Cityscape.
    - \( m=7 \): Fill to zero.
    - \( m=8 \): Sticks and markers.

- **mrkStrokeRGB=(r,g,b)**
Specifies the color for marker stroked lines if useMrkStrokeRGB = 1. \(r\), \(g\), and \(b\) values are the amount of red, green, and blue in the color of the lines as an integer from 0 to 65535. The default is black (0,0,0).

The marker fill color continues to be set with the rgb=(r,g,b) or zColor= […] parameters.

Applies only to the nontext and nonarrow marker modes.

Use mrkStrokeRGB and useMrkStrokeRGB to put a colored outline around filled markers, such as marker=19:

Note: The stroke color of unfilled markers such as marker 8 is also affected by mrkStrokeRGB, but their fill color is only affected by the opaque parameter (and the opaque fill color is always white, so if you want a color-filled marker, don’t use unfilled markers).

\textbf{mrkThick=}\(t\)

Sets the thickness of markers in points, which can be fractional.

\textbf{msize=}\(m\)

Specifies the marker size in points.

\(m=0:\quad\) Autosize markers.
\(m>0:\quad\) Sets marker size.

\(m\) can be fractional, which will only make a difference when the graph is printed because fractional points can not be displayed on the screen.

\textbf{mskip=}\(n\)

Puts a marker on only every \(n\)th data point in Lines and Markers mode (mode=4). Useful for displaying many data points when you want to identify the traces with markers. The maximum value for \(n\) is 32767.

\textbf{mstandoff=}\(s\)

Prevents lines from touching markers in lines and markers mode if \(s\) is greater than zero. \(s\) is in units of points. This feature was added in Igor Pro 8.00.

\textbf{muloffset=}[mx,my]

Sets the display multiplier for X (\(mx\)) and Y (\(my\)). The effective value for a given X or Y data point then becomes \(muloffset\times data+offset\). A value of zero means “no multiplier” — not multiply by zero.

\textbf{negRGB=}\(r, g, b\)

Specifies the color for negative areas if useNegRGB is 1. \(r\), \(g\), and \(b\) specify the amount of red, green, and blue in the color of the trace as an integer from 0 to 65535.

\textbf{offset=}\([x,y]\)

Sets the display offset in horizontal (X) and vertical (Y) axis units.

\textbf{opaque=}\(o\)

Displays transparent (\(o=0\)) or opaque (\(o=1\)) markers.

\textbf{patBkgColor=} 0, 1, 2 or \((r,g,b)\)

Specifies the background color for fill patterns.

0, the default, is white, 1 is graph background, 2 is transparent (does not work when exporting in the Enhanced Metafile or Windows Metafile formats).

Use \((r,g,b)\) for a specific RGB color.

\textbf{plotClip=}\(p\)

\(p=1\) clips the trace by the operating system (not by Igor) to the plot rectangle. This trims overhanging markers and thick lines. On Windows, this may not be supported for certain printers or by certain applications when importing.

\textbf{plusRGB=}\(r, g, b\)

Specifies the color for positive areas if usePlusRGB is 1. \(r\), \(g\), and \(b\) specify the amount of red, green, and blue in the color of the trace as an integer from 0 to 65535.
quickdrag=q  Controls dragging of traces.
  q=0:  Normal traces.
  q=1:  Traces that can be instantly dragged without the normal one second
delay. See the Quickdrag section below.
  q=2:  Causes the mouse cursor to change to 4 arrows when over the trace
and a reduced search is used.

rgb=(r,g,b)  Specifies the amount of red, green, and blue (r, g, and b) in the color of the trace as an
integer from 0 to 65535.

textMarker={<char or wave>,font,style,rot,just,xOffset,yOffset} or 0
  Uses the specified character or text from the specified wave in place of the marker for
each point in the trace.
  If the first parameter is a quoted string or a string expression of the form ""+strexpr
in a user function, ModifyGraph uses the first three bytes of the string as the marker
for all points. Three bytes are supported mainly for non-ASCII characters but can be
used for 3 separate single-byte characters. Otherwise, it interprets the first parameter
as the name of a wave. If the wave is a text wave, it uses the value of each point in the
text wave as the marker for the corresponding point in the trace. If the wave is a
numeric wave, the value for each point is converted into text and the result is used as
the marker for the corresponding point in the trace.
  xOffset and yOffset are offsets in fractional points. Each marker will be drawn offset
from the location of the corresponding point in the trace by these amounts.
  style is a font style code as used with the ModifyGraph fstyle keyword.
  rot is a text rotation between -360 and 360 degrees.
  just is a justification code as used in the DrawText operation except the X and Y codes
are combined as y*4+x. Use 5 for centered.
  The font size is 3*marker size. Note that marker size and color can be dynamically set
via the zColor and zmrkSize keywords.

toMode=t  Modifies the behavior of the display modes as determined by the mode parameter.
  t=0:  Fill to zero.
  t=1:  Fill to next trace. Applies to Sticks to zero (mode=1), histogram bars
(mode=5), and fill to zero (mode=7).
  t=2:  Add the current trace’s Y values to the next trace’s Y values. Works
with all display modes.
  t=3:  Stack on next and is the same as t=2 except that the added value is
clipped to zero. Works with all display modes.
  t=-1:  This mode is used only with category plots and means “keep with
next” (i.e., put in the same subcategory as the next trace). It is used for
special effects only.

For modes 1, 2 and 3, both Y-waves must have the same number of points and
must use the same X values. Igor uses the X values from the first wave for both Y-

useBarStrokeRGB=u
  If u=1 then bar stroked lines use the color specified by the barStrokeRGB keyword.
  Applies only to Histogram Bars drawing mode (mode=5).
  The bar fill color continues to be set with the rgb=(r,g,b), zColor=..., usePlusRGB,
plusRGB=(r,g,b), useNegRGB, and negRGB=(r,g,b) parameters.
  If u=0 then the bar stroked line colors are set with the rgb=(r,g,b) or zColor=... parameters, just like the bar fill color.
useMrkStrokeRGB = u

If \( u = 1 \) then marker stroked lines use the color specified by the mrkStrokeRGB keyword. The marker fill color continues to be set with the rgb=(r,g,b) or zColor=\{\ldots\} parameters. Applies only to the nontext and nonarrow marker modes.

If \( u=0 \) then the marker stroked line colors are set with the rgb=(r,g,b) or zColor=\{\ldots\} parameters, just like the marker fill color.

useNegPat = u

If \( u=1 \), negative fills use the mode specified by the hBarNegFill keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.

useNegRGB = u

If \( u=1 \), negative fills use the color specified by the negRGB keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.

usePlusRGB = u

If \( u=1 \), positive fills use the color specified by the plusRGB keyword. Applies to the fill-to-zero, fill-to-next and histogram bar modes.

userData = \{udName, doAppend, data\}

Attaches arbitrary data to a trace. You should specify a trace name (userData(<traceName>)=\{\ldots\}). Otherwise copies of the data will be attached to every trace, which is most likely not what you intend.

Use the GetUserData function to retrieve the data, with the trace name as the object ID.

\( udName \): The name of your user data. Use "$" for unnamed user data.

\( doAppend=0 \): Do not append. Any pre-existing data is replaced.

\( doAppend=1 \): Append the data. Data is added to the end of any pre-existing data.

\( data \): A string expression containing the data you wish to attach to the trace.

zColor = \{zWave, zMin, zMax, ctName [, reverseMode [, cWave]]\} or 0

Dynamically sets color based on the values in zWave and color table name or mode specified by ctName.

zWave may be a subrange expression such as \( myZWave[2,9] \) when zWave has more points than the trace, in which case \( myZWave[2] \) provides the Z value for the first point of the trace, and autoscaled \( zMin \) or \( zMax \) is determined over only the zWave subrange.

If a value in the zWave is NaN then a gap or missing marker will be observed. If a value is out of range it will be replaced with the nearest valid value. See also the zColorMax and zColorMin keywords.

ctName can be the name of a built-in color table such as returned by the CTabList function, such as Grays or Rainbow, for color table mode, ctableRGB for color table wave mode, cindexRGB for color index wave mode, or directRGB for direct color wave mode.
**ModifyGraph (traces)**

**zColor for Built-in Color Table Mode**
This mode uses `zWave` to select a color from a built-in color table specified by `ctName`. See Image Color Tables on page II-323 for details.

`zWave` contains values that are used to select a color from the built-in color table specified by `ctName`.

`zMin` is the `zWave` value that maps to the first entry in the color table. Use * for `zMin` to autoscale it to the smallest value in `zWave`.

`zMax` is the `zWave` value that maps to the last entry in the color table. Use * for `zMax` to autoscale it to the largest value in `zWave`.

`ctName` is the name of a built-in color table such as Grays or Rainbow. See the CTabList function for a list of built-in color tables.

Set `reverseMode` to 1 to reverse the color table lookup or to 0 to use the normal lookup. If you omit `reverseMode` or specify -1, the reverse mode is unchanged.

`cWave` must be omitted.

Normally the colors from the color table are linearly distributed between `zMin` and `zMax`. Use `logZColor=1` to distribute them logarithmically.

```
// Example zColor command using built-in color table
ModifyGraph zColor(data)={zWave,*,*,*Rainbow}
```

**zColor for Color Table Wave Mode**
This mode is like Built-in Color Table except that the colors are stored in a color table wave that you have created. A color table wave can be a 3 column RGB wave or a 4 column RGBA wave. See Color Table Waves on page II-329 for details.

`zWave` contains values that are used to select a color from the color table wave specified by `cWave`.

`zMin` is the `zWave` value that maps to the first entry in the color table wave. Use * for `zMin` to autoscale it to the smallest value in `zWave`.

`zMax` is the `zWave` value that maps to the last entry in the color table wave. Use * for `zMax` to autoscale it to the largest value in `zWave`.

`ctName` is `ctableRGB`.

Set `reverseMode` to 1 to reverse the color table lookup or to 0 to use the normal lookup. If you omit `reverseMode` or specify -1, the reverse mode is unchanged.

`cWave` is a reference to your color table wave.

Normally the colors from the color table are linearly distributed between `zMin` and `zMax`. Use `logZColor=1` to distribute them logarithmically.

Example `ctableRGB` zColor command:

```
ColorTab2Wave Rainbow  // Creates M_Colors wave
Rename M_Colors, MyColorTableWave
ModifyGraph zColor(data)={zWave,*,*,*ctableRGB,0,MyColorTableWave}
```
ModifyGraph (traces)

**zColor for Color Index Wave Mode**

This mode is like Color Table Wave except that the values in zWave represent X indices with respect to cWave. You must create the RGB or RGBA color index wave and set its X scaling appropriately. See Color Index Wave on page II-303 for details.

zWave contains values that are used to select a color from the color index wave specified by cWave.

zMin and zMax are not used and should be set to *.

cName is cindexRGB.

Set reverseMode to 1 to reverse the color table lookup or to 0 to use the normal lookup. If you omit reverseMode or specify -1, the reverse mode is unchanged. Normally the zWave values select the color from the row of cWave whose X value is closest to the zWave value. reverseMode=1 reverses the colors.

cWave is a reference to your color index wave.

Normally the colors from the color index wave are linearly distributed between the minimum and maximum X values of the color index wave. Use logZColor=1 to distribute them logarithmically.

// Example cindexRGB zColor command
zColor(data)={myZWave,*,*,cindexRGB,0,M_colors}  
// M_colors is generated by ColorTab2Wave

**zColor for Direct Color Wave Mode**

In direct color mode, zWave is an RGB or RGBA wave that directly specifies the color for each point in the trace. If zWave is 8-bit unsigned integer, then color component values range from 0 to 255. For other numeric types, color component values range from 0 to 65535. See ColorTab2Wave, which generates RGB waves, and Direct Color Details on page II-331.

zWave is an RGB or RGBA wave that directly specifies the color for each point of the trace.

zMin and zMax are not used and should be set to *.

cName is directRGB.

reverseMode is not applicable and should be omitted or set to 0.

cWave must be omitted.

// Example directRGB zColor command
zColor(data)={zWaveRGB,*,*,directRGB}  

**Turning zColor Off**

zColor = 0 turns the zColor modes off.

zColorMax=(red, green, blue)

Sets the color of the trace for zColor={zWave, ...} values greater than the zColor’s zMax. Also turns on zColorMax mode.

The red, green, and blue color values are in the range of 0 to 65535.

zColorMax=1, 0, or NaN

Turns zColorMax mode off, on, or transparent. These modes affect the color of zColor={zWave, ...} values greater than the zColor’s zMax.

1: Turns on zColorMax mode. The color of the affected trace pixels is black or the last color set by zColorMax=(red, green, blue).

0: Turns off zColorMax mode (default). The color of the affected trace pixels is the last color in the zColor’s cName color table.

NaN: Transparent zColorMax mode. Affected trace pixels are not drawn.
ModifyGraph (traces)

zColorMin=(red, green, blue)

Sets the color of the trace for zColor=[zWave, …] values less than the zColor’s zMin. Also turns zColorMin mode on.

The red, green, and blue color values are in the range of 0 to 65535.

zColorMin=1, 0, or NaN

1: Turns zColorMin mode on. These modes affect the color of zColor=[zWave, …] values less than the zColor’s zMin.
0: Turns off zColorMin mode (default). The color of the affected trace pixels is the first color in the zColor’s ctname color table.
NaN: Transparent zColorMin mode. Affected trace pixels are not drawn.

zmrkNum=[zWave] or 0

Dynamically sets the marker number for each point to the corresponding value in zWave. The values in zWave are the marker numbers (as used with the marker keyword). If a value in the zWave is NaN then no marker will be drawn at the corresponding point. If a value is out of range it will be replaced with the nearest valid value.

zmrkNum=0 turns this mode off.

zmrkSize=[zWave,zMin,zMax,mrkmin,mrkmax] or 0

Dynamically sets marker size based on values in zWave. Use * or a missing parameter for zMin and zMax to autoscale. mrkmin and mrkmax can be fractional. If a value in the zWave is NaN then a gap or missing mark will be observed. The marker size is clipped to 20 on the high end and 1 on the low end. If a value is out of range it will be replaced with the nearest valid value.

zmrkSize = 0 turns this mode off.

zpatNum=[zWave] or 0

Dynamically sets the positive fill type/pattern number for each point to the corresponding value in zWave. The values in zWave are the pattern numbers (as used with the hbFill keyword). If a value in the zWave is NaN then the corresponding point will not be drawn. If a value is out of range it will be replaced with the nearest valid value.

zpatNum=0 turns this mode off.

Flags

/W=winName

Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the Command Line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/Z

Does not generate an error if the indexed trace, named wave, or named axis does not exist in a style macro.

Details

Waves supplied with zmrkSize, zmrkNum, and zColor may use Subrange Display Syntax on page II-256.

Live Mode

Bit 0 of live=lv controls live mode. Live mode improves graph update performance when one or more of the waves displayed in the graph is frequently modified, for example, if the waves are being acquired from a data acquisition system. Live Mode traces do not autoscale axes.
Fast Line Drawing

Bit 1 of live=lv controls fast line drawing. When enabled, Igor draws traces in lines-between-points mode using custom fast code instead of the normal system drawing code. The result is not as esthetically pleasing but can be much faster and may be critical in data acquisition applications. The custom code is used only for drawing to the screen, not for exporting graphics.

Fast line drawing was added in Igor Pro 8.00.

Quickdrag

Quick drag mode (quickdrag=1) is a special purpose mode for creating cross hair cursors using a package of Igor procedures. (See the Cross Hair Demo example experiment.) Normally you would have to click and hold on a trace for one second before entering drag mode. When quickdrag is in effect, there is no delay. If a trace is in quickdrag mode it should also be set to live mode. With this combination you can click a trace and immediately drag it to a new XY offset. In addition to quick drag mode, the cross hair package relies on Igor to store information about the drag in a string variable if certain conditions are in effect. The string variable name (that you have to create) is S_TraceOffsetInfo, which must reside in a data folder that has the same name as the graph (not title!) which in turn must reside in root:WinGlobals:. If these conditions are met, then after a trace is dragged, information will be stored in the string using the following key-value format: GRAPH:<name of graph>;XOFFSET:<x offset value>;YOFFSET:<y offset value>;TNAME:<trace name>;

Customize at Point

You can customize the appearance of individual points on a trace in a graph for bar, marker, dot and lines to zero modes using key(tracename[pnt]=value syntax. The point number must be a literal number and the trace name is not optional. To turn off a customization, use key(tracename[-pnt-1]=value where value is not important but must match the syntax for the keyword. The offset of -1 is needed because point numbers start from zero.

Although the syntax is allowed for all trace modifiers, it has meaning only for the following: rgb, marker, msize, mrkThick, opaque, mrkStrokeRGB, barStrokeRGB, hbFill, patBkgColor and lSize.

Note that useBarStrokeRGB and useMrkStrokeRGB are not needed. The act of using barStrokeRGB or mrkStrokeRGB is enough to customize the point. But as a convenience, since these are generated by the modify graph dialog, they are ignored if used with [pnt] syntax.

Also note that legend symbols can use [pnt] syntax like so:

\s(<tracename>[pnt])

Automatically generated legends automatically include symbols for customized points.

For example:

Make/O/N=10 jack=sin(x); Display jack
ModifyGraph mode=5,hbFill=6,rgb=(0,0,0)
ModifyGraph hbFill(jack[2])=7,rgb(jack[2])=(0,65535,0)
ModifyGraph rgb(jack[3])=(65535,0,0)
Legend/C/N=text1/F=0/A=MC

Examples

Arrow markers.

Make/N=10 wavel= x; Display wavel
Make/N=(10,2) awave
awave[0][0] = p*5  // length
awave[0][1] = p*pi/9 // angle
ModifyGraph mode=3,arrowMarker(wavel)={awave,1,10,0.3,0}

// Now add an optional column to control headLen
Redimension/N=(-1,3) awave
awave[2][0] = 7+p  // will be head length

// Note: nothing changes until the following is executed
SetDimLabel 1,2,headLen,awave

Create meteorological wind barb symbols.

Make/O/N=50 jack= floor(x/10),jacket= mod(x,10)
Display jack vs jacket
Make/O/N=(50,3) jackbarb
jackbarb[0][0] = 40 // length of stem
jackbarb[1][1] = 45*pi/180 // angle (45deg)
ModifyGraph (axes)

```plaintext
jackbarb[][2] = p // wind speed code
SetDimLabel 1,2,windBarb,jackbarb
ModifyGraph mode=3,arrowMarker(jack)={jackbarb,1,10,0.5,0}
ModifyGraph margin(top)=62,margin(right)=84
```

See also Wind Barb Plots on page II-264.

Inline arrows and barb sharpness.

```plaintext
Make/O/N=20 wavex=cos(x/3),wavey=sin(x)
Display wavey vs wavex
ModifyGraph mode=3,arrowMarker={_inline_,1,20,.5,0,barbSharp= 0.2}
```

Use direct color mode to individually color each point in a trace:

```plaintext
Make jack=sin(x/8)
Make/N=(128,3)/B/U jackrgb
Display jack
ModifyGraph mode=3,marker=19
jackrgb= enoise(128)+128
ModifyGraph zColor(jack)={jackrgb,*,*,directRGB}
```

Use masking.

```plaintext
Make/N=100 jack= (p&1) ? sin(x/8) : cos(x/8)
Display jack
Make/N=100 mjack= (p&1) ? 0 : NaN // just to show NaN can be used
ModifyGraph mask(jack)={mjack,0,NaN}
// now switch which points are shown
mjack= (p&1) ? NaN : 0
```

See Also
Trace Names on page II-222, Programming With Trace Names on page IV-86.

ModifyGraph (axes)

```plaintext
ModifyGraph [/W=winName/Z] key [(axisName)] = value
[, key [(axisName)] = value]...
```

This section of ModifyGraph relates to modifying the appearance of axes in a graph.

Parameters
Each key parameter may take an optional axisName enclosed in parentheses.

axisName is “left”, “right”, “top”, “bottom” or the name of a free axis such as “vertCrossing”. For instance, “ModifyGraph axThick(left)=0.5” sets the axis thickness for only the left axis.

If “(axisName)” is omitted, all axes in the graph are affected. For instance, “ModifyGraph standoff=0” disables axis standoff for all axes in the graph.

The parameter descriptions below omit the optional “(axisName)”.

axisClip=c Specifies one of three clipping modes for traces.

c=0: Clips traces to a plot rectangle as defined by the pair of axes used by a given trace (default).

c=1: Plots traces on an axis with a restricted range (as set by axisEnab) to extend to the full range of the normal plot rectangle.

c=2: Traces extend outside the normal plot rectangle to the full extent of the graph area.

axisEnab=[lowFrac,highFrac] Restricts the length of an axis to a subrange of normal. The axis is drawn from lowFrac to highFrac of graph area height (vertical axis) or width (horizontal axis). For instance, [0.1,0.75] specifies that the axis is drawn from 10% to 75% of the graph area height/width, instead of the normal 0% to 100%. AxisEnab is discussed in Creating Split Axes on page II-276 and Creating Stacked Plots on page II-259.
**axisOnTop** $= t$

Specifies drawing level of axis and associated grid lines.

- $t=0$: Draws axis before traces and images (default).
- $t=1$: Draws the axis after all traces and images.

**axOffset** $= a$

Specifies the distance from default axis position to actual axis position in units of the width of a zero character (0) in a tick mark label. Unlike margin, axOffset adjusts to changes in the size of the graph.

**axThick** $= t$

Specifies the axis thickness in points.

**barGap** $= \text{fraction}$

Sets the fraction of the width available for bars to be used as gap between bars.

- **barGap** sets the gap between bars within a single category while **catGap** sets the gap between categories.

**btLen** $= p$

Sets the length of major (“big”) tick marks to $p$ points. If $p$ is zero, it uses the default length. $p$ may be fractional.

**btThick** $= p$

Sets the thickness of major (“big”) tick marks to $p$ points. If $p$ is zero, it uses the default thickness. $p$ may be fractional.

**catGap** $= \text{fraction}$

The value for catGap is the fraction of the category width to be used as gap. The gap is divided equally between the start and end of the category width. A value of 0.2 would use 20% of the available space for the gap and leave 80% of the available space for the bars.

- **catGap** sets the gap between categories while **barGap** sets the gap between bars within a single category.

**dateFormat** $= \{\text{languageName, yearFormat, monthFormat, dayOfMonthFormat, dayOfWeekFormat, layoutStr, commonFormat}\}$

Sets the custom date format used in the active graph.

**Note:** Use a custom date format only if you turn it on via a **ModifyGraph dateInfo** command. The last parameter to the **ModifyGraph dateInfo** command must be -1 to turn on the custom date format.

Parameters are the same as for the LoadWave/R flag except for the last one.

**commonFormat** selects the common date format to use in the Modify Axis dialog. The legal values correspond to the choices in the Common Format pop-up menu of the Modify Axis dialog. They are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Date Format</th>
<th>Value</th>
<th>Date Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>mm/dd/yy</td>
<td>16</td>
<td>mm/yy</td>
</tr>
<tr>
<td>2</td>
<td>mm-dd-yy</td>
<td>17</td>
<td>mm.yy</td>
</tr>
<tr>
<td>3</td>
<td>mm.dd.yy</td>
<td>18</td>
<td>Abbreviated month and year</td>
</tr>
<tr>
<td>4</td>
<td>mm/ddyy</td>
<td>19</td>
<td>Full month and year</td>
</tr>
<tr>
<td>6</td>
<td>dd/mm/yy</td>
<td>21</td>
<td>mm/dd</td>
</tr>
<tr>
<td>7</td>
<td>dd-mm-yy</td>
<td>22</td>
<td>dd.mm</td>
</tr>
<tr>
<td>8</td>
<td>dd.mm.yy</td>
<td>23</td>
<td>Abbreviated month and day</td>
</tr>
<tr>
<td>9</td>
<td>ddmmyy</td>
<td>24</td>
<td>Full month and day</td>
</tr>
<tr>
<td>11</td>
<td>yy/mm/dd</td>
<td>26</td>
<td>Abbreviated date without day of week</td>
</tr>
<tr>
<td>12</td>
<td>yy-mm-dd</td>
<td>27</td>
<td>Abbreviated date with day of week</td>
</tr>
<tr>
<td>13</td>
<td>yy.mm.dd</td>
<td>28</td>
<td>Full date without day of week</td>
</tr>
<tr>
<td>14</td>
<td>yymmdd</td>
<td>29</td>
<td>Full date with day of week</td>
</tr>
</tbody>
</table>
If the `commonFormat` parameter is negative, then it will select the Use Custom Format radio button in the Modify Axis dialog rather than Use Common Format and will then use the absolute value of `commonFormat` to determine which item to select in the Common Format pop-up menu.

DateInfo=[sd,tm,dt] Controls formatting of date/time axes.

- `sd=0`: Show date in the date&time format.
- `sd=1`: Suppress date.
- `tm=0`: 12 hour (AM/PM) time.
- `tm=1`: 24 hour (military) time.
- `tm=2`: Elapsed time.
- `dt=-1`: Custom date as specified via the dateFormat keyword.
- `dt=0`: Short dates (2/22/90).

Font="fontName" Sets the axis label font, e.g., `font(left)="Helvetica"`.

FreePos(freeAxName)=p

Sets the position of the free axis relative to the edge of the plot area to which the axis is anchored. p is in points, i.e., if the axis was made via `/R=axName` then the axis is placed `p` points from the right edge of the plot area. Positive is away from the central plot area. `freeAxName` may not be any of the standard axes: "left", "bottom", "right", or "top".

FreePos(freeAxName)=[crossAxVal,crossAxName]

Positions the free axis so it will cross the perpendicular axis `crossAxName` where it has a value of `crossAxVal`. `freeAxName` may not be any of the standard axis names "left", "bottom", "right", or "top", though `crossAxName` may.

You can position a free axis as a fraction of the distance across the plot area by using `kwFraction` for `crossAxName`. `crossAxVal` must then be between 0 and 1; any values outside this range are clipped to valid values.

Fsize=s

Autosizes (s=0) tick mark labels and axis labels. If s is between 3 and 99 then the labels are fixed at s points.

Fstyle=f

f is a bitwise parameter with each bit controlling one aspect of the font style for the axis and tick mark labels as follows:

- Bit 0: Bold
- Bit 1: Italic
- Bit 2: Underline
- Bit 4: Strikethrough

See Setting Bit Parameters on page IV-13 for details about bit settings.

FtLen=p

Sets the length of 5th (or emphasized minor) tick marks to p points. If p is zero, it uses the default length. p may be fractional.

FtThick=p

Sets the thickness of 5th (or emphasized minor) tick marks to p points (fractional). If p is zero, it uses the default thickness.
grid=g  Controls grid lines.
  g=0: Grid off.
  g=1: Grid on.
  g=2: Grid on major ticks only.

gridEnab=[lowFrac,highFrac]
  Restricts the length of axis grid lines to a subrange of normal. The grid is drawn from
  lowFrac to highFrac of graph area height (if axis is horizontal) or width (if axis is vertical).

gridHair=h
  Sets the grid hairline thickness (h=0 to 3; 0 for thicker lines, 3 for thinner; default is 2).
  If h=0, the thickness of grid lines on major tick marks is the same as the axis thickness,
  half for a minor tick and one tenth for a subminor tick (log axis only). As h increases
  these thicknesses decrease by a factor of 2^h. If you want to see the effect of different
  values of gridHair, you will need to print a sample graph because you generally can’t
  see the effect of thin lines on the screen. Also see the example experiment
  “Examples:Graphing Techniques:Graph Grid Demo”.

gridStyle=g
  Also see the example experiment “Examples:Graphing Techniques:Graph Grid
  Demo”.

highTrip=h
  If the extrema of an axis are between its lowTrip and its highTrip then tick mark labels use
  fixed point notation. Otherwise they use exponential (scientific or engineering) notation.

lblLatPos=p
  Sets a lateral offset for the axis label. This is an offset parallel to the corresponding
  axis. p is in points. Positive is down for vertical axes and to the right for horizontal
  axes.

lblLineSpacing=linspace
  Specifies an adjustment to the normal line spacing for multi-line axis labels. linspace
  is points of extra (plus or minus) line spacing. For negative values, a blank line may
  be necessary to avoid clipping the bottom of the last line.

  lblLineSpacing affects all lines of the axis label. See also the \sa and \sb line spacing
  escape codes described under General Escape Codes on page III-55. They can be used
  to affect the spacing between individual lines.

lblMargin=l
  Specifies the distance from the edge of graph to a label in points.

lblPos=p
  Sets the distance from an axis to the corresponding axis label in points. If p=0, it
  automatically picks an appropriate distance.

  This setting is used only if the given graph edge has at least one free axis. Otherwise,
  the lblMargin setting is used to position the axis label.
ModifyGraph (axes)

lblPosMode=m
Affects the meaning and usage of lblPos, lblLatPos, and lblMargin parameters. Mainly for use when you have multiple axes on a side and you need axis labels to be properly positioned even as you make graph windows dramatically larger or smaller.

m=0: Default compatibility mode (Margin or Axis absolute depending on presence of free axis).
m=1: Margin absolute.
m=2: Margin scaled.
m=3: Axis absolute.
m=4: Axis scaled.

The absolute modes are measured in points whereas scaled modes have similar values but automatically expand or contract as the axis font height changes. Mode 0 is the default and results in no change relative to previous versions of Igor Pro that used lblMargin unless a given side used a free axis in which case it used lblPos in absolute mode. The margin modes measure relative to an edge of the graph while the axis modes measure relative to the position of the axis. When using stacked axes, use either margin modes. With multiple nonstacked axes, use Axis scaled if the graph edge is not using a fixed margin or use axis absolute if it is.

lblRot=r
Rotates the axis label by r degrees. r is a value from -360 to 360. Rotation is counterclockwise and starts from the label’s normal orientation.

linTkLabel=tl
tl=1 attaches the data units with any exponent or prefix to each tick label on a normal axis. tl=0 removes them.

log=l
Controls axis log mode.

logHTrip=h
Same as highTrip but for log axes.

logLabel=l
Sets the maximum number of decades in a log axis before minor tick labels are suppressed.

logLTrip=l
Same as lowTrip but for log axes.

logLinear=l
Switches to a linear tick method (l=1) on a log axis if the number of decades of ranges is less than 2. It switches to a linear tick exponent method if the number of decades is greater than five.

logTicks=t
Sets the maximum number of decades in log axis before minor ticks are suppressed.

lowTrip=l
If the extrema of an axis are between its lowTrip and its highTrip then tick mark labels use fixed point notation. Otherwise they use exponential (scientific or engineering) notation.

manminor={number, emphasizeEvery}
Specifies how to draw minor ticks in manual tick mode. There will be number ticks between each major (labeled) tick. You will usually want to set this to 4 to make 5 divisions, or 9 to make 10 divisions. A medium-sized tick (an emphasized minor tick) will be drawn every emphasizeEvery minor tick.

manTick={cantick, tickinc, exp, digitsrt [, timeUnit]}
Turns on manual tick mode. The tick from which all other ticks are calculated is the cononic tick (cantick). The numerical spacing between ticks is set by tickinc. cantick and tickinc are multiplied by 10^{exp}. The number of digits to the right of the decimal point displayed in the tick labels is set by digitsrt.

The optional parameter timeUnit is used with Date/Time axes to specify the units of tickinc. In this case, tickinc must be an integer. The value of timeUnit is one of the following keywords:

second, minute, hour, day, week, month, year

On a date/time axis, the exp and digitsrt keywords are ignored, but must be present. You can set them to zero.

manTick=0 Turns off manual tick mode.

margin=m Sets a fixed margin from the edge of the window to the axis in points. Used principally to make axes of multiple graphs on a page line up when "stacked". You can use the left, right, bottom, and top axis names (even if an axis with that name doesn’t exist) to adjust the graph plot area. See Types of Axes on page II-221.

m=0: Sets “automatic” margin size (dependent on the length and height of tick marks and labels).

m=-1: Sets the margin to “none”, or 0. The axis is drawn at the graph window’s edge.

minor=m Disables (m=0) or enables (m=1) minor ticks.

mirror=m Controls axis mirroring.

m=1: Right axis mirroring left or top mirroring bottom.

m=2: Mirror axis without tick marks.

m=3: Mirror axis with tick marks and tick labels.

m=0: No mirroring.

mirrorPos=pos Specifies the position of the mirror axis relative to the normal position. pos is a value between 0 and 1.

noLabel=n Controls axis labeling.

n=0: Normal labels.

n=1: Suppresses tick mark labels.

n=2: Suppresses tick mark labels and axis labels.

notation=n Uses engineering (n=0) or scientific (n=1) notation for tick mark labels.

Affects tick mark labels displayed exponentially. See highTrip and lowTrip. Does not affect log axes.

nticks=n Specifies the approximate number of ticks marks (n) on axis.

prescaleExp=exp Multiplies axis range by 10^{exp} for tick labeling and exp is subtracted from the axis label exponent. In other words, the exponent is moved from the tick labels to the axis label. (This affects the display only, not the source data.)

sep=s Specifies the minimum number of screen points (s) between minor ticks.

standoff=s Suppresses (s=0) or enables (s=1) axis standoff.

Axis standoff prevents waves or markers from covering the axis.

stLen=p Sets the length of minor (“small”) tick marks to p points. If p is zero, it uses the default length. p may be fractional.
## ModifyGraph (axes)

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stThick=p</td>
<td>Sets the thickness of minor (&quot;small&quot;) tick marks to ( p ) points. If ( p ) is zero, it uses the default thickness. ( p ) may be fractional.</td>
</tr>
<tr>
<td>tick=t</td>
<td>Sets tick position.</td>
</tr>
<tr>
<td>( t=0 ):</td>
<td>Outside axis.</td>
</tr>
<tr>
<td>( t=1 ):</td>
<td>Crossing axis.</td>
</tr>
<tr>
<td>( t=2 ):</td>
<td>Inside axis.</td>
</tr>
<tr>
<td>( t=3 ):</td>
<td>None.</td>
</tr>
</tbody>
</table>

In a category plot, adding 4 to the usual values for the tick keyword will place the tick marks in the center of each category rather than at the edges.

In a normal (non-category) plot specifying \( t=4 \) or \( t=5 \) replaces tick marks and axis lines with rectangular regions with alternating fills. This feature, which was added in Igor Pro 8.00, is used for cartographic plots.

\( t=4 \) gives even fills and \( t=5 \) gives odd fills. The btLen keyword determines the thickness of the fill area.

It is recommended that you use mirror axes and axisOnTop=1 as shown in this example:

```plaintext
Make jack=sin(x/8)
Display jack
ModifyGraph axisOnTop=1
ModifyGraph mirror=1
ModifyGraph standoff=0
ModifyGraph tick=4
```

**tickEnab={lowTick,highTick}**

Restricts axis ticking to a subrange of normal. Ticks are drawn and labelled only if they fall within this inclusive numerical range.

**tickExp=te**

\( te=1 \) forces tick labels to exponential notation when labels have units with a prefix. \( te=0 \) turns this off.

**tickUnit=tu**

Suppresses (\( tu =1 \)) or turns on (\( tu =0 \)) units labels attached to tick marks.

**tickZap={v1 [,v2 [,v3]]}**

Suppresses drawing of the tick mark label for values given in the list. This is useful when you have crossing axes to prevent tick mark labels from overlapping. The list may contain zero, one, two or three values. The values must be exact to suppress the label.

**tkLblRot=r**

Rotates the tick mark labels by \( r \) degrees. \( r \) is a value from -360 to 360. Rotation is counterclockwise and starts from the label's normal orientation.

**tlOffset=o**

Offsets the tick mark labels by \( o \) fractional points relative to the default tick mark label position. Positive is away from the axis.

**ttLen=p**

Sets the length of subminor ("tiny") tick marks to \( p \) points. If \( p \) is zero, it uses the default length. \( p \) may be fractional. Subminor ticks are used only in log axes.

**ttThick=p**

Sets the thickness of subminor ("tiny") tick marks to \( p \) points. If \( p \) is zero, it uses the default thickness. \( p \) may be fractional.
Draws axes with purely user-defined tick mark positions and labels. \textit{tickPosWave} is a numeric wave containing the desired positions of the tick marks, and \textit{tickLabelWave} is a text wave containing the labels. See \textbf{User Ticks from Waves} on page II-248 for an example.

The tick mark labels can be multiline and use styled text. For more details, see \textbf{Fancy Tick Mark Labels} on page II-288.

\textit{tickPosWave} need not be monotonic. Igor will plot a tick if a value is in the range of the axis. Both linear and log axes are supported.

Graph margins will adjust to accommodate tick labels. This will not prevent overlap between labels, which you will need fix yourself.

\textbf{Flags}

\textbf{/W=winName} Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with \textit{winName}, see \textbf{Subwindow Syntax} on page III-92 for details on forming the window hierarchy.

\textbf{/Z} Does not generate an error if the named axis does not exist in a style macro.

\textbf{Details}

With the \textbf{prescaleExp} parameter, you can force tick and axis label scaling to values different from the defaults. For example, if you have data whose X scaling ranges from 9pA to 120pA and you display this on a log axis, the tick marks will be labelled 10pA and 100pA. But if you really want the tick marks labeled 10 and 100 with pA in the axis label, you can set the \textbf{prescaleExp} to 12. To see this, execute the following commands:

\begin{verbatim}
Make/O jack=x
Display jack
SetScale x,9e-12,120e-12,"A",jack
ModifyGraph log(bottom)=1
 then execute:
ModifyGraph prescaleExp(bottom)=12
\end{verbatim}

The \textbf{tickExp} parameter applies to units that do not traditionally use SI prefix characters. For example, one usually speaks of 10⁻³ Torr and not mTorr. To see how this feature works, execute the following example commands:

\begin{verbatim}
Make/O jack=x
Display jack
\end{verbatim}
ModifyGraph (colors)

```plaintext
SetScale x,1E-7,1E-5,"Torr",jack
ModifyGraph log(bottom)=1
```
then execute:
```
ModifyGraph tickExp(bottom)=1
```
at this point, the tick mark labels have Torr in them. If you want to eliminate the units from the tick marks, execute:
```
ModifyGraph tickUnit(bottom)=1
```
and if you now want Torr in the label string, use the \U escape in the label string:
```
Label bottom "\U"
```
To see the effect of linTkLabel, execute these commands:
```
Make/O jack=x
Display jack
SetScale x,1E-7,1E-5,"Torr",jack
```
then execute:
```
ModifyGraph linTkLabel(bottom)=1
```
and then try:
```
ModifyGraph tickExp(bottom)=1
```
and finally:
```
ModifyGraph tickUnit(bottom)=1
```

ModifyGraph (colors)

```plaintext
ModifyGraph [/W=winName/Z] key [(axisName)] = (r,g,b)
               [, key [(axisName)] = (r,g,b)]...
```
This section of ModifyGraph relates to modifying the use of colors in a graph.

Parameters
Most (but not all) of the key parameters may take an optional axisName enclosed in parentheses. axisName is “left”, “right”, “top”, “bottom” or the name of an free axis such as “vertCrossing”.

Where the parameter descriptions indicate an “(axisName)”, it may be omitted to change all axes in the graph.

r, g, and b are each an integer from 0 to 65535 where (0, 0, 0) is black and (65535, 65535, 65535) is white.

<table>

ModifyImage

Flags

/W=winName Modifies the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/Z Does not generate an error if the named axis does not exist in a style macro.

Details

On Windows, use maximum white to set the control bar background color to track the 3D Objects color in the Appearance Tab of the Display Properties control panel:

ModifyGraph cbRGB=(65535,65535,65535)

See Also

See Instance Notation on page IV-20.

ModifyImage

ModifyImage [/W=winName] imageInstance, keyword = value

The ModifyImage operation changes properties of the given image in the top graph (or the specified graph if /W is used). imageInstance is the name of the image to be altered. This name is usually simply the name of the matrix wave containing the image data. If the same matrix wave is displayed more than once, you must append #0, #1 etc. to the name to distinguish which is which.

imageInstance can also take the form of a null name with an instance number to affect the instanceth image. That is,

ModifyImage ''#1 modifies the appearance of the second image that was appended to the top graph, no matter what the image names are. Note: two single quotes are used, not a double quote.

Parameters

Here are the keyword-value pairs. These apply to false color images in which the data in the matrix is used as an index into a color table. They do not apply to direct color images in which the data in the matrix specifies the color directly.

cindex=matrixWave Sets the Z value mapping mode such that image colors are determined by doing a lookup in the specified matrix wave.

matrixWave is a 3 column wave that contains red, green, and blue values from 0 to 65535. (The matrix can actually have more than three columns. It ignores any extra columns.)

The color at Z=z is determined by finding the RGB values in the row of matrixWave whose scaled X index is z. In other words, the red value is matrixWave(z)[0], the green value is matrixWave(z)[1] and the blue value is matrixWave(z)[2].

If matrixWave has default X scaling, where the scaled X index equals the point number, then row 0 contains the color for Z=0, row 1 contains the color for Z=1, etc.

If you use cindex, you should not use ctab in the same command.

ctab=[zMin, zMax, ctName, reverse]
Sets the z mapping mode by which values in the matrix are mapped linearly into the
color table specified by ctName.

zMin and zMax set the range of z values to map. Omit zMin or zMax to leave as is or
use * to autoscale.

The color table name can be missing if you want to leave it as is.

tcName can be any color table name returned by the CTabList function, such as Grays
or Rainbow (see Image Color Tables on page II-323) or the name of a 3 column or 4
column color table wave (Color Table Waves on page II-329).

A color table wave name supplied to ctab must not be the name of a built-in color
table (see CTabList). A 3 column or 4 column color table wave must have values that
range between 0 and 65535. Column 0 is red, 1 is green, and 2 is blue. In column 3 a
value of 65535 is opaque, and 0 is fully transparent.

Set reverse to 1 to reverse the color table. Setting it to 0 or omitting it leaves the color
table unreversed.

tcAbscise=autoBits

Sets the range of data used for autoscaling ctab * values.

Bit 0: Autoscales only the XY subset being displayed.

Bit 1: Autoscales only the current plane being displayed.

If neither bit is set (if autoBits = 0, the default), then all of the data in the image wave
is used to autoscale the *'d zMin, zMax values for ctab.

eval=[value, red, green, blue, [alpha]]

If the red, green, and blue values are in the valid range for a color value (0 to 65535)
the explicit value-color pair is added (or updated if value already exists). If the color
values are out of range (-1 is suggested) then the value is removed from the list if it is
present (no error if it is not).

alpha is optional: a value of 65535 is opaque, and 0 is fully transparent.

explicit=1 or 0

Turns explicit (monochrome) mode on (1) or off (0). Meant to be used with
unsigned byte data but will do the best it can for other types. If value of data is
equal to one of the defined explicit values then its defined color is used otherwise
the pixel will be blank. The default predefined values are:

255: black

0: white

You can add, change, or delete explicit values with the eval keyword.

imCmplxMode=m

Sets complex data display mode.

m=0: Magnitude (default).

m=1: Real only.

m=2: Imaginary only.

m=3: Phase in radians.

interpolate= mode

mode = 1 turns on smoothing of the boundaries between pixels. Since this is
implemented via system graphics calls and not by Igor actually doing the
interpolation, it will not affect EPS or EMF export on Windows and will not affect EPS
export on Mac. Although this may create a more aesthetically pleasing display, it is not
clear that it is appropriate for scientific data.

mode = -1 forces pixels to be drawn as individual rectangles. This is sometimes needed
when a third-party program improperly interpolates PDF or EPS exported images.
log= 1 or 0
0 sets the default linearly-spaced false-image colors.
1 turns on logarithmically-spaced false-image colors. This requires that the image values be greater than 0 to display correctly.
Affects the image colors for color table and color index images only (see Color Table Details on page II-326 and Indexed Color Details on page II-330).

lookup= waveName
Specifies an optional 1D wave that can be used to modify the mapping of scaled z values into the color table specified with the ctab parameter. Values should range from 0.0 to 1.0. A linear ramp from 0 to 1 would have no effect while a ramp from 1 to 0 would reverse the image. Used to apply gamma correction to grayscale images or for special effects. Use a NULL wave (""") to remove the option.

maxRGB=(red, green, blue, [alpha])
Sets the color of image values greater than the ctab zMax or greater than the cindex of the matrixWave maximum X scaling value. Also turns max color mode on.
The red, green, and blue color values are in the range of 0 to 65535.
alpha is optional: a value of 65535 is opaque, and 0 is fully transparent.

maxRGB=1 or 0 or NaN
1: Turns on max color mode. The color of the affected image pixels is black or the last color set by maxRGB=(red, green, blue).
0: Turns off max color mode (default). The color of the affected image pixels is the last color table or color index color.
NaN: Transparent max color mode. The affected image pixels are not drawn.

minRGB=(red, green, blue, [alpha])
Sets the color of image values less than the ctab zMin or less than the cindex of the matrixWave minimum X scaling value. Also turns min color mode on.
The red, green, and blue color values are in the range of 0 to 65535.
alpha is optional: a value of 65535 is opaque, and 0 is fully transparent.

minRGB=1 or 0 or NaN
1: Turns on min color mode. The color of the affected image pixels is black or the last color set by minRGB=(red, green, blue).
0: Turns off min color mode (default). The color of the affected image pixels is the first color table or color index color.
NaN: Transparent min color mode. The affected image pixels are not drawn.

plane=p
Determines which part of a 3D or 4D image wave to display.
The meaning of p depends on the nature of the image wave. If the size of the layer dimension of the image wave is exactly three then the wave is treated as RGB data with R, G, and B data in the three layers. If the size of the layer dimension is exactly four, then the wave is treated as RGBA data, with A in the fourth layer. Otherwise each layer of the wave is treated as a separate grayscale image.
ModifyLayout

Plane=p With RGB Data
If the wave is 3D, plane=p has no effect.
If the wave is 4D, each chunk contains a different set of R, G and B layers and p selects which chunk to display.

Plane=p With Grayscale Data
If the wave is 3D, p selects which layer to display.
If the wave is 4D, plane=p acts as if all of the chunks were combined into a virtual 3D wave and p selects which layer of this virtual 3D wave to display.

rgbMult=m  If m is non-zero, direct color values (3 plane RGB) are multiplied by m. This would typically be used for 10, 12 or 14 bit integers in a 16 bit word. For example, if your image data is 14 bits, use rgbMult=4.

Flags
/W=winName  Directs action to a specific window or subwindow rather than the top graph window. When omitted, action will affect the active window or subwindow.
When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

See Also
AppendImage and RemoveImage.

ModifyLayout
ModifyLayout [flags] key [(objectName)] =value [, key [(objectName)] =value]...
The ModifyLayout operation modifies objects in the top layout or in the layout specified by the /W flag.

Parameters
Each key parameter may take an optional objectName enclosed in parentheses. If “(objectName)” is omitted, all objects in the layout are affected.
Though not shown in the syntax, the optional “(objectName)” may be replaced with “[objectIndex][]”, where objectIndex is zero or a positive integer denoting the object to be modified. “[0]” denotes the first object appended to the layout, “[1]” denotes the second object, etc. This syntax is used for style macros, in conjunction with the /Z flag.
The parameter descriptions below omit the optional “(objectName)”.
The “units”, “mag” and “bgRGB” keywords apply to the layout as a whole, not to a specific object and do not accept an objectName.

bgRGB=(r,g,b)  Specifies the background color for the layout. r, g, and b are integers from 0 to 65535.
columns=c  Specifies the number of columns for a table object.
fidelity=f  Controls the drawing of layout objects.
    f=0:  Low fidelity.
    f=1:  High fidelity.
frame=f  Specifities the type of frame enclosing the object.
    f=0:  No frame.
    f=1:  Single frame (default).
    f=2:  Double frame.
    f=3:  Triple frame.
    f=4:  Shadow frame.
gradiant  See Gradient Fills on page III-472 for details.
ModifyPanel

ModifyPanel [/W=winName] keyword = value [, keyword = value ...]

The ModifyPanel operation modifies properties of the top or named control panel window or subwindow.

Parameters

keyword is one of the following:

cbRGB=(r,g,b) Specifies the background color of the entire control panel or the graph’s control bar area. r, g, and b are values from 0 to 65535.
ModifyPanel

\[
\text{drawInOrder} = d \quad \text{Determines the drawing order of controls in the control panel.}
\]

\[
d=0: \quad \text{Draw tab controls before any other controls (default).}
\]
\[
d=1: \quad \text{Draw all controls in the order in which they appear in the recreation macro, which is also the creation order.}
\]

The \text{drawInOrder} keyword was added in Igor Pro 8.00.

Prior to Igor Pro 8.00 tab controls (see \text{TabControl}) were always drawn before all other controls. This prevented placing a tab control inside a groupbox with a colored interior. \text{drawInOrder}=1 forces Igor to draw controls in creation order, which is the same as the order in which they appear in a recreation macro.

\[
\text{fixedSize} = f \quad \text{Controls the resizing of the panel window.}
\]

\[
f=0: \quad \text{Panel can be resized (default).}
\]
\[
f=1: \quad \text{Panel cannot be resized by adjusting the size box or frame (nor maximized on Windows), but the window can be minimized (on Windows) and the MoveWindow operation can still change the size.}
\]

The \text{fixedSize} keyword overrides any previous size limit set using the \text{SetWindow sizeLimit} command. If you try to use \text{SetWindow sizeLimit} on a window with \text{fixedSize}=1, Igor generates an error.

\[
\text{frameInset} = i \quad \text{Specifies the number of pixels by which to inset the frame of the panel subwindow. Mostly useful for overlaying panels in graphs to give a fake 3D frame a better appearance.}
\]

\[
\text{frameStyle} = f \quad \text{Specifies the frame style for a panel subwindow.}
\]

\[
f=0: \quad \text{None.}
\]
\[
f=1: \quad \text{Single.}
\]
\[
f=2: \quad \text{Indented.}
\]
\[
f=3: \quad \text{Raised.}
\]
\[
f=4: \quad \text{Text well.}
\]

The last three styles are fake 3D and will look good only if the background color of the enclosing space and the panel itself is a light shade of gray.

\[
\text{noEdit} = e \quad \text{Sets the editability of the panel.}
\]

\[
e=0: \quad \text{Editable (default).}
\]
\[
e=1: \quad \text{Not editable. For a panel window, the Panel menu item is not present and the ShowTools command is ignored. For a panel subwindow, it can not be activated by clicking.}
\]

\textbf{Flags}

\[
/W= winName \quad \text{Modifies the control panel in the named graph or control panel window or subwindow. When omitted, action will affect the active window or subwindow.}
\]

When identifying a subwindow with \text{winName}, see \text{Subwindow Syntax} on page III-92 for details on forming the window hierarchy.

\textbf{Details}

On Windows, set \(r, g, \) and \(b = 65535\) (maximum white) to set the background color of the control panel to track the 3D Objects color in the Appearance Tab of the Display Properties control panel.

\textbf{See Also}

The \text{NewPanel} operation.

\textbf{Controls in Graphs} on page III-421.
ModifyProcedure

ModifyProcedure [/A[=all] /W=procWinTitleListStr] /Z[=z]

[procedure=functionOrMacroNameStr, lock=ro, writeProtect=wp,
 userCanOverride=ovr]

The ModifyProcedure operation modifies one or more procedure windows, depending on the /A and /W flags and on the procedure keyword.

Use /W="Procedure" to modify the built-in procedure window.

Use /W="<procedure window title>" to modify a procedure window specified by its title.

Use procedure=<function name> to modify a procedure window containing a particular function.

See Specifying Which Procedure Windows to Modify below for other usages.

The ModifyProcedure operation was added in Igor 8.03.

Parameters

procedure=functionOrMacroNameStr

functionOrMacroNameStr is a string containing the name of a function or macro in the procedure window to modify.

functionOrMacroNameStr may be a simple name or may include independent module and/or module name prefixes to designate static functions. For use with independent modules, see Using ModifyProcedure With Independent Modules below.

lock=ro

Sets or clears the read-only state of the targeted procedure windows.

ro=0: Clears the read-only state. This allows the user to change the text if the procedure window is also not write-protected.

ro=1: Sets the read-only state. The procedure window shows a lock icon in the lower left corner.

writeProtect=wp

Sets or clears the write-protect state of the targeted procedure windows.

wp=0: Clears the write-protect state. The user can change the text if the procedure window is also not locked.

wp=1: Sets the write-protect state. The procedure window shows a write-protect icon (a pencil with a red circle-and-line indicator).

userCanOverride=ovr

Controls the ability of the user to change the write-protect state of the targeted procedure windows.

ovr=0: Prevents the user from changing the write-protect state by clicking the write-protect icon.

ovr=1: Allows the user to change the write-protect state by clicking the write-protect icon.

Flags

/A[=all]

Specifies all procedure windows as the targets of the ModifyProcedure operation.

Use /A=1 to target all procedure windows in the ProcGlobal module. /A alone is the same as /A=1.

Use /A=2 to target all procedure windows in independent modules. See Using ModifyProcedure With Independent Modules for details.
ModifyProcedure

/W=procWinTitleListStr  Specifies a particular procedure window or a list of procedure windows as the targets of the ModifyProcedure operation.

If procWinTitleListStr is the title of a single procedure window, this specifies that procedure window as the single target.

If procWinTitleListStr contains a semicolon-separated list of procedure window titles, this specifies those procedure windows as targets.

See Specifying Which Procedure Windows to Modify below for details.

/Z[=z]  Prevents procedure execution from aborting if an error occurs. Use /Z or /Z=1 if you want to handle errors from ModifyProcedure in your procedures rather than having execution abort.

Specifying Which Procedure Windows to Modify

The simplest way to modify one procedure window whose title you know is to use /W:

ModifyProcedure/W="My Procedure.ipf" writeProtect=1
ModifyProcedure/W="Procedure" writeProtect=1 // Modifies built-in procedure window

Use /A=1 to target all procedure windows in the ProcGlobal module:

ModifyProcedure/A=1 writeProtect=1

Don’t specify both /A and /W as this is ambiguous and generates an error.

Use procedure=functionOrMacroNameStr to modify all procedure windows in the ProcGlobal module containing a procedure with the specified name:

ModifyProcedure procedure=MyFunction, writeProtect=1

If you omit procedure=functionOrMacroNameStr, /A, and /W then the built-in procedure window is modified.

Use functionOrMacroNameStr only when you are not certain which procedure window contains the function or macro. If a procedure window has syntax errors that prevent Igor from determining where functions and macros start and end, then ModifyProcedure may not be able to locate the correct procedure window in which case it returns an error.

You can use /W and procedure=functionOrMacroNameStr to search for a function or macro in one or more procedure windows. This is useful when functionOrMacroNameStr is the name of a static function in a procedure window that uses #pragma moduleName.

Using ModifyProcedure With Independent Modules

To work with independent modules, you must enable independent module development. This is for advanced programmers only. See Independent Modules on page IV-231 for details. The material in this section assumes that independent module development is enabled.

/W=procWinTitleListStr can be a list of procedure window titles each followed by a space and an independent module name in brackets. Then procedure=functionOrMacroNameStr applies to the specified procedure windows and independent modules.

For example, if any procedure file contains these statements:

#pragma IndependentModule=myIM
#include <Axis Utilities>

then the commands

ModifyProcedure/W="Axis Utilities.ipf [myIM]" procedure="HVAxisList"
Print S_windowList, V_isReadOnly, V_writeProtect

report the title, read-only state, and write-protect state of the procedure window that contains the HVAxisList function, which is in the "Axis Utilities.ipf" file and the independent module myIM.

Similarly, procedure=functionOrMacroNameStr may also specify an independent module prefix followed by the # character. The preceding ModifyProcedure command can be rewritten as:

ModifyProcedure/W="Axis Utilities.ipf" procedure="myIM#HVAxisList"

or simply:

ModifyProcedure procedure="myIM#HVAxisList"
You can use the same syntax to modify the procedure window containing a static function in a non-independent module procedure file using a module name instead of, or in addition to, the independent module name.

*procWinTitleListStr* can also be just an independent module name in brackets to target all procedure windows that belong to the named independent module containing the specified function:

```plaintext
ModifyProcedure/W="[myIM]" procedure="HVAxisList", writeProtect=0
```

**Output Variables**

The ModifyProcedure operation returns information in the following variables for the last procedure window targeted by the parameters. The information returned reflects the state of affairs after the ModifyProcedure command performs any requested modifications.

- **V_isReadOnly**: If the procedure’s lock icon is showing, V_isReadOnly is set to 1, otherwise to 0.
- **V_writeProtect**: If the pencil with the red line icon is showing, V_writeProtect is set to 1, otherwise to 0.
- **V_userCanOverride**: Set to 1 (the default) if the user can change the write-protect state to writable.
- **S_windowList**: Set to a semicolon-separated list of procedure window titles that match the parameters, with an appended independent module name in brackets if necessary.

If S_windowList is empty, then no procedure windows matched the parameters, and no modifications were performed.

You can obtain the information provided by the output variables without modifying any procedure windows by omitting the lock, writeProtect, and userCanOverride keywords.

**Examples**

```plaintext
// Completely unlock main Procedure window
ModifyProcedure lock=0, writeProtect=0, userCanOverride=1; Print S_windowList

// Completely unlock the procedure window containing the function named MyFunction
ModifyProcedure procedure="MyFunction", lock=0, writeProtect=0, userCanOverride=1
Print S_windowList

// Lock all procedure windows in the myIM independent module, even those included into it,
// and print the titles of the matching procedure windows
Execute "SetIgorOption IndependentModuleDev=1"
ModifyProcedure/W="[myIM]" lock=1, writeProtect=1, userCanOverride=0; Print S_windowList

// Unlock all procedure windows in the ProcGlobal module
ModifyProcedure/A=1 lock=0, writeProtect=0, userCanOverride=1
```

HideProcedures, DisplayProcedure, ProcedureText

DoWindow, WinList

MacroList, FunctionList

**ModifyTable**

```plaintext
ModifyTable [/W=winName/Z] key [(columnSpec)] =value [, key [(columnSpec)] =value]...
```

The ModifyTable operation modifies the appearance the top or named table window or subwindow.

**Parameters**

Many of the parameter keywords take an optional *columnSpec* enclosed in parentheses. Usually *columnSpec* is simply the name of a wave displayed in the table. All table columns are affected when you omit *(columnSpec)*.

More precisely, column specifications are wave names for waves in the current data folder or data folder paths leading to waves in any data folder optionally followed by the suffixes .i, .I, .d, .id or .ld to specify dimension indices, dimension labels, data values, dimension indices and data values, or dimension labels and data values of the wave. For example, *ModifyTable font*(myWave.i)="Helvetica". If the wave is complex, the column specification may be followed by .real or .imag suffixes.
One additional columnSpec is Point, which refers to the first column containing the dimension index numbers. If multidimensional waves are displayed in the table, this column may have the title “Row”, “Column”, “Layer”, “Chunk” or “Element”, but the columnSpec for this column is always Point. See Column Names on page II-182 for details.

Though not shown in the syntax, the optional (columnSpec) may be replaced with [columnIndex], where columnIndex is zero or a positive integer denoting the column to be modified. [0] denotes the Point column, [1] denotes the first column appended to the table, [2] denotes the second appended column, etc. This syntax is used for style macros, in conjunction with the /Z flag.

You can use a range of column numbers instead of just a single column number, for example [0, 3].

The parameter descriptions below omit the optional (columnSpec).

alignment=a
  Sets the alignment of table cell text.
  a=0:  Left aligned.
  a=1:  Center aligned.
  a=2:  Right aligned.

autosize=[mode, options, padding, perColumnMaxSeconds, totalMaxSeconds]
  Autosizes the specified column or columns.
  mode=0:  Sets width of each data column from a given multidimensional wave individually.
  mode=1:  Sets width of all data columns from a given multidimensional wave the same.

  options is a bitwise parameter. Usually 0 is the best choice.
  Bit 0:  Ignores column names.
  Bit 1:  Ignores horizontal indices.
  Bit 2:  Ignores data cells.

  All other bits are reserved and must be set to zero.

  See Setting Bit Parameters on page IV-13 for details about bit settings.

  padding specifies extra padding for each column in points. Use -1 to get the default amount of padding (16 points).
  perColumnMaxSeconds specifies the maximum amount of time to spend autosizing a single column. Use 0 to get the default amount of time (one second).
  totalMaxSeconds specifies the maximum amount of time for autosizing the entire table. Use 0 to get the default amount of time (ten seconds).

digits=d
  Specifies the number of digits after decimal point or, for hexadecimal and octal columns, the number of total digits.

elements=(row, col, layer, chunk)
  Selects the view of a multidimensional wave in the table. The values given to row, col, layer, and chunk specify how to change the view.
  -1:  No change from current view.
  -1:  Display this dimension vertically.
  -3:  Display this dimension horizontally.
  ≥0:  For waves with 3 or 4 dimensions, display this element of the other dimensions.

  See ModifyTable Elements Command on page II-203 for a detailed discussion of
ModifyTable

**entryMode=m**
Queries or sets the table’s entry line mode.

- **m=0**: Just queries.
- **m=1**: Accepts any entry that was started if possible.
- **m=2**: Cancels any entry that was started if possible.

If **m** is 0 then the entry line state is not changed but is returned via V_flag as follows:

- **0**: No entry is in progress.
- **-1**: An entry is in progress and is valid.
- **Other**: An entry is in progress and is invalid.

In Igor Pro 8.03 and later, **S_value** is set to contain the text showing in the entry line.

If **m** is 1 then the entry is accepted if it is valid and its state is returned via V_flag as follows:

- **0**: No entry is in progress.
- **-1**: The entry was accepted.
- **Other**: The entry is invalid and was not accepted.

In Igor Pro 8.03 and later, **S_value** is set to contain the text showing in the entry line whether or not an entry was in progress and whether or not i was accepted.

If **m** is 2 then the entry is cancelled if possible and its state is returned via V_flag as follows:

- **0**: No entry is in progress.
- **-1**: The entry was cancelled.

In Igor Pro 8.03 and later, **S_value** is set to contain the text showing in the entry line after the entry was cancelled.

**font=“fontName”**
Sets font used in the table, e.g., **font=“Helvetica”**.

**format=f**
Sets the data format for the table.

- **f=0**: General.
- **f=1**: Integer.
- **f=2**: Integer with thousands (e.g., ”1,234”).
- **f=3**: Fixed point (e.g., ”1234.56”).
- **f=4**: Fixed point with thousands (e.g., ”1,234.56”).
- **f=5**: Exponential (scientific only).
- **f=6**: Date format.
- **f=7**: Time format (always 24 hour time).
- **f=8**: Date&time format (date followed by time).
- **f=9**: Octal.
- **f=10**: Hexadecimal.

You cannot apply date or date&time formats to a wave that is not double-precision (see **Date, Time, and Date&Time Units** on page II-64). To avoid this error, use **Redimension** to change the wave to double-precision.

**frameInset= i**
Specifies the number of pixels by which to inset the frame of the table subwindow.
ModifyTable

**frameStyle=f** Specifies the frame style for a table subwindow.

- **f=0:** None.
- **f=1:** Single.
- **f=2:** Double.
- **f=3:** Triple.
- **f=4:** Shadow.
- **f=5:** Indented.
- **f=6:** Raised.
- **f=7:** Text well.

The last three styles are fake 3D and will look good only if the background color of the enclosing space and the table itself is a light shade of gray.

**horizontalIndex=h** Controls what is displayed in the horizontal index row when multidimensional waves are displayed.

- **h=0:** Displays dimension labels if the multidimensional wave’s label column is displayed, otherwise displays numeric indices (default).
- **h=1:** Always displays numeric indices for multidimensional waves.
- **h=2:** Always displays dimension labels for multidimensional waves.

The horizontal index row appears below the row of column names if the table contains a multidimensional wave. Use horizontalIndex to override the default behavior in order to display labels for the horizontal dimension while displaying numeric indices for the vertical dimension or vice versa.

horizontalIndex controls the horizontal index row only. To control what is displayed vertically, use **AppendToTable** to append a numeric index or dimension label column.

**rgb=(r, g, b)** Sets color of text. r, g, and b are red, green, and blue components of the color and range from 0 to 65,535. Default is black: (0,0,0).

**selection=(firstRow, firstCol, lastRow, lastCol, targetRow, targetCol)**

Sets the selected cells in the table.

- If any of the parameters have the value -1 then the corresponding part of the selection is not changed.
- Otherwise they set the first and last selected cell and the target cell. Row and column values are 0 or greater. The Point column can not be selected.
- The proposed parameters are clipped to avoid invalid combinations, such as the last selected row being before the first selected row.
- With one exception, it does not support selecting unused cells. Therefore the proposed selection is clipped to prevent this. The exception is that, if the parameters call for selecting the first cell in the first unused column, then this is permitted.

**showFracSeconds=s** Shows (s=1) or hides (s=0; default) fractional seconds.

**showParts=parts** Specifies what elements of the table should be visible. Other elements are hidden.
parts is a bitwise parameter specifying what to show.

bit 0: Entry line and other top line controls.
bit 1: Name row.
bit 2: Horizontal index row.
bit 3: Point column.
bit 4: Horizontal scroll bar.
bit 5: Vertical scroll bar.
bit 6: Insertion cells.
bit 7: Insertion cells.

All other bits are reserved and must be set to zero except that you can pass -1 to indicate that you want to show all parts of the table.

See Setting Bit Parameters on page IV-13 for details about bit settings.

Presentation tables in subwindows in graphs and page layouts do not have an entry line or scroll bars and therefore never show these items.

See Parts of a Table on page II-176 and Showing and Hiding Parts of a Table on page II-178 for further information.

sigdigits=d  
\( d \) is the number of significant digits when the numeric format is general.

size=s  
Font size, e.g., size=14.

style=n  
\( n \) is a bitwise parameter with each bit controlling one aspect of the column’s font style as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Style</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Bold</td>
</tr>
<tr>
<td>1</td>
<td>Italic</td>
</tr>
<tr>
<td>2</td>
<td>Underline</td>
</tr>
<tr>
<td>4</td>
<td>Strikethrough</td>
</tr>
</tbody>
</table>

For example, bold underlined is \( 2^0 + 2^2 = 1 + 4 = 5 \). See Setting Bit Parameters on page IV-13 for details about bit settings.

title="title"  
Sets the title of a column to title.

topLeftCell=(row, column)  
Scrolls the table contents so that the cell identified by (row, column) is the top left visible data cell, or as close as possible.

If row is -1 then the table’s vertical scrolling is not changed. If column is -1 then the table’s horizontal scrolling is not changed.

If they are positive, row and column are zero-based numbers which are clipped to valid values before being used. row=0 refers to the first row of data in the table, column=0 refers to the first column of data.

The Point column can not be scrolled horizontally.

trailingZeros=t  
Shows trailing zeros (t=1). This affects the general numeric format only.

width=w  
Sets column width to w points.

You will not always get the exact number of points that you request. This is because a column must have an even number of screen pixels, so that grid lines look good. Igor will modify your requested number of points to meet this requirement.
ModifyViolinPlot

Flags

/W= winName  Modifies the named table window or subwindow. When omitted, action will affect
the active window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92
for details on forming the window hierarchy.

/Z  No errors generated if the indexed or specified column does not exist in a style macro.

Examples

ModifyTable size(myWave)=14    // change font size of myWave column
ModifyTable width(Point)=0     // hide Point column
ModifyTable style(cmplxWave.imag)=32 // condensed= bit 5 = 2^5 = 32

See Also

See Column Names on page II-182 and ModifyTable Elements Command on page II-203.

ModifyViolinPlot

ModifyViolinPlot [/W=winName] [keyword=value, keyword=value, ...]

The ModifyViolinPlot operation modifies a violin plot trace in the target or named graph.

ModifyViolinPlot was added in Igor Pro 8.00.

For a detailed discussion of violin plots and the parts of a violin plot, see Violin Plots on page II-270.

Parameters

trace=traceName  Specifies the name of a violin plot trace to be modified. An error results if the
named trace is not a violin plot trace. Without the trace keyword,
ModifyViolinPlot uses the first trace in the graph, whether it is a violin plot
trace or not but see the instance keyword for an exception.

instance=instanceNum  The combination of trace and instance works the same as
(traceName#instanceNum) for a ModifyGraph keyword.

The instance keyword without trace keyword accesses the instanceNum'th
trace in the graph, just like [traceNum] used with a ModifyGraph keyword.
See Trace Names on page II-222 and Object Indexing on page IV-21.

bandwidth[(ds)]=bw  Sets the bandwidth used in computing the KDE curves. If you include ds, the
bandwidth is set to bw for data set ds. If you omit ds, the bandwidth is set for
all data sets. bw must be greater than or equal to 0. 0 uses the bandwidth
estimated by the method set by the bandwidthMethod keyword.

bandwidthMethod=m  Sets the method used to estimate the appropriate bandwidth used in
computing the KDE curves. The methods are

m=0:  Silverman
m=1:  Scott (default)
m=2:  Bowman and Azzalini

See StatsKDE for details.

You can override the estimated bandwidth using the bandwidth keyword.
boxWidth=$w$

For a non-category X axis, boxWidth sets the width of the space reserved for displaying the KDE curves. If $w$ is between zero and one, it is taken to be a fraction of the width of the plot rectangle. If $w$ is greater than one, it is in points.

All the KDE curves are normalized such that the maximum density value of the KDEs over all data sets fills the box width so only one of the violin plots will be as wide as $w$. You can control the normalization using the maxDensity keyword.

If the violin plot is displayed using a category X axis, boxWidth is ignored. The space reserved for each data set is controlled by the category axis and is affected by ModifyGraph barGap and catGap.

A new non-category violin plot has box width set as boxWidth=1/(2*$n$) where $n$ is the number of data sets (the number of violin plots) on the trace.

closeOutline[=close]

If close is 1 or omitted, the ends of the KDE curves are connected by a straight line. Closed curves are more visible if side=1 or side=2 in which case the KDE curves are closed by a straight line at the midline between the curves.

curveExtension=ext

Sets the range of the KDE curves. The KDE curves are computed for a range of $y=$minData-$ext$ to $y=$maxData+$ext$, where $ext$ is in units of bandwidth. $ext$ defaults to 1.

dataMarker=marker

Sets the marker number used to display the raw data. If marker is -1, the marker as set by ModifyGraph marker is used. The default is 8 (hollow circle).

jitter=$j$

In order to separate closely-spaced raw data points, the data points can be displaced horizontally. $j$ controls the maximum offset applied to any data point, expressed as a fraction of the box width. The value of $j$ may be greater than 1, but in general values less than 1 look better. The default value is 0.5.

kernel=$k$

Sets the kernel function to be used in computing the KDE curves. Supported values are

$k=1$: Epanechnikov
$k=2$: Bi-weight
$k=3$: Tri-weight
$k=4$: Triangular
$k=5$: Gaussian (default)
$k=6$: Rectangular

It is unusual for a violin plot to use anything other than Gaussian, which is the default. See StatsKDE for details.

lineStyle=style

Sets the line style used to draw the KDE curves. See Dashed Lines on page III-470 for a description of line styles.

A line style of -1 uses the line style set by ModifyGraph lstyle. style defaults to -1.

lineThickness=thick

Sets the thickness of the line used to plot the KDE curves. A thickness less than zero uses the line width set by the ModifyGraph lsize keyword. thick=0 hides the KDE curve. The default value is -1.

markerSize=size

Sets the size of the marker used to display the raw data. A marker size of zero uses one-half of the marker size as set by ModifyGraph msize. size defaults to zero.

maxDensity=$d$

Sets the normalization for the width of the KDE curves to $d$. All the KDE curves are normalized such that the maximum density value of all KDEs fills the box width. The width of each curve gives an indication of the relative maximum density. maxDensity allows you to set the same normalization for multiple violin plots so that the width for all is relative to the same value.
**ModifyViolinPlot**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plotSide=$side$</td>
<td>By default, a violin plot is symmetrical with the KDE curve plotted twice in mirror image. You can control which side is plotted:</td>
</tr>
<tr>
<td></td>
<td>$side=0$: Both sides in mirror image (default)</td>
</tr>
<tr>
<td></td>
<td>$side=1$: The left side</td>
</tr>
<tr>
<td></td>
<td>$side=2$: The right side</td>
</tr>
<tr>
<td></td>
<td>Using 1 or 2 allows you to combine two violin plots in an asymmetric plot.</td>
</tr>
<tr>
<td>showData[=$sd$]</td>
<td>Shows or hides the raw data points. $sd$ is 0 or 1. showData by itself is equivalent to showData=1. The default is 1.</td>
</tr>
</tbody>
</table>

**Mean and Median Parameters**

You can display markers showing the mean and the median of each data set using the keywords documented in this section. See **Markers** on page II-229 for a list of available markers. For both mean and median, a marker size of zero uses the marker size set by ModifyGraph msize.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>showMean[=$show$]</td>
<td>Shows or hides the marker representing the mean value. $show$ is 0 or 1. showMean by itself is equivalent to showMean=1. The default is 0.</td>
</tr>
<tr>
<td>meanMarker=$marker$</td>
<td>Sets the marker to use for the mean value. The default for the mean marker is 27 (hollow horizontal diamond with dot).</td>
</tr>
<tr>
<td>meanMarkerSize=$size$</td>
<td>Sets the size of the marker used to display the mean value. A value of zero uses the trace marker size as set by ModifyGraph msize, or the normal trace default marker size. The default is zero.</td>
</tr>
<tr>
<td>showMedian[=$show$]</td>
<td>Shows or hides the marker representing the median value. $show$ is 0 or 1. showMedian by itself is equivalent to showMedian=1. The default is 0.</td>
</tr>
<tr>
<td>medianMarker=$marker$</td>
<td>Sets the marker to use for the median value. The default for the median marker is 26 (filled horizontal diamond).</td>
</tr>
<tr>
<td>medianMarkerSize=$size$</td>
<td>Sets the size of the marker used to display the median value. A value of zero uses the trace marker size as set by ModifyGraph msize, or the normal trace default marker size. The default is zero.</td>
</tr>
</tbody>
</table>

**Color Parameters**

All colors are specified as $(r,g,b,[a])$ which represent red, green, blue, and optionally alpha (transparency) expressed as integers from 0 to 65535. If you omit $a$, it defaults to 65535 which represents fully opaque. $a=0$ represents fully transparent.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fillColor=$(r,g,b,[a])$</td>
<td>Fills the area between the distribution curves with the specified color. Specifying fillColor=$(0,0,0,0)$ removes the fill. If side=1 or side=2, the fill is between the curve and the mid line.</td>
</tr>
<tr>
<td>lineColor=$(r,g,b,[a])$</td>
<td>Sets the color of the KDE curves. Specify lineColor=$(0,0,0,0)$ to use the trace color set using ModifyGraph rgb as the line color. The default is black $(0,0,0)$.</td>
</tr>
<tr>
<td>markerColor=$(r,g,b,[a])$</td>
<td>Sets the color of markers used to display the raw data. Specify markerColor=$(0,0,0,0)$ to use the trace color set using ModifyGraph rgb as the marker color. This is the default behavior.</td>
</tr>
<tr>
<td>meanMarkerColor=$(r,g,b,[a])$</td>
<td>Sets the color of markers used to display the mean value. Specify meanMarkerColor=$(0,0,0,0)$ to use the trace color set using ModifyGraph rgb as the mean marker color. This is the default behavior.</td>
</tr>
</tbody>
</table>
Examples

A violin plot with transparent marker color used to give a visual indication of the density of data points.

```plaintext
// Create a violin plot with transparent marker color used to give a visual indication of the density of data points
Make/O/N=(25,3) multicol // A three-column wave with 25 rows
SetRandomSeed(.4) // For reproducible "randomness"
multicol = gnoise(1) // Three normally-distributed data sets
multicol[20][1] = 5 // A "far" outlier
multicol[13][2] = -4 // An outlier
Display; AppendViolinPlot multicol
ModifyViolinPlot showData=1
ModifyViolinPlot dataMarker=19
ModifyViolinPlot markerSize=5
ModifyViolinPlot markerColor=(0,0,65535,19661)
ModifyViolinPlot lineColor=(0,0,65535)
ModifyViolinPlot fillColor=(0,0,65535,19661)
ModifyViolinPlot jitter=0
```

// Create a violin plot with asymmetric curves plotted on a category axis
Make/O/N=(25,3) ds1, ds2
SetRandomSeed(.4) // For reproducible "randomness"
ds1 = gnoise(1)
ds2 = gnoise(2)+q
// We need a text wave to make a category plot
Make/N=3/T/O labels={"treatment 1", "treatment 2", "treatment 3"}
Display
AppendViolinPlot ds1 vs labels
AppendViolinPlot ds2 vs labels
// Keep plots together in a single category space
ModifyGraph toMode(ds1)=-1

// Display ds1 on the left, ds2 on the right
ModifyViolinPlot trace=ds1,plotSide=1
ModifyViolinPlot trace=ds2,plotSide=2

// Extend the KDE curves
ModifyViolinPlot trace=ds1,CurveExtension=2
ModifyViolinPlot trace=ds2,CurveExtension=2

// Close the curves with line at the midline
ModifyViolinPlot trace=ds1,closeOutline=1
ModifyViolinPlot trace=ds2,closeOutline=1

// Use the same normalization for both curves
ModifyViolinPlot trace=ds1,maxDensity=0.36
ModifyViolinPlot trace=ds2,maxDensity=0.36
```
// Apply jitter to the data points
ModifyViolinPlot trace=ds1,jitter=0.5
ModifyViolinPlot trace=ds2,jitter=0.5

// Set markers and colors
ModifyViolinPlot trace=ds1,showData=1,dataMarker=16,markerColor=(2,39321,1),lineColor=(2,39321,1)
ModifyViolinPlot trace=ds2,showData=1,dataMarker=19,markerColor=(0,0,65535),lineColor=(0,0,65535)
ModifyViolinPlot trace=ds1,fillColor=(2,39321,1,19661)
ModifyViolinPlot trace=ds2,fillColor=(0,0,65535,19661)

See Also
AppendViolinPlot, AddWavesToViolinPlot, ModifyGraph (traces)
Violin Plots on page II-270

ModifyWaterfall

ModifyWaterfall [/W=winName]  keyword = value [,  keyword = value ... ]
The ModifyWaterfall operation modifies the properties of the waterfall plot in the top or named graph.

Parameters
keyword is one of the following:

angle= a  Angle in degrees from horizontal of the angled Y axis (a =10 to 90).
axlen= len  Relative length of angled Y axis. len is a fraction between 0.1 and 0.9.
hidden= h  Controls the hidden line algorithm.
    h=0:   Turns hidden lines off.
    h=1:   Uses painter’s algorithm.
    h=2:   True hidden.
    h=3:   Hides lines with bottom removed.
    h=4:   Hides lines using a different color for the bottom. When specified, the
top color is the normal color for lines and the bottom color is set using
ModifyGraph negRGB=(r,g,b).

Hidden lines are active only when the mode is lines between points.
ModuleName

Flags

/W = winName  Modifies waterfall plot in the named graph window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details
Painter’s algorithm draws the traces from back to front and erases hidden lines while modes 2, 3 and 4 detect which line segments are hidden and suppresses the drawing of these segments.

See Also
Waterfall Plots on page II-261.
The NewWaterfall and ModifyGraph operations.

ModuleName
#pragma ModuleName = modName
The ModuleName pragma assigns a name, which must be unique, to a procedure file so that you can use static functions and Proc Pictures in a global context, such as in the action procedure of a control or on the Command Line.

Using the ModuleName pragma involves at least two steps. First, within the procedure file assign it a name using #pragma ModuleName = modName, and then access objects in the named file by preceding the object name with the name of the module and the # character, such as or example: ModName#StatFuncName().

See Also
The Regular Modules on page IV-229, Static, Picture, and #pragma.

MoveDataFolder
MoveDataFolder [ /O=options /Z ] sourceDataFolderSpec, destDataFolderPath
The MoveDataFolder operation removes the source data folder (and everything it contains) and places it at the specified location with the original name.

Parameters
sourceDataFolderSpec can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.
destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

Flags
/O = options  Overwrites the destination data folder if it already exists.

The /O flag was added in Igor Pro 8.00.

options=1: Completely overwrites the destination data folder. If the destination data folder exists, MoveDataFolder first deletes it if possible. If it can not be deleted, for example because it contains a wave that is in use, MoveDataFolder generates an error. If the deletion succeeds, MoveDataFolder then copies the source to the destination. Then the source data folder is deleted.

options=2: Merges the source data folder into the destination data folder. If an item in the source data folder exists in the destination data folder, MoveDataFolder overwrites it. Otherwise it copies it. Items in the destination data folder that do not exist in the source data folder remain in the destination data folder. Then the source data folder is deleted.
MoveFile

options=3: Merges the source data folder into the destination data folder and then deletes items that are not in the source data folder if possible. If an item in the source data folder does not exist in the destination data folder, MoveDataFolder attempts to delete it from the destination data folder. If it cannot be deleted because it is in use, no error is generated. Then the source data folder is deleted.

/Z Errors are not fatal - if an error occurs, procedure execution continues. You can check the V_flag output variable to see if an error occurred.

Details
MoveDataFolder generates an error if a data folder of the same name already exists at the destination unless the /O flag is used. When the /O flag is non-zero and the destination data folder already exists, MoveDataFolder is equivalent to DuplicateDataFolder followed by a KillDataFolder on the source.

Output Variables
MoveDataFolder sets the following output variable:

V_flag 0 if the operation succeeded or a non-zero error code. The V_flag output variable was added in Igor Pro 8.00.

Examples
MoveDataFolder root:DF0, root:archive // Move DF0 into archive

See Also
See the DuplicateDataFolder operation. Chapter II-8, Data Folders.

MoveFile

MoveFile [flags] [srcFileStr] [as destFileOrFolderStr]
The MoveFile operation moves or renames a file on disk. A file is renamed by “moving” it to the same folder it is already in using a different name.

Parameters
srcFileStr can be a full path to the file to be moved or renamed (in which case /P is not needed), a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName.

If Igor cannot determine the location of the file from srcFileStr and pathName, it displays an Open File dialog allowing you to specify the source file.

destFileOrFolderStr is interpreted as the name of (or path to) an existing folder when /D is specified, otherwise it is interpreted as the name of (or path to) a possibly existing file.

If destFileOrFolderStr is a partial path, it is relative to the folder associated with pathName.

If /D is specified, the source file is moved inside the folder using the source file’s name.

If Igor cannot determine the location of the destination file from pathName, srcFileStr, and destFileOrFolderStr, it displays a Save File dialog allowing you to specify the destination file (and folder).

If you use a full or partial path for either srcFileStr or destFileOrFolderStr, see Path Separators on page III-429 for details on forming the path.

Folder paths should not end with single Path Separators. See the Details section for MoveFolder.

Flags

/D Interprets destFileOrFolderStr as the name of (or path to) an existing folder (or directory). Without /D, destFileOrFolderStr is the name of (or path to) a file.

If destFileOrFolderStr is not a full path to a folder, it is relative to the folder associated with pathName.
MoveFile

/I [=i] specifies the level of interactivity with the user.

/I=0: Interactive only if srcFileStr or destFileOrFolderStr is not specified or if the source file is missing. (Same as if /I was not specified.)
/I=1: Interactive even if srcFileStr is specified and the source file exists.
/I=2: Interactive even if destFileOrFolderStr is specified.
/I=3: Interactive even if srcFileStr is specified and the source file exists. Same as /I only.

/M=messageStr specifies the prompt message in the Open File dialog. If /S is not specified, then messageStr will be used for both Open File and for Save File dialogs.

/O Overwrite existing destination file, if any. Without /O, the user is asked if replacing the existing file is to be allowed.

/P=pathName specifies the folder to look in for the source file, and the folder into which the file is copied. pathName is the name of an existing symbolic path.

Using /P means that both srcFileStr and destFileOrFolderStr must be either simple file or folder names, or paths relative to the folder specified by pathName.

/S=saveMessageStr specifies the prompt message in the Save File dialog.

/Z[=z] prevents procedure execution from aborting if it attempts to move a file that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.

/Z=0: Same as no /Z.
/Z=1: Moves a file only if it exists. /Z alone is equivalent to /Z=1.
/Z=2: Moves a file if it exists or displays a dialog if it does not exist.

Variables
The MoveFile operation returns information in the following variables:

V_flag Set to zero if the file was moved, to -1 if the user cancelled either the Open File or Save File dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.

S_fileName Stores the full path to where the file was moved from. If an error occurred or if the user cancelled, it is set to an empty string.

S_path Stores the full path where the file was moved to. If an error occurred or if the user cancelled, it is set to an empty string.

Examples
Rename a file, using full paths:
MoveFile "HD:folder:aFile.txt" as "HD:folder:bFile.txt"

Rename a file, using a symbolic path:
MoveFile/P=myPath "aFile.txt" as "bFile.txt"

Move a file into a subfolder (the subfolder must exist):
MoveFile/D "Macintosh HD:folder:aFile.txt" as ":subfolder"

Move a file into an unrelated folder (the subfolder must exist):
MoveFile/D "Macintosh HD:folder:afile.txt" as "Server:archive"

Move a file from one folder to another and rename it:

Move user-selected file into a particular folder:
MoveFile/D as "C:My Data:Selected Files Folder"

Move user-selected file in any folder as bFile.txt in same folder:
MoveFile as "bFile.txt"
MoveFolder

Move user-selected file in any folder as bFile.txt in any folder:
MoveFile/I=2 as "bFile.txt"

See Also
The Open, MoveFolder, CopyFolder, NewPath, and CreateAliasShortcut operations. The IndexedFile function. Symbolic Paths on page II-21.

MoveFolder

MoveFolder [flags] [srcFolderStr] [as destFolderStr]
The MoveFolder operation moves or renames a folder on disk. A folder is renamed by “moving” it into the same folder it is already in, but with a different name.

Warning: The MoveFolder command can destroy data by overwriting another folder and its contents!
If you overwrite an existing folder on disk, MoveFolder will do so only if permission is granted by the user. The default behavior is to display a dialog asking for permission. The user can alter this behavior via the Miscellaneous Settings dialog’s Misc category.
If permission is denied, the folder will not be moved and V_Flag will return 1088 (Command is disabled) or 1275 (You denied permission to overwrite a folder). Command execution will cease unless the /Z flag is specified.

Parameters
srcFolderStr can be a full path to the folder to be moved or renamed (in which case /P is not needed), a partial path relative to the folder associated with pathName, or the name of a folder within the folder associated with pathName.
If the location of the source folder cannot be determined from srcFolderStr and pathName, it displays a Select Folder dialog allowing you to specify the source.
If /P=pathName is given, but srcFolderStr is not, then the folder associated with pathName is moved or renamed.
destFolderStr specifies the final location of the folder or, if /D is used, the parent of the final location of the folder.
destFolderStr can be a full path to the output (destination) folder (in which case /P is not needed), or a partial path relative to the folder associated with pathName.
If the location of the destination folder cannot be determined from destFolderStr and pathName, it displays a Save Folder dialog allowing you to specify the destination.
If you use a full or partial path for either file, see Path Separators on page III-429 for details on forming the path.

Flags
/D Interprets destFolderStr as the name of (or path to) an existing folder (or “directory”) to move the source folder into. Without /D, it interprets destFolderStr as the name of (or path to) the moved folder.
If destFolderStr is not a full path to a folder, it is relative to the source folder.
/I [=i] Specifies the level of interactivity with the user.
/I=0: Interactive only if srcFolderStr or destFolderStr is not specified or if the source folder is missing. (Same as if /I was not specified.)
/I=1: Interactive even if srcFolderStr is specified and the source folder exists.
/I=2: Interactive even if destFolderStr is specified.
/I=3: Interactive even if srcFolderStr is specified and the source folder exists. Same as /I only.
/M=messageStr Specifies the prompt message in the Open File dialog. If /S is not used, then messageStr will be used for both Open File and for Save File dialogs.
/O Overwrite existing destination folder, if any. This deletes the existing destination folder. When /O is specified, the source folder can’t be moved into an existing folder without specifying the name of the moved folder in destFolderStr.
**MoveFolder**

/\P=pathName  
Specifies the folder for relative paths in srcFolderStr and destFolderStr. pathName is the name of an existing symbolic path.

If srcFolderStr is omitted, the folder associated with pathName is moved. If destFolderStr is omitted, the source folder is moved into the folder associated with pathName.

Using /\P means that srcFolderStr (if specified) and destFolderStr must be either simple folder names or paths relative to the folder specified by pathName.

/\S=saveMessageStr  
Specifies the prompt message in the Save File dialog.

/\Z=[z]  
Prevents procedure execution from aborting if it attempts to move a folder that does not exist. Use /\Z if you want to handle this case in your procedures rather than having execution abort.

/\Z=0:  
Same as no /\Z.

/\Z=1:  
Moves a folder only if it exists. /\Z alone is equivalent to /\Z=1.

/\Z=2:  
Moves a folder if it exists or displays a dialog if it does not exist.

**Variables**

The MoveFolder operation returns information in the following variables:

- **V_flag**  
  Set to zero if the file was moved, to -1 if the user cancelled either the Open File or Save File dialogs, and to some nonzero value if an error occurred, such as the specified file does not exist.

- **S_fileName**  
  Stores the full path to the folder that was moved, with a trailing colon. If an error occurred or if the user cancelled, it is set to an empty string.

- **S_path**  
  Stores the full path of the moved folder, with a trailing colon. If an error occurred or if the user cancelled, it is set to an empty string.

**Details**

You can use only /\P=pathName (omitting srcFolderStr) to specify the source folder to be moved.

A folder path should not end with single Path Separators. For example:

MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder:"
MoveFolder "Macintosh HD:folder:" as "Macintosh HD:Renamed Folder"
MoveFolder "Macintosh HD:folder:" as "Macintosh HD:Renamed Folder:"

will do weird, unexpected things (and probably damaging things when /\O is also used). Instead, use:

MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder"

Beware of PathInfo and other command which return paths with an ending path separator. (They can be removed with the RemoveEnding function.)

A folder may not be moved into one of its own subfolders.

Conversely, the command:

MoveFolder/O/P=myPath "afolder"

which attempts to overwrite the folder associated with myPath with a folder that is inside it (namely "afolder") is not allowed. Instead, use:

MoveFolder/O/P=myPath "::afolder"

On Windows, renaming or moving a folder never updates the value of any Igor Symbolic Paths that point to a moved folder:

// Create a folder
NewPath/O/C myPath "C:\\My Data\\My Work"

// Move the folder
MoveFolder/P=myPath as "C:\\My Data\\Moved"

// Display the path's value
PathInfo myPath // (or use the Path Status dialog)
Print S_path
* C:My Data:My Work
You can use PathInfo to determine if a folder referred to by an Igor symbolic path exists and where it is on the disk. Use NewPath/O to reset the path’s value.

On the Macintosh, however, renaming or moving a folder on the same volume does alter the value of symbolic path. This is because MoveFolder uses a Mac OS alias to keep track of the folder. A folder renamed or moved on the same volume retains the original “volume refnum” and “directory ID” stored in the alias mechanism, so that the alias (and hence Igor’s symbolic path) remains pointing to the moved folder. After moving the folder, using the unchanged volume refnum and directory ID (in PathInfo or when you use /P=pathName) returns the updated path.

Moving the folder to a different volume actually creates a new folder with new volume refnum and directory IDs, and symbolic paths pointing to or into the moved folder aren’t updated. They will be pointing at a deleted folder (they’re probably invalid).

**Examples**

Rename a folder (“move” it to the same folder):

```
MoveFolder "Macintosh HD:folder" as "Macintosh HD:Renamed Folder"
```

Rename a folder referred to by only a path:

```
NewPath/O myPath "Macintosh HD:folder"
MoveFolder/P=myPath as "::Renamed Folder"
```

Move a folder from one volume to another. This moves “Macintosh HD:My Folder” inside “Server:My Folder” if “Server:My Folder” already exists:

```
MoveFolder "Macintosh HD:My Folder" as "Server:My Folder"
```

Move a folder from one volume to another. This overwrites “Server:My Folder” (if it existed) with the moved “Macintosh HD:My Folder”:

```
MoveFolder/O "Macintosh HD:My Folder" as "Server:My Folder"
```

Move user-selected folder in any folder as “Renamed Folder” into a user-selected folder (possibly the same one):

```
MoveFolder as "Renamed Folder"
```

Move user-selected file in any folder as “Moved Folder” in any folder:

```
MoveFolder/I=3 as "Moved Folder"
```

**See Also**

---

**MoveString**

MoveString sourceString, destDataFolderPath [newname]

The MoveString operation removes the source string variable and places it in the specified location optionally with a new name.

**Parameters**

sourceString can be just the name of a string variable in the current data folder, a partial path (relative to the current data folder) and variable name or an absolute path (starting from root) and variable name.

destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

**Details**

An error is issued if a variable or wave of the same name already exists at the destination.

**Examples**

```
MoveString :foo:s1,:bar: // Move string s1 into data folder bar
MoveString :foo:s1,:bar:ss1 // Move string s1 into bar with new name ss1
```

**See Also**

The MoveVariable, MoveWave, and Rename operations; and Chapter II-8, Data Folders.
MoveSubwindow

MoveSubwindow [/W=winName] key = (values) [, key = (values)]...

The MoveSubwindow operation moves the active or named subwindow to a new location within the host window. This command is primarily for use by recreation macros; users should use layout mode for repositioning subwindows.

Parameters

fguide=(gLeft, gTop, gRight, gBottom)

Specifies the frame guide name(s) to which the outer frame of the subwindow is attached inside the host window.

The frame guides are identified by the standard names or user-defined names as defined by the host. Use * to specify a default guide name.

When the host is a graph, additional standard guides are available for the outer graph rectangle and the inner plot rectangle (where traces are plotted).

See Details for standard guide names.

fnum=(left, top, right, bottom)

Specifies the new location of the subwindow. The location coordinates of the subwindow sides can have one of two possible meanings:

When all values are less than 1, coordinates are assumed to be fractional relative to the host frame size.

When any value is greater than 1, coordinates are taken to be fixed locations measured in points, or pixels for control panels, relative to the top left corner of the host frame.

guide=(gLeft, gTop, gRight, gBottom)

Specifies the guide name(s) to which the plot rectangle of the graph subwindow is attached inside the host window.

Guides are identified by the standard names or user-defined names as defined by the host. Use * to specify a default guide name.

See Details for standard guide names.

Flags

/W= winName

Moves the subwindow in the named window or subwindow. When omitted, action will affect the active subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

When moving an exterior subwindow, only the fnum keyword may be used. The values are the same as the NewPanel /W flag for exterior subwindows.

The names for the built-in guides are as defined in the following table:

<table>
<thead>
<tr>
<th>Subwindow Type</th>
<th>Left</th>
<th>Right</th>
<th>Top</th>
<th>Bottom</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subwindow Frame</td>
<td>FL</td>
<td>FR</td>
<td>FT</td>
<td>FB</td>
</tr>
<tr>
<td>Outer Graph Rectangle</td>
<td>GL</td>
<td>GR</td>
<td>GT</td>
<td>GB</td>
</tr>
<tr>
<td>Inner Plot Rectangle</td>
<td>PL</td>
<td>PR</td>
<td>PT</td>
<td>PB</td>
</tr>
</tbody>
</table>

The frame guides apply to all window and subwindow types. The graph rectangle and plot rectangle guide types apply only to graph windows and subwindows.
MoveVariable

See Also
The MoveWindow operation. Chapter III-4, Embedding and Subwindows for further details and discussion.

MoveVariable

MoveVariable sourceVar, destDataFolderPath [newname]
The MoveVariable operation removes the source numeric variable and places it in the specified location optionally with a new name.

Parameters
sourceVar can be just the name of a numeric variable in the current data folder, a partial path (relative to the current data folder) and variable name or an absolute path (starting from root) and variable name.
destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

Details
An error is issued if a variable or wave of the same name already exists at the destination.

Examples
MoveVariable :foo:v1,:bar: // Move v1 into data folder bar
MoveVariable :foo:v1,:bar:vv1 // Move v1 into bar with new name vv1

See Also
The MoveString, MoveWave, and Rename operations; and Chapter II-8, Data Folders.

MoveWave

MoveWave sourceWave, destDataFolderPath [newname]
The MoveWave operation removes the source wave and places it in the specified location optionally with a new name.

Parameters
sourceWave can be just the name of a wave in the current data folder, a partial path (relative to the current data folder) and wave name or an absolute path (starting from root) and wave name.
destDataFolderPath can be a partial path (relative to the current data folder) or an absolute path (starting from root).

Details
An error is issued if a variable or wave of the same name already exists at the destination.

Examples
MoveWave :foo:w1,:bar: // Move wave w1 into data folder bar
MoveWave :foo:w1,:bar:ww1 // Move w1 into bar with new name ww1

See Also
The MoveString, MoveVariable, and Rename operations; and Chapter II-8, Data Folders.

MoveWindow

MoveWindow [flags] left, top, right, bottom
The MoveWindow operation moves the target or specified window to the given coordinates.

Flags
/C  Moves Command window instead of the target window.
/F  Windows: Moves the Igor Pro application “frame” and the frame is then adjusted so that no part is offscreen.
     Macintosh: Moves nothing.
/I  Coordinates are in inches.
Details
Note that neither winName nor procedureTitleAsName is a string but is the actual window name or procedure window title. If the procedure window's title (procedure windows don't have names) has a space in it, use $ and quotes:
$$\text{MoveWindow}/P=$"Log Histogram" 0,0,600,400$$
If /W, /F, /C, and /P are omitted, MoveWindow moves the target window.

The coordinates are in points if neither /l nor /M is used.

In Igor Pro 7.00 or later, to move the window without changing its size, pass -1 for both right and bottom.

You can use the MoveWindow operation to minimize, restore, or maximize a window by specifying 0, 1, or 2 for all of the coordinates, respectively, as follows:
$$\text{MoveWindow 0, 0, 0, 0} // \text{Minimize target window.}$$
$$\text{MoveWindow 1, 1, 1, 1} // \text{Restore target window.}$$
$$\text{MoveWindow 2, 2, 2, 2} // \text{Maximize target window.}$$

On Macintosh, “maximize” means to move and resize the window so that it fills the screen. “Minimize” means to minimize to the dock.

If the window size has been constrained by SetWindow sizeLimit, those limits are silently applied to the size set by MoveWindow.

See Also
The MoveSubwindow and DoWindow operations.

MultiTaperPSD

The MultiTaperPSD operation estimates the power spectral density of srcWave using Slepian (DPSS) tapers. The MultiTaperPSD operation was added in Igor Pro 7.00.

Flags

/A Uses Thomson's adaptive algorithm. In this case the operation also creates the wave W_MultiTaperDF that contains the effective degrees of freedom. For each frequency of the PSD the algorithm is expected to converge within few iterations. When it fails to converge, the operation prints in the history the total number of frequencies where it did not converge while the actual output contains the last iteration estimate.

/DB Scale the PSD results as $10\times\log_{10}(\text{spectralEst}(f))$.

/DBF=0 Scale the PSD results as $10\times\log_{10}(\text{spectralEst}(f)/\text{spectralEst}(f_0))$ where $f_0$ must be in the range $[0,0.5/\text{DimDelta}(\text{srcWave},0)]$.

/DEST=destWave Saves the PSD estimate in a wave specified by destWave. The destination wave is created or overwritten if it already exists.

Creates a wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-71 for details.

If you omit /DEST the operation saves the resulting spectral estimate in the wave W_MultiTaperPSD in the current data folder.

/F Computes F-test statistic for each output frequency. The results are stored in the wave W_MultiTaperF.

If /DEST is also used then the F-test results are stored in the same data folder as destWave. Otherwise W_MultiTaperF is created in the current data folder.
The MultiTaperPSD operation estimates the PSD of srcWave by computing a set of discrete prolate spheroidal functions (Slepian DPSS) and using them as optimal window functions. The window functions/tapers are applied to the input signal and squares of the resulting Fourier transforms are weighted together to produce the PSD estimate.

srcWave must be a real-valued numeric wave of single or double precision and must not contain any INFs or NaNs.

The mean value of the input is subtracted prior to multiplication by the tapers. Like DSPPeriodogram, the MultiTaperPSD operation leaves the normalization to the user.

The default PSD estimate is calculated by combining the Fourier transforms of the tapered signal with weights from the DPSS calculation. You can use the /A flag to improve the PSD estimate for increasing tapers. Thomson's adaptive algorithm is reasonably efficient and also provides an estimate of the effective degrees of freedom as a function of frequency.

The operation sets the variable V_Flag to zero if successful or to a -1 if it encounters an error. If you are using Thomson's adaptive algorithm (/A) V_Flag is set to the number of frequencies at which the algorithm failed to converge.

Demos
See the “MultiTaperPSD Demo” example experiment.

References
MultiThread

MultiThread [ /N=numThreads ] wave = expression
In user-defined functions, the MultiThread keyword can be inserted in front of wave assignment statements to speed up execution on multiprocessor computer systems.

Warning: Misuse of this keyword can result in a performance penalty or even a crash. Be sure to read Automatic Parallel Processing with MultiThread on page IV-312 before using MultiThread.

The expression must be thread-safe. This means that if it calls a function, the function must be thread-safe. This goes for both built-in and user-defined functions.

Not all built-in functions are thread-safe. Use the Command Help tab in the Igor Help Browser to see which functions are thread-safe.

User-defined functions are thread-safe if they are defined using the ThreadSafe keyword. See ThreadSafe Functions on page IV-103 for details.

You can specify the number of threads using the /NT flag. The default value, which takes effect if you omit /NT or specify /NT=0, uses the number returned by ThreadProcessorCount. /NT=1 specifies a single thread and is equivalent to omitting the MultiThread keyword; you might want to turn off threading to avoid its overhead when the wave has few points. numThreads values greater than one specify the desired number of threads to be used. Igor may use fewer threads depending on how it is able to partition the task. The /NT flag was added in Igor Pro 8.00.

See Also
Automatic Parallel Processing with MultiThread on page IV-312.
Waveform Arithmetic and Assignments on page II-69.
The “MultiThread Mandelbrot Demo” experiment.

MultiThreadingControl

MultiThreadingControl keyword [=value]
The MultiThreadingControl operation allows you to control how automatic multithreading works with those IGOR operations that support it. Automatic multithreading is described below under Details.

For most purposes you will not need to use this operation.
The MultiThreadingControl operation was added in Igor Pro 7.00.

Keywords

getMode
Writes the current mode value into the variable V_autoMultiThread.

getThresholds
Creates the wave W_MultiThreadingArraySizes in the current data folder. See Automatic Multithreading Thresholds below for details.

setMode=m
Sets the mode for automatic multithreading. The mode controls the circumstances in which automatic multithreading is enabled.

m=0: Disables automatic multithreading unconditionally.

m=1: Enables automatic multithreading based on operation-specific thresholds for operations called from the main thread only. This is the default setting.

m=4: Enables automatic multithreading based on operation-specific thresholds for operations called from the main thread and from user-created explicit threads.

m=8: Enables automatic multithreading unconditionally - regardless of thresholds or the type of the calling thread.
MultiThreadingControl

You can not combine modes by ORing. The only valid values for mode are those shown above.

`setThresholds=tWave` Sets the thresholds for automatic multithreading. See Automatic Multithreading Thresholds below for details.

Details
Some IGOR operations and functions have internal code that can execute calculations in parallel using multiple threads. These operations are marked as "Automatically Multithreaded" in the Command Help pane of the Igor Help Browser.

Running on multiple threads reduces the time required for number-crunching tasks on multi-processor machines when the benefit of using multiple processors exceeds the overhead of running in multiple threads. This is usually the case only for large-scale jobs.

By default Igor uses automatic multithreading in operations that support it when the number of calculations exceeds a threshold value. This is called "automatic multithreading" to distinguish it from the explicit multithreading that you can instruct Igor to do. Explicit multithreading is described under ThreadSafe Functions and Multitasking on page IV-317. You don't need to do anything to benefit from automatic multithreading.

By default automatic multithreading is enabled for operations called from the main thread and disabled for operations called from explicit threads that you create (mode=1). You can change this using the setMode keyword described above.

The state of automatic multithreading is not saved with the experiment. It is initialized to mode=1 with default thresholds every time you start IGOR.

Automatic Multithreading Thresholds
Executing these commands

```
MultiThreadingControl getThresholds
Edit W_MultiThreadingArraySizes.ld
```

creates a wave named W_MultiThreadingArraySizes and displays it in a table. This shows you the current threshold for each operation that supports automatic multithreading. The wave includes dimension labels so you can see which row represents which operation's threshold.

The meaning of a given threshold value depends on the operation. For most operations the threshold is in terms of the number of points in the input wave. For some operations the threshold depends on the complexity of the calculation. For example, the threshold for the CurveFit operation takes the complexity of the fitting function into account.

You can change the threshold for a given operation by setting the data for the appropriate row of W_MultiThreadingArraySizes and passing it back to the MultiThreadingControl operation using the setThresholds keyword. For example:

```
W_MultiThreadingArraySizes[%ICA]=5000 // Set the ICA threshold
MultiThreadingControl setThresholds=W_MultiThreadingArraySizes // Apply
```

You should not change any aspect of the wave other than the threshold values.

Multithreading and Roundoff Error
Every floating point operation can potentially lead to roundoff error. Normally, if you run the exact same code on the exact same data, you get the exact same roundoff error and the exact same result.

This is not necessarily the case with multithreaded calculations. Because the partitioning of work among threads depends on circumstances, such as how many threads are free, different calculation runs on the same data may partition work differently. This can lead to differences in roundoff error and therefore differences in results.

You can obtain reproducibility at the expense of performance by turning off automatic multithreading:

```
MultiThreadingControl setMode=0
```

Although this provides reproducibility, it does not necessarily reduce the size of roundoff error.

Examples
```
MultiThreadingControl setMode=0       // Disable automatic multithreading
MultiThreadingControl setMode=8       // Always multithread regardless of wave size
```

NameOfWave

\texttt{NameOfWave(wave)}

The NameOfWave function returns a string containing the name of the specified wave.

In a user-defined function that has a parameter or local variable of type WAVE, NameOfWave returns the actual name of the wave identified by the WAVE reference. It can also be used with wave reference functions such as \texttt{WaveRefIndexedDFR}.

NameOfWave does not return the full data folder path to the wave. Use \texttt{GetWavesDataFolder} for this information.

A null wave reference returns a zero-length string. This might be encountered, for instance, when using WaveRefIndexedDFR in a loop to act on all waves in a data folder, and the loop has incremented beyond the highest valid index.

Examples

Function \texttt{ZeroWave(w)}

\begin{verbatim}
Wave w
  w = 0
  Print "Zeroed the contents of", NameOfWave(w)
End
\end{verbatim}

See Also
See WAVE; the GetWavesDataFolder and WaveRefIndexed functions; and Wave Reference Functions on page IV-192.

NaN

\texttt{NaN}

The NaN function returns the “Not a Number” value according to the IEEE standards.

Comparison operators do not work with NaN parameters because, by definition, NaN compared to anything, even another NaN, is false. Use \texttt{numtype} to test if a value is NaN.

NeuralNetworkRun

\texttt{NeuralNetworkRun [/Q/Z] Input=testWave, WeightsWave1=w1, WeightsWave2=w2}

The NeuralNetworkRun operation uses the interconnection weights generated by NeuralNetworkTrain, and saved in the waves M_Weights1 and M_Weights2, to execute the network for a given input. The input can contain a single run represented by a 1D wave or M runs represented by M columns of a 2D wave. The output of the calculation is saved in the wave W_NNResults or M_NNResults depending on the dimensionality of the input wave. The structure of the network is completely specified by the two weights waves and must match the number of rows in the input wave.
NeuralNetworkTrain

Flags
/Q Suppresses printing information in the History area.
/Z No error reporting.

Parameters
Input=testWave Specifies the input to the neural network. testWave must be a single or double precision wave containing entries in the range [0,1] and have the correct number of rows to match the weights. Execute the network for multiple runs by using a 2D input wave where each column corresponds to a single run. For a 2D input, the result will be stored in M_NNResults with a corresponding column structure.

WeightsWave1=w1 Specifies the interconnection weights between the input and the hidden layer.
WeightsWave2=w2 Specifies the interconnection weights between the hidden layer and the output.

See Also
The NeuralNetworkTrain operation.

NeuralNetworkTrain

NeuralNetworkTrain [/Q/Z] [keyword = value]...

The NeuralNetworkTrain operation trains a three-layer neural network. The training produces two 2D waves that store the interconnection weights between the network neurodes. Once you obtain the weights, you can use them with NeuralNetworkRun.

Flags
/Q Suppresses printing information in the History area.
/Z No error reporting.

Parameters
Input=inWave Specifies the input patterns for training. inWave is a 2D wave where each row corresponds to a single training event and each column corresponds to the input values. The number of rows in inWave (the number of training sets) and in the output wave must be equal. inWave must be single or double precision and all entries must be in the range [0,1].

Iterations=num Specifies the number of iterations. Default is 10000.

MinError=val Terminates training when the total error drops below val (default is 1e-8). The total error is normalized, and is defined as the sum of the squared errors divided by the number of training sets times outputs.

Momentum=val Specifies a coefficient for the back-propagation algorithm. This coefficient adds to the change in a particular weight a contribution proportional to the error in a previous iteration. Default momentum is 0.075.

NHidden=num Specifies the number of hidden neurodes. You do not need to use the Structure keyword with NHidden because the network is completely specified by the training waves and NHidden.

NReport=num Specifies over how many iterations (default is 1000) to print the global RMS error to the history area. Ignored with /Q.

Output=outWave Specifies the expected outputs corresponding to the entries in the input wave. The number of rows in outWave (the number of training sets) and in the input wave must be equal. outWave must be single or double precision and all entries must be in the range [0,1].
NeuralNetworkTrain is the first half of the implementation of a three-layer neural network in which both inputs and outputs are taken as normalized quantities in the range [0,1]. Network training is based on back-propagation to iteratively minimize the error between the output and the expected output for any given training set. Training creates in two 2D waves that contain the interconnection weights between the neurodes. $M_{Weights1}$ contains the weights between the input layer and the hidden layer and $M_{Weights2}$ contains the weights between the hidden layer and the output layer. During the iteration stage, global error information can be printed in the history area.

The algorithm computes the output of the $k$th neurode by

$$V_k = \left[ 1 + \exp \left( - \sum_{i=1}^{n} w_i s_i \right) \right]^{-1},$$

where $w_i$ is the weight corresponding to input $i$, $s_i$ is the signal corresponding to that input, and $n$ is the number of inputs connected to the neurode.

The total error is defined as the sum (over all training sets and all outputs) of the squared differences between the network outputs and the expected values. The sum is normalized by the product of the number of training sets and the number of outputs. The history reports (see NReport parameter) the square root of the total error (RMS error). The square root of the error computed at the end of the last iteration is stored in the variable $V_{rms}$.

See Also
The NeuralNetworkRun operation.

NewCamera

NewCamera [flags] [keywords]
The NewCamera operation creates a new camera window.

Documentation for the NewCamera operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "NewCamera"
NewDataFolder

NewDataFolder  [/O/S]  dataFolderSpec
The NewDataFolder operation creates a new data folder of the given name.

Parameters

dataFolderSpec can be just a data folder name, a partial path (relative to the current data folder) with name or a full path (starting from root) with name. If just a data folder name is used then the new data folder is created in the current data folder. If a full or partial path is used, all data folders except for the last in the path must already exist.

Flags

/O No error if a data folder of the same name already exists.
/S Sets the current data folder to dataFolderSpec after creating the data folder.

Examples

NewDataFolder foo    // Creates foo in the current data folder
NewDataFolder :bar:foo // Creates foo in bar in current data folder
NewDataFolder root:foo  // Creates foo in the root data folder

See Also
Chapter II-8, Data Folders.

NewFIFO

NewFIFO  FIFOName
The NewFIFO operation creates a new FIFO.

Details
Useless until channel info is added with NewFIFOChan.

An error is generated if a FIFO of same name already exists. FIFOName needs to be unique only among FIFOs. You can not overwrite a FIFO.

See Also
FIFOs are used for data acquisition. See FIFOs and Charts on page IV-301 and the NewFIFOChan operation for more information.

NewFIFOChan

NewFIFOChan  [flags]  FIFOName,  channelName,  offset,  gain, minusFS,  plusFS,  unitsStr  [,  vectPnts]
The NewFIFOChan operation creates a new channel for the named FIFO.

Parameters

channelName must be unique for the specified FIFO.

The offset, gain, plusFS, minusFS and unitsStr parameters are used when the channel's data is displayed in a chart or transferred to a wave. If given, vectPnts must be between 1 and 65535.

Flags

The flags define the type of data to be stored in the FIFO channel:

/B 8-bit signed integer. Unsigned if /U is present.
/C Complex.
/D Double precision IEEE floating point.
/I 32-bit signed integer. Unsigned if /U is present.
/S Single precision IEEE floating point (default).
/U Unsigned integer data.
Wave Data Types
As a replacement for the above number type flags you can use /Y=numType to set the number type as an integer code. See the WaveType function for code values. Do not use /Y in combination with other type flags.

Details
You can not invoke NewFIFOChec while the named FIFO is running.

If you provide a value for vectPnts, you will create a channel capable of holding a vector of data rather than just a single data value. When such a channel is used in a Chart, it is displayed as an image using one of the built-in color tables.

Igor scales values in the FIFO channel before displaying them in a chart or transferring them to a wave as follows:
\[
\text{scaled_value} = (\text{FIFO_value} - \text{offset}) \times \text{gain}
\]

Igor uses the plusFS and minusFS parameters (plus and minus full scale) to set the default display scaling for charts.

The unitsStr parameter is limited to a maximum of three bytes.

When you transfer a channel's data to a wave, using the FIFO2Wave operation, Igor stores the plusFS and minusFS values and the unitsStr in the wave’s Y scaling.

See Also
FIFOs are used for data acquisition. See FIFOs and Charts on page IV-301 and the NewFIFO and FIFO2Wave operations for more information.
The Chart operation for displaying FIFO data.

NewFreeAxis

NewFreeAxis[flags] axisName
The NewFreeAxis operation creates a new free axis that has no controlling wave.

Parameters
axisName is the name for the new free axis.

Flags
/L/R/B/T Specifies whether to attach the free axis to the Left, Right, Bottom, or Top plot edge, respectively. The Left edge is used by default.
/O Replaces axisName if it already exists, which means any existing axis is marked as truly free.
/W=winName Draws in the named graph window. winName may also be the name of a subwindow. winName must not conflict with other axis names except when using the /O flag. If /W is omitted, it creates a new axis in the active graph window or subwindow.

Details
A truly free axis does not use any scaling or units information from any associated waves (which need not exist.) You can set the properties of a free axis using SetAxis or ModifyFreeAxis.

Example
Copy this function to your Procedure window and compile:

Function axhook(s)
    STRUCT WMAxisHookStruct &s
    Variable t = s.max
    s.max = s.min
    s.min = t
    return 0
End

/W 16-bit signed integer. Unsigned if /U is present.
/Y=type Specifies wave data type. See details below.
NewFreeDataFolder

Now execute this code on the Command line:

Make jack=x
Display jack
NewFreeAxis fred
ModifyFreeAxis fred, master=left, hook=axhook

See Also
The SetAxis, KillFreeAxis, and ModifyFreeAxis operations.

NewFreeDataFolder

NewFreeDataFolder()

The NewFreeDataFolder function creates a free data folder and then returns its data folder reference.
Recommended for advanced programmers only.

Details
Free data folders are those that are not a part of the normal data folder hierarchy and can not be located by name.

See Also
Chapter II-8, Data Folders, Free Data Folders on page IV-93 and Data Folder References on page IV-77.

NewFreeWave

NewFreeWave(type, numPoints)

The NewFreeWave function creates a free 1D wave of the given type and number of points and then returns its wave reference.
Recommended for advanced programmers only.

Details
NewFreeWave creates a free wave named '_free_'.
You can also create free waves using Make/FREE and Duplicate/FREE. These are preferable for creating multidimensional free waves and also fine for general use.
The type parameter can be either a code as documented for WaveType or can be 0x100 to create a data folder reference wave or 0x200 to create a wave reference wave.
You can redimension free waves as desired but, for maximum efficiency, you should create the wave with the desired type and total number of points and then use the /E=1 flag with Redimension to simply reshape without moving data.
A free wave is automatically discarded when the last reference to it disappears.

See Also
Free Waves on page IV-89, Make, Duplicate.

NewGizmo

NewGizmo [flags]

The NewGizmo operation creates a new Gizmo display window.
Documentation for the NewGizmo operation is available in the Igor online help files only. In Igor, execute:
DisplayHelpTopic "NewGizmo"

NewImage

NewImage [flags] matrix

The NewImage operation creates a new image graph much like “Display;AppendImage matrix” except the graph is prepared using a style more appropriate for images. Rather than using preferences, NewImage provides several discrete styles to choose from.

Parameters
matrix is usually an MxN matrix containing image data. See AppendImage for details.
Flags

/F  By default, the image is flipped vertically to correspond to normal image orientation. If /F is present then the image is not flipped.

/G=g  Controls treatment of three-plane images as direct (RGB) color.
   g=1: Suppresses the autodetection of three-plane images as direct (RGB) color.
   g=1: Same as no /G flag (default).

/HIDE=h  Hides (h = 1) or shows (h = 0, default) the window.

/HOST=hcSpec  Embeds the new image plot in the host window or subwindow specified byhcSpec.
   When identifying a subwindow withhcSpec, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/K=k  Specifies window behavior when the user attempts to close it.
   k=0: Normal with dialog (default).
   k=1: Kills with no dialog.
   k=2: Disables killing.
   k=3: Hides the window.
   If you use /K=2 or /K=3, you can still kill the window using the KillWindow operation.

/N=name  Requests that the created graph have this name, if it is not in use. If it is in use, thenname0, name1, etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen graph name. Use DoWindow/K name to ensure thatname is available.

/S=s  Specifies one of several window styles.
   s=0: Fills entire window with image. No axes. However, this can result in the lower-right corner not being visible due to the target icon or grow icon (Macintosh).
   s=1: Like s=0 but insets image to avoid corner icon.
   s=2: Provides minimalist axes (default).

Details

The graph is sized to make the image pixels a multiple of the screen pixels with the graph size constrained to be not too small and not too large.

If matrix appears to fit Igor’s standard monochrome category, then explicit mode is set (See ModifyImage explicit). To be considered monochrome the wave must be unsigned byte and contain only values of 0, 64 or 255.

Once the graph is created it is a normal graph and has no special properties other than the settings it was created with. Specifically, it will not autosize itself if the dimensions of matrix are changed. NewImage is just a shortcut for creating a graph window with a style appropriate for images.

This operation is limited in scope by design. If you need to specify the position, size or title, then use the operations Display and AppendImage.

If the styles provided are not what you desire, touch up an image graph to meet your needs and then use Capture Graph Prefs from the Graphs menu. Then use "Display;AppendImage" rather than NewImage.

See Also

The Display, DoWindow, AppendImage, and ModifyImage operations.

NewLayout

NewLayout [flags] [as titleStr]

The NewLayout operation creates a page layout.
Unlike the Layout operation, NewLayout can be used in user-defined functions. Therefore, NewLayout should be used in new programming instead of Layout.

NewLayout just creates the layout window. Use AppendLayoutObject to add objects to the window.

**Parameters**
The optional *titleStr* parameter is a string expression containing the layout’s title. If not specified, Igor will provide one which identifies the objects displayed in the graph.

**Flags**

/B=(r,g,b) Specifies the background color for the layout. *r*, *g*, and *b* are integers from 0 to 65535. Defaults to white (65535, 65535, 65535).

/C=colorOnScreen Obsolete. In ancient times, this flag switched the screen display of the layout between black and white and color. It is still accepted but has no effect.

/HIDE=h Hides (*h* = 1) or shows (*h* = 0, default) the window.

/K=k Specifies window behavior when the user attempts to close it.

- **k=0:** Normal with dialog (default).
- **k=1:** Kills with no dialog.
- **k=2:** Disables killing.
- **k=3:** Hides the window.

If you use /K=2 or /K=3, you can still kill the window using the **KillWindow** operation.

/N=name Requests that the layout have this name, if it is not in use. If it is in use, then name0, name1, etc. are tried until an unused window name is found. In a function or macro, S_name is set to the chosen layout name. Use DoWindow/K name to ensure that *name* is available.

- If /N is not used, a name of the form “Layout* n*”, where *n* is some integer, is assigned.
- In a function or macro, the assigned name is stored in the S_name string. This is the name you can use to refer to the page layout window from a procedure. Use the **RenameWindow** operation to rename the window.

/P=orientation Sets the orientation of the page in the layout to either Portrait or Landscape (e.g., Layout/P=Landscape). See Details.

/W=(left,top,right,bottom) Gives the layout window a specific location and size on the screen. Coordinates for /W are in points.

**Details**
When you create a new page layout window, if preferences are enabled, the page size is determined by the preferred page size as set via the Capture Layout Prefs dialog. If preferences are disabled, as is usually the case when executing a procedure, the page is set to the factory default size.

**See Also**
AppendLayoutObject, DoWindow, RemoveLayoutObjects, and ModifyLayout.

**NewMovie**

**NewMovie** [flags] [as fileNameStr]
The NewMovie operation opens a movie file in preparation for adding frames.

By default, NewMovie creates MP4 movies on both Macintosh and Windows. Prior to Igor Pro 8, it created QuickTime movies on Macintosh and AVI movies on Windows. That older technology is still available using the /A flag, but it is deprecated and may not be available in future operating systems.
Parameters
The file to be opened is specified by `fileNameStr` and `/P=pathName` where `pathName` is the name of an Igor symbolic path. `fileNameStr` can be a full path to the file, in which case `/P` is not needed, a partial path relative to the folder associated with `pathName`, or the name of a file in the folder associated with `pathName`. If NewMovie cannot determine the location of the file from `fileNameStr` and `pathName`, it displays a dialog allowing you to specify the file.

If you use a full or partial path for `fileNameStr`, see Path Separators on page III-429 for details on forming the path.

Flags

/A If you use /A, NewMovie creates movie files using deprecated technology: AVI on Windows and QuickTime on Macintosh. If you omit /A, it creates MP4 movies.

/CF=factor Specifies a compression factor relative to the theoretical uncompressed value. The default compression factor of 200 is used if you omit /CF. /CF was added in Igor Pro 8.00. It is ignored if you use the /A flag.

/CTYPE=typeStr Specifies the compression codec to use.

When using default technology (/A is omitted), /CTYP is ignored on Macintosh. On Windows, it can be "WMV3" to create .wmv files or "mp4v" to create MP4 files (default).

When using alternate technology (/A is present), /CTYP is ignored on Windows. On Macintosh, commonly available compressors in order of increasing file size when used with the FM Modulation Movie example experiment include "smc", "avc1", "png", "rpza", "h263", "icod", "jpeg", "mp4v" and "rle".

/CTYP was added in Igor Pro 7.00.

/F=frameRate Frames per second between 1 and 60. `frameRate` defaults to 30.

/I Obsolete.

/L[=flatten] Obsolete.

/O Overwrite existing file, if any.

/P=pathName Specifies the folder to look in for the file. `pathName` is the name of an existing symbolic path.

/PICT=pictName Uses the specified picture (see Pictures on page III-481) rather than the top graph.

/S=soundWave Adding a sound track is not currently supported. If you would like this feature, let us know.

/Z No error reporting; an error is indicated by nonzero value of the output variable `V_flag`. If the user clicks the cancel button in the Save File dialog, `V_flag` is set to -1.

Details
If either the path or the file name is omitted then NewMovie displays a Save File dialog to let you create a movie file. If both are present, NewMovie creates the file automatically.

If you use `/P=pathName`, note that it is the name of an Igor symbolic path, created via `NewPath`. It is not a file system path like "hd:\Folder1:" or "C:\\Folder1\\". See Symbolic Paths on page II-21 for details. There can be only one open movie at a time.

The target window at the time you invoke NewMovie must be a graph, page layout or Gizmo plot unless the /PICT flag is present. The window size should remain constant while adding frames to the movie. The window and optional sound wave are used to determine the size and sound properties only; they do not specify the first frame.

In Igor7 or later, the target window at the time you call NewMovie is remembered and is used by AddMovieFrame even if it is not the target window when you call AddMovieFrame.
NewNotebook

The /PICT flag allows you to create a movie from a page layout in conjunction with the SavePICT/P= method. See SavePICT on page V-750. This allows creation of a movie from a source other than a graph, page layout or Gizmo window, but is rarely needed.

See Also
Movies on page IV-238.

The AddMovieFrame, AddMovieAudio, CloseMovie, PlayMovie, PlayMovieAction and SavePICT operations.

NewNotebook

NewNotebook [flags] [as titleStr]
The NewNotebook operation creates a new notebook document.

Parameters
The optional titleStr is a string containing the title of the notebook window.

Flags
/HOST=hcSpec Embeds the new notebook in the host window or subwindow specified by hcSpec. The host window or subwindow must be a control panel. Graphs and page layouts are not supported as hosts for notebook subwindows.

When identifying a subwindow with hcSpec, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

See Notebooks as Subwindows in Control Panels on page III-91 for more information.

/ENCG=textEncoding
textEncoding specifies the text encoding for the new notebook. This determines the text encoding used for later saving the notebook to a file.

See Text Encoding Names and Codes on page III-463 for a list of accepted values for textEncoding.

This flag was added in Igor Pro 7.00.

This flag is relevant for plain text notebooks only and has no effect for formatted notebooks because formatted text notebooks can contain multiple text encodings. See Plain Text File Text Encodings on page III-445 and Formatted Text Notebook File Text Encodings on page III-450 for details.

If you omit /ENCG or pass 0 (unknown) for textEncoding, the notebook's text encoding is determined by the default text encoding - see The Default Text Encoding on page III-444 for details.

For most purposes, UTF-8 (textEncoding=1) is recommended. Other values are available for compatibility with software that requires a specific text encoding. This includes Igor Pro 6 which uses MacRoman (textEncoding=2), Windows-1252 (textEncoding=3) or Shift-JIS (textEncoding=4) depending on the operating system and localization.

This flag has an optional form that allows you to control whether the byte order mark is written when the notebook is later saved to disk. It applies to Unicode text encodings also. The form is:
/ENCG = {textEncoding, writeBOM }

If you use the simpler form or omit /ENCG entirely, the notebook's writeBOM property defaults to 1.

See Byte Order Marks on page III-449 for background information.
Details

A notebook has a file name, a window name, and a window title. In the simplest case these will all be the same.

The file name is the name by which the operating system identifies the notebook once it is saved to disk. When you initially create a notebook, it is not associated with any file. However it still has a file name. This is the name that will be used when the file is saved to disk.

The window name is the name by which Igor identifies the window and therefore the name you specify in operations that act on the notebook.

The window title is what appears in the window’s title bar. If you omit the title, NewNotebook uses a default title that is the same as the window name.

If you specify the window name and the notebook format and omit the window title, this is the simplest case. NewNotebook creates the document with no user interaction. The file name, window name and window title will all be the same. For example:

NewNotebook/N=Notebook1/F=0
If you omit the window name, NewNotebook chooses a default name (e.g., “Notebook0”) and presents the standard New Notebook dialog.

If you omit the format or specify a format of -1 (either plain or formatted text), NewNotebook presents the standard New Notebook dialog. For example:

```
NewNotebook/N=Notebook1 // no format specified
```

See Also

The Notebook and OpenNotebook operations, and Chapter III-1, Notebooks. 

Notebooks as Subwindows in Control Panels on page III-91.

---

**NewPanel**

```
NewPanel [flags] [as titleStr]
```

The NewPanel operation creates a control panel window or subwindow, which may contain Igor controls and drawing objects.

**Flags**

- **/EXT=e**
  - Creates an exterior subwindow in combination with /HOST. e specifies the host window side location:
    - e=0: Right.
    - e=1: Left.
    - e=2: Bottom.
    - e=3: Top.

- **/FG=(gLeft, gTop, gRight, gBottom)**
  - Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window.
  - The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name.
  - Guides may override the numeric positioning set by /W.

- **/FLT[]=f**
  - /FLT or /FLT=1 makes the panel a floating panel.
  - /FLT=2 makes it a floating panel with no close box.
  - /FLT=0 is the same as omitting /FLT and creates a regular (non-floating) control panel.
  - You must execute the following after the NewPanel command:
    - `SetActiveSubwindow _endfloat_`
  - See Floating Panels below for further information.

- **/HIDE=h**
  - Hides (h = 1) or shows (h = 0, default) the window.

- **/HOST=hcSpec**
  - Embeds the new control panel in the host window or subwindow specified by hcSpec.
  - When identifying a subwindow with hcSpec, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

- **/I**
  - Sets coordinates to inches.
NewPanel

/K=k Specifies window behavior when the user attempts to close it.
  k=0: Normal with dialog (default).
  k=1: Kills with no dialog.
  k=2: Disables killing.
  k=3: Hides the window.

If you use /K=2 or /K=3, you can still kill the window using the KillWindow operation.
Exterior subwindows never display a dialog when killed.

/M Sets coordinates to centimeters.

/N=name Requests that the created panel have this name, if it is not in use. If it is in use, then
name0, name1, etc. are tried until an unused window name is found. In a function or
macro, S_name is set to the chosen panel name. Use DoWindow/K name to ensure
that name is available.

Note that a function or macro with the same name will cause a name conflict.

/NA= n Sets panel no-activate mode.
  n=0: Normal (default).
  n=1: Button click doesn’t activate window but click outside of any control does.
  n=2: No activation even if click is outside controls. Title bar clicks still activate.

/W=(left,top,right,bottom) Sets the initial coordinates of the panel window. The coordinates are in points unless
/I or /M are used before /W.

When used with the /HOST flag, the specified location coordinates of the sides can
have one of two possible meanings:
When all values are less than 1, coordinates are assumed to be fractional relative to
the host frame size. This applies to interior panels only, not to exterior panels.
When any value is greater than 1, coordinates are taken to be fixed locations measured
in points relative to the top left corner of the host frame.
When the subwindow position is fully specified using guides (using the /HOST or /FG
flags), the /W flag may still be used although it is not needed.

Details
If /N is not used, NewPanel automatically assigns to the panel a window name of the form “Paneln”, where
n is some integer. In a function or macro, the assigned name is stored in the S_name string. This is the name
you can use to refer to the panel from a procedure. Use the RenameWindow operation to rename the panel.

On Windows there are special considerations relating to screen resolution and control panels. See Control
Panel Resolution on Windows on page III-433 for details.

Floating Panels
Floating control panels float above all other windows except dialogs. Because floating panels cover up other
windows, you should use them sparingly and you should take care to make them small and unobtrusive.

Floating panels are not resizable by default. To allow panel resizing use
ModifyPanel fixedSize=0

Because floating panels always act as if they are on top, the standard rules for target windows and keyboard
focus do not apply.

Normally, a floating panel is never the target window and control procedures will need to explicitly designate
the target. But a newly-created floating panel is the default target and will remain so until you execute
SetActiveSubwindow _endfloat_
It also becomes the default target when the tools are showing and in any non-Operate mode. Similarly, a floating panel with tools not in Operate mode has keyboard focus. To avoid confusion, do not attempt to work on other windows when a floating panel is the default target.

When working with a floating panel, you can show or hide tools or create a recreation macro by Control-clicking (Macintosh) or right-clicking (Windows) in the panel.

A floating panel does not have keyboard focus. However, a floating panel gains keyboard focus when a control that needs focus is clicked. Focus remains until you press Enter or Escape for a text entry in a setvariable, press Tab until no control has the focus, or until you click outside a focussable control.

On Macintosh, if a floating panel has focus and you activate another window, focus will leave the panel. However on Windows, if a floating panel has focus and you activate another window, the activate sequence will be fouled up leaving the windows in an indeterminate state. Consequently, it is important that you always finish any keyboard interaction started in a floating panel before moving on to other windows. If this can cause confusion, you should not use controls such as SetVariable and ListBox in a floating panel.

On Macintosh, floating panels are hidden when dialogs are up or when Igor Pro is not the front application.

**Exterior Subwindows**

Exterior subwindows are automatically positioned along the designated side of a host window. The host window can be a graph, table, panel or Gizmo plot. You can designate fixed sizes or automatic size with minima. Subwindows are stacked beside the designated side in their creation order with the first one closest.

Subwindow dimensions have various meanings depending on their location. Interior values are taken to be additional grout, exterior values are taken to be sizes. For left or right panels, top is taken to be the minimum height and bottom, if not zero, is height. For top and bottom, left is taken to be the minimum width and right, if not zero, is width. Zero values default to 50 for width and height or size of host.

Exterior subwindows are nonresizable by default. Use `ModifyPanel fixedSize=0` to allow manual resizing. If you resize a panel, the original window dimensions are lost. You can also use `MoveSubwindow` to resize the subwindow.

Unlike normal subwindows, exterior subwindows have a tools palette. Click in the window and then choose the Show Tools or Hide Tools menu item.

Exterior subwindows have hook functions independent of the host window.

**Examples**

In a new experiment, execute these commands on the command line to create two exterior subwindows:

```plaintext
Display
// Create panel on right with min height of 200 points, width of 100.
NewPanel/HOST=Graph0/EXT=0/W=(0,200,100,0)
// Create another panel on right with grout of 10 and height= width= 100.
NewPanel/HOST=Graph0/EXT=0/W=(10,0,100,100)
```

Now try resizing and moving the graph.

For a demonstration of how the various exterior panels work, copy the following code to the procedure window in a new experiment:

```plaintext
Function bpNewExSw(ba) : ButtonControl
    STRUCT WMBUTTONACTION &ba
        switch(ba.eventCode) 
            case 2: // mouse up
                ControlInfo/W=$ba.win ckUseRect
                Variable useR= V_Value
                ControlInfo/W=$ba.win popSide
                Variable side= V_Value-1
                ControlInfo/W=$ba.win ckResizable
                Variable resizeable= V_Value
                WAVE w=root:epsizes
                if( useR )
                    NewPanel/HOST=$ba.win/EXT=(side)/W=(w[0],w[1],w[2],w[3])
                else
                    NewPanel/HOST=$ba.win/EXT=(side)
                endif
                if( resizeable )
                    ModifyPanel fixedSize=0 // default is 1 for floating and exterior sw
```
NewPath

The NewPath operation creates a new symbolic path name that can be used as a shortcut to refer to a folder on disk.

Parameters

$pathToFolderStr$ is a string containing the path to the folder for which you want to make a symbolic path. $pathToFolderStr$ can also point to an alias (Macintosh) or shortcut (Windows) for a folder.

If you use a full path for $pathToFolderStr$, see Path Separators on page III-429 for details on forming the path. If you use a partial path or just a simple name for $pathToFolderStr$, and you use the /C flag, a new folder is created relative to the Igor Pro folder. No dialog is presented.

If you omit $pathToFolderStr$, you get a chance to select a folder or create a new folder from a dialog.

_flags_ $[flags]$ $pathName$ [ , $pathToFolderStr$]

Flags

/\C\ Create the folder specified by $pathToFolderStr$ if it does not already exist.
/\M=messageStr\ Specifies the prompt message in the dialog.
/O\ Overwrites the symbolic path if it exists.
/Q\ Suppresses printing path information in the history.
/Z\ Doesn’t generate an error if the folder does not exist.

Details

Symbolic paths help to isolate your experiments from specific file system paths that contain files created or used by Igor. By using a symbolic path, if the actual location or name of the folder changes, you won’t need to change all of your commands. Instead, you need only to change the symbolic path so that it points to the changed folder location.
NewPath sets the variable V_flag to zero if the operation succeeded or to nonzero if it failed. The main use for this is to determine if the user clicked Cancel when you use NewPath to display a choose-folder dialog.

On the Macintosh, pressing Command-Option as the Choose Folder dialog comes up will allow you to choose package folders and folders inside packages.

Examples

NewPath Path1, "hd:IgorStuff:Test 1"  // Macintosh
NewPath Path1, "C:IgorStuff:Test 1"   // Windows
creates the symbolic path named Path1 which refers to the specified folder (the path’s “value”). You can then refer to this folder in many Igor operations and dialogs by using the symbolic path name Path1.

Windows Note:

You can use either the colon or the backslash character to separate folders. However, the backslash character is Igor’s escape character in strings. This means that you have to double each backslash to get one backslash like so:

NewPath stuff, "C:\IgorStuff\Test 1"

Because of this complication, it is recommended that you use Macintosh path syntax even on Windows. See Path Separators on page III-429 for details.

See Also
The PathInfo operation; especially if you need to preset a starting path for the dialog.

KillPath

NewWaterfall operation; especially if you need to preset a starting path for the dialog.

NewWaterfall [flags] matrixWave [vs {xWave,yWave}]

The NewWaterfall operation creates a new waterfall plot window or subwindow using each column in the 2D matrix wave as a waterfall trace.

You can manually set x and z scaling by specifying xWave and yWave to override the default scalings. Either xWave or yWave may be omitted by using a “*”.

Flags

/FG=(gLeft, gTop, gRight, gBottom)  
  Specifies the frame guide to which the outer frame of the subwindow is attached inside the host window.

  The standard frame guide names are FL, FR, FT, and FB, for the left, right, top, and bottom frame guides, respectively, or user-defined guide names as defined by the host. Use * to specify a default guide name.

  Guides may override the numeric positioning set by /W.

/HIDE=h  
  Hides (h = 1) or shows (h = 0, default) the window.

/HOST=hcSpec  
  Embeds the new waterfall plot in the host window or subwindow specified by hcSpec. When identifying a subwindow with hcSpec, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/I  
  Sets window coordinates to inches.
The X and Z axes are always at the bottom and left, whereas the Y axis runs at a default 45 degrees along the right-hand side. The angle and length of the Y axis can be changed using the ModifyWaterfall operation.

Each column from matrixWave is plotted in, and clipped by, a rectangle defined by the X and Z axes with the rectangle displaced along the angled Y axis as a function of the Y value.

Except when hidden lines are active, the traces are drawn from back to front.

To modify certain properties of a waterfall plot, you need to use the ModifyWaterfall operation. For other properties, use the usual axis and trace dialogs.

See Also
Waterfall Plots on page II-261.

The ModifyWaterfall and ModifyGraph operations.

### norm

**norm** *(srcWave)*
The norm function evaluate the norm of srcWave. It returns:
This function does not support text waves.

See Also
MatrixOp

NormalizeUnicode

NormalizeUnicode(sourceTextStr, normalizationForm[, options])

The NormalizeUnicode function normalizes the UTF-8-encoded text in sourceTextStr using the specified normalization form. The output text encoding is UTF-8.

NormalizeUnicode was added in Igor Pro 7.00. Most users will have no need for this function and can ignore it.

As explained under Details, in Unicode there are sometimes multiple ways to spell what appears visually to be the same word. This can cause problems when comparing text. Two strings that appear to represent the same word and which you consider equivalent may be spelled differently, causing a comparison operation to indicate that they are unequal. The NormalizeUnicode function converts sourceTextStr to a normalized form, which aides comparison.

Parameters

sourceTextStr is the text that you want to normalize. It must be encoded as UTF-8.

normalizationForm specifies the normalization form to use. These forms are described at http://unicode.org/reports/tr15/#Norm_Forms. The allowed values are:

0: NFD (Canonical Decomposition)
1: NFC (Canonical Decomposition, followed by Canonical Composition)
2: NFKD (Compatibility Decomposition)
3: NFKC (Compatibility Decomposition, followed by Canonical Composition)

options is a bitwise parameter, with the bits defined as follows:

Bit 0: If cleared, in the event of an error, a null string is returned and an error is generated. Use this if you want to abort procedure execution if an error occurs.

If set, in the event of an error, a null string is returned but no error is generated. Use this if you want to detect and handle an error yourself. You can test for null using strlen as shown in String Variable Text Encoding Error Example on page III-457.

All other bits are reserved and must be cleared.

Details

The Unicode standard specifies that some sequences of code points represent essentially the same character. There are two types of equivalence: canonical equivalence and compatibility.

Sequences of code points defined as canonically equivalent are assumed to have the same appearance and meaning when printed or displayed. For example, the code point U+006E (LATIN SMALL LETTER N) followed by U+0303 (COMBINING TILDE) is defined by Unicode to be canonically equivalent to the single code point U+00F1 (LATIN SMALL LETTER N WITH TILDE). The former is called "decomposed" while the later is called "precomposed".

Sequences that are defined as compatible are assumed to have possibly distinct appearances, but the same meaning in some contexts. Thus, for example, the code point U+FB00 (LATIN SMALL LIGATURE FF) is defined to be compatible, but not canonically equivalent, to the sequence U+0066 U+0066 (two Latin "f" letters). Sequences that are canonically equivalent are also compatible, but the opposite is not necessarily true.
Text searching and sorting routines in Igor do not do any form of Unicode normalization. As a consequence, searching for the precomposed form of small letter n with tilde (U+00F1) in a string that contains the decomposed form (U+006E U+0303) will not result in a match. To get the desired result, you would need to first pass both the target string and the string to be searched through NormalizeUnicode using the same value for the *normalizationForm* parameter.

Example

```plaintext
Function TestNormalizeUnicode()
    String precomposed = "Ni" + "\u00F1" + "o"
    String decomposed = "Ni" + "\u006E\u0303" + "o"
    String decomposedTarget = "\u006E\u0303"
    Variable foundPos

    // SUCCESSFUL TESTS
    // Searching the precomposed string for the precomposed target is successful.
    foundPos = strsearch(precomposed, precomposedTarget, 0)
    Print foundPos // Prints 2

    // Likewise, searching the decomposed string for the decomposed target is successful.
    foundPos = strsearch(decomposed, decomposedTarget, 0)
    Print foundPos // Prints 2

    // UNSUCCESSFUL TESTS
    // Searching the precomposed string for the decomposed target fails.
    foundPos = strsearch(precomposed, decomposedTarget, 0)
    Print foundPos // Prints -1

    // Likewise, searching the decomposed string for the precomposed target fails.
    foundPos = strsearch(decomposed, precomposedTarget, 0)
    Print foundPos // Prints -1

    // USING NormalizeUnicode() FUNCTION
    Variable normForm = 2 // Could use 0-3 and the results would be the same.

    String precomposedNorm = NormalizeUnicode(precomposed, normForm)
    String decomposedNorm = NormalizeUnicode(decomposed, normForm)
    String precomposedTargetNorm = NormalizeUnicode(precomposedTarget, normForm)
    String decomposedTargetNorm = NormalizeUnicode(decomposedTarget, normForm)

    // Now, searching either precomposedNorm or decomposedNorm for either
    // precomposedTargetNorm or decomposedTargetNorm will give a match.
    Print strsearch(decomposedNorm, precomposedTargetNorm, 0) // Prints 2
    Print strsearch(precomposedNorm, decomposedTargetNorm, 0) // Prints 2
    Print strsearch(precomposedNorm, decomposedTargetNorm, 0) // Prints 2
    Print strsearch(decomposedNorm, decomposedTargetNorm, 0) // Prints 2
End
```

Text Encodings on page III-437, String Variable Text Encoding Error Example on page III-457

http://unicode.org/reports/tr15/#Norm_Forms

NOTE

The note function returns a string containing the note associated with the specified wave.

See Also

To create a wave note, use the Note operation.

Note

```
Note [ /K/NOCR ] waveName [, str]
```

The Note operation appends *str* to the wave note for the named wave.

Parameters

*str* is a string expression.
Notebook

Flags
/K       Kills existing note for specified wave.
/NOCR    Appends note without a preceding carriage return (\r character). No effect when used with /K.

Examples
Note/K wave0       // remove existing note
Note wave0, "This is the first line of the note"
Note wave0, "This is the second line of the note"
Note/K wave0, "This is now the only line of the note"

See Also
To get the contents of a wave note, use the note function.

Notebook

Notebook winName, keyword=value [, keyword=value]...
The Notebook operation sets various properties of the named notebook window. Notebook also inserts text and graphics. See Chapter III-1, Notebooks, for general information on notebooks.

Notebook returns an error if the notebook is open for read-only. Keywords that don't materially change the notebook, including findText, findPicture, selection, visible, magnification, userKillMode, showRuler and rulerUnits, are still permitted. See Notebook Read/Write Properties on page III-10 for further information.

Parameters
winName is either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0#nb0. See Subwindow Syntax on page III-92 for details on host-child specifications.

If winName is an hcSpec, the host window or subwindow must be a control panel. Graphs and page layouts are not supported as hosts for notebook subwindows.

The parameters to the Notebook operation are of the form keyword=value where keyword says what to do and value is a parameter or list of parameters. Igor limits the parameters that you specify to legal values before applying them to the notebook.

The parameters are classified into related groups of keywords.

See Also
To create or modify a notebook action special character, see NotebookAction.
To create a notebook subwindow in a control panel, see Notebooks as Subwindows in Control Panels on page III-91.
Notebook document property parameters
This section of Notebook relates to setting the document properties of the notebook.

adopt=a
Adopts a notebook if it is a file saved to disk. Adopting a notebook makes it part of the packed experiment file, which becomes more self-contained; if you send the experiment to a colleague you will not need to send a notebook file.

a=0: Checks only whether the notebook is adoptable. Sets V_flag to 0 if the notebook is already adopted or to 1 if it is adoptable.

a=1: Checks only whether the notebook is adoptable. Sets V_flag to 0 if the notebook is already adopted or to 1 if it is adoptable.

backRGB=(r,g,b)
Sets background color. r, g, and b are integers from 0 to 65535.

changeableByCommandOnly=c
This changeableByCommandOnly property is used to prevent manual modifications to the notebook but allow modifications using commands.

ChangeableByCommandOnly off.

changeableByCommandOnly on.

See Notebook Read/Write Properties on page III-10 for details.

defaultTab=dtw
dtw is the default tab width in points.

magnification=m
Specifies the desired magnification in percent (between 25 and 500). Otherwise, m can be one of these special values:

m=1: Default magnification.

m=2: Default magnification.

In Igor Pro 6 this specified the no-longer-supported Fit Width mode.

m=3: Default magnification.

In Igor Pro 6 this specified the no-longer-supported Fit Page mode.

pageMargins={left, top, right, bottom}
Sets page margins in points. left, top, right, and bottom are distances from the respective edges of the physical page.

This setting overrides the margins set via the the page setup dialog and the PrintSettings operation margins keyword.

rulerUnits=r
Sets the units for the ruler:

r=0: Points.

r=1: Inches.

r=2: Centimeters.

showRuler=s
Hides (s=0) or shows (s=1) the ruler.

startPage=sp
Sets the starting page number for printing.

statusWidth=sw
As of Igor7, because of changes to the layout of notebook windows, this keyword does nothing.

In Igor6 it set the width in points of the status area on the left of the horizontal scroll bar.
Notebook (Headers and Footers)

userKillMode=$k$

Specifies window behavior when the user attempts to close it.

$k=0$: Normal with dialog (default).

$k=1$: Clicking the close button kills the notebook with no dialog.

$k=2$: Clicking the close button does nothing.

$k=3$: Clicking the close button hides the notebook with no dialog.

writeBOM=$w$

Sets the document’s writeBOM property which determines if Igor writes a byte order mark when saving the notebook. This applies to plain text notebooks only and is ignored for formatted text notebooks.

$w=-1$: Does not change writeBOM flag.

$w=0$: Sets writeBOM to false.

$w=1$: Sets writeBOM to true.

See Byte Order Marks on page III-449 for details.

This keyword was added in Igor Pro 7.00.

writeProtect=$wp$

The write-protect property is used to prevent inadvertent manual changes to the notebook.

$wp=0$: Turn write-protect off.

$wp=1$: Turn write-protect on.

See Notebook Read/Write Properties on page III-10 for details.

Notebook (Headers and Footers)

Notebook headers and footers

You can turn headers and footers on and off and position headers and footers using the keywords in this section.

There is currently no way to set the content of headers and footers except manually through the Document Settings dialog. You may be able to use stationery files to create files with specific headers and footers.

footerControl={[defaultFooter, firstFooter, evenOddFooter]}

$defaultFooter$ is 1 to turn the default footer on, 0 to turn it off.

$firstFooter$ is 1 to turn the first page footer on, 0 to turn it off.

$evenOddFooter$ is 1 to turn different footers for even and odd pages on, 0 to use the same footer for even and odd pages.

footerPos=pos

$pos$ is the position of the footer relative to the bottom of the page in points.

headerControl={[defaultHeader, firstHeader, evenOddHeader]}

$defaultHeader$ is 1 to turn the default header on, 0 to turn it off.

$firstHeader$ is 1 to turn the first page header on, 0 to turn it off.

$evenOddHeader$ is 1 to turn different headers for even and odd pages on, 0 to use the same header for even and odd pages.

headerPos=pos

$pos$ is the position of the header relative to the top of the page in points.
Notebook (Miscellaneous)

Notebook miscellaneous parameters
This section of Notebook relates to setting miscellaneous properties of the notebook.

autoSave=\(v\)
Controls auto-save mode.

\(v=0\):
Notebook subwindow contents will not be saved in recreation macros.

\(v=1\):
Notebook subwindow contents will be saved in recreation macros (default).

This affects notebook subwindows in control panels only. Use autoSave=0 if you do not want the notebook’s contents to be saved and restored when the control panel is recreated. Otherwise the notebook subwindow’s contents will be restored when recreated.

frameInset= \(i\)
Specifies the number of pixels by which to inset the frame of a notebook subwindow. Does not affect a normal notebook window.

This keyword was added in Igor Pro 7.00.

frameStyle= \(f\)
Specifies the frame style for a notebook subwindow. Does not affect a normal notebook window.

\(f=0\): None.
\(f=1\): Single.
\(f=2\): Double.
\(f=3\): Triple.
\(f=4\): Shadow.
\(f=5\): Indented.
\(f=6\): Raised.
\(f=7\): Text well.

The last three styles are fake 3D and will look best if the background color behind the subwindow is a light shade of gray.

This keyword was added in Igor Pro 7.00.

status=\{messageStr, flags\}
Sets the message in the status area at the bottom left of the notebook window.

flags is interpreted bitwise. Message is erased when:

Bit 0: Selection changes.
Bit 1: Window is activated.
Bit 2: Window is deactivated.
Bit 3: Document is modified.

If all bits are zero, the message stays until a new message comes along. All other bits are reserved for future use and should be zero. See Setting Bit Parameters on page IV-13 for details about bit settings.

updating=\{flags, r\}
Sets parameters related to the updating of special characters.
Notebook (Paragraph Properties)

flags is interpreted bitwise:

- **Bit 0**: Suppress automatic periodic updating of date and time special characters. By default this bit is set so date and time special characters are updated only when the user explicitly requests it or during printing when they appear in headers and footers.

- **Bit 1**: Allow manual updating of special characters via the specialUpdate keyword or via the Special menu. By default this is cleared so manual updating is not allowed.

All other bits are reserved for future use and should be zero. See Setting Bit Parameters on page IV-13 for details about bit settings.

$r$ is the update rate in seconds for updating date and time special characters.

These settings have no effect on the updating of special characters in headers or footers. These characters are always automatically updated when the document is printed.

We recommend that you leave automatic updating off (set bit 0 of the flags parameter to 1) so that updating occurs only via the specialUpdate keyword or via the Special menu.

visible=v

Sets notebook visibility.

- $v=0$: Hides notebook.
- $v=1$: Shows notebook but does not make it top window.
- $v=2$: Shows notebook and makes it top window.

Notebook (Paragraph Properties)

Notebook paragraph property parameters

This section of Notebook relates to setting the paragraph properties of the current selection in the notebook.

The margins, spacing, justification, tabs and rulerDefaults keywords provide control over paragraph properties which are governed by rulers. These keywords, in conjunction with the ruler and newRuler keywords, allow you to set paragraph properties. They are allowed for formatted text notebooks only, not for plain text notebooks.

The ruler keywords are described in detail below. Before we get to the detail, you should understand the different things you can do with rulers.

There are four things you can do with a ruler:

- modify it (analogous to manually adjusting a ruler).
- redefine it (analogous to the Redefine Ruler dialog).
- create it (analogous to the Define New Ruler dialog).
- apply it (analogous to selecting a ruler name from Ruler pop-up menu).

Igor’s behavior in response to ruler keywords depends on the order in which the keywords appear.

To modify the ruler(s) for the selected paragraph(s), use the margins, spacing, justification, tabs and rulerDefaults keywords without using the newRuler or ruler keywords. For example:

Notebook Notebook0 tabs={36,144,288},justification=1

To redefine an existing ruler, invoke the ruler=rulerName keyword before any other keywords. For example:

Notebook Notebook0 ruler=Ruler1,tabs={36,144,288},justification=1

Unlike redefining the ruler manually, when you redefine an existing ruler using ruler=rulerName, it does not apply the ruler to the selected text. However, it does update any text governed by the redefined ruler.

To create a new ruler, invoke the newRuler=rulerName keyword before any other keywords. For example:

Notebook Notebook0 newRuler=Ruler1,tabs={36,144,288},justification=1
Unlike creating it manually, when you create a new ruler using newRuler=rulerName, it does not apply the new ruler to the selected text. If you do not set a particular ruler property when creating a new ruler, the property will be the same as for the Normal ruler. If the specified ruler already exists, newRuler=rulerName overwrites the existing ruler.

To apply an existing ruler to the selected text, invoke the ruler=rulerName keyword without any other keywords. For example:

Notebook Notebook0 ruler=ruler1

You and Igor will get confused if you mix ruler keywords with other types of keywords in the same command. It is alright, however, to put a selection keyword at the start of the command. Mixing will not cause a crash or any drastic problem but it will likely produce results that you don’t understand.

To keep things clear, follow these rules:

- If you use ruler=rulerName or newRuler=rulerName, put them before any other ruler keywords.
- Do not mix ruler keywords with other kinds, except that it is alright to use the selection keyword at the start of the command.

### justification=
j
- Sets text justification:
  - j=0: Left aligned.
  - j=1: Center aligned.
  - j=2: Right aligned.
  - j=3: Fully justified.

### margins={indent, left, right}
- **indent** sets the indentation of first line from left page margin.
- **left** sets the paragraph’s left margin in points measured from the left page margin.
- **right** sets the paragraph’s right margin in points measured from the left page margin.

### newRuler=rulerName
- Creates a new ruler with the specified name. If a ruler with this name already exists, it is overwritten.

### ruler=rulerName
- Applies the named ruler to the selected text or to redefine the named ruler, as explained above.

### rulerDefaults={"fontName", fSize, fStyle, (r, g, b)}
- **"fontName"** sets the ruler’s text font, e.g., "Helvetica".
- **fSize** sets the ruler’s text size.
- **fStyle** sets the ruler’s text style.
- **(r, g, b)** sets the ruler’s text color. r, g, and b are integers from 0 to 65535.

You can only use rulerDefaults if you are redefining an existing ruler, using ruler=rulerName, or you are creating a new ruler using newRuler=rulerName.

### spacing={spaceBefore, spaceAfter, lineSpace}
- **spaceBefore** sets the extra space before paragraph in points.
- **spaceAfter** sets the extra space after paragraph in points.
- **lineSpace** sets the extra space between lines of a paragraph in points.

### tabs={tabSpec}
- **tabSpec** is list of tab stops in points added to special values that change the tab stop type.

Tab stops have two parts: the tab stop position and the tab type. Each integer in the list of tabs encodes both of these parts as follows:

- The low 11 bits contains the tab stop position in points.
- The next two bits are reserved for future use and must be zero.
The high three bits are used to contain the tab type as follows:

- **left tab** 0
- **center tab** 1 add $1 \times 8192$ to tab stop position.
- **right tab** 2 add $2 \times 8192$ to tab stop position.
- **decimal tab** 3 add $3 \times 8192$ to tab stop position.
- **comma tab** 4 add $4 \times 8192$ to tab stop position.

**Tabs Example**

The following puts a left tab at 1 inch, a center tab at 3 inches and a decimal tab at 5 inches:

```
Notebook Notebook1 tabs={1*72, 3*72 + 8192, 5*72 + 3*8192}
```
Notebook (Selection)

Notebook selection parameters
This section of Notebook relates to selecting a range of the content of the notebook.

findPicture=[graphicNameStr, flags]

Searches for the picture containing the named graphic (Macintosh only) or the next picture if you pass "". Sets V_flag to 1 if the picture was found or to 0 if not found.

flags is a bitwise parameter interpreted as follows:
Bit 0: Show selection after the find.

All other bits are reserved for future use. Set bit 0 by setting flags = 1.

The search is always forward from the end of the current selection to the end of the document.

findSpecialCharacter=[specialCharacterNameStr, flags]

Searches for the special character with the specified name or the next special character if you pass "". Selects the special character if it is found.
Sets V_flag to 1 if the special character was found or to 0 if not. Sets S_name to the name of the found special character or to "" if it was not found.

flags is a bitwise parameter interpreted as follows:
Bit 0: Show selection after the find.

All other bits are reserved for future use. Set bit 0 by setting flags = 1.

If specialCharacterNameStr is empty (""), the search proceeds from the end of the current selection to the end of the document. Otherwise the search always covers the entire document.

findText=[textToFindStr, flags]

Searches for the specified text. Sets V_flag to 1 if the text was found or to 0 if not found.

textToFindStr is a string expression for the text you want to find. If the text contains a carriage return, Igor considers only the part of the text before the carriage return.

flags is a bitwise parameter interpreted as follows:
Bit 0: Show selection after the find.
Bit 1: Do case-sensitive search.
Bit 2: Search for whole words.
Bit 3: Wrap around.
Bit 4: Search backward.

All other bits are reserved and must be set to zero.

To set bit 0 and bit 3, use $2^0 + 2^3 = 9$ for flags. See Setting Bit Parameters on page IV-13 for details about bit settings.

If you are searching forward, the search starts from the end of the current selection. If you are searching backward, the search starts from the start of the current selection.

If you specify "" as the text to search for, it ""finds"" the current selection. This displays the current selection using findText={"", 1}.

selection=[selStart, selEnd]
**Notebook (Selection)**

`selStart` and `selEnd` are locations within the document. You can specify these document locations by using the following expressions:

- \((\text{paragraph}, \text{pos})\)  
  - `paragraph` and `pos` are numeric expressions.  
  - `paragraph` is a paragraph number from 0 to \(n-1\) where \(n\) is the number of paragraphs in the document.  
  - `pos` is a byte position from 0 to \(n\) where \(n\) is the number of bytes in the paragraph. Position 0 is to the left of the first character in the paragraph. Position \(n\) is to the right of the last character in the paragraph.

  - `startOfFile`  
    - Start of the document.

  - `endOfFile`  
    - End of the document.

  - `startOfParagraph`  
    - Start of current `selStart` paragraph.

  - `endOfParagraph`  
    - End of current `selStart` paragraph.

  - `startOfNextParagraph`  
    - Start of paragraph after current `selStart` paragraph.

  - `endOfNextParagraph`  
    - End of paragraph after current `selStart` paragraph.

  - `startOfPrevParagraph`  
    - Start of paragraph before current `selStart` paragraph.

  - `endOfPrevParagraph`  
    - End of paragraph before current `selStart` paragraph.

  - `endOfChars`  
    - Just before the carriage return of current `selStart` paragraph.

  - `startOfPrevChar`  
    - Start of the character before the character at the current selection start or selection end. This moves the selection start or selection end like pressing the left arrow key.  
    - Added in Igor Pro 7.00.

  - `startOfNextChar`  
    - Start of the character after the character at the current selection start or selection end. This moves the selection like pressing the right arrow key.  
    - Added in Igor Pro 7.00.

Igor clips the specified locations to legal values. It also sets the V_flag variable to 0 if the `selStart` location that you specified was valid, to 1 if the start paragraph was out of bounds and to 2 if the start position was out of bounds. You can use the `startOfNextParagraph` keyword to step through the document one paragraph at a time. When V_flag is nonzero, you are at the end of the document.

The terms next and prev are relative to the paragraph containing the start of the selected text before the selection keyword was invoked.

The selection keyword just sets the selection. If you also want to scroll the selected text into view you must also use the `findText` keyword as shown in the examples.

**Selection Examples**

Following are some examples of setting the selection:

```plaintext
// select all text in notebook
Notebook Notebook1 selection={startOfFile, endOfFile}

// move selection to the start of the notebook and display the selection
Notebook Notebook1 selection={startOfFile, startOfFile}, findText={"",1}

// move selection to the end of the notebook and display the selection
Notebook Notebook1 selection={endOfFile, endOfFile}, findText={"",1}

// select all of paragraph 3
Notebook Notebook1 selection={(3,0), (4,0)}

// select all of paragraph 3 and display the selection
Notebook Notebook1 selection={(3,0), (4,0)}, findText={"",1}

// select all of current paragraph except for trailing CR, if any
Notebook Notebook1 selection={startOfParagraph, endOfChars}
```
// select the first occurrence of "Hello" in the document and display the selection
Notebook Notebook1 selection={startOfFile,startOfFile}, findText="Hello",1

// select the first picture in the document
Notebook Notebook1 selection={startOfFile,startOfFile}, findPicture="",1

See Also
The GetSelection operation to “copy” the selection.
Notebook (Text Properties)

Notebook text property parameters
This section of Notebook relates to setting the text properties of the current selection in the notebook.

- **font**="fontName"  
  "fontName" is the name of the font. Use "default" to specify the paragraph’s ruler font.
  
  If you specify an unavailable font, it does nothing. This is so that, when you share procedures with a colleague, using a font that the colleague does not have will not cause your procedures to fail. The downside of this behavior is that if you misspell a font name you will get no error message.

- **fSize**=fontSize  
  Text size from 3 to 32000 points.
  
  Use -1 to specify the paragraph’s ruler size.

- **fStyle**=fontStyle  
  A binary coded integer with each bit controlling one aspect of the text style as follows:
  
  Bit 0: Bold
  Bit 1: Italic
  Bit 2: Underline
  Bit 4: Strikethrough
  
  Use -1 to specify the paragraph’s ruler style. To set bit 0 and bit 1 (bold italic), use $2^0+2^1 = 3$ for fontStyle. See Setting Bit Parameters on page IV-13 for details about bit settings.

- **textRGB**=(r,g,b)  
  Specifies text color. r, g, and b are integers from 0 to 65535. (0, 0, 0) specifies black. (65535, 65535, 65535) specifies white.

- **vOffset**=v  
  Sets the vertical offset in points (positive offset is down, negative is up). Use this to create subscripts and superscripts. vOffset is allowed for formatted text files only, not for plain text files.

Notebook (Writing Graphics)

Writing notebook graphics parameters
This section of Notebook relates to inserting graphics at the current selection in the notebook.

These graphics keywords are allowed for formatted text files only, not for plain text files.

- **convertToPNG**=x  
  Converts all pictures in the current selection to cross-platform PNG format. If the picture is already PNG, it does nothing.
  
  x is the resolution expansion factor, an integer from 1 to 16 times screen resolution. x is clipped to legal limits.

- **frame**=f  
  Sets the frame used for the picture and insertPicture keywords.
  
  f=0: No frame (default).
  f=1: Single frame.
  f=2: Double frame.
  f=3: Triple frame.
  f=4: Shadow frame.

- **insertPicture**=[pictureName, pathName, filePath, options]  
  Inserts a picture from a file specified by pathName and filePath. The supported graphics file formats are listed under Inserting Pictures on page III-13.
pictureName is the special character name (see **Special Character Names** on page III-14) to use for the inserted notebook picture or "$" to automatically assign a name.

pathName is the name of an Igor symbolic path created via NewPath or "$" to use no path.

filePath is a full path to the file to be loaded or a partial path or simple file name relative to the specified symbolic path.

If pathName and filePath do not fully specify a file, an Open File dialog is displayed from which the user can choose the file to be inserted.

options is a bitwise parameter interpreted as follows:

Bit 0: If set, an Open File dialog is displayed even if the file is fully specified by pathName and filePath.

Bit 1: Determines what to do in the event of a name conflict. If set, the existing special character with the conflicting name is overwritten. If cleared, a unique name is created and used as the special character name for the inserted picture.

All other bits are reserved and must be set to zero.

See **Setting Bit Parameters** on page IV-13 for details about bit settings.

The variable V_flag is set to 1 if the picture was inserted or to 0 otherwise, for example, if the user canceled from the Open File dialog.

The string variable S_name is set to the special character name of the picture that was inserted or to "" if no picture was inserted.

The string variable S_fileName is set to the full path of the file that was inserted or to "" if no picture was inserted.

picture=[objectSpec, mode, flags [ , expansion]]

Inserts a picture based on the specified object.

objectSpec is usually just an object name, which is the name of a graph, table, page layout, Gizmo plot, or picture from Igor’s picture gallery (Misc→Pictures). See further discussion below.

mode controls what happens when you insert a picture of a graph, table or page layout window. It does not affect insertions of pictures from the picture gallery.

mode specifies the format of the graph, table, or page layout picture as follows:

<table>
<thead>
<tr>
<th>mode</th>
<th>Macintosh</th>
<th>Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td>-9</td>
<td>SVG</td>
<td>SVG</td>
</tr>
<tr>
<td>-8</td>
<td>PDF</td>
<td>8X Enhanced metafile</td>
</tr>
<tr>
<td>-7</td>
<td>TIFF</td>
<td>TIFF</td>
</tr>
<tr>
<td>-6</td>
<td>JPEG</td>
<td>JPEG</td>
</tr>
<tr>
<td>-5</td>
<td>PNG</td>
<td>PNG</td>
</tr>
<tr>
<td>-4</td>
<td>4X PNG</td>
<td>Device-independent bitmap</td>
</tr>
<tr>
<td>-2</td>
<td>PDF</td>
<td>8X Enhanced metafile</td>
</tr>
<tr>
<td>-1</td>
<td>PDF</td>
<td>8X Enhanced metafile</td>
</tr>
<tr>
<td>0</td>
<td>PDF</td>
<td>8X Enhanced metafile</td>
</tr>
<tr>
<td>1</td>
<td>1X PDF</td>
<td>8X Enhanced metafile</td>
</tr>
<tr>
<td>2</td>
<td>2X PDF</td>
<td>8X Enhanced metafile</td>
</tr>
<tr>
<td>4</td>
<td>4X PDF</td>
<td>8X Enhanced metafile</td>
</tr>
<tr>
<td>8</td>
<td>8X PDF</td>
<td>8X Enhanced metafile</td>
</tr>
</tbody>
</table>
When using the picture keyword, you may include a coordinate specification after the object name in `objectSpec`. For example:

```
Notebook Notebook1 picture={Layout0(100, 50, 500, 700), 1, 1}
```

The coordinates are in points. A coordinate specification of (0, 0, 0, 0) behaves the same as no coordinate specification at all.

If the object is a graph, the coordinate specification determines the width and height of the graph. If you omit the coordinate specification, Igor takes the width and height from the graph window.

If the object is a layout, the coordinate specification identifies a section of the layout. If you omit the coordinate specification, Igor selects a section of the layout that includes all objects in the layout plus a small margin.

For any other kind of object, Igor ignores the coordinate specification if it is present.

The scaling and frame keywords affect the selected picture, if any. If no picture is selected, they affect the insertion of a picture using the picture or `insertPicture` keywords. For example, this command inserts a picture of `Graph0` with 50% scaling and a double frame:

```
Notebook Test1 scaling={50, 50}, frame=2, picture={Graph0, 1, 1}
```

If no picture is selected and no picture is inserted, scaling and frame have no effect.

### InsertPicture Example

```iog
Function InsertPictureFromFile(nb)
    String nb // Notebook name or "" for top notebook
    if (strlen(nb) == 0)
        nb = WinName(0, 16, 1)
    endif
    if (strlen(nb) == 0)
        Abort "There are no notebooks"
    endif

    // Display Open File dialog to get the file to be inserted
    Variable refNum // Required for Open but not really used
    String fileFilter = "Graphics Files:.eps,.jpg,.png;All Files:.*;"
    Open /D /R /F=fileFilter refNum
    String filePath = S_fileName
```

Note that this example is only included for illustrative purposes and should not be used as is.

### Modes

Modes -6, -7, -8, and -9 require Igor Pro 7.00 or later. Mode 0 is recommended unless you are concerned about cross-platform compatibility in which case you must use mode -5 (PNG) or mode -9 (SVG).

If `objectSpec` names a Gizmo window, only modes -5, -6, or -7 are allowed.

Modes -2 through 8 are supported for backward compatibility. In previous versions of Igor, they selected other formats that are now obsolete.

See Chapter III-5, **Exporting Graphics (Macintosh)**, Chapter III-6, **Exporting Graphics (Windows)**, and **Metafile Formats** on page III-102 for further discussion of these formats.

### Flags Parameter

`flags` is a bitwise parameter interpreted as follows:

- Bit 0: 0 for black and white, 1 for color.

All other bits are reserved and must be set to zero.

For color, set $flags = 2^0 = 1$.

See **Setting Bit Parameters** on page IV-13 for details about bit settings.

### Expansion Parameter

`expansion` is optional and requires Igor Pro 7.00 or later. On Macintosh, it affects modes -5, -6, -7, and -8 only. On Windows, it affects modes -5, -6, and -7 only.

`expansion` sets the expansion factor over screen resolution. `expansion` must be an integer between 1 and 8 and is usually 1, 2, 4 or 8. The default value is 1.

### Scaling Parameter

```
scaling={h, v}
```

Sets the horizontal ($h$) and vertical ($v$) scaling for the selected picture or the picture and `insertPicture` keywords. $h$ and $v$ are in percent.

When using the picture keyword, you may include a coordinate specification after the object name in `objectSpec`. For example:

```
Notebook Notebook1 picture={Layout0(100, 50, 500, 700), 1, 1}
```

The coordinates are in points. A coordinate specification of (0, 0, 0, 0) behaves the same as no coordinate specification at all.

If the object is a graph, the coordinate specification determines the width and height of the graph. If you omit the coordinate specification, Igor takes the width and height from the graph window.

If the object is a layout, the coordinate specification identifies a section of the layout. If you omit the coordinate specification, Igor selects a section of the layout that includes all objects in the layout plus a small margin.

For any other kind of object, Igor ignores the coordinate specification if it is present.

The scaling and frame keywords affect the selected picture, if any. If no picture is selected, they affect the insertion of a picture using the picture or `insertPicture` keywords. For example, this command inserts a picture of `Graph0` with 50% scaling and a double frame:

```
Notebook Test1 scaling={50, 50}, frame=2, picture={Graph0, 1, 1}
```

If no picture is selected and no picture is inserted, scaling and frame have no effect.
if (strlen(filePath) == 0)
    Print "You cancelled"
    return -1
endif

Notebook $nb, insertPicture={$"", $"", filePath, 0}
if (V_flag)
    Print "Picture inserted"
else
    Print "No picture inserted"
endif

    return 0
End

Save notebook pictures to files
The savePicture keyword is allowed for formatted text files only, not for plain text files.

savePicture={pictureName, pathName, filePath, options}

Saves a picture from a formatted text notebook to a file specified by pathName and filePath.
pictureName is the special character name (see Special Character Names on page III-14) of the picture to be saved or "$" to save the selected picture in which case one picture and one picture only must be selected in the notebook.

pathName is the name of an Igor symbolic path created via newPath or "$" to use no path.

filePath is a full path to the file to be written or a partial path or simple file name relative to the specified symbolic path.
If pathName and filePath do not fully specify a file, a Save File dialog is displayed in which the user can specify the file to be written.

options is a bitwise parameter interpreted as follows:

Bit 0: If set, a Save File dialog is displayed even if the file is fully specified by pathName and filePath.

Bit 1: If set, a file with the same name is overwritten if it exists. If cleared, a Save File dialog is displayed if the specified file already exists.

Bit 2: If set then the leaf name specified by filePath is ignored and a name is automatically generated based on the picture name.

All other bits are reserved and must be set to zero.

See Setting Bit Parameters on page IV-13 for details about bit settings.

The variable V_flag is set to 1 if the picture was written or to 0 otherwise, for example, if the user canceled from the Save File dialog.

The string variable S_name is set to the special character name of the picture that was saved or to "" if no picture was saved.

The string variable S_fileName is set to the full path of the file that was written or to "" if no picture was written.

Notebook (Writing Special Characters)

Writing special character parameters
This section of Notebook relates to inserting special characters at the current selection in the notebook. To insert a notebook action, see NotebookAction.
The special characters are page break, short date, long date, abbreviated date and time. They act in some respects like a single character but have special properties. You can insert the special characters using the specialChar keyword.
The specialChar keyword is allowed for formatted text files only, not for plain text files. Other special characters are allowed in headers and footers only and you cannot insert them in a document using the specialChar keyword. These are window title, page number and total pages. The special characters other than page break character are dynamic and update periodically.

specialChar={type, flags, optionsStr}

type is the special character type as follows:
1: Page break.
2: Short date.
3: Long date.
4: Abbreviated date.
5: Time.

flags is reserved for future use. You should pass 0 for flags.

optionsStr is reserved for future use. You should pass "" for optionsStr.

specialUpdate=flags

Updates special characters in the notebook.

flags is interpreted bitwise:
Bit 0: 0 to update all special characters.
Bit 1: 1 to update special characters in the selected text.

If 1, updates regardless of whether updating is enabled or not.
All other bits are reserved and must be set to zero.

See Setting Bit Parameters on page IV-13 for details about bit settings.

The specialUpdate keyword can update pictures of graphs, tables, and page layouts that were created from windows in the current experiment.

See Also
Chapter III-1, Notebooks. The NewNotebook, NotebookAction, and OpenNotebook operations; the SpecialCharacterInfo and SpecialCharacterList functions.

Notebook (Accessing Contents)

Accessing Notebook Contents

getData=mode

Causes Igor to return the contents of the notebook in the S_value variable. The contents are binary data in a private Igor format encoded as text. The only use for this keyword is to transfer data from one notebook to another by calling getData followed by setData.

Causes Igor to return the contents of the notebook in the S_value variable. The contents are binary data in a private Igor format encoded as text. The only use for this keyword is to transfer data from one notebook to another by callinggetData followed by setData.

mode=1: Stores in S_value plain text or formatted text data, depending on the type of the notebook, from the entire notebook.

mode=2: Stores in S_value plain text data, regardless of the type of the notebook, from the entire notebook.

mode=3: Stores in S_value plain text or formatted text data, depending on the type of the notebook, from the notebook selection only.

mode=4: Stores in S_value plain text data, regardless of the type of the notebook, from the notebook selection only.
See the Notebook In Panel example experiment for examples using getData and setData.

**Notebook (Writing Text)**

**Writing notebook text parameters**

This section of Notebook relates to inserting text at the current selection in the notebook.

- **text=textStr** Inserts the text at the current selection.
  
  Before the text is inserted, Igor converts escape sequences in *textStr* as described in *Escape Sequences in Strings* on page IV-15.
  
  Then, it checks for illegal characters. The only character code that is illegal is zero (ASCII NUL character). If it finds an illegal character, Igor generates an error and does not insert the text.

- **setData=dataStr** Inserts the data at the current selection.
  
  *dataStr* is either a regular string expression or the result returned by Notebook getData.

- **zData=dataStr** This keyword is used by Igor during the recreation of a notebook subwindow in a control panel. *dataStr* is encoded binary data created by Igor when the recreation macro was generated. It represents the contents of the notebook subwindow in a format private to Igor.

- **zDataEnd=1** This keyword is used by Igor during the recreation of a notebook subwindow in a control panel. It marks the end of encoded binary data created by Igor when the recreation macro was generated.

**NotebookAction**

**NotebookAction** [/W=winName] **keyword = value [, keyword = value ...]**

The NotebookAction operation creates or modifies an “action” in a notebook. A notebook action is an object that executes commands when clicked.

NotebookAction returns an error if the notebook is open for read-only. See Notebook Read/Write Properties on page III-10 for further information.

**Parameters**

The parameters are in *keyword = value* format. Parameters are automatically limited to legal values before being applied to the notebook.

- **bgRGB=(r, g, b)** Specifies the action background color. *r*, *g*, and *b* are values from 0 to 65535.

- **commands=** Specifies the command string to be executed when clicking the action. For multiline commands, add a carriage return (\r) between lines.

- **enableBGRGB=** Enables the background color specified by bgRGB (*enable=1*). Background color is ignored for *enable=0*.

- **frame=f** Specifies the frame enclosing the action.
  
  
  - *f*=0: No frame.
  - *f*=1: Single frame (default).
  - *f*=2: Double frame.
  - *f*=3: Triple frame.
  - *f*=4: Shadow frame.

- **helpText=helpTextStr**
NotebookAction

Specifies the help string for the action. The text is limited to 255 bytes. On Macintosh, help appears when the cursor is over the action after choosing Help→Show Igor Tips. On Windows, help appears in the status line when the cursor is over the action.

ignoreErrors=ignore

Controls whether an error dialog will appear (ignore=0) or not (ignore is nonzero) if an error occurs while executing the action commands.

linkStyle=linkStyle

Controls the action title text style. If linkStyle=1, the style is the same as a help link (blue underlined). If linkStyle=0, the style properties are the same as the preceding text.

name=name

Specifies the name of the new or modified notebook action. This is a standard Igor name. See Standard Object Names on page III-475 for details.

padding={leftPadding, rightPadding, topPadding, bottomPadding, internalPadding}

Sets the padding in points. internalPadding sets the padding between the title and the picture when both elements are present.

picture=name

Specifies a picture for the action icon. name is the name of a picture in the picture gallery (see Pictures on page III-481).

If name is null ($""), it clears the picture parameter.

procPICTName=name

Specifies a Proc Picture for the action icon (see Proc Pictures on page IV-57). name is the name of a Proc Picture or null ($"" ) to clear it. This will be a name like ProcGlobal#myPictName or MyModuleName#myPictName. If you use a module name, the Proc Picture must be declared static.

If you specify both picture and procPICTName, picture will be used.

quiet=quiet

Displays action commands in the history area (quiet=0), otherwise (quiet=1) no commands will be recorded.

scaling={h, v}

Scales the picture in percent horizontally, h, and vertically, v.

showMode=mode

Determines if the title or picture are displayed.

mode=1: Title only.
mode=2: Picture only.
mode=3: Picture below title.
mode=4: Picture above title.
mode=5: Picture to left of title.
mode=6: Picture to right of title.

Without a picture specification, the action will use title mode regardless of what you specify.

title=titleStr

Sets the action title to titleStr, which is limited to 255 bytes.

Flags

/W= winName

Specifies the notebook window of interest.

winName is either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0#nb0. See Subwindow Syntax on page III-92 for details on host-child specifications.

If /W is omitted, NotebookAction acts on the top notebook window.

Examples

String nb = WinName(0, 16, 1)    // Top visible notebook
NotebookAction name=Action0, title="Beep", commands="Beep"    // Create action
NotebookAction name=Action0, enableBGRGB=1, padding={4,4,4,4}
num2char

num2char(num [, options])

The num2char function returns a string containing a character.

The options parameter was added in Igor Pro 7.00 and defaults to 0.

As of Igor7, Igor represents text internally as UTF-8, a form of Unicode. Previously it represented text as system text encoding. Because of this change, the behavior of num2char is complicated.

Recommended use of num2char in Igor7 or later

If num is a Unicode code point, pass 0 for options and num2char will return a UTF-8 string containing the character for the Unicode code point represented by num.

If you want a string containing a single byte, even though it may not be a valid UTF-8 string, pass 1 for options and num2char will return a string containing the single byte whose value is num, provided that num is between 0 and 255.

Detailed description of num2char in Igor7 or later

If num is between 0 and 127, num2char returns a string containing a single byte whose value is num. This represents an ASCII character.

If num is between 128 and 255 and options is 1, num2char returns a string containing a single byte whose value is num. This is not valid UTF-8 text, but it is consistent with the behavior of num2char in Igor6.

If num is between 128 and 255 and options is 0 or omitted, num2char returns the UTF-8 representation of the character for the Unicode code point represented by num.

If num is greater than 255, num2char returns the UTF-8 representation of the character for the Unicode code point represented by num regardless of the value of options.

If you provide the options parameter, it must be either 0 or 1. Other values may be used for other purposes in the future.

Examples

Print num2char(65) // Prints A
Print num2char(97) // Prints a
Print num2char(0xF7) // Prints division sign
Print num2char(0xF7,0) // Prints division sign
Print num2char(0xF7,1) // Prints missing character symbol
Print num2char(0x0127) // Prints small letter h with stroke (h-bar)
Print num2char(0x0127,0) // Prints small letter h with stroke (h-bar)
Print num2char(0x0127,1) // Prints small letter h with stroke (h-bar)

// In the case of num2char(0xF7,1), num2char returns a string containing
// a single byte whose value is 0xF7. This is not a valid UTF-8 string.

See Also

The char2num, str2num and num2str functions.

Text Encodings on page III-437.

num2istr

num2istr(num)

The num2istr function returns a string representing num after rounding to the nearest integer.
**num2str**

```markdown
num2str(num)
```

The `num2str` function returns a string representing the number `num`.

Precision is limited to only five decimal places. This can cause unexpected and confusing results. For this reason, we recommend that you use `num2istr` or `sprintf` for better control of the format and precision of the number conversion.

**See Also**

- The `sprintf` operation.
- The `str2num`, `char2num` and `num2char` functions.

**NumberByKey**

```markdown
NumberByKey(keyStr, kwListStr [, keySepStr [, listSepStr [, matchCase]]])
```

The `NumberByKey` function returns a numeric value extracted from `kwListStr` based on the specified key contained in `keyStr`. `kwListStr` should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for `keySepStr` and `listSepStr`.

Use `NumberByKey` to extract a numeric value from a strings containing "key1=value1;key2=value2;" style lists such as those returned by functions like `AxisInfo` or `TraceInfo`.

If the key is not found or if any of the arguments is "" or if the conversion to a number fails then it returns NaN. `keySepStr`, `listSepStr`, and `matchCase` are optional; their defaults are ",", ";", and 0 respectively.

**Details**

- `keyStr` is limited to 255 bytes.
- `kwListStr` is searched for an instance of the key string bound by `listSepStr` on the left and a `keySepStr` on the right. The text up to the next `listSepStr` is converted to the returned number.
- `kwListStr` is treated as if it ends with a `listSepStr` even if it doesn’t.
- Searches for `keySepStr` and `listSepStr` are always case-sensitive. Searches for `keyStr` in `kwListStr` are usually case-insensitive. Setting the optional `matchCase` parameter to 1 makes the comparisons case sensitive.
- In Igor6, only the first byte of `keySepStr` and `listSepStr` was used. In Igor7 and later, all bytes are used.
- If `listSepStr` is specified, then `keySepStr` must also be specified. If `matchCase` is specified, `keySepStr` and `listSepStr` must be specified.

**Examples**

```markdown
Print NumberByKey("AKEY", "AKEY:123;") // prints 123
Print NumberByKey("BKEY", "AKEY=123;Bkey=456;", ";") // prints 456
Print NumberByKey("KEY2", "KEY1=123,KEY2=999,"", ";", ";") // prints 999
Print NumberByKey("Ckey", "CKEY=123;Ckey=456;", ";") // prints 123
Print NumberByKey("ckey", "CKEY=123;Ckey=456;", ";", ";", 1) // prints 456
```

**See Also**

- The `StringByKey`, `RemoveByKey`, `ReplaceNumberByKey`, `ReplaceStringByKey`, `ItemsInList`, `AxisInfo`, `IgorInfo`, `SetWindow`, and `TraceInfo` functions.

**numpnts**

```markdown
numpnts(waveName)
```

The `numpnts` function returns the total number of data points in the named wave. To find the number of elements in a dimension of a multidimensional wave, use the `DimSize` function.

Do not use `numpnts` to test if a wave reference is null as this causes a runtime error. Use `WaveExists`.
numtype

numtype (num)
The numtype function returns a number which indicates what kind of value num contains.

Details
If num is a real number, numtype returns a real number whose value is:

0: If num contains a normal number.
1: If num contains +/-INF.
2: If num contains NaN.

If num is a complex number, numtype returns a complex number in which the real part is the number type of the real part of num and the imaginary part is the number type of the imaginary part of num.

NumVarOrDefault

NumVarOrDefault (pathStr, defVal)
The NumVarOrDefault function checks to see if the pathStr points to a numeric variable. If the numeric variable exists, NumVarOrDefault returns its value. If the numeric variable does not exist, it returns defVal instead.

Details
NumVarOrDefault initializes input values of macros so they can remember their state without needing global variables to be defined first. String variables use the corresponding numeric function, StrVarOrDefault.

Examples
Function DemoNumVarOrDefault()
    Variable nVal = NumVarOrDefault("root:Packages:MyPackage:gNVal",2)
    String sVal = StrVarOrDefault("root:Packages:MyPackage:gSVal","Hello")
    Print nVal, sVal

    // Store values in package data folder for next time
    // Create package data folder if it does not yet exist
    NewDataFolder/O root:Packages
    NewDataFolder/O root:Packages:MyPackage
    DFREF dfr = root:Packages:MyPackage       // Get reference to package data folder

    // Create or overwrite globals in package data folder
    Variable/G dfr:gNVal = nVal
    String/G dfr:gSVal = sVal

    NVAR gNVal = dfr:gNVal
    gNVal += 1

    SVAR gSVal = dfr:gSVal
    gSVal += "!
End

NVAR

NVAR [/C] [/Z] localName [= pathToVar] [, localName1 [= pathToVar1]] ...
NVAR is a declaration that creates a local reference to a global numeric variable accessed in a user-defined function.

The NVAR reference is required when you access a global numeric variable in a function. At compile time, the NVAR statement specifies the local name referencing a global numeric variable. At runtime, it makes the connection between the local name and the actual global variable. For this connection to be made, the global numeric variable must exist when the NVAR statement is executed.

When localName is the same as the global numeric variable name and you want to reference a global variable in the current data folder, you can omit pathToVar.
**NVAR_Exists**

`pathToVar` can be a full literal path (e.g., `root:FolderA:var0`), a partial literal path (e.g., `:FolderA:var0`) or `$` followed by string variable containing a computed path (see **Converting a String into a Reference Using $** on page IV-61).

You can also use a data folder reference or the `/SDFR` flag to specify the location of the numeric variable if it is not in the current data folder. See **Data Folder References** on page IV-77 and **The /SDFR Flag** on page IV-79 for details.

If the global variable may not exist at runtime, use the `/Z` flag and call `NVAR_Exists` before accessing the variable. The `/Z` flag prevents Igor from flagging a missing global variable as an error and dropping into the Igor debugger. For example:

```nvars
NVAR/Z nv=<pathToPossiblyMissingNumericVariable>
if( NVAR_Exists(nv) )
  <do something with nv>
endif
```

Note that to create a global numeric variable, you use the `Variable/G` operation.

**Flags**

- `/C` Variable is complex.
- `/Z` Ignores variable reference checking failures.

**See Also**

`NVAR_Exists` function.

**Converting Global Variables and Waves** on page IV-64.

**NVAR_Exists**

`NVAR_Exists(name)`

The `NVAR_Exists` function returns one if specified `NVAR` reference is valid or zero if not. It can be used only in user-defined functions.

For example, in a user function you can test if a global numeric variable exists like this:

```nvars
NVAR /Z var1 = gVar1 // /Z prevents debugger from flagging bad NVAR
if (!NVAR_Exists(var1)) // No such global numeric variable?
  Variable/G gVar1 = 0 // Create and initialize it
endif
```

**See Also**

`WaveExists`, `SVAR_Exists`, and **Accessing Global Variables and Waves** on page IV-64.

**Open**

`Open [flags] refNum [as fileNameStr]`

The `Open` operation can, depending on the flags passed to it:

- Open an existing file to read data from (/R flag without /D).
- Open a to append results to (/A flag without /D).
- Create a new file or overwrite an existing file to write results to (no /D, /R or /A flags).
- Display an Open File dialog (/D/R or /D/A flags with or without /MULT).
- Display a Save File dialog (/D flag without /R or /A).

**Parameters**

`refNum` is the name of a numeric variable to receive the file reference number. `refNum` is set by `Open` if `Open` actually opens a file for reading or writing (cases 1, 2 and 3). You use `refNum` with the `FReadLine, FStatus, FGetPos, FSetPos, FBinWrite, FBinRead, fprintf`, and `wfprintf` operations to read from or write to the file. When you’re finished, use pass `refNum` to the `Close` operation to close the file.

`Open` does not set the file reference number when the /D flag is used (cases 4 and 5) but you must still supply a `refNum` parameter.
The following discussion of the `pathName` and `fileNameStr` parameters applies when you are attempting to open a file for reading or writing (cases 2, 3, and 5 above).

The targeted file is specified by a combination of the `pathName` parameter and the `fileNameStr` parameter. There are three ways to specify the targeted file:

<table>
<thead>
<tr>
<th>Method</th>
<th>How To Use It</th>
</tr>
</thead>
<tbody>
<tr>
<td>Symbolic path and simple file name</td>
<td>Use `/P=pathName and fileNameStr, where pathName is the name of an Igor symbolic path (see Symbolic Paths on page II-21) that points to the folder containing the file and fileNameStr is the name of the file.</td>
</tr>
<tr>
<td>Symbolic path and partial path</td>
<td>Use `/P=pathName and fileNameStrs, where pathName is the name of an Igor symbolic path that points to the folder containing the file and fileNameStr is a partial path starting from the folder and leading to the file.</td>
</tr>
<tr>
<td>Full path</td>
<td>Use just fileNameStr, where fileNameStr is a full path to the file.</td>
</tr>
</tbody>
</table>

If you use a full or partial path for `fileNameStr`, see Path Separators on page III-429 for details on forming the path.

The targeted file is fully specified if `fileNameStr` is a full path or if both `pathName` and `fileNameStr` are present and not empty strings.

The targeted file is not fully specified in any of these cases:
- `fileNameStr` is omitted
- `fileNameStr` is an empty string
- `fileNameStr` is not a full path and no symbolic path is specified

Opening an Existing File For Reading Only

This covers cases 1 (/R without /D).

If the file is fully-specified but does not exist, an error is generated. If you want to detect and handle the error yourself, use the /Z flag.

If the file is not fully-specified, Open displays an Open File dialog.

If a file is opened, `refNum` is set to the file reference number.

Opening an Existing File For Appending

This covers cases 1 (/R without /D) and 2 (/A without /D).

If the file is fully-specified and exists, it is opened for read/write and the current file position is moved to the end of the file.

If the file is fully-specified but does not exist, the file is created and opened for read/write.

If the file is not fully-specified, Open displays an Open File dialog.

If a file is opened, `refNum` is set to the file reference number.

Opening a File For Write

This covers case 3 (no /R, /A or /D).

If the targeted file exists, it is overwritten.

If the targeted file does not exist and it is fully-specified and targets a valid path, a new file is created.

If the file is fully-specified and targets an invalid path, an error is generated. If you want to detect and handle the error yourself, use the /Z flag.

If the file is not fully-specified, Open displays a Save File dialog.

If a file is opened, `refNum` is set to the file reference number.

Displaying an Open File Dialog To Select a Single File

This covers cases 4 (/D with /R or /A).

Open does not actually open the file but just displays the Open File dialog.
Open

If the user chooses a file in the Open File dialog, the S_fileName output string variable is set to a full path to the file. You can use this in subsequent commands. If the user cancels, S_fileName is set to "".

See the documentation for the /D, /F and /M flags and then read Displaying an Open File Dialog on page IV-142 for details.

refNum is left unchanged.

**Displaying an Open File Dialog To Select Multiple Files**
This covers cases 4 (/D with /R or /A) with the /MULT=1 flag.

Open does not actually open the file but just displays the Open File dialog.

If the user chooses one or more files in the Open File dialog, the S_fileName output string variable is set to a carriage-return-delimited list of full paths to one or more files. You can use this in subsequent commands. If the user cancels, S_fileName is set to "".

See the documentation for the /D, /F, /M and /MULT flags and then read Displaying a Multi-Selection Open File Dialog on page IV-143 for details.

refNum is left unchanged.

**Displaying a Save File Dialog**
This covers cases 5 (/D without /R or /A).

Open does not actually open the file but just displays the Save File dialog.

If the user chooses a file in the Save File dialog, the S_fileName output string variable is set to a full path to the file. You can use this in subsequent commands. If the user cancels, S_fileName is set to "".

See the documentation for the /D, /F and /M flags and then read Displaying a Save File Dialog on page IV-144 for details.

refNum is left unchanged.

**Flags**

/A

Opens an existing file for appending or, if the file does not exist, creates a new file and opens it for appending.

/C=creatorStr

Specifies the file creator code. This is meaningful on Macintosh only and is ignored on Windows. For opening an existing file, creator defaults to "????" which means “any creator”. For creating a new file, creatorStr defaults to “IGR0” which is Igor’s creator code.

/D[=mode]

Specifies dialog-only mode.

/D: A dialog is always displayed.
/D=1: Same as /D.
/D=2: A dialog is displayed only if pathName and fileNameStr do not specify a valid file.

Use this mode to allow the user to choose a file to be opened by a subsequent operation, such as LoadWave.

With /D or /D=1, open presents a dialog from which the user can select a file but does not actually open the file. Instead, Open puts the full path to the file into the string variable S_fileName.

/D=2 does the same thing except that it skips the dialog if pathName and fileNameStr specify a valid file. In this case, if pathName and fileNameStr refer to an alias (Macintosh) or shortcut (Windows), the target of the alias or shortcut is returned.

If the user clicks the Cancel button, S_fileName is set to an empty string.
Use Open/D/R to bring up an Open File dialog. See Displaying an Open File Dialog on page IV-142 for details.

Use Open/D/R/MULT=1 to bring up an Open File dialog to select multiple files. See Displaying a Multi-Selection Open File Dialog on page IV-143 for details.

Use Open/D to bring up a Save File dialog. See Displaying a Save File Dialog on page IV-144 for details.

See Using Open in a Utility Routine on page IV-145 for an example using /D=2.

Do not use /Z with /D.

/F=fileFilterStr /F provides control over the file filter menu in the Open File dialog. See Open File Dialog File Filters on page IV-143 and Save File Dialog File Filters on page IV-145 for details.

/M=messageStr Prompt message text in the dialog used to select the file, if any.

/MULT=m Use /D/R/MULT=1 to display a multi-selection Open File dialog.

/D=R/MULT=0 or just /D/R displays a single-selection Open File dialog.

/MULT=1 is allowed only if /D or /D=1 and /R are specified.

See Displaying a Multi-Selection Open File Dialog on page IV-143 for details.

/P=pathName Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

/R The file is opened read only.

/T=typeStr When creating a new file on Macintosh (/A and /R flag omitted), /T sets the Macintosh file type property for the file if it does not already exist. For example, /T="BINA" sets the Macintosh file type to 'BINA'. If /T is omitted the Macintosh file type will be 'TEXT'. Apple has deemphasized Macintosh file types in favor of file name extensions.

For new code, /F is recommended instead of /T.

When opening an existing file (/A or /R flag used), /T provides control over the file filter menu in the Open File dialog. See Open File Dialog File Filters on page IV-143 for details.

When creating a new file (/A and /R flag omitted), /T provides control over the file filter menu in the Save File dialog. See Save File Dialog File Filters on page IV-145 for details.

/Z[=z] Prevents aborting of procedure execution if an error occurs, for example if the procedure tries to open a file that does not exist for reading. Use /Z if you want to handle this case in your procedures rather than having execution abort.

When using /Z, /Z=1, or /Z=2, V_flag is set to 0 if no error occurred or to a nonzero value if an error did occur.

Do not use /Z with /D.

/Z=0: Same as no /Z.

/Z=1: Suppresses normal error reporting. When used with /R, it opens the file if it exists. /Z alone has the same effect as /Z=1.

/Z=2: Suppresses normal error reporting. When used with /R, it opens the file if it exists or displays a dialog if it does not exist.

Details

When Open returns, if a file was actually opened, the refNum parameter will contain a file reference number that you can pass to other operations to read or write data. If the file was not opened because of an error or because the user canceled or because /D was used, refNum will be unchanged.

If you use /R (open for read), Open opens an existing file for reading only.
If you use /A, Open opens an existing file for appending. If the file does not exist, it is created and then opened for appending.

If both /R and /A are omitted then Open creates and opens a file. If the specified file does not already exist, Open creates it and opens it for writing. If the file does already exist then Open opens it and sets the current file position to the start of the file. The current file position determines where in the file data will be written. Thus, you will be overwriting existing data in the file.

**Warning:** If you open an existing file for writing (you do not use /R) then you will overwrite or truncate existing data in the file. To avoid this, open for read (use /R) or open for append (use /A).

### Output Variables

The Open operation returns information in the following variables:

- **V_flag**: Set only when the /Z flag is used. V_flag is set to zero if the file was opened, to -1 if Open displayed a dialog (because the file was not fully-specified) and the user canceled, and to some nonzero value if an error occurred.

- **S_fileName**: Stores the full path to the file that was opened.
  - If /MULT=1 is used, S_fileName is a carriage-return-separated list of full paths to one or more files.
  - If an error occurred or if the user canceled, S_fileName is set to an empty string.

When using /D, the value of V_flag is undefined. Do not use /Z with /D. Use S_fileName to determine if the user selected a file or canceled.

### Examples

This example function illustrates using Open to open a text file from which data will be read. The function takes two parameters: an Igor symbolic path name and a file name. If either of these parameters is an empty string, the Open operation will display a dialog allowing the user to choose the file. Otherwise, the Open operation will open the file without displaying a dialog.

```igor
Function DemoOpen(pathName, fileName)
    String pathName // Name of symbolic path or "" for dialog.
    String fileName // File name, partial path, full path or "" for dialog.
    Variable refNum
    String str

    // Open file for read.
    Open/R/Z=2/P=$pathName refNum as fileName

    // Store results from Open in a safe place.
    Variable err = V_flag
    String fullPath = S_fileName
    if (err == -1)
        Print "DemoOpen canceled by user."
        return -1
    endif
    if (err != 0)
        DoAlert 0, "Error in DemoOpen"
        return err
    endif
    printf "Reading from file \"%s\". First line is:\r", fullPath
    FReadLine refNum, str // Read first line into string variable
    printf str
    close refNum
    return 0
End
```

### See Also

OpenHelp

OpenHelp flags fileNameStr
The OpenHelp operation opens the specified help file.
The OpenHelp operation was added in Igor Pro 7.00.

Parameters
The help file to be opened is specified by fileNameStr and /P=pathName where pathName is the name of an
Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path
relative to the folder associated with pathName, or the name of a file in the folder associated with pathName.
If OpenHelp can not determine the location of the file from fileNameStr and pathName, it returns an error.
If you use a full or partial path for fileNameStr, see Path Separators on page III-429 for details on forming
the path.

Flags
/INT=interactive Controls whether opening the help file is interactive or not.
/INT=1: If the help file being opened needs to be compiled, OpenHelp
presents a dialog asking the user whether the file should be compiled.
During the compile, a progress dialog is displayed. Any errors are
presented to the user in an error dialog. This is the default behavior if
/INT is omitted.
/INT=0: If the help file being opened needs to be compiled, OpenHelp
compiles it without presenting a dialog. Compilation errors are not
presented to the user but are reflected in the V_Flag output variable.

/P=pathName Specifies the folder to look in for the file. pathName is the name of an existing Igor
symbolic path.

/V=visible Controls help window visibility.
visible=0: The help window will be initially hidden.
visible=1: The help window will be initially visible. This is the default if /V is
omitted.

/W=(left,top,right,bottom) Specifies window size and position. Coordinates are in points.

/Z=z Controls error reporting.
/Z=0: Report errors normally. /Z=0 is the same as omitting /Z altogether.
This is the default behavior if /Z is omitted.
/Z=1: Suppresses normal error reporting.
/Z alone has the same effect as /Z=1.
/Z=1 prevents aborting procedure execution if an error occurs, for example if the file
does not exist or if there is a compilation error. Use /Z=1 if you want to handle errors
in your procedures rather than having execution abort.

When using /Z or /Z=1, check V_Flag to see if an error occurred.
OpenNotebook

Details
If you use /P=\pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\". See Symbolic Paths on page II-21 for details.

If the specified file is already open but not as a help window (for example as a notebook), OpenHelp returns an error.

If the /W or /V flag is used, or both, the window size and position and visibility are set as specified even if the file itself is already open, so long as the file is already opened as a help window.

Output Variables
The OpenHelp operation returns information in the following variables:

- **V_Flag**: Set to a non-zero value if an error occurred and to zero if no error occurred.
- **V_alreadyOpen**: Set to 1 if the specified help file was already open as a help file or to zero otherwise.

See Also
CloseHelp

OpenNotebook

OpenNotebook  [flags]  [\fileNameStr]

The OpenNotebook operation opens a file for reading or writing as an Igor notebook.

Unlike the Open operation, OpenNotebook will not create a file if the specified file does not exist. To create a new notebook, use the NewNotebook operation.

Parameters
The file to be opened is specified by \fileNameStr and /P=\pathName where \pathName is the name of an Igor symbolic path. \fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with \pathName, or the name of a file in the folder associated with \pathName. If Igor can not determine the location of the file from \fileNameStr and \pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for \fileNameStr, see Path Separators on page III-429 for details on forming the path.
OpenNotebook

Flags

/A   Moves the notebook’s selection to the end of the notebook.

/ENC=textEncoding

Specifies the text encoding of the plain text file to be opened as a notebook.

This flag was added in Igor Pro 7.00.

This is relevant for plain text notebooks only and is ignored for formatted notebooks because they can contain multiple text encodings. See Plain Text File Text Encodings on page III-445 and Formatted Text Notebook File Text Encodings on page III-450 for details.

OpenNotebook uses the text encoding specified by /ENC and the rules described under Determining the Text Encoding for a Plain Text File on page III-446 to determine the source text encoding for conversion to UTF-8.

Passing 0 for textEncoding acts as if /ENC were omitted.

See Text Encoding Names and Codes on page III-463 for a list of accepted values for textEncoding.

/K=k

Specifies window behavior when the user attempts to close it.

k=0: Normal with dialog (default).

k=1: Kills with no dialog.

k=2: Disables killing.

k=3: Hides the window.

If you use /K=2 or /K=3, you can still kill the window using the KillWindow operation.

/M=messageStr

Prompt message text in the dialog used to find the file, if any.

/N=winName

Specifies the window name to be assigned to the new notebook. If omitted, it assigns a name like “Notebook0”.

/P=pathName

Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

/R

Opens the file as read only.

/T=typeStr

Specifies the type or types of files that can be opened.

/V=visible

Hides (visible= 0) or shows (visible= 1; default) the notebook.

/W=(left,top,right,bottom)

Specifies window size and position. Coordinates are in points.

/Z

Suppresses error generation. Use this to check if a file exists. If you use /Z, OpenNotebook sets the variable V_flag to 0 if the notebook was opened or to nonzero if there was an error, usually because the specified file does not exist.

Details

The /A (append) flag has no effect other than to move the selection to the end of the notebook after it is opened.

If you use /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See Symbolic Paths on page II-21 for details.

The /T=typeStr flag affects only the dialog that OpenNotebook presents if you do not specify a path and filename. The dialog presents only those files whose type is specified by /T=typeStr. There are two file types that are allowed for notebooks: ‘TEXT’ which is a plain text file and ‘WMT0’ which is a WaveMetrics formatted text file. Therefore, the file type, if you use it, should be either “TEXT” or “WMT0”. If /T=typeStr is missing, it defaults to “TEXTWMT0”. This opens either type of notebook file. On Windows, Igor considers files with “.txt” extensions to be of type TEXT and considers files with “.ifn” to be of type WMT0. See File Types and Extensions on page III-432 for details.
OpenProc

See Also
The Notebook and NewNotebook operations, and Chapter III-1, Notebooks.

OpenProc

OpenProc flags [fileNameStr]
The OpenProc operation opens a file as an Igor procedure file.

Note: This operation is used automatically to open procedure files when you open an Igor experiment. You can invoke OpenProc only from the command line. Do not invoke it from a procedure. To open procedure files from a procedure or from a menu definition, use the Execute/P operation.

Parameters
The file to be opened is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor cannot determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-429 for details on forming the path.

Flags

/A Moves the procedure window’s selection to the end of the window.

/ENCG=textEncoding
Specifies the text encoding of the plain text file to be opened as a procedure file. This flag was added in Igor Pro 7.00.

OpenProc uses the text encoding specified by /ENCG and the rules described under Determining the Text Encoding for a Plain Text File on page III-446 to determine the source text encoding for conversion to UTF-8.

Passing 0 for textEncoding acts as if /ENCG were omitted.

See Text Encoding Names and Codes on page III-463 for a list of accepted values for textEncoding.

/M=messageStr
Prompt message text in the dialog used to find the file, if any.

/P=pathName
Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

/R
The file is opened read only.

/T=typeStr
Specifies the type or types of files that can be opened.

/N=visible
Hides (visible=0) or shows (visible=1; default) the procedure window.

/Z
Suppresses error generation if the specified file does not exist.

Details
The /A (append) flag has no effect other than to move the selection to the end of the procedure file after it is opened.

If you use /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See Symbolic Paths on page II-21 for details.

OpenProc automatically opens procedure files when you open an Igor experiment. Normally, you will have no use for it. You can not open a procedure file while procedures are executing. Thus, you can’t invoke OpenProc from within a procedure. You can only invoke it from the command line or from a user menu definition (actually, you may get away with it in a macro, but it’s not recommend).

See Also
Chapter III-13, Procedure Windows, Execute, CloseProc
The **Execute** operation.

### OperationList

**OperationList**(*matchStr*, *separatorStr*, *optionsStr*)

The OperationList function returns a string containing a list of internal (built-in) or external operation names corresponding to *matchStr*.

**Parameters**

Only operation names that match *matchStr* string are listed. Use "*" to match all names. See WaveList for examples.

*separatorStr* is appended to each operation name as the output string is generated. *separatorStr* is usually ";" for list processing (See **Processing Lists of Waves** on page IV-193 for details).

Use *optionsStr* to further qualify the list of operations. *optionsStr* is a (case-insensitive) string containing one of these values:

- "*internal*" restricts the list to built-in operations.
- "*external*" restricts the list to external operations (see Igor Extensions on page III-483).

Any other value for *optionsStr* ("*all*" is recommended) will return both internal and external operations.

**See Also**

The DisplayProcedure operation and the FunctionList, MacroList, StringFromList, and WinList functions.

### Optimize

**Optimize** *flags*, *funcspec*, *pWave*

The Optimize operation determines extrema (minima or maxima) of a specified nonlinear function. The function must be defined in the form of an Igor user function.

Use the first form for univariate functions (one dimensional functions; functions taking just one variable). Use the second form with multivariate functions (functions in more than one dimension; functions of more than one variable).

Optimize uses Brent’s method for univariate functions. For multivariate functions you can choose several variations of quasi-Newton methods or simulated annealing.

**Flags**

- **/A = findMax** finds a maximum (/A=1 or /A) or minimum (/A=0 or no flag).
- **/D=nDigits** specifies the number of good digits returned (default is 15) by the function being optimized. If you use /X=xWave with a single-precision wave, the default is seven.
  - Ignored with simulated annealing (/M={3,0}).
- **/DSA=destWave** sets a wave to track the current best model only found with simulated annealing (/M={3,0}). *destWave* must have the same number of points as the X vector.
- **/F=trustRegion** sets the initial trust region when /M={1 or 2, …} with multivariate functions. The value is a scaled step size (see **Multivariate Details**). After the first iteration the trust region is adjusted according to conditions.
  - Ignored with simulated annealing (/M={3,0}).
- **/H=highBracket** finds the extrema of a univariate function. *lowBracket* and *highBracket* are X values on either side of the extreme point. An extreme point is found between the bracketing values.
  - If *lowBracket* and *highBracket* are equal, Optimize adds 1.0 to *highBracket* before looking for an extreme point.
  - Default values for *lowBracket* and *highBracket* are zero. Thus, if neither *lowBracket* nor *highBracket* is present, this is the same as /L=0/H=1.
  - Ignored with simulated annealing (/M={3,0}).
/I=maxIters

Sets the maximum number of iterations in searching for an extreme point to maxIters. Default is 100 for stepMethod (/M flag) 0-2, 10000 for stepMethod = 3 (simulated annealing).

If you use this form of the /I flag with simulated annealing, maxItersAtT is set to maxIters/2 and maxAcceptances is set to maxIters/10.

/I=[maxIters, maxItersAtT, maxAcceptances]

Specifies the number of iterations for simulated annealing. The maximum number of iterations is set by maxIters, maxItersAtT sets the maximum number of iterations at a given temperature in the cooling schedule, and maxAcceptances sets the total number of accepted changes in the X vector (whether they increase or decrease the function) at a given temperature.

If you use this form of the flag with any stepMethod (/M flag) other than 3, maxItersAtT and maxAcceptances are ignored.

Defaults for stepMethod = 3 are {10000, 5000, 500}.

/M={stepMethod, hessMethod}

Specifies the method used for selecting the next step (stepMethod) and the method for calculating the Hessian (matrix of second derivatives) with multivariate functions.

</table>

Default values are {0,0}. The hessMethod variable is ignored if you select stepMethod = 3.

/Q

Suppresses printout of results in the history area. Ordinarily, the results of root searches are printed in the history.

/R={typX1, typX2, ...}

Specifies the expected size of X values with multivariate functions. These values are used to scale X values. If the X values you expect are very different from one, you will get more accurate results if you can give a reasonable estimate. Optimize will use typXi to scale X_i to reduce floating-point truncation error.

You must provide the same number of values in either a wave or a list of values as you provide to the /X flag.

Ignored with simulated annealing (/M=[3,0]).

/S=stepMax

Limits the largest scaled step size allowed with multivariate functions. Optimize will stop if five consecutive steps exceed stepMax.

Ignored with simulated annealing (/M=[3,0]).

/SSA=stepWave

Name of a 3-column wave having number of rows equal to the length of the X vector only when used with simulated annealing (/M=[3,0]). stepWave sets information about the step size used to generate new X vectors. The step sizes are in terms of normalized X values. The normalization is such that the X_i ranges from -1 to 1 based on the ranges set by the /XSA flag.

Column zero sets the step size used when creating new trial X vectors. Default is 1.0.
Column one sets the minimum step size. Default is 0.001.
Column two sets the maximum step size. Default is 1.0.
**Optimize**

\[ /T=tol \]

Sets the stopping criterion with univariate functions. Optimize will attempt to find a minimum within ± tol.

When this form is used with a multivariate function, gradTol is set to tol and stepTol is set to gradTol².

Ignored with simulated annealing (/M={3,0}).

\[ /T=[\text{gradtol, stepTol}] \]

Sets the stopping criteria for multivariate functions. Iterations stop if a point is found with estimated scaled gradient less than gradTol, or if an iteration takes a scaled step shorter than stepTol. Default values are \{(8.53618\times10^{-6}, 7.28664\times10^{-11})\}. These values are \{(6.022\times10^{-16})^{1/3}, (6.022\times10^{-16})^{2/3}\} as suggested by Dennis and Schnabel. 6.022\times10^{-16} is the smallest double precision floating point number that, when added to 1, is different from 1.

Ignored with simulated annealing (/M={3,0}).

\[ /TSA=[\text{InitialTemp, CoolingRate}] \]

Used only with simulated annealing (/M={3,0}).

*InitialTemp* sets the initial temperature. If *InitialTemp* is set to zero, Optimize calls your function 100 times to estimate the best initial temperature. This is the recommended setting unless your function is very expensive to evaluate (in which case, you may not want to use simulated annealing at all).

*CoolingRate* sets the factor by which the temperature is decreased.

\[ /X=xWave \]

Sets the starting point for searching for an extreme point with multivariate functions or with simulated annealing (/M={3,0}). The starting point can be specified with a wave having as many points as the number of independent variables, or you can write out a list of X values in braces. If you are finding extreme points of a univariate function, use /L and /H instead unless you are using the simulated annealing method. If you specify a wave, this wave is also used to receive the result of the extreme point search.

\[ /X=[x1, x2, \ldots] \]

\[ /XSA=XLimitWave \]

Name of a 2-column wave having number of rows equal to the length of the X vector only when used with simulated annealing (/M={3,0}).

Column zero sets the minimum value allowed for each element of the X vector.

Column one sets the maximum value allowed for each element of the X vector.

Default is ±Xi*10 if Xi is nonzero, or ±1 if Xi is zero. While a default is provided, it is highly recommended that you provide an XLimitWave.

\[ /Y=\text{funcSize} \]

Specifies expected sizes of function values with multivariate functions. If you expect your function will return values very different from one, you should set *funcSize* to the expected size. Optimize will use this value to scale the function results to reduce floating-point truncation error.

### Parameters

func specifies the name of your user-defined function that will be optimized.

pwave gives the name of a parameter wave that will be passed to your function as the first parameter. It is not modified by Igor. It is intended for your private use to pass adjustable constants to your function.

### Function Format

Finding extreme points of a nonlinear function requires that you realize the function as an Igor user function of a certain form. See Finding Minima and Maxima of Functions on page III-323 for detailed examples.

Your function must look like this:

**Function myFunc(w, x1, x2, …)**

**Wave w**

**Variable x1, x2**
return f(x1, x2, ...) // an expression ...
End

A univariate function would have only one X variable.

A multivariate function can use a wave to pass in the X values:

Function myFunc(w,xw)
    Wave w
    Wave xw
    return f(xw) // an expression ...
End

Replace “f(…)” with an appropriate numerical expression.

Univariate Details
The method used by Optimize to find extreme points of univariate functions requires that the point be bracketed before starting. If you don’t use /L and /H to specify the bracketing X values, the defaults are zero and one. Optimize first attempts to find the requested extreme point using the bracketing values (or the default). If that is unsuccessful, it attempts to bracket an extreme point by expanding the bracketing interval. If a suitable interval is found (the search is by no means perfectly reliable), then the search for an extreme point is made again.

Optimize uses Brent’s method for univariate functions, which requires no derivatives. This combines a quadratic extrapolation with checking for wild results. In the case of wild results (points beyond the best current bracketing values) the method reverts to a golden section bisection algorithm. For well-behaved functions, the quadratic extrapolation converges superlinearly. The golden section bisection algorithm converges more slowly but features global convergence, that is, if an extremum is there, it will be found.

The stopping criterion is

\[
x + \frac{a + b}{2} + \frac{a - b}{2} \leq \frac{2}{3} \text{tol}.
\]

In this expression, \(a\) and \(b\) are the current bracketing values, and \(x\) is the best estimate of the extreme point within the bracketing interval.

The left side of this expression works out to being simply the distance from the current solution to the boundary of the bracketing interval.

Note: Optimizing a univariate function with the simulated annealing method (/M=[3,0]) works like a multivariate function, and this section does not apply. See the sections devoted to simulated annealing.

Multivariate Details
With multivariate functions, Optimize scales certain quantities to reduce floating point truncation error. You enter scaling factors using the /R and /Y flags. The /R flag specifies the expected magnitude of X values; Optimize then uses \(X_i/\text{typ}X_i\) in all calculations. Likewise, /Y specifies the expected magnitude of function values.

This scaling can be important for maintaining accuracy if your X’s or Y’s are very different from one, and especially if your X’s have values spanning orders of magnitude.

The Optimize operation uses a quasi-Newton method with derivatives estimated numerically. The function gradient is calculated using finite differences. For estimation of the Hessian (second derivative matrix) you can use either a secant method (hessMethod = 0) or finite differences (hessMethod = 1). The finite difference method gives a more accurate estimate and may succeed with difficult functions but requires more function evaluations per iteration. The finite difference method’s greater accuracy may reduce the total number of iterations required, so the overall number of function evaluations depends on details of the problem being solved. Usually the secant method requires fewer function evaluations and is preferred for functions that are expensive to evaluate.

Once a Newton step is calculated, there are three choices for the method used to find the best next value-line search along the Newton direction (stepMethod = 0), double dogleg (stepMethod = 1), or More-Hebdon (stepMethod = 2). The best method can be found only by experimentation. See Dennis and Schnabel (cited in References) for details.

The /F=trustRegion, /S=stepMax and /T=\{…, stepTol\} all refer to scaled step sizes. That is,
Optimize

\[ stepX_i = \frac{|\Delta x_i|}{\max(|x_i|, typX_i)}. \]

The Optimize operation presumes that an extreme point has been found when either the gradient at the latest point is less than \(\text{gradTol}\) or when the last step taken was smaller than \(\text{stepTol}\). These criteria both refer to scaled quantities:

\[
\max_{1 \leq i \leq n} \left\{ \max \left( \frac{|g_i|}{\max(|f|, \text{funcSize})}, \frac{|\Delta x_i|}{\max(|x_i|, \text{typX}_i)} \right) \right\} \leq \text{gradTol},
\]

or

\[
\max_{1 \leq i \leq n} \left\{ \frac{|g_i|}{\max(|f|, \text{funcSize})}, \frac{|\Delta x_i|}{\max(|x_i|, \text{typX}_i)} \right\} \leq \text{stepTol}.
\]

**Simulated Annealing Introduction**

The simulated annealing or Metropolis algorithm optimizes a function using a random search of the X vector space. It does not use derivatives to guide the search, making it a good choice if the function to be optimized is in some way poorly behaved. For instance, it is a good method for functions with discontinuities in the function value or in the derivatives.

Simulated annealing also has a good chance of finding a global minimum or maximum of a function having multiple local minima or maxima.

Because simulated annealing uses a random search method, it may require a large number of function evaluations to find a minimum, and it is not guaranteed that it will stop at an actual minimum. For these reasons, it is best to use one of the other methods unless those methods have failed.

The simulated annealing method generates new trial solutions by adding a random vector to the current X vector. The elements of the random vector are set to \(\text{stepsize}_i \cdot R_i\), where \(R_i\) is a random number in the interval \((-1, 1)\). As the solution progresses, the \(\text{stepsize}\) is gradually decreased.

Bad trials, that is, those that change the function value in the wrong direction are accepted with a probability that depends on the simulated temperature. It is this aspect that allows simulated annealing to find a global minimum.

Function values are generated and accepted or rejected for some number of iterations at a given temperature, then the temperature is reduced. The probability of a bad iteration being accepted decreases with decreasing temperature. A too-fast cooling rate can freeze in a bad solution.

**Simulated Annealing Details**

It is highly recommended that you use the XSA flag to specify \(\text{XLimitWave}\). This wave sets bounds on the values of the elements of the X vector during the random search. The defaults may be adequate but are totally \(ad \ hoc\). You are better off to specify bounds that make sense to the problem you are solving.

The values of \(\text{XLimitWave}\) in addition to bounding the search space also scale the X vector during computations of probabilities, temperatures, etc. Consequently, the X limits can affect the performance of the algorithm.

A large number of iterations is required to have a good probability of finding a reasonable solution.

It is recommended that you set the initial temperature to zero so that Optimize can estimate a good initial temperature. If you can’t afford the 100 function evaluations required, you probably shouldn’t be using simulated annealing.

Optimize uses an exponential cooling schedule in which \(T_{i+1} = \text{CoolingRate} \cdot T_i\) (see the /TSA flag). \(\text{CoolingRate}\) must be in the range 0 to 1. A fast cooling rate (small value of \(\text{CoolingRate}\)) can cause simulated quenching; that is, a bad solution can be frozen in. Very slow cooling will result in slow convergence.

When simulated annealing is selected, the optimization is treated as multivariate even if your function has only a single X input. That is, the output variables and waves are the ones listed under multivariate functions.
Optimize

Variables and Waves for Output
The Optimize operation reports success or failure via the V_flag variable. A nonzero value is an error code.

Variables for a univariate function:

V_flag
0: Search for an extreme point was successful.
57: User abort.
785: Function returned NaN.
786: Unable to find bracketing values for an extreme point.

If you searched for a minimum:

V_minloc X value at the minimum.
V_min Function value (Y) at the minimum.

If you searched for a maximum:

V_maxloc X value at the maximum.
V_max Function value (Y) at the maximum.

For simulated annealing only:

V_SANumIncreases Number of “bad” iterations accepted.
V_SANumReductions Number of iterations resulting in a better solution.

Variables for a multivariate function:

V_flag
0: Search for an extreme point was successful.
57: User abort.
788: Iteration limit was exceeded.
789: Maximum step size was exceeded in five consecutive iterations.
790: The number of points in the typical X size wave specified by /R does not match the number of X values specified by the /X flag.
791: Gradient nearly zero and no iterations taken. This means the starting point is very nearly a critical point. It could be a solution, or it could be so close to a saddle point or a maximum (when searching for a minimum) that the gradient has no useful information. Try a slightly different starting point.

V_OptTermCode Indicates why Optimize stopped. This may be useful information even if V_flag is zero. Values are:
1: Gradient tolerance was satisfied.
2: Step size tolerance was satisfied.
3: No step was found that was better than the last iteration. This could be because the current step is a solution, or your function may be too nonlinear for Optimize to solve, or your tolerances may be too large (or too small), or finite difference gradients are not sufficiently accurate for this problem.
4: Iteration limit was exceeded.
Override

5: Maximum step size was exceeded in five consecutive iterations. This may mean that the maximum step size is too small, or that the function is unbounded in the search direction (that is, goes to -inf if you are searching for a minimum), or that the function approaches the solution asymptotically (function is bounded but doesn’t have a well-defined extreme point).

6: Same as V_flag = 791.

If you searched for a minimum:

V_min Function value (Y) at the minimum.

If you searched for a maximum:

V_max Function value (Y) at the maximum.

Variables for all functions:

V_OptNumIters Number of iterations taken before Optimize terminated.
V_OptNumFunctionCalls Number of times your function was called before Optimize terminated.

Waves for a multivariate function:

W_extremum Solution if you didn’t use /X=xWave>. Otherwise the solution is returned in your X wave.
W_OptGradient Estimated gradient of your function at the solution.

See Also
Finding Minima and Maxima of Functions on page III-323 for further details and examples.

References
The Optimize operation uses Brent’s method for univariate functions. Numerical Recipes has an excellent discussion (see section 10.2) of this method (but we didn’t use their code):

For multivariate functions Optimize uses code based on Dennis and Schnabel. To truly understand what Optimize does, read their book:

Override

Override constant objectName = newVal
Override strconstant objectName = newVal
Override Function funcName()

The Override keyword redefines a constant, strconstant, or user function. The objectName or funcName must be the same as the name of the original object or function that is being redefined. The override must be defined before the target object appears in the compile sequence.

See Also
Function Overrides on page IV-104 and Constants on page IV-52 for further details.

p

The p function returns the row number of the current row of the destination wave when used in a wave assignment statement. The row number is the same as the point number for a 1D wave.
p2rect

Details
Outside of a wave assignment statement p acts like a normal variable. That is, you can assign a value to it and use it in an expression.

See Also
Waveform Arithmetic and Assignments on page II-69.

For other dimensions, the q, r, and s functions.
For scaled dimension indices, the x, y, z, and t functions.

p2rect

p2rect(z)
The p2rect function returns a complex value in rectangular coordinates derived from the complex value z which is assumed to be in polar coordinates (magnitude is stored in the real part and the angle, in radians, in the imaginary part of z).

Examples
Assume waveIn and waveOut are complex, then:
waveOut = p2rect(waveIn)
sets each point of waveOut to the rectangular coordinates based on the magnitude in the real part and the angle (in radians) in the imaginary part of the points in waveIn.

You may get unexpected results if the number of points in waveIn differs from the number of points in waveOut.

See Also
The functions cmplx, conj, imag, r2polar, and real.

PadString

PadString(str, finalLength, padValue)
The PadString function returns a string identical to str except that it has been extended to a total length of finalLength using bytes of padValue. Use zero to create a C-language style string or use 0x20 to pad with spaces (FORTRAN style). This is useful when reading or writing binary files using FBinRead and FBinWrite.

See Also
The UnPadString function.

Panel

Panel
Panel is a procedure subtype keyword that identifies a macro as being a control panel recreation macro. It is automatically used when Igor creates a window recreation macro for a control panel. See Procedure Subtypes on page IV-199 and Saving a Window as a Recreation Macro on page II-43 for details.

PanelResolution

PanelResolution(wName)
The PanelResolution function returns the current resolution of the specified panel in pixels per inch. If wName is empty, it returns the current global setting for panel resolution. If wName is the name of a graph window, it returns the resolution for the ControlBar area. wName can be a subwindow specification.

The PanelResolution function was added in Igor Pro 7.00.

In general, PanelResolution and ScreenResolution return the same thing. However, on Windows when the screen resolution is 96 DPI, which is typical for normal-resolution screens, panels can use 72 DPI for compatibility with Igor Pro 6 and earlier.

See Also
Control Panel Resolution on Windows on page III-433, ScreenResolution
ParamIsDefault

**ParamIsDefault**

**ParamIsDefault**(pName)

The ParamIsDefault function determines if an optional user function parameter pName was specified during the function call. It returns 1 when pName is default (not specified) or it returns 0 when it was specified.

**Details**

ParamIsDefault works only in the body of a user function and only with optional parameters. The variable pName must be valid at compile time; you can not defer lookup to runtime with $.

**See Also**

Optional Parameters on page IV-36 and Using Optional Parameters on page IV-60.

ParseFilePath

**ParseFilePath**(mode, pathInStr, separatorStr, whichEnd, whichElement)

The ParseFilePath function provides the ability to manipulate file paths and to extract sections of file paths.

**Parameters**

The meaning of the parameters depends on mode.

<table>
<thead>
<tr>
<th>mode</th>
<th>Information Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Returns the element specified by whichEnd and whichElement. whichEnd is 0 to select an element relative to the beginning of pathInStr, 1 to select an element relative to the end. whichElement is zero-based. Pass &quot;:&quot; if pathInStr is a Macintosh HFS path, &quot;&quot; if it is a Windows path. See Path Separators on page III-429 for details about Macintosh versus Windows paths.</td>
</tr>
<tr>
<td>1</td>
<td>Returns the entire pathInStr, up to but not including the element specified by whichEnd and whichElement. whichEnd is 0 to select an element relative to the beginning of pathInStr, 1 to select an element relative to the end. whichElement is zero-based. Pass &quot;:&quot; if pathInStr is a Macintosh HFS path, &quot;&quot; if it is a Windows path. See Path Separators on page III-429 for details about Macintosh versus Windows paths.</td>
</tr>
<tr>
<td>2</td>
<td>Returns the entire pathInStr with a trailing separator added if it is not already there. This is useful when you have a path to a folder and want to tack on a file name. Pass &quot;:&quot; if pathInStr is a Macintosh HFS path, &quot;&quot; if it is a Windows path. See Path Separators on page III-429 for details about Macintosh versus Windows paths. whichEnd and whichElement are ignored. Pass 0 for them.</td>
</tr>
<tr>
<td>3</td>
<td>Returns the last element of pathInStr with the extension, if any, removed. The extension is anything after the last dot in pathInStr. whichEnd and whichElement are ignored. Pass 0 for them.</td>
</tr>
<tr>
<td>4</td>
<td>Returns the extension in pathInStr or &quot;&quot; if there is no extension. The extension is anything after the last dot in pathInStr. Pass &quot;:&quot; if pathInStr is a Macintosh HFS path, &quot;&quot; if it is a Windows path. See Path Separators on page III-429 for details about Macintosh versus Windows paths. whichEnd and whichElement are ignored. Pass 0 for them.</td>
</tr>
<tr>
<td>5</td>
<td>Returns the entire pathInStr but converts it to a format determined by separatorStr. separatorStr = &quot;:&quot; Converts the path to Macintosh HFS style if it is Windows style. Does nothing to a Macintosh HFS path. separatorStr = &quot;&quot; Converts the path to Windows style if it is Macintosh style. Does nothing to a Windows path.</td>
</tr>
</tbody>
</table>
### ParseFilePath

<table>
<thead>
<tr>
<th>mode</th>
<th>Information Returned</th>
</tr>
</thead>
</table>
| 1    | **separatorStr** = "*"  
Converts the path to the native style of the operating system Igor is running on. Does nothing to a native path. For historical reasons, on Macintosh “native” means colon-separated HFS path, not UNIX path. **separatorStr** = "/"  
Macintosh-only: Converts the Macintosh-style pathInStr input to a Posix (UNIX) path. Unlike the other conversions, the directory or file to which pathInStr refers must exist, otherwise "" is returned. To generate a Posix path for a non-existent file, generate the path for the existing folder and append the file name. This always returns "" on Windows. *whichEnd* and *whichElement* are ignored. Pass 0 for them.  
6 | UNC volume name ("\Server\Share") if pathIn starts with a UNC volume name or "" if not. Pass "*" for **separatorStr**. *whichEnd* and *whichElement* are ignored. Pass 0 for them.  
7 | UNC server name ("Server" from "\Server\Share") if pathIn starts with a UNC volume name or "" if not. Pass "*" for **separatorStr**. *whichEnd* and *whichElement* are ignored. Pass 0 for them.  
8 | UNC share name ("Share" from "\Server\Share") if pathIn starts with a UNC volume name or "" if not. Pass "*" for **separatorStr**. *whichEnd* and *whichElement* are ignored. Pass 0 for them.  
9 | Macintosh only. On Windows this mode returns an error. Returns a Posix version of pathInStr which must be a full HFS path pointing to an existing volume, directory or file. This is the same as mode 5 except that **separatorStr** must be "*". *whichEnd* and *whichElement* are ignored. Pass 0 for them. You would typically use this mode when you are about to execute a Unix command, which requires Posix paths, via ExecuteScriptText. This mode was created in Igor Pro 7.00 to provide an alternative to the obsolete HFSToPosix function provided by the HSFAndPosix XOP. With HFSToPosix, if the input path referred to a directory, the output always ended with a slash. With ParseFilePath(9), the output will end with a slash only if the input path ends with a colon.  
10 | Macintosh only. On Windows this mode returns an error. Returns the HFS path corresponding to the Posix path in pathInStr. pathInStr must be a full Posix path starting with a slash character. It does not need to point to an existing directory or file. The returned path may or may not refer to an existing volume, folder or file, depending on pathInStr. Pass "*" for **separatorStr**. *whichEnd* and *whichElement* are ignored. Pass 0 for them. You would typically use this mode when you receive a Posix path from a Unix command executed via ExecuteScriptText and you want to use that path in Igor. This mode was created in Igor Pro 7.00 to provide an alternative to the obsolete PosixToHFS function provided by the HSFAndPosix XOP. |
Details
When dealing with Windows paths, you need to be aware that Igor treats the backslash character as an escape character. When you want to put a backslash in a literal string, you need to use two backslashes. See Escape Sequences in Strings on page IV-15 and Path Separators on page III-429 for details.

On Windows two types of file paths are used: drive-letter paths and UNC (“Universal Naming Convention”) paths. For example:

// This is a drive-letter path.
C:\Program Files\WaveMetrics\Igor Pro Folder\WaveMetrics Procedures

// This is a UNC path.
\\BigServer\SharedApps\WaveMetrics\Igor Pro Folder\WaveMetrics Procedures

In this example, ParseFilePath considers the volume name to be C: in the first case and \BigServer\SharedApps in the second. The volume name is treated as one element by ParseFilePath, except for modes 7 and 8 which permit you to extract the components of the UNC volume name.

Except for the leading backslashes in a UNC path, ParseFilePath modes 0 and 1 internally strip any leading or trailing separator (as defined by the separatorStr parameter) from pathInStr before it starts parsing. So if you pass ":Igor Pro Folder:WaveMetrics Procedures:", it is the same as if you had passed "Igor Pro Folder:WaveMetrics Procedures".

If there is no element corresponding to whichElement and mode is 0, ParseFilePath returns "".

If there is no element corresponding to whichElement and mode is 1, ParseFilePath returns the entire pathInStr.

Examples
String pathIn, pathOut

// Full path
pathIn= "hd:Igor Pro Folder:WaveMetrics Procedures:Waves:Wave Lists.ipf"

// Extract first element.
Print ParseFilePath(0, pathIn, ":", 0, 0) // Prints "hd"

// Extract second element.
Print ParseFilePath(0, pathIn, ":", 0, 1) // Prints "Igor Pro Folder"

// Extract last element.
Print ParseFilePath(0, pathIn, ":", 1, 0) // Prints "Wave Lists.ipf"

// Extract next to last element.
Print ParseFilePath(0, pathIn, ":", 1, 1) // Prints "Waves"

// Get path to folder containing the file.
Print ParseFilePath(1, pathIn, ":", 1, 0)

// Extract the file name without extension.
Print ParseFilePath(3, pathIn, ":", 0, 0) // Prints "Wave Lists"

// Extract the extension.
Print ParseFilePath(4, pathIn, ":", 0, 0) // Prints "ipf"

// Make sure the given path ends with a colon and concatenate file name.
String path = "routine that returns a Macintosh-style path to a folder"
path = ParseFilePath(path, ":", 0, 0)
path += "AFile.txt"

See Also

ParseOperationTemplate

ParseOperationTemplate [flags] cmdTemplate

The ParseOperationTemplate operation helps XOP programmers and WaveMetrics programmers write code to implement Igor operations. If you are not an XOP programmer nor a WaveMetrics programmer, it will be of no interest.

ParseOperationTemplate generates starter code for programmers who are creating Igor operations. The starter code is copied to the clipboard, overwriting any previous clipboard contents.
ParseOperationTemplate

Flags

/C=c  If c is nonzero, ParseOperationTemplate stores code for your ExecuteOperation and RegisterOperation functions in the clipboard.
   c=0: Do not generate code
   c=1: Generate simplified C code - not recommended
   c=2: Generate C code
   c=6: Generate C++ code

The only difference between /C=6 and /C=2 is that the ExecuteOperation function is declared as extern "C" instead of static. C++ files that use static work fine although extern "C" is correct.

/S=s  Stores a definition of your runtime parameter structure in the clipboard if s is nonzero.
   s=0: Do not generate the runtime parameter structure
   s=1: Use your mnemonic names - recommended
   s=2: Automatically generate mnemonic names - not recommended

We recommend that you use /S=1 and provide unique mnemonic parameter names in your template. ParseOperationTemplate then uses your parameter names as structure field names.

If you use /S=2, ParseOperationTemplate creates unique field names by concatenating flag or keyword text and your mnemonic names. This is left over from the early days of Operation Handler and is not recommended.

/T  Stores a comment listing your command template in the clipboard.

/TS  Identifies a ThreadSafe operation by adding an extra field to the runtime parameter structure. This is only of use to WaveMetrics programmers.

Parameters

cmdTemplate is the template that describes the syntax for your operation. See the Igor XOP Toolkit Reference Manual for details.

Details

ParseOperationTemplate parses your command template, generating structures that embody the syntax of your operation. It then uses these structures to generate code that can serve as a starting point for implementing your operation. The starter code is stored in the clipboard.

For most uses, the recommended flags are:

/T/S=1/C=2  // For non-threadsafe operations
/T/S=1/C=2/TS  // For threadsafe operations

ParseOperationTemplate sets the following output variable, but only when called from a function or macro:

V_flag
   0: cmdTemplate was successfully parsed.
   -1: cmdTemplate was not successfully parsed.

If V_flag is nonzero, this indicates that your cmdTemplate syntax is incorrect. See the Igor XOP Toolkit Reference Manual for details.

Examples

Function Test()
   String cmdTemplate
   cmdTemplate = "MyTest"
   cmdTemplate += " /A={number:aNum1,string:aStrH}"
   cmdTemplate += " /B=wave:bWaveH"
   cmdTemplate += " key1={name:k1N1[,wave:k1WaveH,name:k1N2,string[2]:k1StrHArray]}"

   // If your XOP is C instead of C++, use /C=2 instead of /C=6
   TestOperationParser/T/S=1/C=6 cmdTemplate
PathInfo

PathInfo [/S /SHOW pathName]

The PathInfo operation stores information about the named symbolic path in the following variables:

- \texttt{V\_flag}: 0 if the symbolic path does not exist, 1 if it does exist.
- \texttt{S\_path}: The full path (e.g., "hd:This:That:").

The path returned is a colon-separated path which can be used on Macintosh or Windows. See Path Separators on page III-429 for details.

Flags

- **/S**: Presets the next otherwise undirected open or save file dialog to the given disk folder. This flag is ignored when PathInfo is called from a preemptive thread.
- **/SHOW**: Shows the folder, if it exists, in the Finder (Mac OS X) or Windows Explorer (Windows). This flag is ignored when PathInfo is called from a preemptive thread.

Details

The use of PathInfo in a preemptive thread requires Igor Pro 8.00 or later.

Examples

// The following lines perform equivalent actions:
PathInfo/S myPath;Open refNum
Open/P=myPath refNum

// Show Igor's Preferences folder in the Finder/Windows Explorer.
String fullpath= SpecialDirPath("Preferences",0,0,0)
NewPath/O/Q tempPathName, fullpath
PathInfo/SHOW tempPathName

Symbolic Paths on page II-21.

The \texttt{NewPath}, \texttt{GetFileFolderInfo}, \texttt{ParseFilePath} and \texttt{SpecialDirPath} operations.

PathList

PathList(matchStr, separatorStr, optionsStr)

The PathList function returns a string containing a list of symbolic paths selected based on the \texttt{matchStr} parameter.

Details

For a path name to appear in the output string, it must match \texttt{matchStr}. \texttt{separatorStr} is appended to each path name as the output string is generated.

PathList works like the WaveList function, except that the \texttt{optionsStr} parameter is reserved for future use. Pass "" for it.

Examples

When a new experiment is created there is only one path:
Print PathList("**",";","")

Prints the following in the history area:

Igor;
**PauseForUser**

See Also
The WaveList function for an explanation of the matchStr and separatorStr parameters and for examples. See also Symbolic Paths on page II-21 for an explanation of symbolic paths.

**PauseForUser**

`PauseForUser [/C] mainWindowName [, targetWindowName]`

The PauseForUser operation pauses function execution to allow the user to manually interact with a window. For example, you can call PauseForUser from a loop to allow the user to move the cursors on a graph. In this scenario, targetWindowName would be the name of the graph and mainWindowName would be the name of a control panel containing a message telling the user to adjust the cursors and then click, for example, the Continue button.

If targetWindowName is omitted then mainWindowName plays the role of target window.

PauseForUser works with graph, table, and panel windows only.

**Flags**

/C Tells PauseForUser to return immediately after handling any pending events. See Details.

**Details**

During execution of PauseForUser, only mouse and keyboard activity directed toward either mainWindowName or targetWindowName is allowed.

While waiting for user action, PauseForUser disables double-clicks and any contextual menus that can lead to dialogs in order to prevent changes on the command line. It also disables killing windows by clicking the close icon in the title bar unless the window was originally created with the /K=1 flag (kill with no dialog).

If /C is omitted, PauseForUser returns only when the main window has been killed.

If /C is present, PauseForUser handles any pending events, sets V_Flag to the truth the target window still exists, and then returns control to the calling user-defined function. Use PauseForUser/C in a loop if you need to do something while waiting for the user to finish interacting with the target window, such as updating a progress indicator.

As of Igor Pro 8.00, the PauseForUser operation is allowed only in user-defined functions. It returns an error if called from a macro or from the command line.

See Also
Pause For User on page IV-146 for examples and further discussion.

**PauseUpdate**

**PauseUpdate**

The PauseUpdate operation delays the updating of graphs and tables until you invoke a corresponding ResumeUpdate command.

**Details**

PauseUpdate is useful in a macro that changes a number of things relating to the appearance of a graph. It prevents the graph from being updated after each change. Its effect ends when the macro in which it occurs ends. It also affects updating of tables.

This operation is not allowed from the command line. It is allowed but has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the DoUpdate operation.

See Also
The DelayUpdate, DoUpdate, ResumeUpdate, and Silent operations.
PCA

PCA [flags] [wave0, wave1,... wave99]

The PCA operation performs principal component analysis. Input data can be in the form of a list of 1D waves, a single 2D wave, or a string containing a list of 1D waves. The operation can produce multiple output waves depending on the specified flags.

Flags

/ALL Shortcut for the combination of commonly used flags: /CVAR, /SL, /NF, /IND, /IE, and /RMS.

/COV Calculates the input wave(s) covariance matrix, which as the input for the remainder of the analysis. The covariance matrix is computed by first creating a matrix copying each input 1D wave into sequential columns and then multiplying that matrix by its transpose.

/CVAR Computes the cumulative percent variance defined as 100 * sum of first m eigenvalues divided by the sum of all eigenvalues. The results are stored in the wave W_CumulativeVAR in the current data folder. See also /VAR.

/IE Computes the imbedded error. Returns errors in the wave W_IE in the current data folder. The wave is scaled using SetScale/P x 1,1,"", W_IE. The imbedded error is a function of the number of factors, the number of rows and columns and the sum of the eigenvectors not included in the significant factors. The behavior of IE determines the number of significant factors.

/IND Computes the factor indicator function. Note that if you specify /IND the residual standard deviation will also be calculated. Returns results in the wave W_IND in the current data folder. The wave is scaled using SetScale/P x 1,1,"", W_IND.

/LEIV Limits eigenvalues so that the SVD calculation does not require too much memory. The limit is set to the minimum of the number of rows or columns of the input.

/NF Finds the number of significant factors and stores it in the variable V_npnts. You must use /IND in order to compute the significant factors.

/O Overwrites input waves.

/Q Suppresses printing of factors in the history area.

/RSD[=rsdMode] Computes the Residual Standard Deviation (RSD) and returns the RSD in the wave W_RSD in the current data folder. The first element in W_RSD is NaN and all remaining wave elements correspond to the number of significant factors.

rsdMode =0: Covariance about the origin.

rsdMode =1: Correlation about the origin.

/RMS Computes the RMS error. Returns results in the wave W_RMS in the current data folder. The wave is scaled using SetScale/P x 1,1,"", W_RMS.

/SCMT Saves C matrix after the singular value decomposition (SVD) in the wave M_C in the current data folder.

/SCR Converts the individual wave input into standard scores. Does not work when the input is a single 2D wave. It is an error to convert to standard scores when one or more entries in the waves are NaN or INF. If you use this feature make sure to use the appropriate form of the RSD calculation.

/SDM Saves a copy of the data matrix at the end of the calculation. This is useful if your input consists of individual waves or if you want to save the computed standard scores. If the input is a 2D matrix, you will get a copy of the input matrix in the wave M_D.

/SEVC Saves the eigenvalue vector in the wave W_Eigen, which are the raw eigenvalues generated by the SVD, in the current data folder. Normally, if the SVD was applied to a raw data matrix, i.e., not covariance or correlation matrix, you must square each element of the wave to obtain the PCA eigenvalues. Note that this wave has default wave scaling.
Details
The input is either via /WSTR=waveListStr or a list of up to 100 1D waves or a single 2D wave following the last flag.

waveListStr is string containing a semicolon-separated list of 1D waves to be used for the data matrix.
waveListStr can include any legal path to a wave. Liberal names can be quoted or not quoted. It is assumed that all waves are of the same numerical type (either single or double precision) and that all waves have the same number of points.

Regardless of the inputs, the operation expects that the number of rows in the resulting matrix is greater than or equal to the number of columns.

The operation starts by creating the data matrix from the input wave(s). If you provide a list of 1D waves they become the columns of the data matrix. You can choose to use the covariance matrix (/COV) as the data matrix and you can also choose to normalize each column of the data matrix to convert it into standard scores. This involves computing the average and standard deviation of each column and then setting the new values to be:

$$newValue = \frac{oldValue - colAverage}{colStdv}.$$ 

You can pre-process the input data using MatrixOp with the SubtractMean, NormalizeRows, and NormalizeCols functions.

After creating the data matrix the operation computes the singular value decomposition (SVD) of the data matrix. Results of the SVD can be saved or processed further. Save the C and R matrices using /SCMT and /SRMT. These are related to the input data matrix through: \( D = R \cdot C \).

The remainder of the operation lets you compute various statistical quantities defined by Malinowski (see References). Use the flags to determine which ones are computed.

The operation generates a number of output waves. All waves are stored in the current data folder.

You can save the input matrix D in the wave M_D, the optional SVD results are stored in the waves M_C that contains the column matrix C, M_R that contains the row matrix R, and W_Eigen that contains the eigenvalues of the data matrix. Note that these can be the eigenvalues or the square of the eigenvalues depending on the input matrix being a covariance matrix or not (see /SQEV).

The optional 1D output waves (W_RSD, W_RMS, W_IE, W_IND, W_PSL) are saved with wave scaling to make it easier to display the wave as a function of the number of factors.

References

ICA

**pcsrs**

```plaintext
pcsrs(cursorName [, graphNameStr])
```

The pcsr function returns the point number of the point which the specified cursor (A through J) is on in the top (or named) graph. When used with cursors on images or waterfall plots, pcsr returns the row number, and when used with a free cursor, it returns the relative X coordinate.

**Parameters**

cursorName identifies the cursor, which can be cursor A through J.

graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with graphNameStr, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Details**
The pcsr result is not affected by any X axis.

**See Also**
The hcsr, qcsr, vcsr, xcsr, and zcsr functions.

**Programming With Cursors** on page II-256.

**Pi**

Pi

The Pi function returns π (3.141592...).

**PICTInfo**

```
PICTInfo(pictNameStr)
```

The PICTInfo function returns a string containing a semicolon-separated list of information about the named picture. If the named picture does not exist, then "" is returned. Valid picture names can be found in the Pictures dialog.

**Details**
The string contains six pieces of information, each prefaced by a keyword and colon and terminated with a semicolon.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTES</td>
<td>Amount of memory used by the picture.</td>
</tr>
<tr>
<td>WIDTH</td>
<td>Width of the picture in pixels.</td>
</tr>
<tr>
<td>HEIGHT</td>
<td>Height of the picture in pixels.</td>
</tr>
<tr>
<td>PHYSWIDTH</td>
<td>Physical width of the picture in points.</td>
</tr>
<tr>
<td>PHYSHEIGHT</td>
<td>Physical height of the picture in points.</td>
</tr>
</tbody>
</table>

**Examples**

Print PICTInfo("PICT_0")

will print the following in the history area:

```
TYPE:PICT;BYTES:55734;WIDTH:468;HEIGHT:340;PHYSWIDTH:468;PHYSHEIGHT:340;
```

**See Also**
The ImageLoad operation for loading PICT and other image file types into waves, and the PICTList function. The StringFromList operation for parsing the information string.
PICTList

See Pictures on page III-481 and Pictures Dialog on page III-482 for general information on picture handling.

PICTList

PICTList(matchStr, separatorStr, optionsStr)
The PICTList function returns a string containing a list of pictures based on matchStr and optionsStr parameters. See Details for information on listing pictures in graphs, panels, layouts, and the picture gallery.

Details
For a picture name to appear in the output string, it must match matchStr and also must fit the requirements of optionsStr. separatorStr is appended to each picture name as the output string is generated.

The name of each picture is compared to matchStr, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

- "*" Matches all picture names.
- "xyz" Matches picture name xyz only.
- "*xyz" Matches picture names which end with xyz.
- "xyz*" Matches picture names which begin with xyz.
- "*xyz*" Matches picture names which contain xyz.
- "abc*xyz" Matches picture names which begin with abc and end with xyz.

matchStr may begin with the ! character to return windows that do not match the rest of matchStr. For example:

- "!*xyz" Matches picture names which do not end with xyz.

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of matchStr.

optionsStr is used to further qualify the picture.

Use "" accept all pictures in the Pictures Dialog that are permitted by matchStr.

Use the WIN: keyword to limit the pictures to the named or target window:

- "WIN:" Match all pictures displayed in the top graph, panel, or layout.
- "WIN:windowName" Match all pictures displayed in the named graph, panel, or layout window.

Examples

- PICTList("*", ";", "") Returns a list of all pictures in the Pictures Dialog.
- PICTList("*", ";", "WIN:" ) Returns a list of all pictures displayed in the top panel, graph, or layout.
- PICTList("*_bkg", ";", "WIN:Layout0") Returns a list of pictures whose names end in "_bkg" and which are displayed in Layout0.

See Also
The ImageLoad operation for loading PICT and other image file types into waves, and the PICTInfo function. Also the StringFromList function for retrieving items from lists.

See Pictures on page III-481 and Pictures Dialog on page III-482 for general information on picture handling.
The Picture keyword introduces an ASCII code picture definition of binary image data.

See Also
Proc Pictures on page IV-57 for further information.

PixelFromAxisVal

PixelFromAxisVal(graphNameStr, axNameStr, val)
The PixelFromAxisVal function returns the local graph pixel coordinate corresponding to the axis value in the graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

If the specified axis is not found and if the name is "left" or "bottom" then the first vertical or horizontal axis will be used.

If graphNameStr references a subwindow, the returned pixel value is relative to top left corner of base window, not the subwindow.

See Also
The AxisValFromPixel and TraceFromPixel functions.

PlayMovie

PlayMovie [flags] [as fileNameStr]
The PlayMovie operation opens a movie file in a window and plays it.

Parameters

The file to be opened is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-429 for details on forming the path.

On Windows the file is passed to the operating system to be opened with the default program for the given filename extension and the /W flag is ignored.

On Macintosh, QuickTime is use to play the movie and the playback can be controlled using PlayMovieAction. However, QuickTime has been deprecated and this feature may be removed in the future.

Flags

/I Coordinates are in inches.

/M Coordinates are in centimeters.

/P=pathName Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

/W=(left,top,right,bottom) Sets the initial coordinates of the movie window (in points unless /I or /M are used before /W).

/Z No error reporting; an error is indicated by nonzero value of the variable V_flag. If the user clicks the cancel button in the Open File dialog, V_flag is set to -1.
PlayMovieAction

Details
Coordinates are the initial coordinates of the movie window in points unless /I or /M are used before /W. Only the top and left coordinates are used. The window has the standard width and height for movies.

If either the path or fileNameStr is omitted then PlayMovie will bring up a dialog to let you find a movie file. If both are present, PlayMovie opens the file automatically.

If you use /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See Symbolic Paths on page II-21 for details.

Any movie file can be played, not just movies made by Igor. There is no limit on the number of movie windows opened for playing.

Movie windows are considered transient and are not restored when an experiment is reopened.

See Also
Movies on page IV-238.
The PlayMovieAction operation.

PlayMovieAction [/A/Z] keyword [=value] [, keyword [=value]]
On Macintosh PlayMovieAction operates on the top movie window, opened via PlayMovie, or on a movie file opened via the open keyword (requires Igor Pro 7.00 or later).

On Windows only movies opened via the open keyword are supported.

If the /Z flag is present, errors are not fatal. V_flag is set to error return regardless.

If the /A flag is present, alternate deprecated technology is used. On Windows the old is AVI and the new is MMF. On Macintosh, the old is QuickTime and the new is AVFoundation. The new technology on both platforms, but especially Macintosh, has dropped support for many of the codecs used by the old technology. If you have a movie file that can not be used, try using the /A flag.

Parameters
extract Extracts current frame into an 8-bit RGB image wave named M_MovieFrame. (Can be combined with frame=f.)
extract=e Extracts e frames into a single multiframe wave, M_MovieChunk. This wave will have 3 planes for RGB and will have e chunks.
  e=1 is the same as plain extract.
  For e>1, the current time is automatically updated.
frame=f Moves to specified movie frame (and stops movie).
getID Returns top movie ID number in V_Value. Do not use in same call with getTime.
getTime Reads current movie time into variable V_value (in seconds).
gotoBeginning Goes to beginning of movie.
gotoEnd Goes to end of movie.
kills Kills movie window or closes open movie window.
loop=mode On Macintosh only, when used with the open keyword, mode chooses between two extraction methods. The default, equivalent to loop=0, is fast but can not back up; an attempt to extract a frame previous to the last one extracted results in an error. The alternate method, loop=1, provides random access but can be very slow when reading sequential frames.
  The loop keyword was added in Igor Pro 8.00. It is ignored on Windows.
### PlayMovieAction

| **open=fullPath** | Opens the specified movie file to enable frame extraction. No movie window is involved. V_Flag is set to zero if no error occurred and V_Value is set to the file reference number. Prior to Igor Pro 7 the open keyword was supported on Windows only. It now also works on Macintosh. Prior to Igor Pro 7, the ref keyword was required for PlayMovieAction calls after the open keyword. Now it is needed only if multiple files or windows are open. Even then, you can use setFrontMovie to set the active movie window. |
| **ref=refNum** | The ref keyword is used with all PlayMovieAction commands after using the open keyword to access a movie file. refNum must be the file reference number returned in V_Value in the open step. Prior to Igor Pro 7 the ref keyword was supported on Windows only. It now also works on Macintosh. |
| **setFrontMovie= id** | Sets movie with given id as top window or active file. Error if no such window or file (use /Z to suppress errors). Do not use in same call with getID. |
| **start** | Starts movie playing. The start keyword works on Macintosh only and only with movie windows, not with files. |
| **step=s** | Moves by s frames into movie (0 is same as 1, negative values move backwards). |
| **stop** | Stops movie. The stop keyword works on Macintosh only and only with movie windows, not with files. |

#### Flags

| **/Z** | No error reporting; an error is indicated by nonzero value of the variable V_flag. |

#### Details

Operations are performed in the following order: kill, stop, gotoBeginning, gotoEnd, frame, step, getTime, extract, start. Kill overrides all other parameters.

If you want to extract a grayscale image, you can convert the RGB image into grayscale using the ImageTransform command as follows:

```
PlayMovieAction extract
ImageTransform rgb2gray M_MovieFrame
NewImage M_RGB2Gray
```

The open and ref keywords support extracting frames from files without the need for an open movie window. Prior to Igor Pro 7, this was a Windows only feature. It now also works on Macintosh.

When accessing a file using the open keyword, none of the keywords related to movie windows or playing a movie are supported.

When you are finished extracting frames, use the kill keyword to close the file.

To get a full path for use with the open keyword, use the PathInfo or Open /D/R commands.

#### Examples

These commands show to determine the number of frames in a simple movie:

```
PlayMovieAction open = <full path to movie file>
PlayMovieAction stop,gotoEnd,getTime
Variable tend= V_value
PlayMovieAction step=-1,getTime
Print "frames= ", tend/(tend-V_value)
PlayMovieAction kill
```

#### See Also

Movies on page IV-238.
PlaySnd

The PlayMovie operation.

PlaySnd

PlaySnd [flags] fileNameStr

Note: PlaySnd is obsolete. Use PlaySound instead.

Available only on the Macintosh.

The PlaySnd operation plays a sound from the file’s data fork, or from an ‘snd’ resource.

Parameters

The file containing the sound is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-429 for details on forming the path.

Flags

/I=resourceIndex Specifies the ‘snd’ resource to load by resource index, starting from 1.

/M=promptStr Specifies a prompt if PlaySnd needs to put up a dialog to find the file.

/N=resNameStr Specifies the resource to load by resource name.

/P=pathName Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

/Q Quiet: suppresses the insertion of ‘snd’ info into the history area.

/R=resourceID Specifies the ‘snd’ resource to load by resource ID.

/Z Does not play the sound, just checks for its existence.

Details

If none of /I, /N or /R are specified, PlaySnd tries to play a sound stored in the data fork of the file. If the file dialog is used, only files of type ‘sfil’ are shown.

If any of /I, /N or /R are specified, PlaySnd tries to play a sound from an ‘snd’ resource. Most programs store sounds in ‘snd’ resources. If the file dialog is used, files of all types are shown.

If /P=pathName is omitted, then fileNameStr can take on three special values:

“Clipboard” Loads data from Clipboard.

“System” Loads data from System file.

“Igor” Loads data from Igor Pro application.

If you specify /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See Symbolic Paths on page II-21 for details.

There are no sounds in the Igor Pro application file.

If the file is not fully specified and fileNameStr is not one of these special values, then PlaySnd presents a dialog from which you can select a file. “Fully specified” means that Igor can determine the name of the file (from the fileNameStr parameter) and the folder containing the file (from the /P=pathName flag or from the fileNameStr parameter).

PlaySnd sets the variable V_flag to 1 if the sound exists and fits in available memory or to 0 otherwise.

If the sound exists, PlaySnd also sets the string variable S_Info to:

"SOURCE: sourceName; RESOURCENAME: resourceName; RESOURCEID: resourceID"

If the sound is not a resource then resourceName is "" and resourceID is 0. sourceName will be the name of the file that was loaded or “Clipboard”, “System” or “Igor”.

V-678
Examples

PlaySnd/I=1/P=mySnds/Z "Wild Eep"
If (V_flag) // Any 'snd ' in the "Wild Eep" file?
  Print S_info // Yes, print resource number, etc.
Endif

This prints the following into the history area:
SOURCE:resource fork;RESOURCENAME:Wild Eep;RESOURCEID:8;

PlaySound

PlaySound [/A=\a] /C soundWave
PlaySound /A=\a \{soundWave1, soundWave2 [...], soundWaveN...\}

The PlaySound operation plays the audio samples in the named wave. The various sound output parameters — number of samples, sample rate, number of channels, and number of bits of resolution — are determined by the corresponding parameters of the wave.

Flags

/A=\a
Plays sounds asynchronously so that sounds will continue to play after the command itself has executed.
/A=0: Same as no /A flag.
/A=1: Plays sounds asynchronously; same as /A.
/A=2: Stop playing any current sound before starting this one.
/A=3: Return with user abort error if output buffers are full (rather than waiting.) Use GetRTErrror(1) to detect and clear the error condition.

/C
Obsolete - do not use.
On Windows /C causes sound wave data greater than 16-bits to be converted to 16-bit integer. Such data should range from -32768 to +32767.
On Macintosh /C is ignored.

Details

The wave's time per point, as determined by its X scaling, must be a valid sampling rate. A value of 1/44100 (CD standard) is typical.

Sound waves should be 16 bit integers with a range of -32768 to +32767. On Macintosh as of Igor version 6.11, 32-bit floating point data with a range of -1 to +1 can also be used. For backward compatibility, 8-bit integer data with a range of -128 to +127 is also supported.

With the /A flag, the sound plays asynchronously (i.e., the command returns before the sound is finished). If another command is issued before the sound is finished then the new command will wait until the last sound finishes. A PlaySound without the /A flag can play on top of the current sound. The transition between sounds should be seamless on Macintosh but may be slightly delayed on Windows.

It is OK to kill a sound wave immediately after PlaySound returns even if the /A flag is used.

To play a stereo sound, provide a 2 column wave with the left channel in column 0. Actually, the software will attempt to play as many channels as there are columns in the wave. You can also use multiple 1D waves with the /A flag. To use this method, enclose the list of 1D waves in braces

Note: The SoundInput operations provide matching sound recording capabilities. See the SoundInStatus operation.

Examples

Under Windows, support for sound is somewhat idiosyncratic so these sound examples may not work correctly with your particular hardware configuration.

Make/B/C/N=1000 sineSound // 8 bit samples
SetScale/P x,0,1e-4,sineSound // Set sample rate to 10Khz
sineSound= 100*sin(2*Pi*1000*x) // Create 1Khz sinewave tone
PlaySound sineSound

The following example will create a rising pitch in the left channel and a falling pitch in the right channel.
Multichannel sounds as in the previous example but from multiple 1D waves:

```plaintext
Make/W/O/N=(20000,2) stereoSineSound // 16 bit data
SetScale/P x,0,1e-4,stereoSineSound // Set sample rate to 10Khz
stereoSineSound= 20000*sin(2*Pi*(1000 + (1-2*q)*150*x)*x)
PlaySound/A stereoSineSound // 16 bit, asynchronous
```

See Also
SoundLoadWave, SoundSaveWave

---

**pnt2x**

`pnt2x(waveName, pointNum)`

The `pnt2x` function returns the X value of the named wave at the point `pointNum`. The point number is truncated to an integer before use.

For higher dimensions, use `IndexToScale`.

**Details**

The result is derived from the wave’s X scaling, not any X axis of a graph it may be displayed in.

If you would like to convert a fractional point number to an X value you can use:

```
leftx(waveName) + deltax(waveName) * pointNum.
```

**See Also**
DimDelta, DimOffset, x2pnt, IndexToScale

**Waveform Model of Data** on page II-57 and **Changing Dimension and Data Scaling** on page II-63 for an explanation of waves and dimension scaling.

---

**Point**

The Point structure is used as a substructure usually to store the location of the mouse on the screen.

```
Structure Point
  Int16 v
  Int16 h
EndStructure
```

**PointF**

The PointF structure is the same as `Point` but with floating point fields.

```
Structure Point
  float v
  float h
EndStructure
```

---

**poissonNoise**

`poissonNoise(num)`

The `poissonNoise` function returns a pseudo-random value from the Poisson distribution whose probability distribution function is

```
f(x; λ) = \frac{e^{-λ}λ^x}{x!},
```

with mean and variance equal to `numI (= λ)`.

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use `SetRandomSeed`.

The algorithm uses the Mersenne Twister random number generator.
See Also
The SetRandomSeed operation.

Noise Functions on page III-372.

Chapter III-12, Statistics for a function and operation overview.

poly

\[
\text{poly}(\text{coefsWaveName, } x_1) \\
\]  

The poly function returns the value of a polynomial function at \( x = x_1 \).

\( \text{coefsWaveName} \) is a wave that contains the polynomial coefficients. The number of points in the wave determines the number of terms in the polynomial.

Examples

To fill wave0 with 100 points containing the polynomial \( 1 + 2x + 3x^2 + 4x^3 \) evaluated over the range from \( x = -1 \) to \( x = 1 \) (and graph it):

\[
\text{Make coefs} = \{1, 2, 3, 4\} \quad // \quad f(x) = 1 + 2x + 3x^2 + 4x^3 \\
\text{Make/N=100/O wave0}; \text{SetScale/I x, -1, 1, wave0}; \text{Display wave0} \\
\text{wave0} = \text{poly}(\text{coefs, } x) \\
\]

poly2D

\[
\text{poly2D}(\text{coefsWaveName, } x_1, y_1) \\
\]  

The poly2D function returns the value of a 2D polynomial function at \( x = x_1, y = y_1 \).

\( \text{coefsWaveName} \) is a wave that contains the polynomial coefficients. The number of points in the wave determines the number of terms in the polynomial and therefore the polynomial degree.

Details

The coefficients wave contains polynomial coefficients for low degree terms first. All coefficients for terms of a given degree must be present, even if they are zero. Among coefficients for a given degree, those for terms having higher powers of \( X \) are first. Thus, poly2D returns, for a coefficient wave \( \text{cw} \):

\[
f(x,y) = \text{cw}[0] + \text{cw}[1]*x + \text{cw}[2]*y + \text{cw}[3]*x^2 + \text{cw}[4]*x*y + \text{cw}[5]*y^2 + \ldots \\
\]

A 2D polynomial of degree \( N \) has \( (N+1)(N+2)/2 \) terms.

Examples

To fill wave0 with 400 points (20 by 20) containing the polynomial \( 1 + 2x + 2.5y + 3x^2 + 3.5xy + 4y^2 \) evaluated over the range \( x = (-1, 1) \) and \( y = (-1, 1) \) and make a contour plot of it:

\[
\text{Make/O coefs} = \{1, 2, 2.5, 3, 3.5, 4\} \\
\text{Make/N=(20,20)/O wave0} \\
\text{SetScale/I x, -1, 1, wave0} \\
\text{SetScale/I y, -1, 1, wave0} \\
\text{wave0} = \text{poly2D}(\text{coefs, } x, y) \\
\text{Display; AppendMatrixContour wave0} \\
\]

The polynomial is second degree, so the first command above made the wave \( \text{coefs} \) with six elements because \( (2+1)(2+2)/2 = 6 \).

To fill wave0 with 100 points containing the polynomial \( 1 + 2x + 3y + 4x^2 + 4y^2 + 5x^3 + 6y^3 \) (note the lack of cross terms) evaluated over the range \( x = (-1, 1) \) and \( y = (-1, 1) \) (the contour plot already made should update with the new data). The first zero eliminates the second-order cross term \( x*y \) and the second and third zeros eliminate the third-order cross terms \( x^2*y \) and \( x*y^2 \):

\[
\text{Make/O coefs} = \{1, 2, 3, 4, 0, 4, 5, 0, 0, 6\} \\
\text{wave0} = \text{poly2D}(\text{coefs, } x, y) \\
\]

PolygonArea

\[
\text{PolygonArea}(xWave, yWave) \\
\]  

The PolygonArea function returns the area of a simple, closed, convex or nonconvex planar polygon described by consecutive vertices in \( xWave \) and \( yWave \).

A simple polygon has no internal “holes” and its boundary curve does not intersect itself. Both \( xWave \) and \( yWave \) must be 1D, real, numerical waves of the same dimensions. The minimum number of vertices is 3.
The function uses the shoelace algorithm to compute the area (see theorem 1.3.3 in the reference below). If there is any error in the input, the function returns NaN.

**Example**

```plaintext
Function estimatePi(num)
  Variable num
  Make/O/N=(num+1) xxx,yyy
  xxx=sin(2*pi*x/num)
  yyy=cos(2*pi*x/num)
  printf "Relative Error=%g\r",(pi-PolygonArea(xxx,yyy))/pi
End
```

**See also**
The `areaXY` and `faverageXY` functions.

**References**

**popup**

The `popup` keyword is used with Prompt statements in Functions and Macros. It indicates that you want a pop-up menu instead of the normal text entry item in a DoPrompt simple input dialog (or a Macro’s missing parameter dialog (archaic)). `menuList` is a string expression containing a list of items, separated by semicolons, that are to appear in the pop-up menu.

Pop-up menus accept both numeric and string parameters. For numeric parameters, the number of the item selected is placed in the variable. Numbering starts from one. For string parameters, the selected item’s text is placed in the string variable.

Pop-up items support all of the special characters available for user-defined menu definitions (see **Special Characters in Menu Item Strings** on page IV-131) with the exception that items in pop-up menus are limited to 50 bytes, keyboard shortcuts are not supported, and special characters must be enabled.

**See Also**
Prompt, DoPrompt, and **Pop-Up Menus in Simple Dialogs** on page IV-139.

See WaveList, TraceNameList, ContourNameList, ImageNameList, FontList, MacroList, FunctionList, StringList, and VariableList for functions useful in generating lists of Igor objects.

Chapter III-14, **Controls and Control Panels** for details about control panels and controls.

**PopupContextualMenu**

```plaintext
PopupContextualMenu [ /C=(xpix, ypix) /N /ASYN[=func] ] popupStr
```

The PopupContextualMenu operation displays a pop-up menu.

The menu appears at the current mouse position or at the location specified by the /C flag.

The content of the menu is specified by `popupStr` as a semicolon-separated list of items or, if you include the /N flag, by a user-defined menu definition referred to by the name contained in `popupStr`.

If you omit the /ASYN flag, the menu is tracked and the operation does not return until the user makes a selection or cancels the menu by clicking outside of its window.

If you include /ASYN, the menu is displayed and the operation returns immediately. When the user makes a selection, then the result is sent to the specified function or to the user-defined menu’s execution text. You can use /ASYN to allow a background task to continue while a contextual menu is popped up. /ASYN requires Igor Pro 7.00 or later.

**Parameters**

If `popupStr` specifies the pop-up menu’s items (/N is not specified), then `popupStr` is a semicolon-separated list of items such as “yes;no;maybe;”, or a string expression that returns such a list, such as TraceNameList.

The menu items can be formatted and checkmarked, like user-defined menus can. See **Special Characters in Menu Item Strings** on page IV-131.
If /N is specified, `popupStr` must be the name of a user-defined menu that also has the `popupcontextualmenu` keyword. See Example 3.

**Flags**

/ASYN When used with /N: The user-defined menu is displayed and operation returns immediately. The result of menu selection is handled by the user-defined menu’s execution text. See User-Defined Menus on page IV-123.

/ASYN=func When used without /N: The user-defined menu is displayed and operation returns immediately. The result of menu selection is handled by calling the named function, which must have the following format:

```plaintext
Function func(popupStr, selectedText, menuItemNum)
    String popupStr
    String selectedText
    Variable menuItemNum
```

/C=(xpix, ypix) Sets the coordinates of the menu’s top left corner.

Units are in pixels relative to the top-most window or the window specified by /W, like the MOUSEX and MOUSEY values passed to a window hook. See the window hook example, below and SetWindow.

If /C is not specified, the menu’s top left corner appears at the current mouse position.

/N Indicates that `popupStr` contains the name of a menu definition instead of containing a list of menu items.

/W=winName The /C coordinates are relative to the top/left corner of the named window or subwindow. If you omit /W, /C uses the top-most window having focus.

When identifying a subwindow with `winName`, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/W was added in Igor Pro 7.00.

**Details**

If you omit /N and /ASYN, `PopupContextualMenu` sets the following variables:

V_flag=0 User cancelled the menu without selecting an item, or there was an error such as an empty `popupStr`.

V_flag>=1 1 if the first menu item was selected, 2 for the second, etc.

S_selection "" if the user cancelled or error, else the text of the selected menu item.
If you include /N and omit /ASYN, PopupContextualMenu sets the following variables in a manner similar to GetLastUserMenuInfo:

**V_kind**
The kind of menu that was selected:

<table>
<thead>
<tr>
<th>V_kind</th>
<th>Menu Kind</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Normal text menu item, including Optional Menu Items (see page IV-128) and Multiple Menu Items (see page IV-128).</td>
</tr>
<tr>
<td>3</td>
<td>&quot;<em>FONT</em>&quot;</td>
</tr>
<tr>
<td>6</td>
<td>&quot;<em>LINESTYLEPOP</em>&quot;</td>
</tr>
<tr>
<td>7</td>
<td>&quot;<em>PATTERNPOP</em>&quot;</td>
</tr>
<tr>
<td>8</td>
<td>&quot;<em>MARKERPOP</em>&quot;</td>
</tr>
<tr>
<td>9</td>
<td>&quot;<em>CHARACTER</em>&quot;</td>
</tr>
<tr>
<td>10</td>
<td>&quot;<em>COLORPOP</em>&quot;</td>
</tr>
<tr>
<td>13</td>
<td>&quot;<em>COLORTABLEPOP</em>&quot;</td>
</tr>
</tbody>
</table>

-1 if the user didn't select any item, otherwise V_flag returns a value which depends on the kind of menu the item was selected from:

<table>
<thead>
<tr>
<th>V_kind</th>
<th>V_flag Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Text menu item number (the first menu item is number 1).</td>
</tr>
<tr>
<td>3</td>
<td>Font menu item number (use S_selection, instead).</td>
</tr>
<tr>
<td>6</td>
<td>Line style number (0 is solid line)</td>
</tr>
<tr>
<td>7</td>
<td>Pattern number (1 is the first selection, a SW-NE light diagonal).</td>
</tr>
<tr>
<td>8</td>
<td>Marker number (1 is the first selection, the X marker).</td>
</tr>
<tr>
<td>9</td>
<td>Character as an integer, = char2num(S_selection). Use S_selection instead.</td>
</tr>
<tr>
<td>10</td>
<td>Color menu item (use V_Red, V_Green, V_Blue, and V_Alpha instead).</td>
</tr>
<tr>
<td>13</td>
<td>Color table list menu item (use S_selection instead).</td>
</tr>
</tbody>
</table>

The menu item text, depending on the kind of menu it was selected from:

<table>
<thead>
<tr>
<th>V_kind</th>
<th>S_selection Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Text menu item text.</td>
</tr>
<tr>
<td>3</td>
<td>Font name or &quot;default&quot;.</td>
</tr>
<tr>
<td>6</td>
<td>Name of the line style menu or submenu.</td>
</tr>
<tr>
<td>7</td>
<td>Name of the pattern menu or submenu.</td>
</tr>
<tr>
<td>8</td>
<td>Name of the marker menu or submenu.</td>
</tr>
<tr>
<td>9</td>
<td>Character as string.</td>
</tr>
<tr>
<td>10</td>
<td>Name of the color menu or submenu.</td>
</tr>
<tr>
<td>13</td>
<td>Color table name.</td>
</tr>
</tbody>
</table>
If you include /N and /ASYN, PopupContextualMenu sets the following variables:

- `V_flag=0` There was an error such as an empty `popupStr` or `popupStr` did not name a compiled user-defined menu.
- `V_flag=-1` No error. The named user menu was valid and no item was selected yet.
- `S_selection = ""`

If you include /N and omit /ASYN, PopupContextualMenu sets the following variables:

- `V_flag=0` There was an error such as an empty `popupStr`.
- `V_flag=-1` No error. `popupStr` was valid and no item was selected yet.
- `S_selection = ""`

**Examples**

**Example 1 - `popupStr` contains a list of menu items**

```c
// Menu formatting example
String checked = "\M0:!:" + num2char(18) + ":" // checkmark code
String items = "first;\M1-;" + checked + "third;" // 2nd is divider, 3rd is checked
PopupContextualMenu items
switch( V_Flag )
  case 1:
    // do something because first item was chosen
    break;
  case 3:
    // do something because first item was chosen
    break;
endswitch
```

**Example 2 - `popupStr` contains a list of menu items**

```c
// Window hook example
SetWindow kwTopWin hook=TableHook, hookevents=1 // mouse down events
Function TableHook(infoStr)
  String infoStr
  Variable handledEvent=0
  String event= StringByKey("EVENT",infoStr)
  strswitch(event)
  case "mousedown":
    Variable isContextualMenu= NumberByKey("MODIFIERS",infoStr) & 0x10
    if( isContextualMenu )
      Variable xpix= NumberByKey("MOUSEX",infoStr)
      Variable ypix= NumberByKey("MOUSEY",infoStr)
      PopupContextualMenu/C=(xpix,ypix) "yes;no;maybe;"
      strswitch(S_selection)
      case "yes":
        // do something because "yes" was chosen
        break
      case "no":
        break
      case "maybe":
        // do something because "maybe" was chosen
        break
```

In the case of **Specialized Menu Item Definitions** (see page IV-129), `S_selection` will be the title of the menu or submenu, etc.

**V_Red, V_Green, V_Blue, V_Alpha**

- If a user-defined color menu ("COLORPOP" menu item) was selected then these values hold the red, green, and blue values of the chosen color. The values range from 0 to 65535.
- Will be 0 if the last user-defined menu selection was not a color menu selection.
Example 3 - popupStr contains the name of a user-defined menu

// User-defined contextual menu example
// dynamic menu (to keep WaveList items updated), otherwise not required.
// contextualmenu keyword is required, and implies /Q for all menu items.
//
// NOTE: Actions here are accomplished by the menu definition's
// execution text, such as DoSomethingWithColor.
// See Example 4 for another approach.
//
Menu "ForContext", contextualmenu, dynamic
   "Hello", Beep
   Submenu "Color"
      "*COLORPOP*", DoSomethingWithColor()
   End
   Submenu "Waves"
      WaveList("*",";",""), /Q, DoSomethingWithWave()
   End
End

Function DoSomethingWithColor()
   GetLastUserMenuInfo
   Print V_Red, V_Green, V_Blue, V_Alpha
End

Function DoSomethingWithWave()
   GetLastUserMenuInfo
   WAVE w = $S_value
   Print "User selected " + GetWavesDataFolder(w,2)
End

// Use this code in a function or macro:
PopupContextualMenu/N "ForContext"
if( V_flag < 0 )
   Print "User did not select anything"
endif

Example 4 - popupStr contains the name of a user-defined menu

// User-defined contextual menu example
Menu "JustColorPop", contextualmenu
   "*COLORPOP*(65535,0,0)"; // initially red, empty execution text
End

// Use this code in a function or macro
PopupContextualMenu/C=(xpix, ypix)/N "JustColorPop"
if( V_flag < 0 )
   Print "User did not select anything"
else
   Print V_Red, V_Green, V_Blue, V_Alpha
endif

Example 5 - popupStr contains a list of menu items, asynchronous popup result

Function YourFunction()
   // Use this code in a function or macro:
   PopupContextualMenu/ASYN=Callback "first;second;third;"
   (YourFunction continues...)
End

// Routine called when/if popup menu item is selected. selectedItem=1 is the first item.
Function Callback(String list, String selectedText, Variable selectedItem)
Example 6 - popupStr contains the name of a user-defined menu, asynchronous popup result

Function YourFunction()
    PopupContextualMenu/ASYN/N "ForContext"
    (YourFunction continues...)
End

// Selection result is handled in "ForContext" menu's execution texts, as in Example 4

Creating a Contextual Menu on page IV-156, User-Defined Menus on page IV-123.

Special Characters in Menu Item Strings on page IV-131 and Chapter III-14, Controls and Control Panels, for details about control panels and controls.
The SetWindow and PopupMenu operations.

PopupMenu

PopupMenu [/[Z] ctrlName [keyword = value [, keyword = value ...]]]
The PopupMenu operation creates or modifies a pop-up menu control in the target or named window.

For information about the state or status of the control, use the ControlInfo operation.

Parameters

ctrlName is the name of the PopupMenu control to be created or changed.

The following keyword=value parameters are supported:

align=alignment
Sets the alignment mode of the control. The alignment mode controls the interpretation of the leftOrRight parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.

If alignment=0 (default), leftOrRight specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.

If alignment=1, leftOrRight specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

appearance={kind [, platform]}
Sets the appearance of the control. platform is optional. Both parameters are names, not strings.

kind can be one of default, native, or os9.

platform can be one of Mac, Win, or All.

See Button and DefaultGUIControls for more appearance details.

bodyWidth=width
Specifies an explicit size for the body (nontitle) portion of a PopupMenu control. By default (bodyWidth=0), the body portion autosizes depending on the current text. If you supply a bodyWidth>0, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.

disable=d
Sets user editability of the control.

d=0: Normal.
d=1: Hide.
d=2: Draw in gray state; disable control action.

fColor=(r,g,b)
Sets the initial color of the title. r, g, and b range from 0 to 65535. fColor defaults to black (0,0,0). To further change the color of the title text, use escape sequences as described for title=titleStr.
focusRing=fr

Enables or disables the drawing of a rectangle indicating keyboard focus:
fr=0: Focus rectangle will not be drawn.
fr=1: Focus rectangle will be drawn (default).

On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.

font="fontName"

Sets the font used for the pop-up title, e.g., font="Helvetica".

fs

Sets the font size for the pop-up title.

fstyle=fs

fs is a bitwise parameter with each bit controlling one aspect of the font style as follows:
Bit 0: Bold
Bit 1: Italic
Bit 2: Underline
Bit 4: Strikethrough

See Setting Bit Parameters on page IV-13 for details about bit settings.

help={helpStr}

Sets the help for the control. The help text is limited to a total of 255 bytes. You can insert a line break by putting “\r” in a quoted string.

mode=m

Specifies the pop-up title location.
m=0: Title is in pop-up menu.
m=1: Title is to the left of pop-up menu, the chosen menu item appears in the pop-up menu, and menu item number m is initially selected.

noproc

Specifies that no procedure is to execute when choosing in the pop-up menu.

popColor=(r,g,b)

 Specifies the color initially chosen in the color pop-up palette. r, g, and b are integers from 0 to 65535. See the Colors, Color Tables, Line Styles, Markers, and Patterns section.

popmatch=matchStr

Sets mode to the enabled menu item that matches matchStr. matchStr may be a "wildcard" expression. See StringMatch. If no item is matched, mode is unchanged.

popvalue=valueStr

Sets the string displayed by the menu when first created, if mode is not zero. See Popvalue Keyword section.

pos={leftOrRight,top}

Sets the position in pixels of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

pos+=dx,dy

Offsets the position of the pop-up in pixels.

proc=procName

Specifies the procedure to execute when the pop-up menu is clicked. See Pop-up Menu Action Procedure below.

rename=newName

Gives pop-up menu a new name.

size={width,height}

Sets pop-up menu size in pixels.

title=titleStr

Sets title of pop-up menu to the specified string expression. Defaults to "" (no title).

Using escape codes you can change the font, size, style, and color of the title. See Annotation Escape Codes on page III-54 or details.

userdata(UDName)=UDStr

Sets the unnamed user data to UDStr. Use the optional (UDName) to specify a named user data to create. You can retrieve the data using GetUserData.
PopupMenu

 userdata(UDName) += UDStr

    Appends UDStr to the current unnamed user data. Use the optional (UDName) to append to the named UDStr.

 value=itemListSpec  Specifies the pop-up menu’s items. itemListSpec can take several forms as described below under Setting The Popup Menu Items.

 win=winName    Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

 When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

 Flags

 /Z       No error reporting.

 Details

 The target window, or the window named with the win=winName keyword, must be a graph or panel.

 Pop-up Menu Action Procedure

 The action procedure for a pop-up menu control takes a predefined WMPopupAction structure as a parameter to the function:

 Function PopupMenuAction(PU_Struct) : PopupMenuControl
     STRUCT WMPopupAction &PU_Struct
     ...
     return 0
 End

 The ":[PopupMenuControl]" designation tells Igor to include this procedure in the list of available popup menu action procedures in the PopupMenu Control dialog used to create a popup menu.

 See WMPopupAction for details on the WMPopupAction structure.

 Although the return value is not currently used, action procedures should always return zero.

 You may see an old format pop-up menu action procedure in old code:

 Function PopupMenuAction (ctrlName,popNum,popStr) : PopupMenuControl
     String ctrlName
     Variable popNum    // which item is currently selected (1-based)
     String popStr     // contents of current popup item as string
     ...
     return 0
 End

 This old format should not be used in new code.

 Setting The Popup Menu Items

 This section discusses popup menus containing lists of text items. The next section discusses popup menus for choosing colors, line styles, markers and patterns.

 The items in the popup menu are determined by the itemListSpec parameter used with the value keyword. itemListSpec can take several different forms from simple to complex.

 No matter what the form, Igor winds up storing an expression that returns a string in the popup menu’s internal structure. This expression may be a literal string ("Red;Green;Blue;"), a call to a built-in or user-defined function that returns a string, or the path to a global string variable. Igor evaluates this expression when the popup menu is first created and again each time the user clicks on the menu. You can see the string expression for a given popup menu using the PopupMenu Control dialog.

 The right form for itemListSpec depends on your application. Here is a guide to choosing the right form with the simpler forms first.

 A literal string expression

 Use this if you know the items you want in your popup menu when you write the PopupMenu call. For example:
Function PopupDemo1() // Literal string
   NewPanel
   PopupMenu popup0, value="Red;Green;Blue;"
End

This method is limited to 2500 bytes of menu item text.

**A function call**

Use this if you need to compute the popup menu item list when the user clicks the popup menu. The function must return a string containing a semicolon-separated list of menu items. This example creates a popup menu which displays the name of each wave in the current data folder at the time the menu is clicked:

Function PopupDemo2() // Built-in function
   NewPanel
   PopupMenu popup0, value=WaveList("***", ";", "")
End

You can also use a user-defined function. This example shows how to list waves from other than the current data folder:

Function/S MyPopupWaveList()
   DFREF saveDF
   // Create some waves for demo purposes
   saveDF = GetDataFolderDFR()
   NewDataFolder/O/S root:Packages
   NewDataFolder/O/S PopupMenuDemo
   Make/O demo0, demo1, demo2
   SetDataFolder saveDF
   saveDF = GetDataFolderDFR()
   SetDataFolder root:Packages:PopupMenuDemo
   String list = WaveList("***", ";", "")
   SetDataFolder saveDF
   return list
End

Function PopupDemo3() // User-defined function
   NewPanel
   PopupMenu popup0, value=MyPopupWaveList()
End

**# followed by a local string variable specifying items**

Use this when the popup menu item list is not known when you write the code but you can compute it at runtime. For example:

Function PopupDemo4() // Local string variable specifying items
   NewPanel
   String quote = "\"
   String list
   if (CmpStr(IgorInfo(2),"Windows") == 0)
      list = quote + "Windows XP; Windows VISTA;" + quote
   else
      list = quote + "Mac OS X 10.4; Mac OS X 10.5;" + quote
   endif
   PopupMenu popup0, value=#list
End

The strange-looking use of the quote string variable is necessary because the parameter passed to the value=# keyword is evaluated once when the PopupMenu command executes and the result of that evaluation is evaluated again when the PopupMenu is created or clicked. The result of the first evaluation must be a legal string expression.

This method is limited to 2500 bytes of menu item text.

**# followed by a local string variable specifying a function**

Use this when you need to compute the popup menu item list at click time and you need to select the function which computes the list when the popup menu is created. For example:

Function/S WindowsItemList()
   String list
PopupMenu

Function/S MacItemList()
    String list
    list = "Mac OS X 10.4;Mac OS X 10.5;"
    return list
End

Function PopupDemo5() // Local string variable specifying function
    String listFunc
    if (CmpStr(IgorInfo(2), "Windows") == 0)
        listFunc = "WindowsItemList()"
    else
        listFunc = "MacItemList()"
    endif
    NewPanel
    PopupMenu popup0, value=#listFunc
End

This form is useful when you create a control panel in an independent module. Since the control panel runs in the global name space, you must specify the independent module name in the invocation of the function that provides the popup menu items. For example:

// Calling a non-static function in an independent module from #included code
#pragma IndependentModuleName=IM
...
String listFunc= GetIndependentModuleName()+"#PublicFunctionInIndepMod()"
PopupMenu popup0, value=#listFunc

// Calling a static function in an independent module from #included code
#pragma IndependentModuleName=IM
#pragma ModuleName=ModName
...
String listFunc= GetIndependentModuleName()+"#ModName#StaticFunctionInIndepMod()"
PopupMenu popup0, value=#listFunc

We use GetIndependentModuleName rather than hard-coding the name of the independent module so that the code will continue to work if the name of the independent module is changed. Also, because this code does not depend on the specific name of the independent module, it can be added to an independent module via a #included procedure file.

Also see GetIndependentModuleName and Independent Modules and Popup Menus on page IV-234.

# followed by a quoted literal path to a global string variable
Use this if you want to compute the popup menu item list before it is clicked, not each time it is clicked. This would be advantageous if it takes a long time to compute the item list, and the list changes only at well-defined times when you can set the global string variable.

The global string variable must exist when the PopupMenu command executes and when the menu is clicked. In this example, the gPopupMenuItems global string variable is created and initialized when the popup menu is created but can be changed to a different value later before the menu is clicked:

Function PopupDemo6() // Global string variable containing list
    NewDataFolder/O root:Packages
    NewDataFolder/O root:Packages:PopupMenuDemo
    String/G root:Packages:PopupMenuDemo:gPopupMenuItems = "Red;Green;Blue;"
    NewPanel
    PopupMenu popup0 ,value=#"root:Packages:PopupMenuDemo:gPopupMenuItems"
End

# followed by a local string variable containing a path to a global string variable
Use this when the popup menu item list contents will be stored in a global string variable whose location is not known until the popup menu is created. For example:

Function PopupDemo7() // Local string containing path to global string
    String graphName = WinName(0, 1, 1)// Name of top graph
    if (strlen(graphName) == 0)
        Print "There are no graphs."
        return -1
    endif
NewDataFolder/O root:Packages
NewDataFolder/O root:Packages:PopupMenuDemo

// Create data folder for graph
NewDataFolder/O root:Packages:PopupMenuDemo:$(graphName)

String list = "Red;Green;Blue;"
String/G root:Packages:PopupMenuDemo:$(graphName):gPopupMenuItems = list

NewPanel

String path // Local string containing path to global string
path = "root:Packages:PopupMenuDemo:" + graphName + ":gPopupMenuItems"
PopupMenu popup0, value=#path

return 0
End

Colors, Color Tables, Line Styles, Markers, and Patterns

You can create PopupMenu controls for color, color tables, line style (dash modes), markers, and patterns. To do so, simply specify the itemListSpec parameter to the value keyword as one of "*COLORPOP*", "*COLOORTABLEPOP*", "*COLOORTABLEPOPNAMES*", "*LINESTYLEPOP*", "*MARKERPPOP*", or "*PATTERNPOP*". In these modes the body of the control will contain a color box, a color table (gradient), a line style sample, a marker, or a pattern sample.

For these special pop-up menus, mode=0 ("Title in Box" checked) is not used.

For a line style pop-up menu, the mode value is the line style number plus one. Thus line style 0 (a solid line) is mode=1.

For a marker pop-up, the mode value is the marker number plus one, and marker 0 (the + marker) is mode=1.

For a line style pop-up, the mode value is the SetDrawEnv fillPat number minus 4, so mode=1 corresponds to fillpat=5, the SW-NE lines fill pattern shown above.

For a color table pop-up, the mode value is the CTabList() index plus 1, so mode=1 corresponds to the first item in the list returned by CTabList, which is "Grays":

ControlInfo $ctrlName // Sets V_Value
Print StringFromList(V_Value-1,CTabList()) // Prints "Grays"

ControlInfo also returns the color table name in S_Value.

To set the pop-up to a given color table name, you can use code like this:

Variable m = 1 + WhichListItem(ctabName, CTabList())
PopupMenu $ctrlName mode=m

For color pop-up menus, you set the current value using the popColor=(r, g, b) keyword. On output (via the popStr parameter of your action procedure or via the S_value output from ControlInfo) the color is encoded as "(r,g,b)" where r, g, and b are numbers. To get these numerical values, you can extract them from the string using the MyRGBstrToRGB function below or use ControlInfo which sets V_Red, V_Green, V_Blue and V_Alpha.

The following example demonstrates the line style and color pop-up menus. To run the example, copy the following code to the procedure window of a new experiment and then run the panel macro.

Window Panel0() : Panel
PauseUpdate; Silent 1 // building window ...
NewPanel /W=(150,50,400,182)
PopupMenu popup0,pos={74,31},size={96,20},proc=ColorPopMenuProc,title="colors"
PopupMenu popup0,mode=1,popColor= (0,65535,65535),value= "*COLORPOP*"
PopupMenu popup1,pos={9,68},size={221,20},proc=LStylePopMenuProc
PopupMenu popup1,title="line styles",mode=1,value= "*LINESTYLEPOP*"
EndMacro

Function ColorPopMenuProc(ctrlName,popNum,popStr) : PopupMenuControl
String ctrlName
Variable popNum
String popStr

Variable r,g,b
MyRGBstrToRGB(popStr,r,g,b) // One way to get r, g, b
print popStr," gives: ",r,g,b
ControlInfo $ctrlName  // Another way: Sets V_Red, V_Green, V_Blue, V_Alpha
Printf "ControlInfo returned (%d,%d,%d,%d)\r", V_Red, V_Green, V_Blue, V_Alpha

  return 0
End

// Take (r,g,b) string and extract out numeric r,g,b values
Function MyRGBstrToRGB(rgbStr,r,g,b)
  String rgbStr
  Variable &r, &g, &b
  r= str2num(rgbStr[1,inf])
  variable spos= strsearch(rgbStr,"",0)
  g= str2num(rgbStr[spos+1,inf])
  spos= strsearch(rgbStr,"",spos+1)
  b= str2num(rgbStr[spos+1,inf])
  return 1
End

Function LStylePopMenuProc(ctrlName,popNum,popStr) : PopupMenuControl
  String ctrlName
  Variable popNum
  String popStr
  print "style:",popNum-1

  return 0
End

Popvalue Keyword
There are times when the displayed value cannot be determined and saved such that it can be displayed when the pop-up menu is recreated. For instance, because window recreation macros are evaluated in the root folder, a pop-up menu of waves may not contain the correct list when a panel is recreated. That is, the intention may be to have the menu show a particular wave from a data folder other than root. When the panel recreation macro runs, the function that lists waves will list waves in the root data folder. The desired selection may be wrong or nonexistent.

Similarly, a pop-up menu of fonts may need to display a particular font upon recreation on a different computer having a different list of fonts. The mode=m keyword probably won’t pick the correct font from the new list.

The solution to these problems is to save the correct selection with the popvalue=valueStr keyword. The list function will not be executed when the menu is first created. If the menu is popped, the list function will be evaluated, and the correct list will be displayed then.

It is a good idea to set the mode=m keyword to the correct number, if it is known. That way, when the menu is popped the correct item is chosen.

Normally you can let Igor redraw the pop-up menu when it redraws the graph or control panel containing it. However, there are situations in which you may want to force the pop-up menu to be redrawn. This can be done using the ControlUpdate operation.

See Also
The ControlInfo operation for information about the control. The ControlUpdate, WaveList, and TraceNameList operations. Chapter III-14, Controls and Control Panels, for details about control panels and controls. The GetUserData operation for retrieving named user data. Special Characters in Menu Item Strings on page IV-131.

PopupMenuControl
PopupMenuControl
PopupMenuControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined pop-up menu control. See Procedure Subtypes on page IV-199 for details. See PopupMenu for details on creating a popup menu control.

PossiblyQuoteName
PossiblyQuoteName(nameStr)
The PossiblyQuoteName function returns the input name string if it conforms to the rules of standard wave or Data Folder names. If it does not, then the name is returned in single quotes. This is used when
Preferences

generating a command string that you will pass to the Execute command. You might get the input name string from a function such as NameOfWave or CsrXWave.

Examples

Print PossiblyQuoteName("wave0")  // prints wave0
Print PossiblyQuoteName("wave 0")  // prints 'wave 0'

Details
See Programming with Liberal Names on page IV-163 for an example.

Preferences

Preferences [/Q] [newPrefsState]
The Preferences operation sets or displays the state of user preferences.

User preferences affect the creation of new graphs, panels, tables, layouts, notebooks, procedure windows, and the command window. They also affect the appearance of waves appended to graphs and tables, and objects appended to layouts.

Parameters
If newPrefsState is present, it sets the state of user preferences as follows:

newPrefsState=0: Preferences off (use factory defaults).
newPrefsState=1: Preferences on.

If newPrefsState is omitted, the state of user preferences is printed in the history area.

Flags
/Q Disables printing to the history.

Details
The Preferences operation sets the variable V_flag to the state of user preferences that were in effect before the Preferences command executed: 1 for on, 0 for off.

You can also set the state of Preferences with the Misc menu.

Under most circumstances we want procedures to be independent of preferences so that a particular procedure will do the same thing regardless of the state of preferences. To achieve this, preferences are automatically off when you initiate procedure execution. When execution is complete, the state of preferences is restored to what it was before.

If you want preferences to be in effect during procedure execution, you must turn it on with the Preferences operation.

If the preferences setting is changed by a procedure, the effect of the call is propagated down the calling chain. If a macro changes the preferences setting, that change is undone when the macro returns. If a function changes the preferences setting, the change persists after the function returns. However, even with a function, the changed preferences state does not persist when Igor regains control.

Examples

Function Test()
    Variable oldPrefState
    Preferences 1; oldPrefState=V_flag  // remember prefs setting
    Make wave0=x
    Display wave0  // Display uses preferences
    Preferences oldPrefState  // put prefs back, like a macro would
End

Chapter III-18, Preferences.
PrimeFactors

**PrimeFactors [/Q] inNumber**

PrimeFactors calculates the prime factors of \textit{inNumber}. By default factors are printed in the history and are also stored in the wave W_PrimeFactors in the current data folder.

**Flags**

[/Q] Suppresses printing of factors in the history area.

**Details**

The largest number that this operation can handle is $2^{32}-1$.

**Print**

**Print [flags] expression [, expression]...**

The Print operation prints the evaluated expressions in the history area.

**Parameters**

An expression can be a wave, a numeric expression (e.g., $3 \times \pi / 4$), a string expression (e.g., "Today is " + date()), or a individual structure element or an entire structure variable.

**Flags**

[/C] Evaluates all numeric expressions as complex.

[/D] Prints a greater number of digits.

[/F] Prints numeric wave data (1D and 2D waves only) using “nice,” easily readable formatting.

[/LEN=len] Sets the string break length to \textit{len} number of bytes. The default is 200 and \textit{len} is clipped to between 200 and 2500.

[/S] Obsolete. Numeric results are printed with a moderate number of digits whether you use /S or not. To print more digits, use /D.

[/SR] Prints a wave subrange for expressions that start as “\textit{waveName}[]”. Without /SR, such an expression is taken as the start of a numeric expression such as \textit{wave}[3] - \textit{wave}[2]. (You can still use \textit{wave}[pnt] but only if it does not start the numeric expression.)

Wave subrange printing is not done with /F.

You can specify a single row or column using [r] syntax. For example, to print column 4 of a matrix, use:

\begin{verbatim}
Print mymat[][4]
\end{verbatim}

**Details**

Numeric expressions are always evaluated in double precision. The /D flag just controls the number of digits displayed.

Print determines if an expression is real, complex, or string from the first symbol in the expression. Usually this works fine, but occasionally Print guesses wrong and you may have to rearrange your expression. For example:

\begin{verbatim}
Print 1+cmplx(1,2)
\end{verbatim}

will give an error because the first symbol, “1”, is real but the expression should be complex. Changing this to

\begin{verbatim}
Print cmplx(1,2)+1
\end{verbatim}

will work.

Printing numeric or string expressions involving structure elements must not start with the structure element. Instead an appropriate numeric or string literal must appear first so that Igor can determine what kind of expression to compile. For example rather than

\begin{verbatim}
Print astruct.astring + "hello"
\end{verbatim}

use

\begin{verbatim}
Print "" + astruct.astring + "hello"
\end{verbatim}
printf

Print breaks long strings into multiple lines. If there are no natural breaks (carriage returns or semicolons) within a default length, then it breaks the string arbitrarily.

The default line length is 200 bytes. You can override this using the /LEN flag. The maximum number of bytes that can be printed on a line in the history area is 2500.

When printing waves, you can use either formatted (specified by /F) or unformatted (default) methods. Unformatted output is in an executable syntax for each printed line: wave={ }.

Note: Executing lines printed from floating point waves will not exactly reproduce the source data due to roundoff or insufficient digits in the printed output.

Printing formatted wave data gives easily (human) readable output, and works best for small 1D and 2D waves. If the data are too large or in an unsupported format (3D or greater, or the wave is text), then the output will be unformatted. Formatting is done using spaces, so the output will look best in a fixed-width font.

Printed wave data, both formatted and unformatted, are limited to no more than 100 lines of output. When the line limit is exceeded a warning message will be printed at the end of the truncated output. For text waves, output is limited to 50 bytes of each string element, and there is no warning when a string is truncated.

The PrintGraphs, PrintTable, PrintLayout and PrintNotebook operations.

printf

printf formatStr [, parameter [, parameter]]...
The printf operation prints formatted output to the history area.

Parameters
formatStr is a string which specifies the formatting of the output.
The type of the parameter, string or numeric, must agree with the corresponding conversion specification in formatStr, or else the results will be indeterminate.
The printf parameters can be numeric or string expressions. Numeric and string structure fields are allowed except that complex structure fields and non-numeric (e.g., WAVE, FUNCREF) structure fields are not allowed.

Details
The formatStr contains literal text and conversion specifications.
A conversion specification starts with the % character and ends with a conversion character (for example, g, e, f, d, or s as illustrated below). In between the % and the conversion character you may include one or more flag characters, a field width specifier, and a precision specifier. The first % corresponds to the first parameter, the second % corresponds to the second parameter, etc. If formatStr contains no % characters, no parameters are expected.

Here are some simple examples. numVar is a numeric variable and strVar is a string variable.
printf "The answer is: %g\r", numVar
printf "Created wave %s\r", strVar
printf "Created wave %s, %d points\r", strVar, numVar

%g is a general-purpose format (floating point or scientific notation) that represents the value of numVar.
%d is an integer format that represents the value of numVar. %s specifies that the corresponding parameter (strVar) is a string.
The "\r" in these examples appends a carriage return to the end of the printed text.
Here is a complex example using all of these elements of a conversion specification:
printf "%+015.4f\r", 1e6*PI
This prints:
The answer is: +003141592.6536
"+" is a flag character that tells printf to put a + or - sign in front of the number.
"015" is a field width specifier that tells printf to print the number in a field of at least 15 bytes, padded with leading zeros. Using "15" instead of "015" would cause printf to pad with spaces before the + sign instead of zeros after it.

".4" is a precision specifier that tells printf to print four digits after the decimal point.

"f" tells printf to use a floating point format.

The most common conversions characters are “f” for floating point, “g” for general, “d” for decimal, and “s” for string. They are interpreted as for the printf() function in the C programming language.

The escape codes \t and \r represent the tab and return characters respectively. See Escape Sequences in Strings on page IV-15 for more information.

Printf Flag Characters

The supported flag characters and their meanings are as follows:

- Left align the result in the field.
+ Put a plus or minus sign before the number.
<space> Put a space before a positive number.
# Specifies alternate form for e, f, g, and x formats.

The meaning of the precision specifier depends on the numeric format (%g, %e, %f, %d, etc.) being used:

e, E, f Precision specifies number of digits after decimal point.
g, G Precision specifies maximum number of significant digits.
d, o, u, x, X Precision specifies minimum number of digits.

You can replace both the field width and precision specifiers with an asterisk. This gets the field width or precision specifier from a parameter. For example:

printf "%*.f\r", 4, 3, 1e6*PI

means that the field width is 4 and the precision is 3. You could use numeric expressions instead of the literal numbers to control the field width and precision algorithmically.

Printf Conversion Characters

Here is a complete list of the conversion characters supported by printf:

f Converts a numeric parameter as [-]ddd.d, where the number of digits after the decimal point is determined by the precision specifier and defaults to 6. If the # flag is present, a decimal point will be used even if there are no digits to the right of it.

This conversion character uses the “round-to-half-even” rule, also known as “banker’s rounding”. When the truncated digits are exactly 0.5000..., the quantity is rounded to an even number. For example:

Printf "%.0f\r", 15.5 // Prints 16 (rounded up to even)
Printf "%.0f\r", 16.5 // Prints 16 (rounded down to even)

e, E Converts a numeric parameter as [-]d.dde+/dd, where the number of digits after the decimal point is determined by the precision specifier and defaults to 6. If you use “E” instead of “e” then printf uses a capital “E” in the number. If the # flag is present, a decimal point will be used even if there are no digits to the right of it.

g, G Converts a numeric parameter using “f” or “e” style conversion depending on the magnitude of the number. “e” is used if the exponent is less than -4 or greater than the precision. “G” uses “f” or “E” style conversion. If the # flag is present, a decimal point will be used even if there are no digits to the right of it and trailing zeros will not be removed.
printf

d, o, u
Converting a numeric parameter as a signed decimal integer, unsigned octal integer or unsigned decimal integer. The precision defaults to one and specifies the minimum number of digits to print.
These conversion characters use the “round-away-from-zero” rule, like Igor’s round function. For example:

```
Printf "%d\r", 15.5          // Prints 16 (rounded away from zero)
Printf "%d\r", 16.5          // Prints 17 (rounded away from zero)
```

Unlike printf, sprintf and fprintf, wfprintf truncates rather than rounding.

x, X
Converting a numeric parameter as an unsigned hexadecimal integer, rounding floating point values. Also supports integer data up to 64 bits. Unlike printf, sprintf and fprintf, wfprintf truncates rather than rounding.
The “X” style uses lower case for the hexadecimal numerals “abcdef” where the “X” style uses upper case.
The precision defaults to one and specifies the minimum number of digits to print.
If the # flag is present, the string “0x” or “0X” is prepended to the number if it is not zero.
s
Converting a string parameter which can contain no more than 2400 bytes. If a precision is specified, it sets the maximum number of bytes from the string parameter to be printed.
b
WaveMetrics extension. Converts a numeric parameter to binary.
c
Converting a numeric parameter to a single ASCII character.
%
Prints a % sign. No parameter is used.

%W
WaveMetrics extension. See description below.

To include a literal percent character, use two consecutive % characters, like this:

```
Variable percentage = 37.3
Printf "%.1f%% of participants had prior medical conditions", percentage
```

Igor also supports a non-C, WaveMetrics extension to the conversion characters recognized by printf. This conversion specification starts with “%W”. It is followed by a flag digit and a format character. For example, printf "%W0Ps", 12.345E-6

```
prints 12.345000µs. In this example, the “%W0” introduces the WaveMetrics conversion specification. The “0” (zero) following the “W” is the flag digit. The “P” that follows is the format specifier character, which prints the number using a prefix, in this case, “µ”.
```

There is only one WaveMetrics format specifier character, “P”, which prints using a prefix such as μ, m, k, or M. It recognizes two flag-digits, “0” or “1”. Option “0” prints with no space between the numeric part and the prefix character while flag “1” prints with 1 space. Numbers greater than tera or less than femto print using a power of ten notation. Here are a few examples:

```
printf "%0.2W0PHz", 12.342E6   // prints 12.34MHz
printf "%0.2W1PHz", 12.342E6   // prints 12.34 MHz
printf "%0W0Ps", 12.342E-6     // prints 12µs
printf "%0W1Ps", 12.342E-9     // prints 12 ns
```

See Also
The sprintf, fprintf, and wfprintf operations; Creating Formatted Text on page IV-252 and Escape Sequences in Strings on page IV-15.
**PrintGraphs**

*PrintGraphs [flags] graphSpec [, graphSpec]...*

The PrintGraphs operation prints one or more graphs.

PrintGraphs prints one or more graphs on a single page from the command line or from a procedure. The graphs can be overlaid or positioned any way you want.

**Parameters**

The *graphSpec* specifies the name of a graph to print, the position of the graph on the page and some other options.

**Flags**

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/C=num</td>
<td>Renders graphs in black and white (<em>num</em>=0) or in color (<em>num</em>=1; default).</td>
</tr>
<tr>
<td>/D</td>
<td>Disables high resolution printing. This flag is of use only on Macintosh. It has no effect on Windows.</td>
</tr>
<tr>
<td>/G=grout</td>
<td>Specifies grout, the spacing between objects, for tiling in prevailing units.</td>
</tr>
<tr>
<td>/I</td>
<td>Coordinates are in inches.</td>
</tr>
<tr>
<td>/M</td>
<td>Coordinates are in centimeters.</td>
</tr>
<tr>
<td>/R</td>
<td>Coordinates are in percent of page size (see Examples).</td>
</tr>
<tr>
<td>/PD[=d]</td>
<td>Displays print dialog. This allows the user to use Print Preview or to print to a file. If present the /PD flag must be the last flag.</td>
</tr>
<tr>
<td></td>
<td><em>d</em>=0: Default. Prints without displaying the Print dialog.</td>
</tr>
<tr>
<td></td>
<td><em>d</em>=1: Displays the Print dialog. /PD is equivalent to /PD=1.</td>
</tr>
<tr>
<td></td>
<td><em>d</em>=2: Displays the Print Preview dialog. Requires Igor Pro 7.00 or later.</td>
</tr>
<tr>
<td>/S</td>
<td>Stacks graphs.</td>
</tr>
<tr>
<td>/T</td>
<td>Tiles graphs.</td>
</tr>
</tbody>
</table>

**Details**

Graph coordinates are in inches (/I) or centimeters (/M) relative to the top left corner of the physical page. If none of these options is present, coordinates are assumed to be in points.

The form of a *graphSpec* is:

*graphName* [(left, top, right, bottom)] [/F=f] [/T]

Here are some examples:

// Take size and position from window size and position.
PrintGraphs Graph0, Graph1

// Specify size and position explicitly.
PrintGraphs/I Graph0(1, 1, 6, 5)/F=1, Graph1(1, 6, 6, 10)/F=1

If the coordinates are missing and the /T or /S flags are present before *graphSpec* then the graphs are tiled or stacked. If the coordinates are missing but no /T or /S flags are present then the graph is sized and positioned based on its position on the desktop.

Finally there are these *graphSpec* options, which appear after the graph name:

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/F=f</td>
<td>Specifies a frame around the graph.</td>
</tr>
<tr>
<td></td>
<td><em>f</em>=0: No frame (default).</td>
</tr>
<tr>
<td></td>
<td><em>f</em>=1: Single frame.</td>
</tr>
<tr>
<td></td>
<td><em>f</em>=2: Double frame.</td>
</tr>
<tr>
<td></td>
<td><em>f</em>=3: Triple frame.</td>
</tr>
<tr>
<td></td>
<td><em>f</em>=4: Shadow frame.</td>
</tr>
</tbody>
</table>
PrintLayout

/T Graph is transparent. This allows special effects when graphs are overlaid. For this to be effective, the graph and its contents must also be transparent. Graphs are transparent only if their backgrounds are white. Annotations have their own transparent/opaque settings. PICTs may have been created transparent or opaque; an opaque PICT cannot be made transparent.

Examples
You can put an entire graphSpec into a string variable and use the string variable in its place. In this case the name of the string variable must be preceded by the $ character. This is handy for printing from a procedure and also keeps the PrintGraphs command down to a reasonable number of characters. For example:

```
String spec0, spec1, spec2
spec0 = "Graph0(1, 1, 6, 5)/F=1"
spec1 = "Graph1(1, 6, 6, 10)/F=1"
spec2 = "" // PrintGraphs will ignore spec2.
PrintGraphs/I $spec0, $spec1, $spec2
```

If you use a string for a graphSpec and that string contains no characters then PrintGraphs will ignore that graphSpec.

See Also
The PrintSettings, PrintTable, PrintLayout and PrintNotebook operations.

PrintLayout

```
PrintLayout [/C=num /D] winName
```

The PrintLayout operation prints the named page layout window.

Parameters

winName is the window name of the page layout to print.

Flags

/C=num Renders graphs, tables, and annotations in black-and-white (num=0) or in color (num=1; default). It has no effect on pictures, which are colored independently.

/D Prints the layout at the default resolution of the output device. Otherwise it is printed at the highest resolution. This flag is of use only on Macintosh. It has no effect on Windows.

Details

Normally page layouts are printed at the highest available resolution of the output device (printer, plotter, or whatever). On Macintosh, it may not work properly at high resolution with some unusual output devices. If this happens, you can try using the /D flag to see if it works properly at the default resolution.

See Also
The PrintSettings, PrintGraphs, PrintTable and PrintNotebook operations.

PrintNotebook

```
PrintNotebook [flags] notebookName
```

The PrintNotebook operation prints the named notebook window.

Parameters

notebookName is either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0#nb0. See Subwindow Syntax on page III-92 for details on host-child specifications.
Flags

/B=hiResMethod  Macintosh only; this flag has no effect on Windows.
  hiResMethod=1:  Print HiRes PICTs using high resolution bitmaps.
  hiResMethod=0:  Don’t print HiRes PICTs using high resolution bitmaps.
  hiResMethod=-1:  Print using the default method. Prints HiRes PICTs using high resolution bitmaps and is the same as method 1.

/P=(startPage,endPage)  Specifies a page range to print. 1 is the first page.

/S=selection  Controls what is printed.
  selection=0:  Print entire notebook (default).
  selection=1:  Print selection only.

Details

If no /B flag is given, the default method of handling HiRes PICTs is used (/B=1). Printing of HiRes PICTs is not well supported on the Macintosh, so by default it prints them using temporary high resolution bitmaps. If a future version of the Mac OS improves in this respect, we will change the default method to print directly.

See Also

Chapter III-1, Notebooks.

The PrintSettings, PrintGraphs, PrintTable and PrintLayout operations.

PrintSettings

PrintSettings [I /M /W=winName] [copySource=source, orientation=o, margins={left, top, right, bottom}, scale=s, colorMode=m, getPrinterList, getPrinter, setPrinter=printerNameStr, getPageSettings, getPageDimensions]

The PrintSettings operation gets or sets parameters associated with printing, such as a list of available printers or page setup information for a particular window.

An exception is the graphMode and graphSize keyword pair which affect printing of all graphs. This pair was added in Igor Pro 7.00.

Prior to Igor Pro 7.00, PrintSettings applied to a page layout affected the size and orientation of the layout page. In Igor Pro 7.00 and later, the size and orientation of the layout page are independent of print settings. See Page Layout Page Sizes on page II-411 for details.

When getting or setting page setup information, PrintSettings acts on a particular window called the destination window. The destination window is the top graph, table, page layout, or notebook window or the window specified by the /W flag.

PrintSettings can not act on page setup records associated with the command window, procedure windows, help windows, control panel, XOP windows, or any type of window other than graphs, tables, page layouts, and notebooks.

The PrintSettings operation services the keywords in the order shown above, not in the order in which they appear in the command. Thus, for example, the getPageSettings and getPageDimensions keywords report the settings after all other keywords are executed.
**PrintSettings**

### Flags

- **/I**
  Measurements are in inches. If both /I and /M are omitted, measurements are in points.

- **/M**
  Measurements are in centimeters. If both /I and /M are omitted, measurements are in points.

- **/W=winName**
  Acts on the page setup record of the graph, table, page layout, or notebook window identified by winName. If winName is omitted or if winName is "", then it used the page setup for the top window.

### Keywords

- **colorMode=m**
  Sets the color mode for the page setup to monochrome (m=0) or to color (m=1).
  This keyword does nothing on Macintosh because it is not supported by Mac OS X.

- **copySource=source**
  Copies page setup settings from the specified source to the destination window. source can be the name of a graph, table, page layout, or notebook window or it can be one of the following special keywords:

  - Default_Settings: Sets the page setup record to the default for the associated printer as specified by the printer driver.
  - Factory_Settings: Sets the page setup record to the WaveMetrics factory default. This is the page setup you get when creating a new window with user preferences turned off.
  - Preferred_Settings: Sets the page setup record to the user preferred page setup. This is the page setup you get when creating a new window with user preferences turned on. Because there is only one page setup for all graphs and one page setup for all tables, this has no effect when the destination window is a graph or table. It does work for layouts and notebooks.

- **getPageDimensions**
  Returns page dimensions via the string variable S_value, which contains keyword-value pairs that can be extracted using NumberByKey and StringByKey. See Details for keyword-value pair descriptions.

- **getPageSettings**
  Returns page setup settings in the string variable S_value, which contains keyword-value pairs that can be extracted using NumberByKey and StringByKey. See Details for keyword-value pair descriptions.

- **getPrinter**
  Returns the name of the selected printer for the destination window in the string variable S_value. On Macintosh the returned value will be " " if the setPrinter keyword was never used on the destination window. This means that the window will use the operating system’s “current printer”.

- **getPrinterList**
  Returns a semicolon-separated list of printer names in the string variable S_value.

  - Mac OS X: Returns a list of printers added through Print Center.
  - Windows: Returns the names of any local printers and names of network printers to which the user has made previous connections.

- **graphMode=g**
  Sets the printing mode for graphs:
  - 1: Fill page
  - 2: Same size
  - 3: Same aspect ratio
  - 4: Custom size as set by graphSize keyword
  - 5: Same size or shrink to fit page (default)

  The graphMode keyword was added in Igor Pro 7.00.

- **graphSize=[left, top, width, height]**
PrintSettings

Sets the custom graph size used when graphMode is 4. Parameters are in points unless /I or /M is used.

Invoking the graphSize keyword automatically sets the graphMode to 4.

left and top are clipped so that they are no smaller than the minimum allowed by the printer driver. width and height are not clipped.

This setting is not saved and is set to a default value when Igor starts.

The graphSize keyword was added in Igor Pro 7.00.

margins={left, top, right, bottom}

Sets the page margins. Dimensions are in points unless /I or /M is used.

This setting is ignored for notebook windows. Use the Notebook operation pageMargins keyword instead.

The margins are clipped so that they are no smaller than the minimum allowed by the printer driver and no larger than one-half the size of the paper.

The terms left, top, right, and bottom refer to the sides of the page after possible rotation for landscape orientation.

Passing zero for all four margins sets the margins to the minimum margin allowed by the printer.

On Macintosh only, passing -1 for all four margins sets the margins to whatever minimum margin is allowed by the printer, even if the printer is changed later. This is how Igor Pro behaved on Macintosh prior to the creation of the PrintSettings operation, when the minimum printer margins were always used.

orientation=o

Sets the paper orientation to portrait (o=0) or to landscape (o=nonzero).

scale=s

In Igor Pro 7 and later, the scale keyword returns an “unimplemented” error, unless s=100, because it is currently not supported. Let us know if this feature is important to you. Though s=100 does not generate an error, it does nothing. You can still set the scaling manually using the Page Setup dialog.

setPrinter=printerNameStr

Sets the selected printer for the destination window.

SetPrinter attempts to preserve orientation, margins, scale, and color mode but other settings may revert to the default state.

printerNameStr is a name as returned by the getPrinterList keyword and may not be identical to the name displayed in various dialogs. For example, on Mac OS X, the printer name “DESKJET 840C” is returned by getPrinterList as “DESKJET_840C”. The latter is the “Queue Name” displayed by the Mac OS X Print Center or Printer Setup Utility programs.

If printerNameStr is "", the printer for the destination window is set to the default state. This means different things depending on the operating system:

Mac OS X: The destination window will use the operating system’s “current printer”, as if the setPrinter keyword had never been used.

Windows: The destination window will use the system default printer.

If you receive an error when using setPrinter, use the getPrinterList keyword to verify that the printer name you are using is correct. Verify that the printer is connected and turned on.

Windows printer names are sometimes UNC names of the form “\Server\Printer”. You must double-up backslashes when using a UNC name in a literal string. See UNC Paths on page III-429 for details.
**PrintSettings**

**Details**
All graphs in the current experiment share a single page setup record so if you change the page setup for one graph, you change it for all graphs.

All tables in the current experiment share a single page setup record.

Each page layout window has its own page setup record.

Each notebook window has its own page setup record.

The keyword-value pairs for the getPageSettings keyword are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORIENTATION:</td>
<td>0 if the page is in portrait orientation, 1 if it is in landscape orientation.</td>
</tr>
<tr>
<td>MARGINS:</td>
<td>The left, top, right, and bottom margins in points, separated by commas.</td>
</tr>
<tr>
<td></td>
<td>These margins are ignored for notebook windows. Use the Notebook operation pageMargins keyword instead.</td>
</tr>
<tr>
<td>SCALE:</td>
<td>The page scaling expressed in percent. 50 means that the graphics are drawn at 50% of their normal size.</td>
</tr>
<tr>
<td>COLORMODE:</td>
<td>0 for black&amp;white, 1 for color. This is not supported on Macintosh and always returns 1.</td>
</tr>
</tbody>
</table>

The keyword-value pairs for the getPageDimensions keyword are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAPER:</td>
<td>The left, top, right, and bottom coordinates of the paper in points, separated by commas.</td>
</tr>
<tr>
<td></td>
<td>The top and left are negative numbers so that the page can start at (0,0).</td>
</tr>
<tr>
<td>PAGE:</td>
<td>The left, top, right, and bottom coordinates of the page in points, separated by commas.</td>
</tr>
<tr>
<td></td>
<td>The term page refers to the part of the paper inside the margins. The top/left corner of the page is always at (0, 0).</td>
</tr>
<tr>
<td>PRINTAREA:</td>
<td>The left, top, right, and bottom coordinates of the page in points, separated by commas.</td>
</tr>
<tr>
<td></td>
<td>The print area is the part of the paper on which printing can occur, as determined by the printer. This is equal to the paper inset by the minimum supported margins. The top and left are negative numbers so that the page can start at (0,0).</td>
</tr>
</tbody>
</table>

**Examples**
For an example using the PrintSettings operation, see the PrintSettings Tests example experiment file in the “Igor Pro Folder:Examples:Testing” folder.

Here are some simple examples showing how you can use the PrintSettings operation.

```plaintext
Function GetOrientation(name) // Returns 0 (portrait) or 1 (landscape)
  String name // Name of graph, table, layout or notebook
  PrintSettings/W=$name getPageSettings
  Variable orientation = NumberByKey("ORIENTATION", S_value)
  return orientation
End

Function SetOrientationToLandscape(name)
  String name // Name of graph, table, layout or notebook
  PrintSettings/W=$name orientation=1
End

Function/S GetPrinterList()
  PrintSettings getPrinterList
  return S_value
End

Function SetPrinter(destWinName, printerName)
  String destWinName, printerName
  PrintSettings/W=$destWinName setPrinter=printerName
  return 0
End
```
See Also
The PrintGraphs, PrintTable, PrintLayout and PrintNotebook operations.

PrintTable

PrintTable [\(\text{winName}\)]

The PrintTable operation prints the named table window.

Parameters

\(\text{winName}\) is the window name of the table to print.

Flags

\[\text{P=(startPage,endPage)}\]

Specifies a page range to print. 1 is the first page.

If \(\text{P}\) is omitted all pages are printed unless \(\text{S}\) is used.

\[\text{S=selection}\]

Controls what is printed.

\(\text{selection}=0:\) Print entire table (default).

\(\text{selection}=1:\) Print selection only.

See Also
Chapter II-11, Tables.

The PrintSettings, PrintGraphs, PrintLayout and PrintNotebook operations.

Proc

Proc macroName([\(\text{parameters}\)]) [\(\text{:macro type}\)]

The Proc keyword introduces a macro that does not appear in any menu. Otherwise, it works the same as Macro. See Macro Syntax on page IV-116 for further information.

ProcedureText

ProcedureText(macroOrFunctionNameStr [,\(\text{linesOfContext}\) [,\(\text{procedureWinTitleStr}\)]])

The ProcedureText function returns a string containing the text of the named macro or function as it exists in some procedure file, optionally with additional lines that are before and after to provide context or to collect documenting comments.

Alternatively, all of the text in the specified procedure window can be returned.

Parameters

\(\text{macroOrFunctionNameStr}\) identifies the macro or function. It may be just the name of a global (nonstatic) procedure, or it may include a module name, such as "myModule#myFunction" to specify the static function myFunction in a procedure window that contains a #pragma ModuleName=myModule statement.

If \(\text{macroOrFunctionNameStr}\) is set to "", and \(\text{procedureWinTitleStr}\) specifies the title of a single procedure window, then all of the text in the procedure window is returned.

\(\text{linesOfContext}\) optionally specifies the number of lines around the function to include in the returned string. The default is 0 (no additional contextual lines of text are returned). This parameter is ignored if \(\text{macroOrFunctionNameStr}\) is "" and \(\text{procedureWinTitleStr}\) specifies the title of a single procedure window.

Setting \(\text{linesOfContext}\) to a positive number returns that many lines before the procedure and after the procedure. Blank lines are not omitted.

Setting \(\text{linesOfContext}\) to -1 returns lines before the procedure that are not part of the preceding macro or function. Usually these lines are comment lines describing the named procedure. Blank lines are omitted.

Setting \(\text{linesOfContext}\) to \(-n\), where \(n>1\), returns at most \(n\) lines before the procedure that are not part of the preceding macro or function. Blank lines are not omitted in this case. \(n\) can be \(-\inf\), which acts the same as \(-1\) but includes blank lines.

The optional \(\text{procedureWinTitleStr}\) can be the title of a procedure window (such as "Procedure" or "File Name Utilities.ipf"). The text of the named macro or function in the specified procedure window is returned.
You can use `procedureWinTitleStr` to select one of several static functions with identical names among different procedure windows, even if they do not use a `#pragma moduleName=myModule` statement.

**Advanced Parameters**
If `SetIgorOption IndependentModuleDev=1`, `procedureWinTitleStr` can also be a title followed by a space and, in brackets, an independent module name. In such cases `ProcedureText` retrieves function text from the specified procedure window and independent module. (See Independent Modules on page IV-231 for independent module details.)

For example, in a procedure file containing:

```
#pragma IndependentModule=myIM
#include <Axis Utilities>
```

A call to `ProcedureText` like this:

```java
String text=ProcedureText("HVAxisList",0,"Axis Utilities.ipf [myIM]")
```

will return the text of the `HVAxisList` function located in the `Axis Utilities.ipf` procedure window, which is normally a hidden part of the `myIM` independent module.

You can see procedure window titles in this format in the Windows→Procedure Windows menu when `SetIgorOption IndependentModuleDev=1` and when an experiment contains procedure windows that comprise an independent module, as does `<New Polar Graphs>`.

`procedureWinTitleStr` can also be just an independent module name in brackets to retrieve function text from any procedure window that belongs to the named independent module:

```java
String text=ProcedureText("HVAxisList",0,"[myIM]")
```

See Also
Regular Modules on page IV-229 and Independent Modules on page IV-231.
The WinRecreation and FunctionList functions.

---

**ProcGlobal**

**ProcGlobal procPictureName**
The ProcGlobal keyword is used with Proc Pictures to avoid possible naming conflicts with any other global pictures in the experiment. When you add a picture to an experiment using the Pictures dialog, such a picture is global in scope and may potentially have the same name as a Proc Picture. When a Proc Picture is global (and only then), you should use the ProcGlobal keyword to make sure that the Proc Picture is used with your code and to avoid confusion with pictures in the Pictures dialog.

See Also
See Proc Pictures on page IV-57 for details. Pictures Dialog on page III-482.

---

**Project**

**Project [/C={long, lat}/M=method /P={p1, p2, ...}] longitudeWave, latitudeWave**
The Project operation calculates projections of XY data, which most often are longitude and latitude waves of geographic coordinates. The output waves are W_XProjection and W_YProjection. Longitude and Latitude are in degrees.

**Parameters**
`longitudeWave` is the name of the wave supplying the longitude or equivalent coordinates. `latitudeWave` is the name of the wave supplying the latitude or equivalent coordinates.

**Flags**

```
/C=[long, lat]  Specifies longitude and latitude center of projection. By default long=0 and lat=90.
```
\(/M=method\) Indicates the type of projection. \textit{method} can be one of the following:

0: Orthographic (default).
1: Stereographic.
2: Gnomonic.
3: General perspective.
4: Lambert equal area.
5: Equidistant.
6: Mercator.
7: Transverse Mercator.
8: Albers Equal Area conic.

\(/P=[p1,p2,…]\) One or more parameters required by a particular projection. See the following sections for parameters required by the various projections.

\textbf{Gnomonic}

Here there is one extra parameter that defines the boundaries based on the angle. The specific expression for the limit is that \(\cos(c)\) in Eq. (5-3) of Snyder is greater than the specified parameter:

\(/P=\{\cos(c)\}\)

The actual transformation uses Eqs. (22-4) and (22-5) of Snyder with \(k'\) given by (22-3).

\textbf{General Perspective}

Here there is one extra parameter that defines the boundaries based on the angle. The specific expression for the limit is that \(\cos(c)\) in Eq. (5-3) of Snyder is greater than the specified parameter.

The actual transformation uses Eqs. (22-4) and (22-5) with \(k'\) given by (22-3). Here we specify the height \(H\) is units of sphere radius. The tilt of the plane is specified by \(\omega\) and \(\gamma\) following the notation of Snyder page 175.

The parameters actually specified by the command are:

\(/P=\{H, \omega, \gamma, \text{deltax}, \text{deltay}\}\)

\(H\) is the height (in radii) above the surface of the earth, \(\gamma\) is the azimuth east of north of the Y axis, and \(\omega\) is the tilt angle or the angle between the projection plane and the tangent plane. The \(x\) output will be limited to \(\pm \text{deltax}\) and the \(y\) output will be limited to the range \(\pm \text{deltay}\).

\textbf{Mercator}

This projection requires the following parameters:

\(/P=\{\text{minLong}, \text{maxLong}, \text{minLat}, \text{maxLat}\}\)

If \(P\) is not specified, the default is \([0,360,-90,90]\)

Note that this projection flips the sign of \(y\) when \(\cos(\text{longitude-long}_0)\) changes sign. If you are plotting a continuous path in which consecutive points exhibit the sign change, you should add a NaN entry in the wave so that the path does not wrap.

\textbf{Albers Equal Area Conic}

This projection requires:

\(/P=[\text{minLong}, \text{maxLong}, \text{minLat}, \text{maxLat}, \text{Phi1}, \text{Phi2}]\)

\(\text{Phi1}\) and \(\text{Phi2}\) are the specification of the two standard parallels, the other four parameters determine the boundary of the map area for display.

\textbf{References}

\textbf{See Also}

“Transforming Data into a Common Spatial Reference” in the “IgorGIS Help” file.
Prompt

**Prompt**

```
Prompt variableName, titleStr [, popup, menuListStr]
```

The Prompt command is used in functions for the simple input dialog and in macros for the missing parameter dialog. Prompt supplies text to describe `variableName` to the user, and optionally provides a pop-up menu of choices for the value of `variableName`.

**Parameters**

- `variableName` is the name of a macro input parameter or function variable.
- `titleStr` is a string or string expression containing the text to present in the dialog to describe what `variableName` is. `titleStr` is limited to 255 bytes.

The optional keyword `popup` is used to provide a pop-up list of choices for the values of `variableName`. If `popup` is used, then `menuListStr` is required.

- `menuListStr` is a string or string expression that contains a semicolon-separated list of choices for the value of `variableName`. If `variableName` is a string, choosing from this list will set the string to the selection. If it is a numeric variable, then it is set to the item number of the selection (if the first item is selected, the numeric variable is set to 1, etc.).

**Details**

In macros, there must be a blank line after the set of input parameter declarations and prompt statements and there must not be any blank lines within the set.

In user-defined functions, Prompt may be used anywhere within the body of the function, but must precede any DoPrompt that uses the Prompt variable.

`menuListStr` may be continued on succeeding lines only in macros, as long as no comment is appended to the Prompt line. The additional lines should start with a semicolon, and are appended to the `menuListStr` on preceding lines.

**See Also**

For use in user-defined functions, see *The Simple Input Dialog* on page IV-138.

For use in macros, see *The Missing Parameter Dialog* on page IV-120.

For use in functions and macros, see the `DoPrompt` and `popup` keywords.

**PulseStats**

```
PulseStats [flags] waveName
```

The PulseStats operation produces simple statistics on a region of the named wave that is expected to contain three edges as shown below. If more than three edges exist, PulseStats works on the first three edges it finds.

PulseStats handles other cases in which there are only one or two edges.
Flags

/\textasciitilde{A}=n \quad \text{Determines startLevel and endLevel automatically by averaging } n \text{ points centered at startX and endX. This does not work in case 2, which requires that you use the /L flag. Default is } /A=1.\

/B=\text{box} \quad \text{Sets box size for sliding average. This should be an odd number. If } /B=\text{box} \text{ is omitted or box equals 1, no averaging is done.}\

/F=f \quad \text{Specifies levels 1, 2, and 3 as a fraction of } (\text{endLevel-startLevel}):\quad \text{level1} = \text{level2} = \text{level3} = f*(\text{endLevel-startLevel}) + \text{startLevel}\

\text{f must be between 0 and 1. The default value is 0.5 which sets the levels to midway between the base levels.}\

/L=(\text{startLevel, endLevel}) \quad \text{Sets startLevel and endLevel explicitly.}\

/M=dx \quad \text{Sets minimum edge width. Once an edge is found, the search for the next edge starts } dx \text{ units beyond the found edge. Default } dx = 0.\

/P \quad \text{Output edge locations (see Details) are set in terms of point number. If } /P \text{ is omitted, edge locations are set in terms of X values.}\

/Q \quad \text{Prevents results from being printed in history and prevents error if edge is not found.}\

/R=(startX, endX) \quad \text{Specifies an X range of the wave to search. You may exchange startX and endX to reverse the search direction.}\

/R=[startP, endP] \quad \text{Specifies a point range of the wave to search. You may exchange startP and endP to reverse the search direction.}\

\text{If you specify the range as } /R=[startP] \text{ then the end of the range is taken as the end of the wave. If } /R \text{ is omitted, the entire wave is searched.}\

/T=dx \quad \text{Forces search in two directions for a possibly more accurate result. } dx \text{ controls where the second search starts.}\

Details

The /B=\text{box}, /T=dx, /P and /Q flags behave the same as for the \textbf{FindLevel} operation.

PulseStats considers a region of the input wave between two X locations, called startX and endX. startX and endX are set by the /R=(startX, endX) flag. If this flag is missing, startX and endX default to the start and end of the entire wave.

The startLevel and endLevel values define the base levels of the pulse. You can explicitly set these levels with the /L=(startLevel, endLevel) flag or you can let PulseStats find the base levels for you by using the /A=n flag. With this flag, PulseStats determines startLevel and endLevel by averaging n points centered at startX and at endX. In case 2, you must use /L=(startLevel, endLevel) since startLevel is not at point 0.
Given \( \text{startLevel} \) and \( \text{endLevel} \) and an \( f \) value (which you can set with the \(/F=f\) flag), PulseStats computes level1, level2 and level3 which are always equal. With the default \( f \) value of 0.5, level1 is midway between \( \text{startLevel} \) and \( \text{endLevel} \).

With these levels defined, PulseStats searches the wave from \( \text{startX} \) to \( \text{endX} \) looking for one, two or three level crossings. PulseStats sets the following variables:

- \( V\_\text{flag} \):
  - 0: All three level crossings were found.
  - 1: One or two level crossings were found.
  - 2: No level crossings were found.
- \( V\_\text{PulseLoc1} \): X location where level1 was found.
- \( V\_\text{PulseLoc2} \): X location where level2 was found.
- \( V\_\text{PulseLoc3} \): X location where level3 was found.
- \( V\_\text{PulseLvl0} \): \( \text{startLevel} \) value.
- \( V\_\text{PulseLvl123} \): Level1 value that is the same as level2 and level3.
- \( V\_\text{PulseLvl4} \): \( \text{endLevel} \) value.
- \( V\_\text{PulseAmp4}_0 \): Pulse amplitude \((\text{endLevel} - \text{startLevel})\).
- \( V\_\text{PulseWidth2}_1 \): Left pulse width (x distance between point 2 and point 1).
- \( V\_\text{PulseWidth3}_2 \): Right pulse width (x distance between point 3 and point 2).
- \( V\_\text{PulseWidth3}_1 \): Pulse period (x distance between point 3 and point 1).
- \( V\_\text{PulsePolarity} \): Trend of the edge at point 1 (-1 if decreasing, +1 if increasing).

X locations and distances are in terms of the X scaling of the source wave, unless you use the \(/P\) flag in which case they are in terms of point number.

If any level crossings are missing then PulseStats sets the associated variables to NaN (Not a Number). If one crossing is missing, variables depending on point 3 are set to NaN. If two crossings are missing, variables depending on points 2 and 3 are set to NaN. If all crossings are missing, variables depending on points 1, 2, and 3 are set to NaN. You can use the numtype function to test a variable to see if it is NaN.

The PulseStats operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-89 for details.

See Also
The FindLevel operation about the \(/B=box, /T=dx, /P\) and \(/Q\) flags, EdgeStats and the numtype function.

PutScrapText

The PutScrapText operation places \textStr{} on the Clipboard (aka “scrap”). This text will be used when the user subsequently chooses Paste from the Edit menu.

Details
All contents of the Clipboard (including pictures) are cleared before the text is placed there.

Examples
Put two lines of text into the Clipboard:

```java
String text = "This is the first line.\rAnd this is the second."
PutScrapText text
```
Empty the Clipboard:

```
PutScrapText ""
```

See Also
The GetScrapText function and the SavePICT operation.
pwd

pwd
The pwd operation prints the full path of the current data folder to the history area. It is equivalent to Print GetDataFolder(1).

pwd is named after the UNIX "print working directory" command.

See Also
GetDataFolder, cd, Dir, Data Folders on page II-101

q

q
The q function returns the current column index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled column index is available as the y function.

Details
Unlike p, outside of a wave assignment statement, q does not act like a normal variable.

See Also
Waveform Arithmetic and Assignments on page II-69.
For other dimensions, the p, r, and s functions.
For scaled dimension indices, the x, y, z and t functions.

qcsr

qcsr(cursorName [, graphNameStr])
The qcsr function can be used with cursors on images or waterfall plots to return the column number. It can also be used with free cursors to return the relative Y coordinate.

Parameters
cursorName identifies the cursor, which can be cursor A through J.
graphNameStr specifies the graph window or subwindow.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

See Also
The hcsr, pcsr, vcsr, xcsr, and zcsr functions.
Programming With Cursors on page II-256.

Quit

Quit [/N/Y]
The Quit operation quits Igor Pro.

Flags
/N Quits without saving changes and without dialog.
/Y Saves current experiment before quitting without putting up dialog unless current experiment is “Untitled”.

r

r
The r function returns the current layer index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled layer index is available as the z function.

Details
Unlike p, outside of a wave assignment statement, r does not act like a normal variable.
See Also
Waveform Arithmetic and Assignments on page II-69. For other dimensions, the p, q, s, and t functions. For scaled dimension indices, the x, y, z, and t functions.

r2polar

\begin{verbatim}
r2polar(z)
\end{verbatim}

The \texttt{r2polar} function returns a complex value in polar coordinates derived from the complex value \texttt{z}, which is assumed to be in rectangular coordinates. The magnitude is stored in the real part and the angle (in radians) is stored in the imaginary part of the returned complex value.

\textbf{Examples}

Assume \texttt{waveIn} and \texttt{waveOut} are complex.

\begin{verbatim}
waveOut = r2polar(waveIn)
\end{verbatim}

sets each point of \texttt{waveOut} to the polar coordinates derived from the real and imaginary parts of \texttt{waveIn}.

You may get unexpected results if the number of points in \texttt{waveIn} differs from the number of points in \texttt{waveOut}.

See Also
The functions \texttt{cmplx, conj, imag, p2rect, and real}.

\textbf{RatioFromNumber}

\begin{verbatim}
RatioFromNumber [flags] num
\end{verbatim}

The \texttt{RatioFromNumber} operation computes two integers whose ratio is equal to \texttt{num} \pm \texttt{maxError} (/MERR flag). The ratio is returned in \texttt{V_numerator} and \texttt{V_denominator}.

\textbf{Parameters}

\texttt{num} is the number to approximate by \texttt{V_numerator}/\texttt{V_denominator}.

\textbf{Flags}

\begin{verbatim}
/MERR=maxError
\end{verbatim}

Specifies the maximum tolerable error. The computed ratio differs from \texttt{num} by no more than \texttt{maxError} (default value is \texttt{num}\texttt{*1e-6}).

\texttt{maxError} must be a value between 0 and \texttt{num}. See Details about setting \texttt{maxError} to 0.

\begin{verbatim}
/MITIS=maxIterations
\end{verbatim}

Keeps returned values small by specifying a small number for \texttt{maxIterations}.

\texttt{maxIterations} must be a value between 1 and 32767 (default is 100).

\begin{verbatim}
/V[v]
\end{verbatim}

Prints output variables to history.

\texttt{v}=1: Prints variables (same as /V).
\texttt{v}=0: Nothing printed (same as no /V).

\textbf{Details}

The ratio is computed by continued fraction expansion and recurrence relations for the convergents and checking \texttt{num} - (\texttt{V_numerator}/\texttt{V_denominator}) against \texttt{maxError}.

Setting \texttt{maxError} = 0 computes a maximally accurate ratio. The returned values can be surprisingly large:

\begin{verbatim}
RatioFromNumber/V/MERR=0 (1/1666)
\end{verbatim}

\begin{verbatim}
V_numerator= 4398046511104; V_denominator= 7.3271454874993e+15;
\end{verbatim}

\begin{verbatim}
ratio= 0.00060024009603842; V_difference= 0;
\end{verbatim}

Using the default /MERR returns the expected 1 and 1666. The difference is attributable to floating-point roundoff errors.

The ratio is computed by continued fraction expansion and recurrence relations for the convergents and checking \texttt{num} - (\texttt{V_numerator}/\texttt{V_denominator}) against /MERR.

\textbf{Output Variables}

\texttt{RatioFromNumber} sets the following output variables:

\begin{verbatim}
V_difference \quad V_{numerator}/V_{denominator} - num (positive if the approximation is too big).
\end{verbatim}
Rect

V_flag

0: V_difference less than or equal to /MERR.
1: V_difference greater than /MERR.

V_numerator, V_denominator

Values for the numerator and denominator. The ratio of V_numerator/V_denominator approximates num.

V_iterations

The number of iterations actually used.

Examples

RatioFromNumber/V pi

V_numerator = 355; V_denominator = 113; ratio = 3.141592920354;
V_difference = 2.6676418940497e-07; V_iterations = 3;

RatioFromNumber/V/MITS=2 pi

V_numerator = 22; V_denominator = 7; ratio = 3.1428571428571;
V_difference = 0.0012644892673497; V_iterations = 1;

See Also

The gcd and trunc functions.

Rect

The Rect structure is used as a substructure usually to store the coordinates of a window or control.

Structure Rect

Int16 top
Int16 left
Int16 bottom
Int16 right
EndStructure

RectF

The RectF structure is the same as Rect but with floating point fields.

Structure RectF

float top
float left
float bottom
float right
EndStructure

ReadVariables

ReadVariables

The ReadVariables operation reads variables into an experiment.

ReadVariables is used automatically when you open an experiment. You need not invoke it.

real

real(z)

The real function returns the real component of the complex value z.

See Also

The functions cmplx, conj, imag, p2rect, and r2polar.

Redimension

Redimension [flags] waveName [, waveName]...

The Redimension operation remakes the named waves, preserving their contents as much as possible.

Flags

/B

Converts waves to 8-bit signed integer or unsigned integer if /U is present.

/C

Converts real waves to complex.
Wave Data Types
As a replacement for the above number type flags you can use /Y=numType to set the number type as an integer code. See the WaveType function for code values. Do not use /Y in combination with other type flags. This technique cannot be used to change the number type without changing the real/complex setting.

Details
The waves must already exist. New points in waves that are extended are zeroed.
In general, Redimension does not move data from one dimension to another. For instance, if you have a 6x6 matrix wave, and you would like it to be 3x12, the rows have been shortened and the data for the last three rows is lost.
As a special case, if converting to or from a 1D wave, Redimension will leave the data in place while changing the dimensionality of the wave. For example, you can use Redimension to convert a 36-element 1D wave into a 6x6 matrix in which the elements in the first column (column 0) are the first 6 elements of the 1D wave, the elements of the second column are the next 6, etc. When redimensioning from a 1D wave, columns are filled first, then layers, followed by chunks.

Examples
Reshaping a 1D wave having 4 elements to make a 2x2 matrix:
Make/N=4 vector=x
Redimension/N=(2,2) vector

See Also
Make, DeletePoints, InsertPoints, Concatenate, SplitWave

Remez
Remez [/N=num /Q=iter] frWave, wtWave, gridWave, coefsWave
The Remez operation calculates the coefficients for digital filters given a desired frequency response as input.
Remez is primarily used for the MPR filter feature of the Igor Filter Design Laboratory (IFDL) package.
Parameters

*frWave* contains the desired response.

*wtWave* contains the weight function array. For a differentiator, the weight function is inversely proportional to frequency.

*gridWave* contains the frequencies corresponding to each point in *frWave* and *wtWave*. Its values range from 0 to 0.5 with gaps where the band edges occur.

*coefsWave* receives the resulting coefficients. Its length defines the number of coefficients (nfilt in the IEEE program referenced below).

Flags

\(/N=mode\)

\(mode=0\): Selects multiple passband/stopband filter (default).

\(mode=1\): Selects differentiator or Hilbert transform filter.

\(/Q=[iter]\)

Determines if execution stops if the filter doesn’t converge.

If you omit \(/Q\), execution stops if the filter doesn’t converge.

If you specify \(/Q\) or \(/Q=0\), execution continues if the filter doesn’t converge, regardless of the number of iterations.

For \(iter=1\), execution stops if the filter fails to converge in \(iter\) iterations or less. If the filter does converge after \(iter\) iterations, execution does stop.

Use \(/Q=3\) to stop execution for serious errors (after only 1, 2, or 3 iterations) but not for minor errors (after 4 or more iterations).

Details

Remez returns symmetrical coefficients suitable for use with FilterFIR in *coefsWave*.

The algorithm is based upon the McClellan-Parks-Rabiner Fortran program as found in the IEEE and Elliot references cited below.

If the filter converged, Remez sets V_Flag to 0. Otherwise it sets it to the number of iterations before it failed.

Example

This example specifies a length 41 lowpass filter with passband 0 to 0.14 x fs and stopband 0.18 x fs to 0.5 x fs. The passband weight is equal to the stopband weight.

```plaintext
Make/O/N=41 coefs = NaN
Make/O/N=(41*16) fr, wt, grid
grid = 0.5*p/numpnts(grid) // Frequencies where fr and wt define desire response
wt = 1
fr[0,0.14*numpnts(fr)] = 1 // Low pass from 0 to 0.14 x fs
// Remove transition frequencies
DeletePoints 0.14*numpnts(fr), 0.04*numpnts(fr), fr, wt, grid
// Compute filter coefs
Remez fr, wt, grid, coefs
// Analyze the filter's frequency response
FFT/OUT=3/PAD={256}/DEST=coefs_FFT coefs
// Display filter response for 1Hz sample rate
Display coefs_FFT
```

References

Remove

When interpreting a command, Igor treats the Remove operation as RemoveFromGraph, RemoveFromTable, or See Also, depending on the target window. This does not work when executing a user-defined function. Therefore, we recommend that you use RemoveFromGraph, RemoveFromTable, or RemoveLayoutObjects rather than Remove.

RemoveByKey

RemoveByKey(keyStr, kwListStr [, keySepStr [, listSepStr [, matchCase]]])

The RemoveByKey function returns kwListStr after removing the keyword-value pair specified by keyStr. kwListStr should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for keySepStr and listSepStr.

Use RemoveByKey to remove information from a string containing a "key1:value1;key2:value2;" or "key1=value1,key2=value2," style list such as those returned by functions like AxisInfo or TraceInfo.

If keyStr is not found then kwListStr is returned unchanged.

keySepStr, listSepStr, and matchCase are optional; their defaults are ":", ";", and 0 respectively.

Details

keyStr is limited to 255 bytes.

kwListStr is searched for an instance of the key string bound by listSepStr on the left and a keySepStr on the right. The key, the keySepStr, and the text up to and including the next listSepStr (if any) are removed from the returned string.

If the resulting string contains only listSepStr characters, then an empty string (" ") is returned.

kwListStr is treated as if it ends with a listSepStr even if it doesn’t.

Searches for keySepStr and listSepStr are always case-sensitive. Searches for keyStr in kwListStr are usually case-insensitive. Setting the optional matchCase parameter to 1 makes the comparisons case sensitive.

In Igor6, only the first byte of keySepStr and listSepStr was used. In Igor7 and later, all bytes are used.

If listSepStr is specified, then keySepStr must also be specified. If matchCase is specified, keySepStr and listSepStr must be specified.

Examples

Print RemoveByKey("AKEY", "AKEY:123;BKEY:val") // prints "BKEY:val"
Print RemoveByKey("AKey", "Akey=1;BK=b;", ";") // prints "Bk=b;"
Print RemoveByKey("AKEY", "AKey=1,BK=b;","=") // prints "Bk=b;"
Print RemoveByKey("ckey", "Ckey:1;BKey:2") // prints "BKey:2"
Print RemoveByKey("ckey", "Ckey:1;BKey:2;":",";",1) // prints "Ckey:1;BKey:2"

See Also

The NumberByKey, StringByKey, ReplaceNumberByKey, ReplaceStringByKey, ItemsInList, AxisInfo, IgorInfo, SetWindow, and TraceInfo functions.

RemoveContour

RemoveContour [/W=winName] contourInstanceName [, contourInstanceName]...

The RemoveContour operation removes the traces, and releases memory associated with the contour plot of contourInstanceName in the target or named graph.

Parameters

countourInstanceName is usually simply the name of a wave. More precisely, contourInstanceName is a wave name, optionally followed by the # character and an instance number to identify which contour plot of a given wave is to be removed.
If the axes used by the contour plot are no longer in use, they will also be removed.

A contour instance name in a string can be used with the $ operator to specify contourInstance.

Examples

Display;AppendMatrixContour zw //new graph, contour of zw matrix
AppendMatrixContour zw    //two contours of zw
RemoveContour zw#1       //remove the second contour

See Also
The AppendMatrixContour and AppendXYZContour operations.

RemoveEnding

RemoveEnding(str [, endingStr])
The RemoveEnding function removes one character from the end of str, or it removes the endingStr from the end of str.

The RemoveEnding function returns str with endingStr removed from the end. If you omit endingStr, it returns str with one grapheme removed from the end.

Details
If you specify endingStr, RemoveEnding compares it to the end of str using case-insensitive comparison. If there is a match, RemoveEnding returns the contents of str up to endingStr. If there is no match, RemoveEnding returns the entirety of str.

If you omit endingStr, RemoveEnding returns str with the last grapheme removed. A grapheme is whatever visually appears to be one character even if it consists of more than one character. In "ABC", the last grapheme is "C" which is also the last character. In "ABÇ", "Ç" consists of two characters: a C character and a "combining cedilla" character; RemoveEnding removes "Ç" which is the last grapheme.

Examples

Print RemoveEnding("123")   // Prints "12"
Print RemoveEnding("ABÇ")   // Prints "AB"
Print RemoveEnding("no semi", ",;") // Prints "no semi"
Print RemoveEnding("trailing semi;", ",;") // Prints "trailing semi"
Print RemoveEnding("file.txt", ".TXT") // Prints "file"

See Also
The CmpStr and ParseFilePath functions.

RemoveFromGizmo

RemoveFromGizmo [flags]
The RemoveFromGizmo operation removes the specified object from the specified list and optionally performs an update.

Documentation for the RemoveFromGizmo operation is available in the Igor online help files only. In Igor, execute:

DisplayHelpTopic "RemoveFromGizmo"
RemoveFromGraph

RemoveFromGraph [/W=winName/Z] traceName [, traceName]...

The RemoveFromGraph operation removes the specified wave traces from the target or named graph. A trace is a representation of the data in a wave, usually connected line segments.

Parameters

traceName is usually just the name of a wave.

More generally, traceName is a wave name, optionally followed by the # character and an instance number - for example, wave0#1. See Instance Notation on page IV-20 for details.

Flags

/W=winName Removes traces from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/Z Suppresses errors if specified trace or image is not on the graph.

Details

Up to 100 traceNames may be specified, subject to the 2500 byte command length limit.

If the axes used by the given trace are not in use after removing the trace, they will also be removed.

A string containing a trace name can be used with the $ operator to specify traceName.

Specifying "$#0" for traceName removes the first trace in the graph. "$#1" removes the second trace in the graph, and so on. "$" is equivalent to "$#0".

Note that removing all the contour traces from a contour plot is not the same as removing the contour plot itself. Use the RemoveContour operation.

Examples

The command:

Display myWave,myWave;Modify mode(myWave#1)=6

appends two instances of myWave to the graph. The first/backmost instance of myWave is instance 0, and its trace name is just myWave as a synonym for myWave#0. The second or frontmost instance of myWave is myWave#1 and it is displayed with the cityscape mode.

To remove the second instance from the graph requires the command:

RemoveFromGraph myWave#1

or

String MyTraceName="myWave#1"
RemoveFromTrace $MyTraceName

See Also

Trace Names on page II-222, Programming With Trace Names on page IV-86.

RemoveFromLayout

RemoveFromLayout objectSpec [, objectSpec]...

Deprecated — use RemoveLayoutObjects.

The RemoveFromLayout operation removes the specified objects from the top layout.

Parameters

objectSpec is either an object name (e.g., Graph0) or an objectName with an instance (e.g., Graph0#1). An instance is needed only if the same object appears in the layout more than one time. Graph0 is equivalent to Graph0#0 and Graph0#1 refers to the second instance of Graph0 in the layout.

See Also

The RemoveLayoutObjects operation.
RemoveFromList

RemoveFromList(itemOrListStr, listStr [, listSepStr [, matchCase]])

The RemoveFromList function returns listStr after removing the item or items specified by itemOrListStr. listStr should contain items separated by listSepStr which typically is ";".

If itemOrListStr contains multiple items, they should be separated by the listSepStr character, too.

Use RemoveFromList to remove item(s) from a string containing a list of items separated by a string (usually a single ASCII character), such as those returned by functions like TraceNameList or AnnotationList, or a line from a delimited text file.

If all items in itemOrListStr are not found or if any of the arguments is "" then listStr is returned unchanged (unless listStr contains only list separators, in which case an empty string is returned).

listSepStr and matchCase are optional; their defaults are ";" and 1 respectively.

Details

itemStr may have any length.

listStr is searched for an instance of the item string(s) bound by listSepStr on the left and right. All instances of the item(s) and any trailing listSepStr (if any) are removed from the returned string.

If the resulting string contains only listSepStr characters, then an empty string (""") is returned.

listStr is treated as if it ends with a listSepStr even if it doesn’t.

Searches for listSepStr are case-sensitive. Searches for items in itemOrListStr are usually case-sensitive. Setting the optional matchCase parameter to 0 makes the comparisons case insensitive.

In Igor6, only the first byte of listSepStr was used. In Igor7 and later, all bytes are used.

If matchCase is specified, then listSepStr must also be specified.

Examples

Print RemoveFromList("wave1", "wave0;wave1;") // prints "wave0;"
Print RemoveFromList("wave1", ";wave1;;;") // prints ""
Print RemoveFromList("KEY=joy", "AX=3,KEY=joy", ";") // prints "AX=3,"
Print RemoveFromList("fred", "fred\twilma", ";") // prints "wilma"
Print RemoveFromList("fred;barney","fred;wilma;barney")// prints "wilma;"
Print "X"+RemoveFromList("",";;;")+"Y" // prints "XY"
Print RemoveFromList("FRED", "fred;wilma") // prints "fred;wilma"
Print RemoveFromList("FRED", "fred;wilma", ";", 0) // prints "wilma"

See Also

The FindListItem, FunctionList, ItemsInList, RemoveByKey, RemoveListItem, StringFromList, StringList, TraceNameList, UpperStr, VariableList, and WaveList functions.

RemoveFromTable

RemoveFromTable [/W=winName] columnSpec [, columnSpec]…

The RemoveFromTable operation removes the specified columns from the top table.

Parameters

columnSpecs are the same as for the Edit operation; usually they are just the names of waves.

Flags

/W=winName Removes columns from the named table window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

See Also

Edit about columnSpecs, and AppendToTable.
RemoveImage

RemoveImage [/W=winName/Z] imageInstance [, imageInstance]...

The RemoveImage operation removes the given image from the target or named graph.

Parameters
imageInstance is usually simply the name of a wave. More precisely, imageInstance is a wave name, optionally followed by the # character and an instance number to identify which image of a given wave is to be removed.

Flags
/W=winName Removes an image from the named graph window or subwindow. When omitted, action will affect the active window or subwindow. Must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.
/Z Suppresses errors if specified image is not on the graph.

Details
If the axes used by the given image are not in use after removing the image, they will also be removed.
An image name in a string can be used with the $ operator to specify imageInstance.

See Also
The AppendImage operation.

RemoveLayoutObjects

RemoveLayoutObjects [/PAGE=page/W=winName/Z] objectSpec [, objectSpec]... The RemoveLayoutObjects operation removes the specified object or objects from the top page layout, or from the layout specified by the /W flag. It targets the active page or the page specified by the /PAGE flag.

Unlike the RemoveFromLayout operation, RemoveLayoutObjects can be used in user-defined functions. Therefore, RemoveLayoutObjects should be used in new programming.

Parameters
objectSpec is either an object name (e.g., Graph0) or an objectName with an instance (e.g., Graph0#1). An instance is needed only if the same object appears in the layout more than one time. Graph0 is equivalent to Graph0#0 and Graph0#1 refers to the second instance of Graph0 in the layout.

Flags
/PAGE=page Removes the object from the specified page.
Page numbers start from 1. To target the active page, omit /PAGE or use page=0.
The /PAGE flag was added in Igor Pro 7.00.
/W=winName winName is the name of the page layout window from which the object is to be removed. If /W is omitted or if winName is "$", the top page layout is used.
/Z Does not report errors if the specified layout object does not exist.

See Also
NewLayout, AppendLayoutObject, ModifyLayout, LayoutPageAction

RemoveListItem

RemoveListItem(index, listStr [, listSepStr [, offset]])
The RemoveListItem function returns listStr after removing the item specified by the list index index.
RemoveListItem removes an item from a string containing a list of items separated by a separator, such as strings returned by functions like TraceNameList and AnnotationList.
Parameters

*index* is the zero-based index of the list item that you want to remove.

*listStr* contains a series of text items separated by *listSepStr*. The trailing separator is optional though recommended.

*listSepStr* is optional. If omitted it defaults to ";". Prior to Igor Pro 7.00, only the first byte of *listSepStr* was used. Now all bytes are used.

*offset* is optional and requires Igor Pro 7.00 or later. If omitted it defaults to 0. The search begins *offset* bytes into *listStr*. When iterating through lists containing large numbers of items, using the *offset* parameter provides dramatically faster execution. For an example using the *offset* parameter, see *StringFromList*.

Details

RemoveListItem differs from *RemoveFromList* in that it specifies the item to be removed by index and removes only that item, while *RemoveFromList* specifies the item to be removed by value, and removes all matching items.

If *index* less than 0 or greater than *ItemsInList(listStr) - 1*, or if *listSepStr* is "" then *listStr* is returned unchanged (unless *listStr* contains only list separators, in which case an empty string is returned).

If the resulting string contains only *listSepStr* characters, then an empty string (""") is returned.

Examples

Print RemoveListItem(1, "wave0;wave1;w2;") // Prints "wave0;w2;"

See Also

The *AddListItem, FindListItem, FunctionList, ItemsInList, RemoveByKey, RemoveFromList, StringFromList, StringList, TraceNameList, VariableList, WaveList*, and *WhichListItem* functions.

**RemovePath**

`RemovePath` [A/Z] *pathName*

The RemovePath operation removes a path from the list of symbolic paths. RemovePath is an old name for the new *KillPath* operation, which we recommend you use instead.

**Rename**

`Rename` *oldName, newName*

The Rename operation renames waves, strings, or numeric variables from *oldName* to *newName*.

Parameters

*oldName* may be a simple object name or a data folder path and name. *newName* must be a simple object name.

Details

You can not rename an object using a name that already exists. The following will result in an error:

Make wave0, wave1
// Rename wave0 and overwrite wave1.
Rename wave0, wave1 // This will not work.

However, you can achieve the desired effect as follows:

Make wave0, wave1
Duplicate/O wave0, wave1; KillWaves wave0

See Also

The *Duplicate* operation.

**RenameDataFolder**

`RenameDataFolder` *sourceDataFolderSpec, newName*

The RenameDataFolder operation changes the name of the source data folder to the new name.

*sourceDataFolderSpec* can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.

*newName* is just the new name for the data folder, without any path.
RenamePath

Details
RenameDataFolder generates an error if the new name is already in use as a data folder contained within the source data folder.

Examples
RenameDataFolder root:foo,foo2 // Change name of foo to foo2

See Also
Chapter II-8, Data Folders.

RenamePath

RenamePath oldName, newName
The RenamePath operation renames an existing symbolic path from oldName to newName.

See Also
Symbolic Paths on page II-21

RenamePICT

RenamePICT oldName, newName
The RenamePICT operation renames an existing picture to from oldName to newName.

See Also
Pictures on page III-481.

RenameWindow

RenameWindow oldName, newName
The RenameWindow operation renames an existing window or subwindow from oldName to newName.

Parameters
oldName is the name of an existing window or subwindow.

When identifying a subwindow with oldName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

See Also
The DoWindow operation.

ReorderImages

ReorderImages [/W=winName] anchorImage, {imageA, imageB, …}
The ReorderImages operation changes the ordering of graph images to that specified in the braces.

Flags

/W=winName Reorders images in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details
Igor keeps a list of images in a graph and draws the images in the listed order. The first image drawn is consequently at the bottom. All other images are drawn on top of it. The last image is the top one; no other image obscures it.

ReorderImages works by removing the images in the braces from the list and then reinserting them at the location specified by anchorImage. If anchorImage is not in the braces, the images in braces are placed before anchorImage.

If the list of images is A, B, C, D, E, F, G and you execute the command
ReorderTraces F, \{B,C\}
images B and C are placed just before F: A, D, E, B, C, F, G.

The result of
ReorderTraces E, \{D,E,C\}
is to reorder C, D and E and put them where E was. Starting from the initial ordering this gives A, B, D, E, C, F, G.

ReorderTraces generates an error if the same trace is in the list twice.
In Igor\textsuperscript{7} or later, anchorImage can be \_front\_ or \_back\_. To move A to the front, you can write:
ReorderImage \_front\_, \{A\}

See Also
The ReorderTraces operation.

ReorderTraces

ReorderTraces [/W=winName /L=axisName /R=axisName] anchorTrace, \{traceA, traceB, ...\}
The ReorderTraces operation changes the ordering of graph traces to that specified in the braces.

Flags

/W=winName Reorders traces in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.
When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/L[axisName] Moves traces to a new or existing axis. This feature was added in Igor Pro 8.00.

/R[axisName] To reference the built-in left or right axes, you can use /L or /R without specifying the axis name. To reference a free axis, you must specify the axis name.
If the specified axis does not already exist, a new axis is created by cloning the axis controlling traceA.
If the move results in no traces assigned to an axis, then that axis is deleted.
Reordering is optional. Specify \_none\_ for anchorTrace for no reordering.
You can move a trace manually by right-clicking a trace and choosing Move to Opposite Axis.

Details
Igor keeps a list of traces in a graph and draws the traces in the listed order. The first trace drawn is consequently at the bottom. All other traces are drawn on top of it. The last trace is the top one; no other trace obscures it.

ReorderTraces works by removing the traces in the braces from the list and then reinserting them at the location specified by anchorTrace. If anchorTrace is not in the braces, the traces in braces are placed before anchorTrace.
If the list of traces is A, B, C, D, E, F, G and you execute the command
ReorderTraces F, \{B,C\}
traces B and C are placed just before F: A, D, E, B, C, F, G.

The result of
ReorderTraces E, \{D,E,C\}
is to reorder C, D and E and put them where E was. Starting from the initial ordering results in A, B, D, E, C, F, G.

ReorderTraces generates an error if the same trace is in the list twice.
In Igor\textsuperscript{7} or later, anchorImage can be \_front\_ or \_back\_. To move A to the front, you can write:
ReorderTraces \_front\_, \{A\}
ReplaceNumberByKey

See Also
Trace Names on page II-222, Programming With Trace Names on page IV-86.

The ReorderImages operation.

ReplaceNumberByKey
ReplaceNumberByKey(keyStr, kwListStr, newNum [, keySepStr
[ , listSepStr [, case]]])
The ReplaceNumberByKey function returns kwListStr after replacing the numeric value of the keyword-value pair specified by keyStr. kwListStr should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for keySepStr and listSepStr.

Use ReplaceNumberByKey to add or modify numeric information in a string containing a "key1:value1;key2:value2;" style list such as those returned by functions like AxisInfo or TraceInfo.

If keyStr is not found in kwListStr, then the key and the value are appended to the end of the returned string, keySepStr, listSepStr, and case are optional; their defaults are ":", ";", and 0 respectively.

Details
The actual string appended is:
[listSepStr] keyStr keySepStr newNum listSepStr

The optional leading list separator listSepStr is added only if kwListStr does not already end with a list separator.
keyStr is limited to 255 bytes.

kwListStr is searched for an instance of the key string bound by listSepStr on the left and a keySepStr on the right. The text up to the next ";" is replaced by newNum after conversion to text using the %.15g format (see printf for format conversion specifications).

kwListStr is treated as if it ends with a listSepStr even if it doesn’t.

Searches for keySepStr and listSepStr are always case-sensitive. Searches for keyStr in kwListStr are usually case-insensitive. Setting the optional case parameter to 0 makes the comparisons case sensitive.

In Igor6, only the first byte of keySepStr and listSepStr was used. In Igor7 and later, all bytes are used.

If listSepStr is specified, then keySepStr must also be specified. If case is specified, keySepStr and listSepStr must be specified.

Examples
Print ReplaceNumberByKey("K1", "K1:7;", 4) // prints "K1:4;"
Print ReplaceNumberByKey("k2", "K2=8;", 5, ";=") // prints "K2=5;"
Print ReplaceNumberByKey("K3", "K3:9;", 6, ";: ;", ";") // prints "K3:6;"
Print ReplaceNumberByKey("k3", "K0:9", 6, ": ;", ";") // prints "K0:9,k3:6;"
Print ReplaceNumberByKey("k3", "K3:9", 6, ": ;", ";", 1) // prints "K3:9,k3:6;"

See Also
The ReplaceStringByKey, NumberByKey, StringByKey, RemoveByKey, ItemsInList, AxisInfo, IgorInfo, SetWindow, and TraceInfo functions.

ReplaceString
ReplaceString(replaceThisStr, inStr, withThisStr [, caseSense [, maxReplace]])
The ReplaceString function returns inStr after replacing any instance of replaceThisStr with withThisStr.

The comparison of replaceThisStr to the contents of inStr is case-insensitive. Setting the optional caseSense parameter to nonzero makes the comparison case-sensitive.

Usually all instances of replaceThisStr are replaced. Setting the optional maxReplace parameter limits the replacements to that number.

Details
If replaceThisStr is not found, inStr is returned unchanged.

If maxReplace is less than 1, then no replacements are made. Setting maxReplace = Inf is the same as omitting it.
ReplaceStringByKey

ReplaceStringByKey(keyStr, kwListStr, newTextStr [, keySepStr
                 [, listSepStr [, matchCase]]])

The ReplaceStringByKey function returns kwListStr after replacing the text value of the keyword-value pair specified by keyStr. kwListStr should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for keySepStr and listSepStr.

Use ReplaceStringByKey to add or modify text information in a string containing a "key1:value1;key2:value2;" style list such as those returned by functions like AxisInfo or TraceInfo.

If keyStr is not found in kwListStr, then the key and the value are appended to the end of the returned string. keySepStr, listSepStr, and matchCase are optional; their defaults are ":", ";", and 0 respectively.

Details
The actual string appended is:
[listSepStr] keyStr keySepStr newTextStr listSepStr

The optional leading list separator listSepStr is added only if kwListStr does not already end with a list separator.

keyStr is limited to 255 bytes.

kwListStr is searched for an instance of the key string bound by a ";" on the left and a ";" on the right. The text up to the next ";" is replaced by newTextStr.

If newTextStr is ",", any existing value is deleted, but the key, the key separator, and the list separator are retained. To remove a keyword-value pair, use the RemoveByKey function.

kwListStr is treated as if it ends with a listSepStr even if it doesn’t.

Searches for keySepStr and listSepStr are always case-sensitive. Searches for keyStr in kwListStr are case-insensitive. Setting the optional matchCase parameter to 1 makes the comparisons case-sensitive.

In Igor6, only the first byte of keySepStr and listSepStr was used. In Igor7 and later, all bytes are used.

If listSepStr is specified, then keySepStr must also be specified. If matchCase is specified, keySepStr and listSepStr must be specified.

Examples
Print ReplaceStringByKey("KY", "KY:a;a[Z;:c", ", b") // prints "KY:b;KZ:c"
Print ReplaceStringByKey("KY", "ky=a;", ", b", ", =") // prints "ky=b;"

See Also
The ReplaceString, ReplaceNumberByKey, NumberByKey, StringByKey, ItemsInList, RemoveByKey, AxisInfo, IgorInfo, SetWindow, and TraceInfo functions.
ReplaceText

ReplaceText [/W=winName/N=name] textStr
The ReplaceText operation replaces the text in the most recently created or changed annotation or in the annotation specified by /W=winName and/N=name.

Parameters

textStr can contain escape codes to set the font, size, style, color and other properties. See Annotation Escape Codes on page III-54 for details.

If the annotation is a color scale, this command replaces the text of the color scale’s main axis label.

Flags

/W=winName Replaces text in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

See Also
Tag, TextBox, ColorScale, Legend, AppendText, Annotation Escape Codes on page III-54.

ReplaceWave

ReplaceWave [/W=winName] allinCDF
ReplaceWave [/X/W=winName] trace=traceName, waveName
ReplaceWave [/X/Y/W=winName] image=imageName, waveName
ReplaceWave [/X/Y/W=winName] contour=contourName, waveName

The ReplaceWave operation replaces waves displayed in a graph with other waves. The waves to be replaced, and the replacement waves are chosen by the flags, the keyword and the wave names on the command line.

Flags

/W=winName Replaces the wave in the named graph window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/X Replaces the wave supplying X coordinates.

If the trace represents a category plot, the wave must be either a text wave or the special keyword '_labels_' to use dimension labels from the Y wave controlling the axis.

/Y Replaces the wave supplying Y data.

Keywords

allinCDF Searches the current data folder for waves with the same names as waves used in the graph. If found and if the waves are of the correct type, they replace the existing waves. Thus, if you have several data folders with identically-named waves containing data from different experimental runs, you can browse through the runs by moving from one data folder to another, using ReplaceWave allinCDF to update the graph.

contour=contourName Replaces the wave supplying the Z data for contourName. If /X or /Y is used, replaces the wave used to set the X or Y data spacing (if the Z data are in a matrix) or the wave used to supply the X or Y positions if XYZ triplets were specified with three separate waves.
Resample

image=imageName
Replaces the wave supplying the Z data for imageName. If /X or /Y is used, replaces the wave used to set the X or Y data spacing.

trace=traceName
Replaces the wave associated with traceName. With the /X flag, waveName will replace the X wave associated with traceName, otherwise it will replace the Y wave. Note that traceName is derived from the Y wave name; if you created a graph using Display jack vs sam, you would use ReplaceWave/X trace=jack,newsam to replace the X wave.

Details
Waves are replaced in the graph specified by /W=winName otherwise waves are replaced in the top graph.

Updating a contour plot in response to replacing a wave can be time-consuming. If you must replace more than one wave, put all the commands separated by semicolons on a single line. In a macro, use DelayUpdate to prevent updates between command lines.

When using the allinCDF keyword, ReplaceWave cannot find waves buried in dynamic annotation text (for instance, using the \{} syntax in an annotation). ReplaceWave will not replace waves used for error bars, either.

Subsets of data, including individual rows or columns from a matrix, may be specified using Subrange Display Syntax on page II-256.

Examples
Make XY plot, then replace the waves:

Make fred=x, sam=log(x)
Display fred vs sam
Make fred2=2*x, sam2=ln(x)
ReplaceWave/X trace=fred, sam2
ReplaceWave trace=fred, fred2 // trace is now named fred2

Make contour plot with XYZ triplet waves, then replace the waves. Note the DelayUpdate commands after the first two ReplaceWave commands:

Make/N=100 junkx, junky, junkz // Waves for XYZ triplets
junkx=trunc(x/10) // X wave for XYZ triplets
junky=mod(x,10) // Y wave for XYZ triplets
junkz=sin(junkx[p])*cos(junky[p]) // Z wave for XYZ triplets
Display; AppendXYZContour junkz vs {junkx, junky} // Make contour plot
Make/O/N=150 junkx2, junky2, junkz2 // Make replacement waves
junkx2=trunc(x/15)
junky2=mod(x,15)
junkz2=sin(junkx2[p])*cos(junky2[p])
ReplaceWave/X contour=junkz,junkx2; DelayUpdate
ReplaceWave/Y contour=junkz,junky2; DelayUpdate
ReplaceWave contour=junkz,junkz2

This example is suitable for copying all the lines and pasting into the command line, or for use in a macro. If you are typing on the command line, you would want to put the ReplaceWave commands all on one line:

ReplaceWave/X contour=junkz,junkx2; ReplaceWave/Y contour=... 

See Also
Trace Names on page II-222, Programming With Trace Names on page IV-86.

Resample

Resample [flags] waveName [, waveName]...

The Resample operation resamples waveName by interpolating or up-sampling (set by /UP=upSample), lowpass filtering, and decimating or down-sampling (set by /DOWN=downSample).

Lowpass filtering is specified with /N and /WINF or with /COEF=coefsWaveName.

The sampling frequency (1/DimDelta) of a resampled output wave waveName is changed by the ratio of downSample/upSample. For example, if upSample=4 and downSample=3, then the final sampling rate is 4/3 of the original value.

Straight interpolation can be accomplished by setting upSample to the interpolation factor and downSample=1, in which case the sample rate is multiplied by upSample. Deltax(waveName) will be proportionally smaller. Linear interpolation is accomplished by setting numReconstructionSamples=3 and windowKind=None.
For decimation only, set `upSample=1` and `downSample` to the decimation factor. The sample rate is divided by `downSample`, and `deltax(waveName)` will be proportionally larger.

Use `RatioFromNumber` to choose appropriate values for `upSample` and `downSample`, or use `/SAME=sWaveName` or `/RATE=sampRate`. See Resampling Rates Example for details.

When using `/COEF=coefsWaveName`, the filter coefficients should implement a low-pass filter appropriate for the `upSample` and `downSample` values or aliasing (filtering errors) will result. See Advanced Externally-Supplied Low Pass Filter Example for details.

### Resampling Rates Flags

The `upSample` and `downSample` values define how much interpolation and decimation to perform. They can be set directly with `/UP` and `/DOWN` or indirectly with `/SAME` or `/RATE`.

- **/DOWN=downSample**: Down-samples or decimates the filtered result by this integer factor after upsampling and lowpass filtering. The default is 1 (no down-sampling).
  
  For example, `/DOWN=3` places only every third value in the output wave.

  Down-sampling divides the sampling rate of the filtered data by a factor of `downSample`. The `DimDelta(waveName, dim)` value is multiplied by the same factor.

- **/RATE=sampRate**: Converts the output `waveName` to the specified sampling rate frequency (normally Hz).
  
  The necessary `upSample` and `downSample` values for each `waveName` are computed internally as if you had executed:

  ```
  RatioFromNumber (deltax(waveName) \times sampRate) 
  upSample = V_{\text{numerator}} 
  downSample = V_{\text{denominator}} 
  
  /RATE returns V_{\text{numerator}} and V_{\text{denominator}} set to these automatically-determined values for the last `waveName`. 
  ```

- **/SAME=sWaveName**: Converts the output `waveName` to the same sampling rate as `sWaveName`, `1/DimDelta(sWaveName, dim)`. The necessary `upSample` and `downSample` values are computed internally as if you had executed:

  ```
  Variable dd = DimDelta(waveName, dim) 
  RatioFromNumber dd/DimDelta(sWaveName, dim) 
  upSample = V_{\text{numerator}} 
  downSample = V_{\text{denominator}} 
  
  /SAME returns V_{\text{numerator}} and V_{\text{denominator}} set to these automatically-determined values for the last `waveName`. 
  ```

- **/UP=upSample**: Up-samples or interpolates the input by this integer factor. The default is 1 (no up-sampling).

  For example, `/UP=4` inserts three extra points between each input point (producing 4 times as many values) before the lowpass filtering and down-sampling occurs.

  Up-sampling multiplies the sampling rate of the input data by a factor of `upSample`, though no additional signal information is created. The `DimDelta(waveName, dim)` value is divided by the same factor.

### Internal Sinc Reconstruction Filter Flags

If `/COEF=coefsWaveName` is not specified, Resample computes a windowed sinc filter from `/N`, `/DOWN`, `/UP`, and `/WINF` flag values.
If /COEF=coefsWaveName is specified, then coefsWaveName supplies the filter, and /N and /WINF are ignored. See Externally-Supplied Low Pass Filter Flags.

/COEF

Replaces the first waveName with coefficients generated by downSample, upSample, numReconstructionSamples, and windowKind, a windowed sinc impulse response.

When resampling multiple waveNames with different filters (because /RATE or /SAME were specified and the multiple waveNames had different sampling rates), the filter used to resample the last waveName is returned.

/N=numReconstructionSamples

Specifies the number of input values used to created the up-sampled values (default is 21).

The value of numReconstructionSamples must be odd.

The size of the computed filter is (numReconstructionSamples-1) * upSample + 1.

Bigger is better: 15 is usually on the low side for yielding reasonably accurate results, and although 101 will nearly always give very good results, it will be slow.

Use /COEF to output the impulse response, and the FFT to display the frequency response of the interpolator:

Make/O coefs
Variable numReconstructionSamples= 51, upSample= 5
Resample/COEF/N=(numReconstructionSamples)/UP=(upSample) coefs
Variable evenNum= 2*floor((numpnts(coefs)+1)/2)
FFT/OUT=3/PAD={evenNum}/DEST=coefs_FFT coefs
Display coefs_FFT

Bigger is also slower: the filtering is computed in the time-domain, and execution time is linearly related to

upSample/downSample * numReconstructionSamples.

/WINF=windowKind

Applies the window, windowKind, to the computed filter coefficients. If /WINF is omitted, the Hanning window is used. For no coefficient windowing, use /WINF=None, though this is discouraged unless you want linear interpolation, in which case it should be paired with /N=3.

Windows alter the frequency response of the filter in obvious and subtle ways, enhancing the stop-band rejection or steepening the transition region between passed and rejected frequencies. They matter less when numReconstructionSamples is large.

Choices for windowKind are:

Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, Riemann and None.

See FFT for window equations and details.

Externally-Supplied Low Pass Filter Flags

/COEF =coefsWaveName

Identifies the wave, coefsWaveName, containing filter coefficients that implement a low-pass filter with a cutoff frequency of the lesser of 0.5/upSample and 0.5/downSample, where 0.5 corresponds to the Nyquist frequency of the up-sampled data.

For example, if upSample=2, then the filter must contain the classic “half-band” filter, which stops the higher half of the frequencies and passes the lower half. If upSample=10, then the filter must pass only the lowest 1/10th of the frequencies.
For `downSample > upSample`, the low-pass filter’s cutoff frequency must be `0.5/downSample`. This prevents the decimation from introducing aliasing to the resampled data.

To avoid shifting the output with respect to the input, `coefsWaveName` must have an odd length with the “center” coefficient in the middle of the wave.

The length of `coefsWaveName` must be `1+upSample*n`, where `n` is any even integer.

**Note:** Instead of using `/N=numReconstructionSamples` with `/COEF=coefsWaveName`, `numReconstructionSamples` is computed from `upSample` and the number of points in `coefsWaveName`:

\[
\text{numReconstructionSamples}=1+(\text{numpnts(coefsWaveName)}-1)/\text{upSample}.
\]

Coefficients are usually symmetrical about the middle point, but this is not enforced. `coefsWaveName` must not be a destination `waveName`. `coefsWaveName` must be single- or double-precision numeric and one-dimensional.

### Data Range Flags

- **/DIM=d**: Specifies the wave dimension to resample.
  - For `d = 0, 1, …`, resampling is along rows, columns, etc.
  - The default is `/DIM=0`, which resamples each individual column (each one a channel, say left and right) in a multidimensional `waveName` where each row comprises all sound samples at a particular time.
  - To resample in multiple dimensions, execute the command once for each dimension. For example, use `/DIM=0` followed by another command with `/DIM=1` to resample a two-dimensional wave in each direction.

- **E=endEffect**: Determines how to handle the ends of the resampled wave(s) (w) when fabricating missing neighbor values.
  - `endEffect=0`: Bounce method. Uses `w[i]` in place of the missing `w[-i]` and `w[n-i]` in place of the missing `w[n+i]`.
  - `endEffect=1`: Wrap method. Uses `w[n-i]` in place of the missing `w[-i]` and vice versa.
  - `endEffect=2`: Zero method (default). Uses 0 for any missing value.
  - `endEffect=3`: Repeat method. Uses `w[0]` in place of the missing `w[-i]` and `w[n]` in place of the missing `w[n+i]`.

### Parameters

`waveName` can be a wave with any number of dimensions. Only one dimension is resampled. Use multiple `Resample` calls to resample across multiple dimensions.

Without `/DIM`, resampling is done along the row (first) dimension. Each column is resampled as if it were a separate one-dimensional row. This allows multichannel audio to be resampled to another frequency.

If `/DIM=1`, then resampling proceeds across all the columns of each row.

If `/COEF` is specified without `coefsWaveName`, then the first `waveName` is overwritten by the filter coefficients instead of being resampled.

### Details

The filtering convolution is performed in the time-domain. That is, the FFT is not employed to filter the data. For this reason the coefficients length (`/N` or the length of `coefsWaveName`) should be small in comparison to the resampled waves.

`Resample` assumes that the middle point of `coefsWaveName` corresponds to the delay=0 point. The “middle” point number = `trunc(numpnts(coefsWaveName)-1)/2`. `coefsWaveName` usually contains the two-sided impulse response of a filter, an odd number of points, and implements a low-pass filter whose cutoff
Resample

frequency is the lesser of $0.5 / \text{upSample}$ and $0.5 / \text{downSample}$ (0.5 corresponds to the Nyquist frequency = 1/2 sampling frequency).

When /COEF creates a coefficients wave it sets the X scale deltax to 1 and alters the leftx value so that the zero-phase (center) coefficient is located at $x=0$.

Simple Examples

// Interpolation by factor of 4, default filter
Resample/UP=4 data

// Interpolation by factor of 7, linear interpolation
Resample/UP=7/N=3/WINF=None data

// Decimation by factor of 3, default filter
Resample/DOWN=3 data

// Match sampling rates, default filter
Resample/SAME=dataAtDesiredRate dataAtWrongRate1, dataAtWrongRate2, ...

// Resample waves to 10 KHz sampling rate
Resample/RATE=10e3 dataAtWrongRate1, dataAtWrongRate2, ...

// Interpolate an image by a factor of 2
Resample/UP=2 image // default is /DIM=0, resample rows
Resample/UP=2/DIM=1 image // resample across columns

Note: Interpolating by a factor of two does not produce an image with twice as many rows and columns. The new number of rows = (original rows-1)*\text{upSample} + 1, and a similar computation applies to columns.

Resampling Rates Example

Suppose we have an audio wave sampled at 44,100 Hz and we wish to resample it to a higher 192,000 Hz frequency.

We can use /RATE= 192000 and let Resample determine the correct values (provided waveName has its X scaling set properly to reflect sampling at 44100 Hz), but let’s compute \text{upSample} and \text{downSample} ourselves.

Because the sampling rate = 1/deltax(wave), we can recast the /SAME formula to RatioFromNumber (desiredSamplingRate/currentSamplingRate):

$\text{RatioFromNumber/V} (\text{192000 / 44100})$

$\text{V numerator} = 640$; $\text{V denominator} = 147$

$\text{ratio} = 4.3537414965986$

$\text{V difference} = 0$

Then \text{upSample}=640 and \text{downSample}=147.

The 44100 Hz input data will be interpolated by 640 to 28,224,000 Hz.

The result is low-pass filtered with a “cutoff frequency” of 1/640th of the interpolated Nyquist frequency = (28224000/2)/640 = 22,050 Hz, the same as the input signal’s original Nyquist frequency.

The result will be decimated by 147 to 192,000 Hz, which is the desired output sampling frequency.

Note: If \text{downSample} had been greater than \text{upSample}, then the low-pass filter’s cutoff frequency would have been 1/\text{downSample}th of the interpolated Nyquist frequency = (28224000/2)/\text{downSample}. This prevents the decimation from introducing aliasing to the resampled data.

Resample/UP=640/DOWN=147 sound // convert 44.1 KHz to 192 KHz

Advanced Externally-Supplied Low Pass Filter Example

You can generate an appropriate filter by executing commands like these:

// Compute a filter for after the input is upsampled
// to restore the frequency content to the original range.
Variable fc = min(0.5 / \text{upSample}, 0.5 * \text{upSample} / \text{downSample})
// Transition width, small widths need big n
Variable tw= fc/10
// Set end of pass band
Variable f1= fc-tw/2
// Set start of stop band
Variable f2= fc+tw/2
// Use bigger values of n to make the filter smoother
Variable nReconstruct = 31
Variable n = (nReconstruct - 1) * upSample + 1 // odd = no phase shift
// Create a wave to hold the coefficients; it gets resized to n
Make/O/N=0 coefsWaveName
FilterFIR/COEF/LO={f1,f2,n} coefsWaveName

However, FilterFIR does not create windowed sinc low pass filters that have the endearing property that the original input values are unaltered in the filtered output, though only if \texttt{upSample > downSample}. This is called a “Nyquist filter” or “Kth-band filter” in the literature.

If \texttt{upSample > downSample}, you can enforce the Nyquist criterion by “zeroizing” the designed filter by setting every \texttt{upSample}th value to 0 except the center one.

// coefsWaveName length must be 1+upSample*n, where n is any even integer

Function Zeroize(w, upSample)
Wave w // coefsWaveName
Variable upSample // upSample value
Variable n = DimSize(w, 0)
Variable centerP = floor((n - 1) / 2) // if n=101, centerP= 50
Variable i
for (i = 0; i < n; i += upSample)
  if (i != centerP)
    w[i] = 0
  endif
endfor
End

Resample zeroizes the internally-generated low pass filter when \texttt{upSample > downSample}.

Additionally, the FilterFIR command generates a low-pass filter whose gain needs to be multiplied by \texttt{upsample}:
\texttt{coefsWaveName} *= \texttt{upSample}

When designing an externally supplied filter, you should also consider the filter’s “polyphase” nature; \texttt{coefsWaveName} is actually a set of \texttt{upSample} interleaved filters, each with its own response. It makes sense to adjust these filters to produce consistent responses. If you don’t, the results will contain ringing with a period of \texttt{upSample/downSample}. This is most apparent when \texttt{downSample} is 1.

Using the filter we’ve designed so far with \texttt{upSample=4}, here’s the output of a constant-input wave:

Make/O constantData = 1
Resample/COEF=coefsWaveName/UP=4 constantData

![Graph showing filter response](image)

The graph shows that the filter response at 0 Hz for the first of 4 filters is 1.0010, the second and fourth filter’s responses are very close to 1.0, and the third filter’s response at 0 Hz is a little less than 1.0.

These variations can be eliminated by normalizing the sum of each polyphase filter to 1.0:

Function PolyphaseNormalize(w, upSample)
Wave w // coefsWaveName
Variable upSample // upSample value
Variable n = DimSize(w, 0)
Variable filt
// for each filter (0..upSample-1)
for (filt = 0; filt < upSample; filt++)
  Variable total = 0
  Variable pt
  // compute total for this filter
  for (pt = filt; pt < n; pt += upSample)
    total += w[pt]
End
endfor

// divide by total to normalize total to 1
for (pt=filt; pt<n; pt+=upSample)
  w[pt] /= total
endfor
End
End

Now the filter is ready to be used to filter data:
Resample/COEF=coefsWaveName/UP=(upSample)/DOWN=(downSample) dataWave

You can see that designing an externally-supplied lowpass filter is much more complicated than using the internal sinc reconstruction filter, which does all this zeroizing, scaling, and polyphase normalization for you.

ResumeUpdate
ResumeUpdate
The ResumeUpdate operation cancels the corresponding PauseUpdate.

This operation is of use in macros. It is not allowed from the command line. It is allowed but has no effect in user-defined functions. During execution of a user-defined function, windows update only when you explicitly call the DoUpdate operation.

See Also
The DelayUpdate, DoUpdate, and PauseUpdate operations.

return
return [expression]
The return flow control keyword immediately stops execution of the current procedure. If called by another procedure, it returns expression and control to the calling procedure.

Functions can return only a single value directly to the calling procedure with a return statement. The return value must be compatible with the function type. A function may contain any number of return statements; only the first one encountered during procedure execution is evaluated.

A macro has no return value, so return simply quits the macro.

See Also
The Return Statement on page IV-38.

Reverse
The Reverse operation reverses data in a wave in a specified dimension. It does not accept text waves.
RGBColor

Flags

/DIM = d  Specifies the wave dimension to reverse.

\[ d = \begin{cases} -1 & \text{for entire wave as 1D (default).} \\ 0, 1, \ldots & \text{operates along rows, columns, etc.} \end{cases} \]

/P  Suppresses adjustment of dimension scaling. Without /P the scaled dimension value of reversed points remains the same.

Type Flags (used only in functions)

Reverse also can use various type flags in user functions to specify the type of destination wave reference variables. These type flags do not need to be used except when it is needed to match another wave reference variable of the same name or to identify what kind of expression to compile for a wave assignment. See WAVE Reference Types on page IV-72 and WAVE Reference Type Flags on page IV-73 for a complete list of type flags and further details.

Wave Parameters

Note: All wave parameters must follow wave in the command. All wave parameter flags and type flags must appear immediately after the operation name (Reverse).

/D = destWave  Specifies the name of the wave to hold the reversed data. It creates destWave if it does not already exist or overwrites it if it exists.

Details

If the optional /D = destWave flag is omitted, then the wave is reversed in place.

Sorting on page III-132, Sort, SortColumns

RGBColor

The RGBColor structure is used as a substructure usually to store various color settings.

Structure RGBColor

| UInt16 red |
| UInt16 green |
| UInt16 blue |

EndStructure

RGBAColor

The RGBAColor structure is the same as RGBColor but with an alpha field to represent translucency.

Structure RGBAColor

| UInt16 red |
| UInt16 green |
| UInt16 blue |
| UInt16 alpha |

EndStructure

rightx

rightx(waveName)
The rightx function returns the X value corresponding to point N of the named 1D wave of length N.

Details

Note that the point numbers in a wave run from 0 to N-1 so there is no point with this X value. To get the X value of the last point in a wave (point N-1), use the following:

\[ \text{pnt2x(waveName, numpnts(waveName) - 1)} \]

which is more accurate than:

rightx(waveName) - deltax(waveName)
The rightx function is not multidimensional aware. See **Analysis on Multidimensional Waves** on page II-89 for details. The equivalent information for any dimension can be calculated this way:

\[
\text{Index}_N = \text{DimSize}(\text{wave}, \dim) \ast \text{DimDelta}(\text{wave}, \dim) + \text{DimOffset}(\text{wave}, \dim)
\]

Here \(\text{Index}_N\) is the value of the scaled dimension index corresponding to element \(N\) of the dimension \(\dim\) in a wave named \(\text{wave}\) that has \(N\) elements in that dimension.

**See Also**
The `deltax` and `leftx` functions, also the `pnt2x` and `numpnts` functions.

For an explanation of waves and dimension scaling, see **Changing Dimension and Data Scaling** on page II-63.

For multidimensional waves, see `DimDelta`, `DimOffset`, and `DimSize`.

**root**

```
root [:dataFolderName][:dataFolderName[...]] [:objectName]
```

Igor’s data folder hierarchy starts with the root folder as its basis. The root data folder always exists and it contains all other objects (waves, variables, strings, and data folders). By default, the root data folder is the current data folder in a new experiment. In commands, root is used as part of a path specifying the location of a data object in the folder hierarchy.

**See Also**
Chapter II-8, Data Folders.

**Rotate**

```
Rotate rotPoints, waveName [, waveName]...
```

The Rotate operation rotates the Y values of waves in wavelist by `rotPoints` points.

**Parameters**

If `rotPoints` is positive then values are rotated from the start of the wave toward the end and `rotPoints` values from the end of a wave wrap around to the start of the wave.

If `rotPoints` is negative then values are rotated from the end of the wave toward the start and `rotPoints` values from the start of a wave wrap around to the end of the wave.

**Details**

The X scaling of the named waves is changed so that the X values for the Y values remains the same except for the points that wrap around.

The Rotate operation is not multidimensional aware. To rotate rows or columns of 2D waves, see the `rotateRows`, `rotateCols`, `rotateLayers` and `rotateChunks` keywords for **MatrixOp** and the `rotateRows` and `rotateCols` keywords for **ImageTransform**.

For general information about multidimensional analysis, see **Analysis on Multidimensional Waves** on page II-89.

**See Also**
The shift parameter of the **WaveTransform** operation.

**round**

```
round (num)
```

The round function returns the integer value closest to `num`.

The rounding method is “away from zero”.

**See Also**
The `ceil`, `floor`, and `trunc` functions.

**rtGlobals**

```
#pragma rtGlobals = 0, 1, 2, or 3
#pragma rtGlobals=<n> is a compiler directive that controls compiler and runtime behaviors for the procedure file in which it appears.
```
This statement must be flush against the left edge of the procedure file with no indentation. It is usually placed at the top of the file.

#pragma rtglobals=0 turns off runtime creation of globals. This is obsolete.

#pragma rtglobals=1 is a directive that turns on runtime lookup of globals. This is the default behavior if #pragma rtGlobals is omitted from a given procedure file.

#pragma rtglobals=2 turns off compatibility mode. This is mostly obsolete. See Legacy Code Issues on page IV-111 for details.

#pragma rtglobals=3 turns on runtime lookup of globals, strict wave reference mode and wave index bounds checking.

rtGlobals=3 is recommended.

See The rtGlobalsPragma on page IV-53 for a detailed explanation of rtGlobals.

s

The s function returns the current chunk index of the destination wave when used in a multidimensional wave assignment statement. The corresponding scaled chunk index is available as the t function.

Details

Unlike p, outside of a wave assignment statement, s does not act like a normal variable.

See Also

Waveform Arithmetic and Assignments on page II-69.

For other dimensions, the p, r, and q functions.

For scaled dimension indices, the x, y, z and t functions.

Save

Save [flags] waveList [as fileNameStr]

The Save operation saves the named waves to disk as text (/F, /G or /J) or as Igor binary.

Parameters

waveList is either a list of wave names or, if the /B flag is present, a string list of references to waves. For example, the following commands are equivalent, assuming that the waves in question are in the root data folder and root is the current data folder:

Save/J wave0,wave1 as "Test.dat"
Save/J root:wave0,root:wave1 as "Test.dat"
Save/J/B "wave0;wave1;" as "Test.dat"
Save/J/B "root:wave0;root:wave1;" as "Test.dat"

String list="root:wave0;root:wave1;"; Save/J/B list as "Test.dat"

The form using the /B flag and a string containing a list of references to waves saves a very large number of waves using one command. This is not possible using a list of wave names because of the 2500 byte command line length limit. When using this form, the string must contain semicolon-separated wave names or data folder paths leading to waves. Liberal names in the string may be quoted or unquoted.

The file to be written is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If it cannot determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-429 for details on forming the path.
## Flags

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/A[a]</td>
<td>Appends to the file rather than overwriting it (with /T, /G or /J).&lt;br&gt;(a=0): Does not append.&lt;br&gt;(a=1): Appends to the file with a blank line before the appended data (same as /A only).&lt;br&gt;(a=2): Appends to the file with no blank line before the appended data.</td>
</tr>
<tr>
<td>/B</td>
<td>The <code>waveList</code> parameter is a string containing a list of references to waves instead of a literal list of waves.</td>
</tr>
<tr>
<td>/C</td>
<td>Saves a copy of the wave when saving as Igor binary.</td>
</tr>
<tr>
<td>/DLIM=delimStr</td>
<td>Specifies the string to use as a column delimiter. This flag affects general text saves (/G) and delimited text saves (/J) only. <code>delimStr</code> defaults to tab. It can consist of multiple characters. If you choose a delimiter that also appears in the data you are saving, for example if you choose to save text waves containing commas using comma as the separator, the resulting file is likely to be misinterpreted by any software loading it. /DLIM was added in Igor Pro 7.00.</td>
</tr>
<tr>
<td>/DSYM=dsStr</td>
<td>Specifies a string containing the character to use as the decimal symbol for all numbers (default is a period). If <code>dsStr</code> is empty (&quot;&quot;), then the decimal symbol is as defined in system preferences as of when Igor was launched.</td>
</tr>
<tr>
<td>/E=useEscapeCodes</td>
<td>Determines whether to use escape sequences for special characters. <code>/E=1</code>: Converts carriage-return, linefeed, tab, and backslash characters to escape sequences when writing general or delimited text files (default; same as no /E). <code>/E=0</code>: No escape sequences used in general or delimited text files. When saving text waves containing backslashes (such as Windows paths) in a file intended for another program, you probably should use /E=0.</td>
</tr>
<tr>
<td>/F</td>
<td>Writes delimited and general text files with numeric formatting as it appears in the top table. Has no effect if there is no top table or if the wave being saved does not appear in the top table. <strong>Note:</strong> The text written to the file is exactly as displayed in the table. Set the table to display as many digits of precision as you want in the file. <strong>Note:</strong> Fractional and out-of-range floating point wave data can not be formatted as octal or hex. See Octal Numeric Formats on page II-198 and Hexadecimal Numeric Formats on page II-198 for details. <strong>Note:</strong> When saving a multi-column wave (1D complex wave or multidimensional wave), all columns of the wave are saved using the table format for the first table column from the wave.</td>
</tr>
<tr>
<td>/G</td>
<td>Saves waves in general text format.</td>
</tr>
<tr>
<td>/H</td>
<td>&quot;Adopts&quot; the waves specified by <code>waveList</code>. &quot;Adopt&quot; means that any connection between the waves and external files is severed. The waves become part of the current experiment. When the experiment is next saved, the waves are saved in the experiment file (for an packed experiment) or in the experiment folder (for an unpacked experiment).</td>
</tr>
</tbody>
</table>
Save

When you use the /H flag, all other flags and the fileNameStr parameter are ignored. The wave is not actually saved but rather is marked for saving as part of the current experiment.

You would normally do this to make an experiment more self-contained which makes it easier to send to other people. See Sharing Versus Copying Igor Binary Wave Files on page II-141 and the LoadWave /H flag.

/I

Presents a dialog from which you can specify file name and folder.

/J

Saves waves in delimited text format.

The delimiter defaults to tab unless you specify another delimiter using /DLIM.

/M=termStr

Specifies the terminator character or characters to use at the end of each line of text. The default is /M="\r\n", which uses a carriage return character. This is the Macintosh convention. To use the Windows convention, carriage return plus linefeed, specify /M="\r\n\n". To use the Unix convention, just a linefeed, specify /M="\n".

/O

Overwrites file if it exists already.

/P=pathName

Specifies the folder to store the file in. pathName is the name of an existing symbolic path.

/T

Saves waves in Igor Text format.

/U=[writeRowLabels, rowPositionAction, writeColLabels, colPositionAction]

These parameters affect the saving of a matrix (2D wave) to a delimited text (/J) or general text (/G) file. They are accepted no matter what the save type is but are ignored when they don’t apply.

If writeRowLabels is nonzero, Save writes the row labels of the matrix as the first column of data in the file.

rowPositionAction has one of the following values:

0: Don’t write a row position column.
1: Writes a row position column based on the row scaling of the matrix wave.
2: Writes a row position column based on the contents of the row position wave for the matrix. The row position wave is an optional 1D wave whose name is the same as the matrix wave but with the prefix “RP_”.

writeColumnLabels and columnPositionAction have analogous meanings. The prefix used for the column position wave is “CP_”.

See Chapter II-9, Importing and Exporting Data, for further details.

/W

 Saves wave names (with /G or /J).

Details

The Save operation saves only the named waves; it does not save the entire experiment.

Waves saved in Igor binary format are saved one wave per file. If you are saving more than one wave, you must not specify a fileNameStr. Save will give each file a name which consists of the wave name concatenated with “.ibw”.

When you save a wave as Igor binary, unless you use the /C flag to save a copy, the current experiment subsequently references the file to which the wave was saved. See References to Files and Folders on page II-23 for details.

In a general text file (/G), waves with different numbers of points are saved in different groups. Waves with different precisions and number types are saved in same group if they have the same number of points.

In a delimited text file (/J), all waves are saved in one group whether or not they have the same number of points.

If you save multiple 2D waves, the blocks of data are written one after the other.
If you save 3D waves, the data for each wave is written as a contiguous block having as many columns as there are columns in the wave, and \( R \times L \) rows, where \( R \) is the number of rows in the multidimensional wave and \( L \) is the number of layers. All rows for layer 0 are saved followed by all rows for layer 1, and so on.

If you save 4D waves, the data for each wave is written as a contiguous block having \( R \times L \times C \) rows, where \( R \) is the number of rows, \( L \) is the number of layers and \( C \) is the number of chunks. Igor writes all data for chunk 0 followed by all data for chunk 1, and so on.

The Save operation will always present a save dialog if you try to save to an existing file without using the overwrite flag.

Here are some details about saving an Igor binary wave file.

If you omit the path or the file name, the Save operation will normally present a save dialog. However, if the wave has already been saved to a stand-alone file and if you use the overwrite flag, it will save the wave to the same file without a dialog. Also, if the wave has never been saved and the current experiment is an unpacked experiment, it will save to the home folder without a dialog.

If you use \( /P=\text{pathName} \), note that it is the name of an Igor symbolic path, created via \texttt{NewPath}. It is not a file system path like “\texttt{hd:Folder1:"} or “\texttt{C:\Folder1\"}. See \textit{Symbolic Paths} on page II-21 for details.

\textbf{Examples}

This function uses the string list of references to waves to save some or all of the waves in the current data folder:

\begin{verbatim}
Function SaveWavesFromCurrentDF(matchStr)

String matchStr // As for the WaveList function.

String list // As for the WaveList function.
list = WaveList(matchStr, ";", "")
Save/O/J/W/I/B list

End

For example, to save all of the waves in the current data folder, execute:

\texttt{SaveWavesFromCurrentDF("")}

To save those waves in the current data folder whose name starts with “wave”, execute:

\texttt{SaveWavesFromCurrentDF("wave")}

This function saves all of the waves used in a particular graph:

\begin{verbatim}
Function SaveWavesFromGraph(graphName) // Saves all waves in graph.

String graphName // "" for top graph.

String list, traceList, traceName

Variable index = 0
list = ""
traceList = TraceNameList(graphName, ";", 1)
do
traceName = StringFromList(index, traceList, ";")
if (strlen(traceName) == 0)
break
endif
Wave w = TraceNameToWaveRef(graphName, traceName)
list += GetWavesDataFolder(w, 2) + ";"
index += 1
while(1)
if (strlen(list) > 0)
Save/O/J/W/I/B list
endif

End

See Also
Exporting Data on page II-160.
\end{verbatim}
SaveData

SaveData [flags] fileOrFolderNameStr

The SaveData operation writes data from the current data folder of the current experiment to a packed experiment file on disk or to a file system folder. “Data” means Igor waves, numeric and string variables, and data folders containing them. The data is written as a packed experiment file or as unpacked Igor binary wave files in a file-system folder.

Warning: If you make a mistake using SaveData, it is possible to overwrite critical data, even entire folders containing critical data. It is your responsibility to make sure that any file or folder that you cannot afford to lose is backed up. If you provide procedures for use by other people, you should warn them as well.

SaveData provides a way to save data for archival storage or unload data from memory during a lengthy process like data acquisition. The file or files that SaveData writes are disassociated from the current experiment.

Use SaveData to save experiment data using Igor procedures. To save experiment data interactively, use the Save Copy button in the Data Browser (Data menu).

Parameters

fileOrFolderNameStr specifies the packed experiment file (if /D is omitted) or the file system folder (if /D is present) in which the data is to be saved. The documentation below refers to this file or folder as the “target”.

If you use a full or partial path for fileOrFolderNameStr, see Path Separators on page III-429 for details on forming the path.

If fileOrFolderNameStr is omitted or is empty (""), SaveData displays a dialog from which you can select the target. You also get a dialog if the target is not fully specified by fileOrFolderNameStr or the /P=pathName flag.

Flags

/D [=d] Writes to a file-system folder (a directory). If omitted, SaveData writes to an Igor packed experiment file.

d=1: If the target folder already exists, the new data is “mixed-in” with the data already there (same as /D).

d=2: If the target folder already exists, it is completely deleted before the writing of data starts.

If in doubt, use /D=1. See Details below.

/I Presents a dialog in which you can interactively choose the target.

/J=objectNamesStr Saves only the objects named in the semicolon-separated list of object names. See Details below.

/L=saveFlags Controls what kind of data objects are saved with a bit for each data type:

<table>
<thead>
<tr>
<th>saveFlags</th>
<th>Bit Number</th>
<th>Saves this Type of Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>Waves</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>Numeric variables</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>String variables</td>
</tr>
</tbody>
</table>

To save multiple data types, sum the values shown in the saveFlags column. For example, /L=1 saves waves only, /L=2 saves numeric variables only and /L=3 saves both waves and numeric variables.

If /L is not specified, all of these object types are saved. This is equivalent to /L=7. All other bits are reserved and must be set to zero. See Setting Bit Parameters on page IV-13 for details about bit settings.
SaveData

/M=modDateTime  Saves waves modified on or after the specified modification date/time. Waves modified before modDateTime will not be saved. Applies to waves only (not variables or strings).

modDateTime is in standard Igor time format — seconds since 1/1/1904. If modDateTime is zero, all waves will be saved, as if there were no /M flag at all.

/O  Overwrites existing files or folders on disk.

Warning: If you use the /O flag and if the target already exists, it will be overwritten without any warning. If you use /O with /D=2, you will completely overwrite the target folder and all of its contents, including subfolders. Do not use /O with /D unless you are absolutely sure you know what your doing.

/P=pathName  Specifies the folder in which to save the specified file or folder.

pathName is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd:Folder1:" or "C:\\Folder1\". See Symbolic Paths on page II-21 for details.

When used with the /D flag, if /P=pathName is present and fileOrFolderNameStr is ":", the target is the directory specified by /P=pathName.

/Q  Suppresses normal messages in the history area.

/R  Recursively saves subdata folders.

/T [=topLevelName]  Creates an enclosing data folder in the target with the specified name, topLevelName, and writes the data to the new data folder.

If just /T is specified, it creates an enclosing data folder in the target using the name of the data folder being saved. However, if the data folder being saved is the root data folder, the name Data is used instead of root. In packed experiment files and unpacked experiment folders, the root data folder is implicit.

If /T is omitted, the contents of the current data folder are saved with no enclosing data folder.

Details

If /J=objectNamesStr is used, then only the objects named in objectNamesStr are saved. For example, specifying /J="wave0;wave1;" will save only the two named waves, ignoring any other data in all data folders.

The list of object names used with /J must be semicolon-separated. A semicolon after the last object name in the list is optional. The object names must not be quoted even if they are liberal. The list is limited to 1000 characters.

Using /J="" acts like no /J at all.

The /M=modDateTime flag can be used in data acquisition projects to save only those waves modified since the previous save. For example, assume that we have a global variable in the root data folder named gLastWaveSaveDateTime. Then this function will write out only those waves modified since the previous save:

Function SaveModifiedWaves(savePath)
    String savePath // Symbolic path pointing to output directory
    NVAR lastSave = root:gLastWaveSaveDateTime
    SaveData/O/P=$savePath/D=1/L=1/M=(lastSave) ":"  
    lastSave = datetime
End

Because the datetime function and the wave modification date have a coarse resolution (one second), this function may sometimes save the same wave twice.

The /M flag makes sense only in conjunction with the /D=1 flag because /D=1 is the only way to mix-in new data with existing data.

Writing to a Packed Experiment File

When writing to a packed file, SaveData creates a standard packed Igor experiment file which you can open as an experiment, browse using the Data Browser, or access using the LoadData operation.
If you do not use the /O (overwrite) flag and the packed file already exists on disk, SaveData will present a dialog to confirm which file you want to write to. If you use the /O flag, SaveData will overwrite without presenting a dialog. When writing a packed file, SaveData always completely overwrites the preexisting packed file.

Appending to a packed experiment file is not supported because dealing with the possibility of name conflicts (e.g., two waves with the same name in the same data folder in the packed experiment file) would be technically difficult, very slow and errors would result in corrupted files.

**Writing to a File-System Folder**

When saving to a folder on disk, SaveData writes wave files, variables files, and subfolders. This resembles the experiment folder of an unpacked experiment, but it does not contain other unpacked experiment files, such as history or procedures. You can browse the folder using the Data Browser or access it using the **LoadData** operation.

If the target directory does not exist, SaveData creates it.

If you do not use the /O (overwrite) flag and the target folder already exists on disk, SaveData will present a dialog to confirm that you want to write to it. SaveData checks for the existence of the top file system folder only. For example, if you write data to hd:Data:Run1, SaveData will display a dialog if hd:Data:Run1 exists. But SaveData will not display a dialog for any folders inside hd:Data:Run1.

If you use the /O flag, SaveData will write without presenting a dialog.

When writing to a directory, SaveData can operate in one of two modes. If you use /D=1 or just /D, SaveData operates in “mix-in” mode. If you use /D=2, SaveData operates in “delete” mode.

**Warning:** If the target directory exists and delete mode is used, SaveData deletes the target directory and all of its contents. Then SaveData creates the target directory and writes the data to it. This is a complete overwrite operation.

If the target directory exists and mix-in mode is used, SaveData does not do any explicit deletion. It writes data to the target directory and any subdirectories. Conflicting files in any directory are overwritten but other files are left intact.

To prevent you from inadvertently deleting an entire volume, SaveData will not permit you to target the root directory of any volume. You must target a subdirectory.

The /J flag will not work as expected when writing numeric and string variables in mix-in mode. Instead of mixing-in the specified variables, SaveData will overwrite all variables already in the target. This is because all numeric and string variables in a particular data folder are stored in a single file-system folder (named “variables”), so it is not possible to mix-in. Since waves are written one-to-a-file, /J will work as expected for waves.

When SaveData writes a wave to a file-system folder, the file name for the wave is the same as the wave name, with the extension “.ibw” added. This is true even if the wave in the experiment was loaded from a file with a different name.

**Outputs**

SaveData sets the variable V_flag to zero if the operation succeeded or to nonzero if it failed. The main use for this is to determine if the user clicked Cancel during an interactive save. This would occur if you use the /I flag or if you omit /O and the target already exists. V_flag will also be nonzero if an error occurs during the save.

SaveData sets the string variable S_path to the full file system path to the file or folder that was written. S_path uses Macintosh path syntax (e.g., “hd:FolderA:FolderB:”), even on Windows. When saving unpacked, S_path includes a trailing colon.

**Examples**

Write the contents of the current data folder and all subdata folders to a packed experiment file:

```vbscript
Function SaveDataInPackedFile(pathName, fileName)
    String pathName // Name of symbolic path
    String fileName // Name of packed file to be written
    SaveData/R/P=$pathName fileName
End
```

Write the contents of the current data folder and all subdata folders to an unpacked file-system folder:

```vbscript
Function SaveDataInUnpackedFolder(pathName, folderName)
```
The `SaveExperiment` operation saves the current experiment.

**Warning:** `SaveExperiment` overwrites any previously-existing file named `fileName`.

**Parameters**

The optional `fileName` string contains the name of the experiment to be saved. `fileName` can be the currently open experiment, in which case it overwrites the experiment file.

If `fileName` and `pathName` are omitted and the experiment is Untitled, you will need to locate where the experiment file will be saved interactively via a dialog.

If you use a full or partial path for `pathName`, see **Path Separators** on page III-429 for details on forming the path.

**Flags**

- `/C` Saves an experiment copy (valid only when `fileName` or `pathName` is provided or both if experiment is Untitled).

- `/F={format, unpackedExpFolderNameStr, unpackedExpFolderMode}`

  Specifies the experiment file format.

  See **Experiment File Format** below for details.

- `/P=pathName` Specifies folder in which to save the experiment. `pathName` is the name of an existing symbolic path.

**Details**

`SaveExperiment` acts like the Save menu command in the File menu. If the experiment is associated with an already saved file, then `SaveExperiment` with no parameters will simply save the current experiment. If the experiment resides only in memory and has not yet been saved, then a dialog will be presented unless the path and file name are specified.

If you use a full path in the name you will not need the `/P` flag. If instead you use `/P=pathName`, note that it is the name of an Igor symbolic path, created via **NewPath**. It is not a file system path like "hd:Folder1:" or "C:\Folder1\". See **Symbolic Paths** on page II-21 for details.
Experiment File Format
For background information on experiment file formats, see Experiments on page II-17.

The /F flag provides control of the file format of a previously-unsaved experiment independent of the user's preferences as set in the Experiment Settings section of the Miscellaneous Settings dialog. It also allows you to save a previously-saved experiment using a different experiment file format.

If you just want to save the current experiment in its current format, you don't need to use /F.

If you use /F, you must fully-specify the location of the experiment file through the /P flag and the fileName parameter or through fileName alone if it contains a full path.

The format parameter controls the experiment file format used by SaveExperiment:

format = -1: Default format.
format = 0: Unpacked experiment file
format = 1: Packed experiment file

If /F is omitted or if format is -1 then the experiment is saved in its current format or, if it was never saved to disk, in the format specified in the Experiment Settings section of the Miscellaneous Settings dialog.

If format = 0, the experiment is saved in unpacked experiment file format. fileName must end with ".uxp" or ".uxt".

If format = 1, the experiment is saved in packed experiment file format. fileName must end with ".pxp" or ".pxt".

Unpacked Experiment Folder
The unpacked experiment folder is the folder in which wave files, the history file, the variables file, and other experiment files are stored for an unpacked experiment. See Saving as an Unpacked Experiment File on page II-17 for details.

The /F unpackedExpFolderNameStr parameter specifies the name of the experiment folder for an unpacked experiment. It contains a folder name, not a full or partial path. It is ignored unless saving in unpacked experiment format.

The unpacked experiment folder is created in the same directory as the experiment file.

If /F=0 is used and unpackedExpFolderNameStr is "" then the experiment folder name is the same as the experiment file name with the extension removed and a space and "Folder" added.

If the specified unpacked experiment folder already exists and is the current experiment's unpacked experiment folder, it is reused. "Reuse" means that SaveExperiment saves files in the unpacked experiment folder, possibly overwriting files already in it, but does not delete any files or folders already in it.

The unpackedExpFolderMode parameter controls what happens if the folder to be used as the unpacked experiment folder already exists and is not the current experiment's unpacked experiment folder:

unpackedExpFolderMode=0 : SaveExperiment returns an error.
unpackedExpFolderMode=1 : SaveExperiment displays a dialog asking the user if it is OK to reuse the folder. If the user answers yes, the operation proceeds. Otherwise, it returns an error.
unpackedExpFolderMode=2 : SaveExperiment reuses the folder without asking the user.

Warning: If you pass 2 for unpackedExpFolderMode, files and folders in the unpacked experiment folder may be overwritten without the user's express permission.

See Also
ExperimentInfo

SaveGizmoCopy
SaveGizmoCopy [flags] [as fileNameStr]
The SaveGizmoCopy operation saves a Gizmo window and its waves in an Igor packed experiment file.
SaveGizmoCopy was added in Igor Pro 8.00.

**Parameters**
The file to be written is specified by `fileNameStr` and `/P=pathName` where `pathName` is the name of an Igor symbolic path. `fileNameStr` can be a full path to the file, in which case `/P` is not needed, a partial path relative to the folder associated with `pathName`, or the name of a file in the folder associated with `pathName`. If Igor can not determine the location of the file from `fileNameStr` and `pathName`, it displays a dialog allowing you to specify the file.

If you use a full or partial path for `fileNameStr`, see **Path Separators** on page III-429 for details on forming the path.

**Flags**

- `/I` Presents a dialog from which you can specify file name and folder.
- `/O` Overwrites file if it exists already.
- `/P=pathName` Specifies the folder to store the file in. `pathName` is the name of an existing symbolic path.
- `/W=winName` `winName` is the name of the Gizmo window to be saved. If `/W` is omitted or if `winName` is "", the top Gizmo window is saved.
- `/Z` Errors are not fatal and error dialogs are suppressed. See Details.

**Details**
The main uses for saving as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see **Merging Experiments** on page II-19). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the Gizmo window starting from the root data folder. Only the Gizmo window, its waves as well as the objects on Gizmo's object list and attribute list are saved in the packed experiment file. Associated procedures including hook functions are not saved.

SaveGizmoCopy does not know about dependencies. If a Gizmo window contains a wave, wave0, that is dependent on another wave, wave1 which is not used in the Gizmo window, SaveGizmoCopy will save wave0 but not wave1. When the saved experiment is open, there will be a broken dependency.

SaveGizmoCopy sets the variable `V_flag` to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the `/Z` flag and check `V_flag` after calling SaveGizmoCopy.

*SaveGraphCopy, SaveTableCopy, SaveData, Merging Experiments* on page II-19

---

**SaveGraphCopy**

`SaveGraphCopy [flags] [as fileNameStr]`

The SaveGraphCopy operation saves a graph and its waves in an Igor packed experiment file.

**Parameters**
The file to be written is specified by `fileNameStr` and `/P=pathName` where `pathName` is the name of an Igor symbolic path. `fileNameStr` can be a full path to the file, in which case `/P` is not needed, a partial path relative to the folder associated with `pathName`, or the name of a file in the folder associated with `pathName`. If Igor can not determine the location of the file from `fileNameStr` and `pathName`, it displays a dialog allowing you to specify the file.

If you use a full or partial path for `fileNameStr`, see **Path Separators** on page III-429 for details on forming the path.

**Flags**

- `/I` Presents a dialog from which you can specify file name and folder.
- `/O` Overwrites file if it exists already.
- `/P=pathName` Specifies the folder to store the file in. `pathName` is the name of an existing symbolic path.
The main uses for saving as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see Merging Experiments on page II-19). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the graph starting from the “top” data folder, which is the data folder that encloses all waves displayed in the graph. The top data folder becomes the root data folder of the resulting experiment file. Only the graph, its waves, dashed line settings, and any pictures used in the graph are saved in the packed experiment file, not procedures, variables, strings or any other objects in the experiment.

SaveGraphCopy does not work well with graphs containing controls. First, the controls may depend on waves, variables or FIFOs (for chart controls) that SaveGraphCopy will not save. Second, controls typically rely on procedures which are not saved by SaveGraphCopy.

SaveGraphCopy does not know about dependencies. If a graph contains a wave, wave0, that is dependent on another wave, wave1 which is not in the graph, SaveGraphCopy will save wave0 but not wave1. When the saved experiment is open, there will be a broken dependency.

SaveGraphCopy sets the variable V_flag to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates an error occurred. If you want to detect the user canceling an interactive save, use the /Z flag and check V_flag after calling SaveGraphCopy.

The SaveData operation also has the ability to save data from a graph to a packed experiment file. SaveData is more complex but a bit more flexible than SaveGraphCopy.

Examples
This function saves all graphs in the experiment to individual packed experiment files.

Function SaveAllGraphsToPackedFiles(pathName)
    String pathName // Name of an Igor symbolic path.
    String graphName
    Variable index
    index = 0
    do
        graphName = WinName(index, 1)
        if (strlen(graphName) == 0)
            break
        endif
        String fileName
        sprintf fileName, "%s.pxp", graphName
        SaveGraphCopy/P=pathName/W=$graphName as fileName
        index += 1
    while(1)
End

See Also
SaveTableCopy, SaveGizmoCopy, SaveData, Merging Experiments on page II-19

SaveNotebook

SaveNotebook [flags] notebookName [as fileNameStr]
The SaveNotebook operation saves the named notebook.

Parameters
notebookName is either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0#nb0. See Subwindow Syntax on page III-92 for details on host-child specifications.

If notebookName is an host-child specification, /S must be used and saveType must be 3 or higher.

The file to be written is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative
to the folder associated with *pathName*, or the name of a file in the folder associated with *pathName*. If Igor can not determine the location of the file from *fileNameStr* and *pathName*, it displays a dialog allowing you to specify the file.

If you use a full or partial path for *fileNameStr*, see **Path Separators** on page III-429 for details on forming the path.

**Flags**

/ENCG=\text{\textencoding}

Specifies text encoding in which the notebook is to be saved. This flag was added in Igor Pro 7.00. This is relevant for plain text notebooks only and is ignored for formatted notebooks because they can contain multiple text encodings. See **Plain Text File Text Encodings** on page III-445 and **Formatted Text Notebook File Text Encodings** on page III-450 for details.

If omitted, the file is saved in its original text encoding. Normally you should omit /ENCG. Use it only if you have some reason to change the file's text encoding.

Passing 0 for *textEncoding* acts as if /ENCG were omitted.

See **Text Encoding Names and Codes** on page III-463 for a list of accepted values for *textEncoding*.

This flag does not affect HTML export. Use /H instead.

/H={\text{\textencodingName}, \text{writeParagraphProperties}, \text{writeCharacterProperties}, \text{PNGOrJPEG}, \text{quality}, \text{bitDepth}}

Controls the creation of an HTML file.

*textencodingName* specifies the HTML file text encoding. The recommended value is "UTF-8".

*writeParagraphProperties* determines what paragraph properties SaveNotebook will write to the HTML file. This is a bitwise parameter with the bits defined as follows:

- Bit 0: Write paragraph alignment.
- Bit 1: Write first indent.
- Bit 2: Write minimum line spacing.
- Bit 3: Write space-before and space-after paragraph.

All other bits are reserved for future use and should be set to zero.

*writeCharacterProperties* determines what character properties SaveNotebook will write to the HTML file. This is a bitwise parameter with the bits defined as follows:

- Bit 0: Write font families.
- Bit 1: Write font sizes.
- Bit 2: Write font styles.
- Bit 3: Write text colors.
- Bit 4: Write text vertical offsets.

All other bits are reserved for future use and should be set to zero.

If you set bit 2, SaveNotebook exports only the bold, underline, and italic styles because other character styles are not supported by HTML.

\text{PNGOrJPEG} determines whether SaveNotebook will write picture files as PNG or JPEG:

- 0: PNG (default).
- 1: JPEG.
- 2: JPEG.

In Igor7 and later, there is no difference between \text{PNGOrJPEG}=1 and \text{PNGOrJPEG}=2. See **Details** for more on HTML picture files.
Details
Interactive (/I) means that Igor displays the Save, Save As, or Save a Copy dialog.
The save will be interactive under the following conditions:
• You include the /I flag and the saveType is 2, 3, 4, 5, 6, 7 or 8.
• saveType is 2, 3, 4, 5, 6, 7 or 8 and you do not specify the path or filename.
If the saveType is normal and the notebook has previously been saved to a file then the /I flag, the path and file name that you specify, if any, are ignored and the notebook is saved to its associated file without user intervention.
The full path to the saved file is stored in the string S_path. If the save was unsuccessful, S_path will be "".
If you use /P=pathName, note that it is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\\Folder1\". See Symbolic Paths on page II-21 for details.
saveType=8 applies to formatted notebooks only. It exports the notebook as plain text with line breaks where text wraps in the formatted notebook. This feature was added in Igor Pro 8.00. Special characters such as pictures are skipped. If the notebook is plain text then saveType=8 acts like saveType=6.

Exporting as RTF
For background information on writing RTF files, see Import and Export Via Rich Text Format Files on page III-20.

Exporting as HTML
For background information on writing HTML files, see Exporting a Notebook as HTML on page III-21.
You can pass “UTF-8” or “UTF-2” for the encodingName parameter. In virtually all cases, you should use “UTF-8”.
When creating an HTML file, SaveNotebook can write pictures using the PNG or JPEG graphics formats. PNG is recommended because it is lossless.

See Also
Chapter III-1, Notebooks.
The SavePackagePreferences operation saves preference data in the specified structure so that it can be accessed later via the LoadPackagePreferences operation.

Note: The package preferences structure must not use fields of type Variable, String, WAVE, NVAR, SVAR or FUNCREF because these fields refer to data that may not exist when LoadPackagePreferences is called.

The structure can use fields of type char, uchar, int16, uint16, int32, uint32, int64, uint64, float and double as well as fixed-size arrays of these types and substructures with fields of these types.

The data is stored in memory and by default flushed to disk when the current experiment is saved or closed and when Igor quits.

If the /P flag is present then the location on disk of the preference file is determined by pathName and prefsFileName. However in the usual case the /P flag will be omitted and the preference file is located in a file named prefsFileName in a directory named packageName in the Packages directory in Igor’s preferences directory.

Note: You must choose a very distinctive name for packageName as this is the only thing preventing collisions between your package and someone else’s package.

See Saving Package Preferences on page IV-244 for background information and examples.

Parameters
packageName is the name of your package of Igor procedures. It is limited to 31 bytes and must be a legal name for a directory on disk. This name must be very distinctive as this is the only thing preventing collisions between your package and someone else’s package.

prefsFileName is the name of a preference file to be saved by SavePackagePreferences. It should include an extension, typically ".bin".

prefsStruct is the structure containing the data to be saved in the preference file on disk.

recordID is a unique positive integer that you assign to each record that you store in the preferences file. If you store more than one structure in the file, you would use distinct recordIDs to identify which structure you want to save. In the simple case you will store just one structure in the preference file and you can use 0 (or any positive integer of your choice) as the recordID.

Flags

/FLSH=flush Controls when the data is actually written to the preference file:

flush=0: The data will be flushed to disk when the current experiment is saved, reverted or closed or when Igor quits. This is the default behavior used when /FLSH is omitted and is recommended for most purposes.

flush=1: The data is flushed to disk immediately.

/KILL Instead of saving prefsStruct under the specified record ID, that record is deleted from the package’s preference if it exists. If it does not exist, nothing is done and no error is returned.

/P=pathName Specifies the directory in which to save the file specified by prefsFileName.

pathName is the name of an existing symbolic path. See Symbolic Paths on page II-21 for details.

/P=$<empty string variable> acts as if the /P flag were omitted.
SavePICT

Details
SavePackagePreferences sets the following output variables:

- **V_flag**
  Set to 0 if preferences were successfully saved or to a nonzero error code if they were not saved. The latter case is unlikely and would indicate some kind of corruption such as if Igor’s preferences directory were deleted.

- **V_structSize**
  Set to the size in bytes of prefsStruct. This may be useful in handling structure version changes.

Example
See the example under *Saving Package Preferences in a Special-Format Binary File* on page IV-245.

See Also
LoadPackagePreferences.

SavePICT

SavePICT [flags] [as fileNameStr]
The SavePICT operation creates a picture file representing the top graph, table or layout. The picture file can be opened by many word processing, drawing, and page layout programs.

Parameters
The file to be written is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor cannot determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see *Path Separators* on page III-429 for details on forming the path.

If you omit fileNameStr but include /P=pathName, SavePICT writes the file using a default file name. The default file name is the window name followed by an extension, such as ".png", ".emf" or ".svg", that depends on the graphic format being exported.

If you specify the file name as “Clipboard”, and do not specify a /P=pathName, Igor copies the picture to the Clipboard, rather than to a file. EPS is a file-only format and cannot be stored in the clipboard.

If you specify the file name as “string_” the output will be saved into a string variable named S_Value, which is used with the *ListBox* binary bitmap display mode.

If you use the special name _PictGallery_ with the /P flag, then the picture will be stored in Igor’s picture gallery (see *Pictures* on page III-481) with the name you provide via fileNameStr. This feature was added in support of making movies using the /PICT flag with *NewMovie*.

Flags

- **/B=dpi**
  Controls image resolution in dots-per-inch (dpi). The legal values for dpi are $n*72$ where $n$ can be from 1 to 8. The actual image dpi is not used. Igor calculates $n$ from your value of dpi and then multiplies $n$ by your computer’s screen resolution. This is because bitmap images that are not an integer multiple of the screen resolution look quite bad.
  Also see the /RES flag.

- **/C=c**
  Specifies color mode.
  
  - $c=0$: Black and white.
  - $c=1$: RGB color (default).
  - $c=2$: CMYK color (EPS and native TIFF only).

- **/D=d**
  Obsolete in Igor Pro 7 or later.
/E=e  
Sets graphics format used when exporting a graphic. See Details for formats. See also Chapter III-5, Exporting Graphics (Macintosh), or Chapter III-6, Exporting Graphics (Windows), for a description of these modes and when to use them.

/EF=e  
Sets font embedding.

e=0: No font embedding. Not honored in Igor Pro 7 or later.

e=1: Embed nonstandard fonts.

e=2: Embed all fonts.

/I  
Specifies that /W coordinates are inches.

/M  
Specifies that /W coordinates are centimeters.

/N=winSpec  
/N is antiquated but still supported. Use /WIN instead.

/O  
Overwrites file if it exists.

/P=pathName  
Saves file into a folder specified by pathName, which is the name of an existing symbolic path.

/PGR=(firstPage, lastPage)  
Controls which pages in a multi-page layout are saved.

firstPage and lastPage are one-based page numbers. All pages from firstPage to lastPage are saved if the file format supports it.

The special value 0 refers to the current page and -1 refers to the last page in the layout.

Currently only the PDF formats support saving multiple pages. Other file formats save only firstPage and ignore the value of lastPage.

/PGR was added in Igor Pro 7.00.

/PICT=pict  
Saves specified named picture rather than the target window. Native format of the picture is used and all format flags are ignored.

/PLL=p  
Specifies Postscript language level when used in conjunction with EPS export.

p=1: For very old Postscript printers.

p=2: For all other uses (default).

/Q=q  
Sets quality factor (0.0 is lowest, 1.0 is highest). Default is dependent on individual format. Used only by lossy formats such as JPEG.

/R=resID  
Obsolete in Igor Pro 7 or later.

/RES=dpi  
Controls the resolution of image formats in dots-per-inch. Unlike the similar /B flag, the value for /RES is the actual output resolution and is useful when your publisher demands a specific resolution.

/S  
Suppresses the preview that is normally included with an EPS file.

Obsolete in Igor Pro 7 or later.

/SNAP=s  
Saves a snapshot (screen dump) of a graph or panel window.

s=1: Include all controls in capture.

s=2: Capture only window data content.

Snapshot mode is available only for graphs and panels and only for bitmap export formats PNG, JPEG, and TIFF at screen resolution. When using /W to specify the size of a graph, the capture is sized to fit within the specified rectangle while maintaining the window aspect ratio. Coordinates used with /W are in pixels.

/T=t  
Obsolete QuickTime export type. Not supported in Igor Pro 7 or later.
SavePICT

/TRAN[=1 or 0]  Makes white background areas transparent using an RGBA type PNG when used with native PNG export of graphs or page layouts.

/W=(left, top, right, bottom)  
Specifies the size of the picture when exporting a graph. If /W is omitted, it uses the graph window size.
When exporting a page layout, specifies the part of the page to export. Only objects that fall completely within the specified area are exported. If /W is omitted, the area of the layout containing objects is exported.
When exporting a page layout in Igor Pro 7.00 or later, you can specify /W=(0,0,0,0) to use the full page size.
Coordinates for /W are in points unless /I or /M are specified before /W.

/WIN=winSpec  Saves the named window or subwindow. winSpec can be just a window name, or a window name following by a “#” character and the name of the subwindow, as in /WIN=Panel0#G0.

/Z  Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

Details

SavePICT sets the variable V_flag to 0 if the operation succeeds or to a nonzero error code if it fails.

If you specify a path using the /P=pathName flag, then Igor saves the file in the folder identified by the path.
Note that pathName is the name of an Igor symbolic path, created via NewPath. It is not a file system path like “hd:Folder1:” or “C:\Folder1\”. See Symbolic Paths on page II-21 for details. Otherwise, with no path specified, Igor presents a standard save dialog to let you specify where the file is to be saved.

Graphics formats, specified via /E, are as follows:

<table>
<thead>
<tr>
<th>/E Value</th>
<th>Macintosh File Format</th>
<th>Windows File Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>-9</td>
<td>SVG file.</td>
<td>SVG file.</td>
</tr>
<tr>
<td>-8</td>
<td>PDF file.</td>
<td>PDF file.</td>
</tr>
<tr>
<td>-7</td>
<td>TIFF file. Lossless but larger file than PNG; best for text, graph traces, and simple images with sharp edges. The default resolution is 72 dpi. You can specify the resolution with the /B or /RES flag. Cross-platform compatible.</td>
<td></td>
</tr>
<tr>
<td>-6</td>
<td>JPEG file. Lossy compression; best used for grayscale and color images with smooth tones. The /Q flag specifies compression quality and the /B or /RES flag sets the resolution. Cross-platform compatible.</td>
<td></td>
</tr>
<tr>
<td>-5</td>
<td>PNG (Portable Network Graphics) file. Lossless compression; best for text, graph traces, and simple images with sharp edges. The default resolution is 72 dpi. Specify the resolution with /B or /RES. Cross-platform compatible.</td>
<td></td>
</tr>
<tr>
<td>-4</td>
<td>High resolution bitmap PICT file. Default resolution is 288 dpi. Specify the resolution with /B or /RES.</td>
<td>Device-independent bitmap file (DIB). Default resolution is 4x screen resolution. Specify the resolution with /B or /RES.</td>
</tr>
<tr>
<td>-3</td>
<td>Encapsulated PostScript (EPS) file. Use /S to suppress the screen preview if exporting to Latex.</td>
<td>Encapsulated PostScript (EPS) file. Use /S to suppress the screen preview if exporting to Latex.</td>
</tr>
<tr>
<td>-2</td>
<td>Quartz PDF.</td>
<td>High-resolution Enhanced Metafile (EMF).</td>
</tr>
<tr>
<td>-1</td>
<td>Quartz PDF (was PostScript PICT).</td>
<td>Obsolete (was PostScript-enhanced metafile).</td>
</tr>
<tr>
<td>0</td>
<td>Quartz PDF (was PostScript PICT with QuickDraw text).</td>
<td>Obsolete (was PostScript-enhanced metafile).</td>
</tr>
<tr>
<td>1</td>
<td>Low resolution Quartz PDF at 1x normal size.</td>
<td>High-resolution Enhanced Metafile (EMF).</td>
</tr>
</tbody>
</table>
SaveTableCopy

SaveTableCopy [flags] [as fileNameStr]
The SaveTableCopy operation saves a copy of the data displayed in a table on disk. The saved file can be an Igor packed experiment file, a tab-delimited text file, or a comma-separated values text file.

When saving as text, by default the data format matches the format shown in the table. This causes truncation if the underlying data has more precision than shown in the table. If you specify /F=1, SaveTableCopy uses as many digits as needed to represent the data with full precision.

The point column is never saved.
To save data as text with full precision, use the Save operation.

When saving 3D and 4D waves as text, only the visible layer is saved. To save the entirety of a 3D or 4D wave, use the Save operation.

Parameters
The file to be written is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If Igor cannot determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-429 for details on forming the path.

Flags
/A=a
Appears data to the file rather than overwriting.

a=0: Does not append.
a=1: Appends to the file with a blank line before the appended data.
a=2: Appends to the file with no blank line before the appended data.

/A applies when saving text files and is ignored when saving packed experiment files.

If the file does not exist, a new file is created and /A has no effect.

/F=f
Controls the precision of saved numeric data.

f=0: Numeric data is written exactly as shown in the table. This may cause truncation. This is the default behavior if /F is omitted.

f=1: Numeric data is written with as many digits as needed to represent the data with full precision.

The /F flag was added in Igor Pro 7.00

/I
Presents a dialog from which you can specify file name and folder.
SaveTableCopy

/M=termStr
Specifies the terminator character or characters to use at the end of each line of text. The default is /M="\r"
on Macintosh and /M="\r\n" on Windows; it is used when /M is omitted. To use the Unix convention, just a linefeed, specify /M="\n".

/N=n
Specifies whether to use column names, titles, or dimension labels.

n is a bitwise parameter with the bits defined as follows:

Bit 0: Include column names or titles. The column title is included if it is not empty. If it is empty, the column name is included.

Bit 1: Include horizontal dimension labels if they are showing in the table.

The default setting for n is 1. All other bits are reserved and must be zero.

/O
Overwrites file if it exists already.

/P=pathName
Specifies the folder to store the file in. pathName is the name of an existing symbolic path.

/S=s
Saves all of the data in the table (s=0; default) or the selection only (s=1).

/T=saveType
Specifies the file format of the saved table.

saveType=0: Packed experiment file.
saveType=1: Tab-delimited text file.
saveType=2: Comma-separated values text file.
saveType=3: Space-delimited values text file.

/W=winName
winName is the name of the table to be saved. If /W is omitted or if winName is ",", the top table is saved.

/Z
Errors are not fatal and error dialogs are suppressed. See Details.

Details
The main uses for saving a table as a packed experiment are to save an archival copy of data or to prepare to merge data from multiple experiments (see Merging Experiments on page II-19). The resulting experiment file preserves the data folder hierarchy of the waves displayed in the table starting from the “top” data folder, which is the data folder that encloses all waves displayed in the table. The top data folder becomes the root data folder of the resulting experiment file. Only the table and its waves are saved in the packed experiment file, not variables or strings or any other objects in the experiment.

SaveTableCopy does not know about dependencies. If a table contains a wave, wave0, that is dependent on another wave, wave1 which is not in the table, SaveTableCopy will save wave0 but not wave1. When the saved experiment is open, there will be a broken dependency.

The main use for saving as a tab or comma-delimited text file is for exporting data to another program.

When calling SaveTableCopy from a procedure, you should call DoUpdate before calling SaveTable copy. This insures that the table is up-to-date if your procedure has redimensioned or otherwise changed the number of points in the waves in the table.

SaveTableCopy sets the variable V_flag to 0 if the operation completes normally, to -1 if the user cancels, or to another nonzero value that indicates that an error occurred. If you want to detect the user canceling an interactive save, use the /Z flag and check V_flag after calling SaveTableCopy.

The SaveData operation also has the ability to save a table to a packed experiment file. SaveData is more complex but a bit more flexible than SaveTableCopy.

Examples
This function saves all tables to a single tab-delimited text file.

Function SaveAllTablesToTextFile(pathName, fileName)
  String pathName  // Name of an Igor symbolic path.
  String fileName
  String tableName
  Variable index

Details
index = 0
do
    tableName = WinName(index, 2)
    if (strlen(tableName) == 0)
        break
    endif
    SaveTableCopy/P=${pathName}/W=${tableName}/T=1/A=1 as fileName
    index += 1
End

See Also
SaveGraphCopy, SaveGizmoCopy, SaveData, Merging Experiments on page II-19

sawtooth

sawtooth(num)
The sawtooth function returns \((num + n2\pi) \mod 2\pi)/2\pi\) where \(n\) is used to correct if \(num\) is negative. Sawtooth is used to create arbitrary periodic waveforms like sine and cosine.

Examples
wave1 = sawtooth(x)
creates a sawtooth in wave1 whose Y values range from 0 to 1 as its X values go through \(2\pi\) units.

wave1 = exp(sawtooth(x))
creates a series of exponentials in wave1 of amplitude \(\exp(1)\) and period \(2\pi\).

You can also use sawtooth to create periodic repetitions of a given part of a wave:
wave1 = wave2(sawtooth(x))
creates a periodic repetition of wave2 in wave1 given the correct X scaling for the waves.

ScaleToIndex

ScaleToIndex(wave, coordValue, dim)
The ScaleToIndex function returns the number of the element in the requested dimension whose scaled index value is closest to \(coordValue\).

The ScaleToIndex function was added in Igor Pro 7.00.

Parameters
\(dim\) is a dimension number: 0 for rows, 1 for columns, 2 for layers, 3 for chunks.
\(coordValue\) is a scaled index in that dimension.

Details
The ScaleToIndex function returns the value of the expression:
round((coordValue - DimOffset(wave, dim)) / DimDelta(wave, dim))
With \(dim=0\), ScaleToIndex is equivalent to using x2pnt.

See Also
IndexToScale, x2pnt, DimDelta, DimOffset
Waveform Model of Data on page II-57 for an explanation of wave scaling.

ScreenResolution

ScreenResolution
The ScreenResolution function returns the logical resolution of your video display screen in dots per inch (dpi). On Macintosh this is always 72. On Windows it is usually 96 (small fonts) or 120 (large fonts).

Examples
// 72 is the number of points in an inch which is constant.
Variable pixels = numPoints * (ScreenResolution/72)  // Convert points to pixels
Variable points = numPixels * (72/ScreenResolution)  // Convert pixels to points
sec

See Also
PanelResolution

sec

\texttt{sec(\textit{angle})}

The sec function returns the secant of \textit{angle} which is in radians:

\[
\sec(x) = \frac{1}{\cos(x)}.
\]

In complex expressions, \textit{angle} is complex, and \text{sec}(\textit{angle}) returns a complex value.

See Also
\text{sin}, \text{cos}, \text{tan}, \text{csc} \text{, cot}

sech

\texttt{sech(\textit{x})}

The sech function returns the hyperbolic secant of \textit{x}.

\[
\csch(x) = \frac{1}{\cosh(x)} = \frac{2}{e^x + e^{-x}}.
\]

In complex expressions, \textit{x} is complex, and \text{sech}(\textit{x}) returns a complex value.

See Also
\text{cosh}, \text{tanh}, \text{coth}, \text{csch}

Secs2Date

\texttt{Secs2Date(\textit{seconds}, \textit{format} [, \textit{sep}])}

The Secs2Date function returns a string containing a date.

With \textit{format} values 0, 1, and 2, the formatting of dates depends on operating system settings entered in the Language & Region control panel (Macintosh) or the Region control panel (Windows). These date formats do not work with dates before 0001-01-01 in which case Date2Secs returns an empty string.

If \textit{format} is -1, the format is independent of operating system settings. The fixed-length format is “day/month/year (dayOfWeekNum)”, where \textit{dayOfWeekNum} is 1 for Sunday, 2 for Monday... and 7 for Saturday.

If \textit{format} is -2, the format is YYYY-MM-DD.

The optional \textit{sep} parameter affects format -2 only. If \textit{sep} is omitted, the separator character is “-”. Otherwise, \textit{sep} specifies the separator character.

Parameters

\textit{seconds} is the number of seconds from 1/1/1904 to the date to be returned.

\textit{seconds} is limited to the range -1094110934400 (-32768-01-01) to 973973807999 (32768-12-31). For \textit{seconds} outside that range, Secs2Date returns an empty string.

\textit{format} is a number between -2 and 2 which specifies how the date is to be constructed.

Examples

Print Secs2Date(DateTime,-2) // 1993-03-14
Print Secs2Date(DateTime,-2,”/”) // 1993/03/14
Print Secs2Date(DateTime,-1) // 15/03/1993 (2)
Print Secs2Date(DateTime,0) // 3/15/93 (depends on system settings)
Print Secs2Date(DateTime,1) // Monday, March 15, 1993 (depends on system settings)
Print Secs2Date(DateTime,2) // Mon, Mar 15, 1993 (depends on system settings)

See Also

For further discussion of how Igor represents dates, see \textbf{Date/Time Waves} on page II-79.
Secs2Time

Secs2Time(seconds, format, [fracDigits])
The Secs2Time function returns a string containing a time.

Parameters
seconds is the number of seconds from 1/1/1904 to the time to be returned.
format is a number between 0 and 5 that specifies how the time is to be constructed. It is interpreted as follows:

0: Normal time, no seconds.
1: Normal time, with seconds.
2: Military time, no seconds.
3: Military time, with seconds and optional fractional seconds.
4: Elapsed time, no seconds.
5: Elapsed time, with seconds and optional fractional seconds.

“Normal” formats (0 and 1) follow the preferred formatting of the short time format as set in the International control panel (Macintosh) or in the Regional and Language Options control panel (Windows).
“Military” means that the hour is a number from 0 to 23. Hours greater than 23 are wrapped.
“Elapsed” means that the hour is a number from -9999 to 9999. The result for hours outside that range is undefined.

The fracDigits parameter is optional and specifies the number of digits of fractional seconds. The default value is 0. The fracDigits parameter is ignored for format=0, 1, 2, and 4.

Examples
Print Secs2Time(DateTime,0) // prints 1:07 PM
Print Secs2Time(DateTime,1) // prints 1:07:28 PM
Print Secs2Time(DateTime,2) // prints 13:07
Print Secs2Time(DateTime,3) // prints 13:07:29
Print Secs2Time(30*60*60+45*60+55,4) // Prints 30:45
Print Secs2Time(30*60*60+45*60+55,5) // Prints 30:45:55

See Also
For a discussion of how Igor represents dates, see Date/Time Waves on page II-79.
The Secs2Date, date, date2secs and DateTime functions. Also, Operators on page IV-7 for ?: details.

SelectNumber

SelectNumber(whichOne, val1, val2 [, val3])
The SelectNumber function returns one of val1, val2, or (optionally) val3 based on the value of whichOne.
SelectNumber(whichOne, val1, val2) returns val1 if whichOne is zero, else it returns val2.
SelectNumber(whichOne, val1, val2, val3) returns val1 if whichOne is negative, val2 if whichOne is zero, or val3 if whichOne is positive.

Details
SelectNumber works with complex (or real) val1, val2, and val3 when the result is assigned to a complex wave or variable. (Print expects a real result, see the “causes error” example, below).
If whichOne is NaN, then NaN is returned.
whichOne must always be a real value.

Unlike the ? : conditional operator, SelectNumber always evaluates all of the numeric expression parameters val1, val2, ...
SelectNumber works in a macro, whereas the conditional operator does not.
SelectString

Examples
Print SelectNumber(0,1,2) // prints 1
Print SelectNumber(0,1,2,3) // prints 2
wv=SelectNumber(numType(wv[p])==2,wv[p],0) // replace NaNs with zeros

// chooses among complex values
Variable/C x= SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1))

// causes error because Print expects a real value (not complex)
Print SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1))

// The real function expects a complex result
Print real(SelectNumber(negZeroPos,cmplx(-1,-1),0,cmplx(1,1)))

See Also
The SelectString and limit functions, and Waveform Arithmetic and Assignments on page II-69. Also, Operators on page IV-7 for details about the ?: operator.

SelectString

SelectString(whichOne, str1, str2 [, str3])
The SelectString function returns one of str1, str2, or (optionally) str3 based on the value of whichOne.
SelectString(whichOne, str1, str2) returns str1 if whichOne is zero, else it returns str2.
SelectString(whichOne, str1, str2, str3) returns str1 if whichOne is negative, str2 if whichOne is zero, or str3 if whichOne is positive.

Details
If whichOne is NaN, then "" is returned.
whichOne must always be a real value.
Unlike the ?: conditional operator, SelectString always evaluates all of the string expression parameters str1, str2, ...
SelectString works in a macro, whereas the conditional operator does not.

Examples
Print SelectString(0,"hello","there") // prints "hello"
Print SelectString(1,"hello","there") // prints "there"
Print SelectString(-3,"hello","there","jack") // prints "hello"
Print SelectString(0,"hello","there","jack") // prints "there"
Print SelectString(100,"hello","there","jack") // prints "jack"

See Also
The SelectNumber function and String Expressions on page IV-14. Also, Operators on page IV-7 for details about the ?: operator.

SetActiveSubwindow

SetActiveSubwindow subWinSpec
The SetActiveSubwindow operation specifies the subwindow that is to be activated. This operation is mainly for use by recreation macros.

Parameters
subWinSpec specifies an existing subwindow. See Subwindow Syntax on page III-92 for details on subwindow specifications.
Use _endfloat_ for subWinSpec to make a newly-created floating panel not be the default target.

See Also
GetWindow with the activeSW keyword.
SetAxis

SetAxis [flags] axisName [, num1, num2]

The SetAxis operation sets the extent (or “range”) of the named axis.

Parameters

axisName is usually “left”, “right”, “top” or “bottom”, but it can also be the name of a free axis, such as “vertCrossing”.

If axisName is a vertical axis such as “left” or “right” then num1 sets the bottom end of the axis and num2 sets the top end of the axis.

If axisName is a horizontal axis such as “top” or “bottom” then num1 sets the left end of the axis and num2 sets the right end of the axis.

You can flip the graph by reversing num1 and num2 (or by using /A/R). This is particularly useful for images, because Igor plots an image inverted.

If you pass * (asterisk) for num1 and/or num2 then the corresponding end of the axis will be autoscaled.

Flags

/A[a] Autoscale axis (when used, num1, num2 should be omitted).

a=0: No autoscale. Same as no /A flag.

a=1: Normal autoscale. Same as /A.

a=2: Autoscale Y axis to a subset of the data defined by the current X axis range.

/E=z Sets the treatment of zero when the axis is in autoscale mode.

z=0: Normal mode where zero is not treated special.

z=1: Forces the smaller end of the axis to be set to zero (autoscale from zero).

z=2: Axis is symmetric about zero.

z=3: If the data is unipolar (all positive or all negative), this behaves like /E=1 (autoscale from zero). If the data is bipolar, it behaves like /E=0 (normal autoscaling).

/N=n Sets the algorithm for axis autoscaling.

n=0: Normal mode; sets the axis limits equal to the data limits.

n=1: Picks nice values for the axis limits.

n=2: Picks nice values; also ensures that the data is inset from the axis ends.

/R Reverses the autoscaled axis (smaller values at the left for horizontal axes, at the top for vertical axes) when used with /A. Although it only has an effect for autoscale, it can be used with nonautoscale version of SetAxis so that the next time the Axis Range tab is used the “reverse axis” checkbox will already be set.

/W=winName Sets axes in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/Z No error reporting if named axis doesn’t exist in a style macro.

SetBackground

SetBackground numericExpression

The SetBackground operation sets numericExpression as the current unnamed background task.

SetBackground works only with the unnamed background task. New code should used named background tasks instead. See Background Tasks on page IV-307 for details.
The background task runs while Igor is not busy with other things. Normally, there won’t be a background task. The most common use for the background task is to monitor or drive a continuous data acquisition process.

**Parameters**

`numericExpression` is a single precision numeric expression that Igor executes when it isn’t doing anything else.

**Details**

`numericExpression` is expected to return one of three numeric values:

- **0**: Background task executed normally.
- **1**: Background task wants to stop.
- **2**: Background task encountered error and wants to stop.

Usually the expression will be a call to a user-defined numeric function or external function to drive or monitor data acquisition. The expression should be designed to execute very quickly and it should not present a dialog to the user nor should it create or destroy windows. Generally, it should do nothing more than store data into waves or variables. You can use Igor’s dependency mechanism to perform more extensive tasks.

SetBackground designates the background task but you must use CtrlBackground to start it. You can also use KillBackground to stop it. You can not call SetBackground from the background function itself.

**See Also**

The *BackgroundInfo*, *CtrlBackground*, *CtrlNamedBackground*, *KillBackground*, and *SetProcessSleep* operations, and *Background Tasks* on page IV-307.

---

**SetDashPattern**

*SetDashPattern* *dashNumber*, `{d1, s1 [, d2, s2]...}

The *SetDashPattern* operation defines a dashed-line pattern for a user-defined dashed line. These dashed lines are used by the drawing tools and the Modify Waves Appearance dialog, and are elsewhere referred to as “line styles”.

**Parameters**

*dashNumber* specifies which dash pattern is to be set. It must be between 1 and 17. Dash pattern 0 is reserved for a solid line.

```plaintext
0  ______________________
1  ______________________
2  ______________________
3  ______________________
4  ______________________
5  ______________________
6  ______________________
7  ______________________
8  _______________     9  ________________
10 _______________     10 ________________
12 _______________     12 ________________
13 _______________     13 ________________
14 _______________     14 ________________
15 _______________     15 ________________
16 _______________     17 ________________
```

{d1,s1 [,d2,s2]...} defines the dash pattern. The dash pattern consists of 1 to 8 “dash,skip” pairs. Each pair consists of the number of drawn points followed by the number of skipped points.

- *d1* specifies the number of drawn points and *s1* specifies the number of skipped points in the first “dash,skip” pair. *d2* and *s2* specify the number of drawn and skipped points in the second pair and so on. Each draw or skip value must be between 1 and 127.

**Details**

*SetDashPattern* updates *all* graphs, panels and layouts so that any dashed lines will be updated with the new pattern. If you repeatedly call *SetDashPattern* from within a macro, you should precede the commands with the *PauseUpdate* operation to prevent multiple updates (which would be slow).

Dashed lines may also be redefined by the Dashed Lines dialog which you can choose from the Misc menu.

The dashed line patterns are saved as part of the experiment. When a new experiment is opened, the preferred dash patterns are restored.
Some programs and printer drivers do not properly render dashed lines with many “dash,skip” pairs.

**Examples**

Make test; Display test
SetDashPattern 17, {20,3,15,8}   // sets last dashed line pattern
ModifyGraph lstyle(test)=17     // apply pattern to trace

**See Also**

PauseUpdate and ResumeUpdate operations, and Dashed Lines on page III-470.

### SetDataFolder

**SetDataFolder** `dataFolderSpec`

The SetDataFolder operation sets the current data folder to the specified data folder.

**Parameters**

`dataFolderSpec` can be a simple name (MyDataFolder), a path (root:MyDataFolder) or a string expression containing a name or path. It can also be a data folder reference created by the DFREF keyword or returned by GetDataFolderDFR.

If `dataFolderSpec` is a path it can be a partial path relative to the current data folder (:MyDataFolder) or an absolute path starting from root (root:MyDataFolder).

**Examples**

SetDataFolder foo // Sets CDF to foo in the current data folder
SetDataFolder :bar:foo // Sets CDF to foo in bar current data folder
SetDataFolder root:foo // Sets CDF to foo in the root data folder
NewDataFolder/O/S root:MyDataFolder // Set CDF to a new data folder
Variable/G newVariable=1 // Do work in the new data folder
SetDataFolder savedDF // Restore current data folder

**See Also**

Chapter II-8, Data Folders and Data Folder References on page IV-77.

### SetDimLabel

**SetDimLabel** `dimNumber, dimIndex, label, wavelist`

The SetDimLabel operation sets the dimension label or dimension element label to the specified label.

**Parameters**

Use `dimNumber=0` for rows, 1 for columns, 2 for layers and 3 for chunks.

If `dimIndex` is -1, it sets the label for the entire dimension. For `dimIndex` ≥ 0, it sets the dimension label for that element of the dimension.

`label` is a name (e.g., time), not a string (e.g., “time”).

`label` is limited to 255 bytes. If you use more than 31 bytes, your wave will require Igor Pro 8.00 or later.

**Details**

Dimension labels can contain up to 255 bytes and may contain spaces and other normally-illegal characters if you surround the name in single quotes or if you use the $ operator to convert a string expression to a name.

Dimension labels have the same characteristics as object names. See **Object Names** on page III-475 for a discussion of object names in general.

**See Also**

GetDimLabel, FindDimLabel, CopyDimLabels

**Dimension Labels** on page II-87 and **Example: Wave Assignment and Indexing Using Labels** on page II-76 for further usage details and examples.
SetDrawEnv

SetDrawEnv [/W=winName] keyword [=value] [, keyword [=value]] ...

The SetDrawEnv operation sets properties of the drawing environment.

If one or more draw objects are selected in the top window then the SetDrawEnv command will apply only to those objects.

If no objects are selected and if the keyword save is not used then the command applies only to the next object drawn.

If no objects are selected and if the keyword “save” is used then the command sets the environment for all following objects.

Each draw layer has its own draw environment settings.

Parameters

SetDrawEnv can accept multiple keyword=value parameters on one line.

In the following descriptions, (r, g, b) specifies a color. r, g, and b are each a number from 0 to 65535. (0, 0, 0) specifies black. (65535, 65535, 65535) specifies white.

Also note that the abs and rel values for the coordinate keywords “xcoord” and “ycoord” are the literal strings “abs” and “rel”; they are not substitute names for numbers, names, or strings.

arrow=arr Specifies the arrow head position on lines.
  arr=0: No arrowhead (default).
  arr=1: Arrowhead at end.
  arr=2: Arrowhead at start.
  arr=3: Arrowhead at start and end.

arrowfat=afat Sets ratio of arrowhead width to length (default is 0.5).

arrowlen=alen Sets length of arrowhead in points (default is 10).

arrowSharp=s Specifies the continuously variable barb sharpness between -1.0 and 1.0.
  s=1: No barb; lines only.
  s=0: Blunt (default).
  s=-1: Diamond.

arrowframe=f Specifies the stroke outline thickness of the arrow in points (default is f=0 for solid fill).

astyle=s Specifies which side of the line has barbs relative to a right-facing arrow.
  s=0: None.
  s=1: Top.
  s=2: Bottom.
  s=3: Both (default).

clipRect=(top, left, right, bottom) Clips drawing to the specified rectangle. The clipRect keyword was added in Igor Pro 8.00.

  top, left, right, and bottom are specified in the current coordinate system of the drawing environment.

  If a save is in effect, you can use values of all 0 to cancel the clipping or, better, you can use push, clipRect, save, drawing, pop sequence. When a save is in effect, the clipping is set once and remains unchanged for the remaining objects even if the coordinate system is changed.

dash=dsh dsh is a dash pattern number between 0 and 17 (see SetDashPattern for patterns). 0 (solid line) is the default.

fillbgc=(r, g, b) Specifies fill background color. Default is the window’s background color.
SetDrawEnv

fillfgc=(r, g, b) Specifies fill foreground color. The default is white.
fillpat=fpatt Specifies fill pattern density.
   
   fpatt=-1: Erase to background color.
   fpatt=0: No fill.
   fpatt=1: 100% (solid pattern, default).
   fpatt=2: 75% gray.
   fpatt=3: 50% gray.
   fpatt=4: 25% gray.

fname="fontName" Sets font name, default is the default font or the graph font.
fsize=size Sets text size, default is 12 points.
fsstyle=fs is a bitwise parameter with each bit controlling one aspect of the font style as follows:
   
   Bit 0: Bold
   Bit 1: Italic
   Bit 2: Underline
   Bit 4: Strikethrough

See Setting Bit Parameters on page IV-13 for details about bit settings.

gedit=flag Supplies optional edit flag for a group of objects. Use with gstart.
   
   flag=0: Select entire group, moveable (default).
   flag=1: Individual components editable as if not grouped. Allows objects to be grouped by name but still be editable.

gname=name Supplies optional name for an object group. Use with gstart.
gstart Marks the start of a group of objects.
gstop Marks the end of a group of objects.
ggradient See Gradient Fills on page III-472 for details.
ggradientExtra See Gradient Fills on page III-472 for details.
linebgc=(r, g, b) Sets the line background color. Default is window’s background color.
linecap=cap Sets the line end cap style:
   
   cap=0: Flat caps
   cap=1: Round caps
   cap=2: Square caps (default)

See Line Join and End Cap Styles on page III-470 for further information.
linecap was added in Igor Pro 8.00.

linefgc=(r, g, b) Sets the line foreground color, default is black.
linejoin=j Sets the line join style:
   
   j=0: Miter joins
   j=1: Round joins
   j=2: Bevel joins (default)

For a miter join, you can also set the miter limit using the lineMiterLimit keyword.
See Line Join and End Cap Styles on page III-470 for further information.
linejoin was added in Igor Pro 8.00.
SetDrawEnv

lineMiterLimit=\textit{ml}  Applies only to a miter line join style. See the linejoin keyword.

\texttt{ml} \geq 1: \quad \text{Sets miter limit to} \texttt{ml}
\texttt{ml} = \text{INF}: \quad \text{Sets miter limit to unlimited}
\texttt{ml} = 0: \quad \text{Leaves miter limit unchanged}
\texttt{ml} = -1: \quad \text{Sets miter limit to default (10)}

See Line Join and End Cap Styles on page III-470 for further information.

lineMiterLimit was added in Igor Pro 8.00.

\texttt{linepat=\textit{patt}}  Specifies the line pattern/density.

\texttt{patt}=1: \quad 100\% (solid pattern, default).
\texttt{patt}=2: \quad 75\% gray.
\texttt{patt}=3: \quad 50\% gray.
\texttt{patt}=4: \quad 25\% gray.

\texttt{linethick=\textit{thick}}  \texttt{thick} is a line thickness $\geq 0$, default is 1 point.

\texttt{origin=\textit{x0},\textit{d0}}  Moves coordinate system origin to \texttt{x0},\texttt{d0}. Unlike translate, rotate, and scale, this survives a change in coordinate system and is most useful that way. See Coordinate Transformation.

\texttt{pop}  Pops a draw environment from the stack. Pops should always match pushes.

\texttt{push}  Pushes the current draw environment onto a stack (limited to 10).

\texttt{rotate=\textit{deg}}  Rotates coordinate system by \texttt{deg} degrees. Only makes sense if X and Y coordinate systems are the same. See Coordinate Transformation.

\texttt{rounding=\textit{rnd}}  Radius for rounded rectangles in points, default is 10.

\texttt{rsabout}  Redefines coordinate system rotation or scaling to occur at the translation point instead of the current origin. To use, combine rotate or scale with translate and rsabout parameters.

\texttt{save}  Stores the current drawing environment as the default environment.

\texttt{scale=\textit{sx},\textit{sy}}  Scales coordinate system by \texttt{sx} and \texttt{sy}. Affects only coordinates — not line thickness or arrow head sizes. See Coordinate Transformation.

\texttt{textrgb=(r,g,b)}  Sets text color, default is black.

\texttt{textrot=\textit{rot}}  Text rotation in degrees.

\texttt{rot} is a value from -360 to 360.

0 is normal (default) horizontal left-to-right text,
90 is vertical bottom-to-top text, etc.

\texttt{textxjust=\textit{xj}}  Sets horizontal text alignment.

\texttt{xj}=0: \quad \text{Left aligned text (default).}
\texttt{xj}=1: \quad \text{Center aligned text.}
\texttt{xj}=2: \quad \text{Right aligned text.}

\texttt{textyjust=\textit{yj}}  Sets vertical text alignment.

\texttt{yj}=0: \quad \text{Bottom aligned text (default).}
\texttt{yj}=1: \quad \text{Middle aligned text.}
\texttt{yj}=2: \quad \text{Top aligned text.}

\texttt{translate=\textit{dx},\textit{dy}}  Shifts coordinate system by \texttt{dx} and \texttt{dy}. Units are in the current coordinate system. See Coordinate Transformation.
SetDrawEnv

xcoord=abs X coordinates are absolute window coordinates (default for all windows except graphs where the default is xcoord=prel). The unit of measurement is pixels if the window is a panel, otherwise they are points. The left edge of the window (or of the printable area in a layout) is at x=0.

xcoord=rel X coordinates are relative window coordinates. x=0 is at the left edge of the window; x=1 is at the right edge.

xcoord=prel X coordinates are relative plot rectangle coordinates (graphs only). x=0 is at the left edge of the rectangle; x=1 is at the right edge of the rectangle. This coordinate system ideal for objects that should maintain their size and location relative to the axes, and is the default for graphs.

xcoord=axisName X coordinates are in terms of the named axis (graphs only).

ycoord=abs Y coordinates are absolute window coordinates (default for all windows except graphs where the default is ycoord=prel). The unit of measurement is pixels if the window is a panel, otherwise they are points. The top edge of the window (or the of the printable area in a layout) is at y=0.

ycoord=rel Y coordinates are relative window coordinates. y=0 is at the top edge of the window; y=1 is at the bottom edge.

ycoord=prel Y coordinates are relative plot rectangle coordinates (graphs only). y=0 is at the top edge of the rectangle; y=1 is at the bottom edge of the rectangle. This coordinate system ideal for objects that should maintain their size and location relative to the axes, and is the default for graphs.

ycoord=axisName Y coordinates are in terms of the named axis (graphs only).

Flags

/W=winName Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Coordinate Transformation

The execution order for the translate, rotate, scale, and origin parameters is important. Translation followed by rotation is different than rotation followed by translation. When using multiple keywords in one SetDrawEnv operation, the order in which they are applied is origin, translate, rotate followed by scale regardless of the command order (with the exception of the rsabout parameter). Before using origin with the save keyword, you should use push to save the current draw environment and then use pop after drawing objects using the new origin.

Examples

Following is a simple example of arrow markers:

NewPanel
SetDrawEnv arrow= 1,arrowlen= 30,save
SetDrawEnv arrowsharp= 0.3
DrawLine 61,67,177,31
SetDrawEnv arrowsharp= 1
DrawLine 65,95,181,59
SetDrawEnv astyle= 1
DrawLine 69,123,185,87
SetDrawEnv arrowframe= 1
DrawLine 73,151,189,115

You can position objects in one coordinate system and then draw them in another with the origin keyword. In the following coordinate transformation example, we position arrows in axis units but size them in absolute units.

Make/O jack=sin(x/8)
Display jack
SetDrawEnv xcoord=bottom,ycoord=left,save
SetDrawLayer

SetDrawLayer push
SetDrawEnv origin=50,0
SetDrawEnv xcoord=abs,ycoord=abs,arrow=1,arrowlen=20,arrowsharp=0.2,save
DrawLine 0,0,50,0 // arrow 50 points long pointing to the right
DrawLine 0,0,0,50 // arrow 50 points long pointing down
// now let's move over, rotate a bit and draw the same arrows:
SetDrawEnv translate=100,0
SetDrawEnv rotate=30,save
DrawLine 0,0,50,0
DrawLine 0,0,0,50
SetDrawEnv pop

Now try zooming in on the graph. You will see that the first pair of arrows always starts at 50 on the bottom axis and 0 on the left axis whereas the second pair is 100 points to the right of the first.

See Also
Chapter III-3, Drawing, and DrawAction.

SetDrawLayer

SetDrawLayer [/K/W=winName] layerName
The SetDrawLayer operation makes all future drawing operations use the named layer.

Parameters
Valid layerNames for graphs:

<table>
<thead>
<tr>
<th>ProgBack</th>
<th>UserBack</th>
<th>ProgAxes</th>
<th>UserAxes</th>
<th>ProgFront</th>
<th>UserFront</th>
<th>Overlay</th>
</tr>
</thead>
</table>

Valid layerNames for page layouts:

<table>
<thead>
<tr>
<th>ProgBack</th>
<th>UserBack</th>
<th>ProgFront</th>
<th>UserFront</th>
<th>Overlay</th>
</tr>
</thead>
</table>

Valid layerNames for control panels:

<table>
<thead>
<tr>
<th>ProgBack</th>
<th>UserBack</th>
<th>ProgFront</th>
<th>UserFront</th>
<th>Overlay</th>
</tr>
</thead>
</table>

There are really only three layers for control panels. ProgFront is treated as an alias for ProgBack and UserFront is treated as an alias for UserBack.

Flags

/K
Kills (erases) the given layer.

/W=winName
Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details
The Overlay layer is drawn above all else. It is not included when printing or exporting graphics and is provided for programmers who wish to add user-interface drawing elements without disturbing graphics drawing elements. Overlay was added in Igor Pro 7.00.

The back-to-front order of the layers is shown by the layer pop-up menu obtained by clicking the Layer icon in the drawing palette: 🌐. A checkmark indicates the current layer. Non-drawing layers are indicated with gray text.

See Also
Drawing Layers on page III-72 and the DrawAction operation.
**SetEnvironmentVariable**

SetEnvironmentVariable(varName, varValue)

The `SetEnvironmentVariable` function creates an environment variable in Igor's process and sets its value to `varValue`. If a variable named `varName` already exists, its value is set to `varValue`.

The function returns 0 if it succeeds or a nonzero value if it fails.

The `SetEnvironmentVariable` function was added in Igor Pro 7.00.

**Parameters**

- **varName**: The name of an environment variable which does not need to actually exist. It must not be an empty string and may not contain an equals sign (=).
- **varValue**: The new contents for the variable.

On Windows, if `varValue` is an empty string, the variable is removed. On other platforms, the variable is always set to `varValue`.

**Details**

The environment of Igor's process is composed of a set of key=value pairs that are known as environment variables. Any child process created by calling `ExecuteScriptText` inherits the environment variables of Igor's process.

`SetEnvironmentVariable` changes the environment variables present in Igor's process and any future process created by `ExecuteScriptText` but does not affect any other processes already created.

On Windows, environment variable names are case-insensitive. On other platforms, they are case-sensitive.

**Examples**

```
Variable result
result = SetEnvironmentVariable("SOME VARIABLE", "15")
result = SetEnvironmentVariable("SOME_OTHER_VARIABLE", "string value")
```

**See Also**

`GetEnvironmentVariable`, `UnsetEnvironmentVariable`

**SetFileFolderInfo**

SetFileFolderInfo [flags] [fileOrFolderNameStr]

The `SetFileFolderInfo` operation changes the properties of a file or folder.

**Parameters**

- **fileOrFolderNameStr**: specifies the file or folder to be changed.

If you use a full or partial path for `fileOrFolderNameStr`, see **Path Separators** on page III-429 for details on forming the path.

Folder paths should not end with single Path Separators. See the **MoveFolder Details** section.

If Igor cannot determine the location of the file or folder from `fileOrFolderNameStr` and `/P=pathName`, it displays a dialog allowing you to specify the file to be deleted. Use /D to select a folder in this event, otherwise Igor prompts your for a file.

**Flags**

At least one of the seven following flags is required, or nothing is actually accomplished:

- **/CDAT=cdate**: Specifies the number of seconds since midnight January 1, 1904 when the file or folder was first created.
- **/INV=[inv]**: Sets the visibility of a file.
  - `inv=0`: File is visible.
  - `inv=1`: Default; file is invisible (Macintosh) or Hidden (Windows).
- **/MDAT=mDate**: Specifies the number of seconds since midnight January 1, 1904 when the file or folder was modified most recently.
SetFileFolderInfo

/RO[=ro] Sets the read/write state of a file or folder.
  ro=0: File or folder is writable.
  ro=1: File or folder is locked (default).

On Macintosh, locking the file or folder is equivalent to setting the locked property manually using the Get Info window in the Finder.

On Windows, locking the file or folder is equivalent to setting the read-only property manually using the Properties window in Windows Explorer.

If fileOrFolderNameStr refers to a file (not a folder), SetFileFolderInfo updates the file properties to reflect values given with the following keywords:

/CRE8=creatorStr Sets the four-character creator code string, such as 'IGR0' (Igor Pro creator code).
  Ignored on Windows, where files have no "creator code"; instead file extensions are "registered" or "owned" by one, and only one, application. You cannot change that ownership from Igor Pro.

/FTYP=fTypeStr Sets the four-character file type code, such as 'TEXT' or 'IGsU' (packed experiment).
  Ignored on Windows. Use MoveFile to change the file extension.

/STA[=st] Specifies whether the file is a stationery file or not.
  st=1: Stationery file (default).
  st=0: Normal file.
  Ignored on Windows. Use MoveFile to change the file extension.

Optional Flags

/D Uses the Select Folder dialog rather than Open File dialog when pathName and fileOrFolderNameStr do not specify an existing file or folder.

/P=pathName Specifies the folder to look in for the file. pathName is the name of an existing symbolic path.

/R[=r] Recursively applies change(s) to all files or folders in the folder specified by /P=pathName or fileOrFolderNameStr, and the folder itself:
  r=0: No recursion. Same as no /R.
  r=1: Recursively apply changes to files.
  r=2: Recursively apply changes to folders, including the folder specified by pathName or fileOrFolderNameStr.
  r=3: Recursively apply changes to both files and folders (default).
  /R requires /D and a folder specification.

/Z[=z] Prevents procedure execution from aborting if SetFileFolderInfo tries to set information about a file or folder that does not exist. Use /Z if you want to handle this case in your procedures rather than having execution abort.
  /Z=0: Same as no /Z at all.
  /Z=1: Used for setting information for a file or folder only if it exists. /Z alone has the same effect as /Z=1.
  /Z=2: Used for setting information for a file or folder if it exists and displaying a dialog if it does not exist.

Variables

SetFileFolderInfo returns information about the file or folder in the following variables:

v_flag 0: File or folder was found.
Examples
Change the file creator code; no complaint if it doesn’t exist:
SetFileFolderInfo/Z /CRE8="CWIE", "Macintosh HD:folder:afile.txt"
Set the file modification date:
Variable mDate= Date2Secs(2000,12,25) + hrs*3600+mins*60+secs
SetFileFolderInfo/P=myPath/MDAT=(mDate), "afile.txt"
Remove read-only property from a folder and everything within it:
SetFileFolderInfo/P=myPath/D/R/RO=0

See Also
The SetFileFolderInfo, MoveFile, and FStatus operations. The IndexedFile, date2secs, and ParseFilePath functions.

SetFormula

SetFormula waveName, expressionStr
SetFormula variableName, expressionStr
The SetFormula operation binds the named wave, numeric or string variable to the expression or, if the expression is "", unbinds it from any previous expression. In user functions, SetFormula must be used to create dependencies.

Parameters
expressionStr is a string containing a numeric or string expression, depending on the type of the bound object.
Pass an empty string (" ") for expressionStr to clear any previous dependency expression associated with the wave or variable.

Details
The dependent object (the wave or variable) will depend on the objects referenced in the string expression.
The expression will be reevaluated any time an object referred to in the expression is modified.
Besides being set from a string expression this differs from just typing:
name := expression
in that syntax errors in expressionStr are not reported and are not fatal. You end up with a dependency assignment that is marked as needing to be recompiled. The recompilation will be attempted every time an object is created or when the procedure window is recompiled.
Use the Object Status dialog in the Misc menu to check up on dependent objects.

Examples
This command makes the variable v_sally dependent on the user-defined function anotherFunction, waves wave_fred and wave_sue, and the system variable K2:
SetFormula v_sally, "anotherFunction(wave_fred[1]) + wave_sue[0] + K2"
This is equivalent to:
v_sally := anotherFunction(wave_fred[1]) + wave_sue[0] + K2
except that no error will be generated for the SetFormula if, for instance, wave_fred does not exist.
A string variable dependency can be created by a command such as:
SetFormula myStringVar, "note(wave_joe)"
observe that expressionStr is a string containing a string expression, and that:
SetFormula myStringVar,note(wave_joe)
is not the same thing. In this case the note of wave_joe would contain the expression that myStringVar would depend on! Also, wave_joe would have to exist for Igor to understand the statement.

S_path
File system path of the selected file or folder.

-1: User cancelled the Open File dialog.
>0: An error occurred, such as the specified file or folder does not exist.

V-769
SetIdlePeriod

See Also
Chapter IV-9, Dependencies, and the GetFormula function.

SetIdlePeriod

SetIdlePeriod period

The SetIdlePeriod operation changes and reports the period of Igor's main idle loop. The units of period are milliseconds. Setting period to zero does not change the period.

SetIdlePeriod was added in Igor Pro 8.00.

The default idle period is 20 milliseconds. Setting the period higher may make a slight improvement in the performance of some computation-heavy tasks.

Setting the period lower can make some parts of Igor more responsive. In particular, background tasks can be made to run more often, as the minimum period between runs of a background task is determined by Igor's idle period. Reducing the period too far increases the likelihood that your background task will run too long. Setting the period to very low values can make Igor very sluggish.

Output Variables

SetIdlePeriod creates the output variable V_value and sets it to the idle period before the call was made. You can use this value to restore the idle period after temporarily changing it. If period is zero, the idle period is not changed, but the current value is returned in V_value.

Background Tasks on page IV-307

SetIgorHook

SetIgorHook [/K/L] [hookType = [procName]]

The SetIgorHook operation tells Igor to call a user-defined "hook" function at the following times:

- After procedures have been successfully compiled (AfterCompiledHook)
- After a file is opened (AfterFileOpenHook)
- After the MDI frame window is resized on Windows (AfterMDIFrameSizedHook)
- After a window is created (AfterWindowCreatedHook)
- Before the debugger is opened (BeforeDebuggerOpensHook)
- Before an experiment is saved (BeforeExperimentSaveHook)
- Before a file is opened (BeforeFileOpenHook)
- Before a new experiment is opened (IgorBeforeNewHook)
- Before Igor quits (IgorBeforeQuitHook)
- When a menu item is selected (IgorMenuHook)
- During Igor's quit processing (IgorQuitHook)
- When Igor starts or a new experiment is created (IgorStartOrNewHook)

The term “hook” is used as in the phrase “to hook into”, meaning to intercept or to attach.

Hook functions are typically used by a sophisticated procedure package to make sure that the package's private data is consistent.

In addition to using SetIgorHook, you can designate hook functions using fixed function names (see User-Defined Hook Functions on page IV-272). The advantage of using SetIgorHook over fixed hook names is that you don’t have to worry about name conflicts.

You can designate hook functions for specific windows using window hooks (see SetWindow on page V-786).

Flags

/K Removes procName from the list of functions called for the hookType events.

If procName is not specified all hookType functions are removed.

If hookType is not specified all functions are removed for all hookType events, returning Igor to the pre-SetIgorHook state.
The parameters and return type of the user-defined function `procName` varies depending on the `hookType` it is registered for.

For example, a function registered for the `AfterFileOpenHook` type must have the same parameters and return type as the shown for the `AfterFileOpenHook` on page IV-274.

The `procName` function is called after any window-specific hook for these `hookTypes`, and the `procName` function is called before any other hook functions previously registered by calling SetIgorHook unless the `/L` flag is given, in which case it still runs after window-specific hook functions, but also after all other previously registered hook functions.

The `procName` function should return a nonzero value (1 is typical) to prevent later functions from being called. Returning 0 allows successive functions to be called.

SetIgorHook does not work at Igor start or new experiment time, so SetIgorHook IgorStartOrNewHook is disallowed. Define a global or static fixed-name `IgorStartOrNewHook` function (see page IV-284).

The saved Igor experiment file remembers the SetIgorHooks that are in effect when the experiment is saved:

### Hook Function Interactions
After all the SetIgorHook functions registered for `hookType` have run (and all have returned 0), any static fixed-name hook functions are called and then the (only) fixed-name user-defined hook function, if any, is called. As an example, when a menu event occurs, Igor handles the event by calling routines in this order:

---

**Parameters**

- `hookType` Specifies one of the fixed-name hook function names:
  - `AfterCompiledHook`
  - `AfterFileOpenHook`
  - `AfterMDIFrameSizedHook`
  - `AfterWindowCreatedHook`
  - `BeforeDebuggerOpensHook`
  - `BeforeExperimentSaveHook`
  - `BeforeFileOpenHook`
  - `IgorBeforeNewHook`
  - `IgorBeforeQuitHook`
  - `IgorMenuHook`
  - `IgorQuitHook`
  - `IgorStartOrNewHook`

See the note below about these `hookType` names.

- `hookType` is required except with `/K`.

- `procName` Names the user-defined hook function that is called for the `hookType` event.

---

**Details**

The parameters and return type of the user-defined function `procName` varies depending on the `hookType` it is registered for.

For example, a function registered for the `AfterFileOpenHook` type must have the same parameters and return type as the shown for the `AfterFileOpenHook` on page IV-274.

The `procName` function is called after any window-specific hook for these `hookTypes`, and the `procName` function is called before any other hook functions previously registered by calling SetIgorHook unless the `/L` flag is given, in which case it still runs after window-specific hook functions, but also after all other previously registered hook functions.

The `procName` function should return a nonzero value (1 is typical) to prevent later functions from being called. Returning 0 allows successive functions to be called.

SetIgorHook does not work at Igor start or new experiment time, so SetIgorHook IgorStartOrNewHook is disallowed. Define a global or static fixed-name `IgorStartOrNewHook` function (see page IV-284).

The saved Igor experiment file remembers the SetIgorHooks that are in effect when the experiment is saved:
1. The top window's hook function as set by **SetWindow**
2. Any SetIgorHook-registered hook functions
3. Any static fixed-named IgorMenuHook functions (in any independent module)
4. The one-and-only non-static fixed-named IgorMenuHook function (in only the ProcGlobal independent module)

<table>
<thead>
<tr>
<th>1. SetWindow event (called first)</th>
<th>2. SetIgorHook <em>hookType</em> (called second)</th>
<th>3. User-defined Hook Function(s) (called last)</th>
</tr>
</thead>
<tbody>
<tr>
<td>enableMenu</td>
<td>IgorMenuHook</td>
<td>IgorMenuHook</td>
</tr>
<tr>
<td>menu</td>
<td>IgorMenuHook</td>
<td>IgorMenuHook</td>
</tr>
</tbody>
</table>

**Note:** Although you can technically use one of the fixed-name functions, as described in **User-Defined Hook Functions** on page IV-272, for *procName*, the result would be that the function will be called twice: once as a registered named hook function and once as the fixed-named hook function. That is, don’t use SetIgorHook this way:

```
SetIgorHook AfterFileOpenHook=AfterFileOpenHook // NO
```

**Variables**

SetIgorHook returns information in the following variables:

- **S_info** Semicolon-separated list of all current hook functions associated with *hookType*, listed in the order in which they are called. *S_info* includes the full independent module paths (e.g., "ProcGlobal#MyMenuHook;MyIM#MyModule#MyMenuHook;").

**Examples**

This hook function invokes the Export Graphics menu item when Command-C (**Macintosh**) or Ctrl+C (**Windows**) is selected for a graph, preventing the usual Copy.

```
SetIgorHook IgorMenuHook=CopyIsExportHook
```

**Function** CopyIsExportHook

```
Function CopyIsExportHook(isSelection,menuName,itemName,itemNo,win,wType)
  Variable isSelection
  String menuName,itemName
  Variable itemNo
  String win
  Variable wType
  Variable handledIt= 0
  if( isSelection && wType==1 ) // menu was selected, window is graph
    if( Cmpstr(menuName,"Edit")==0 && CmpStr(itemName,"Copy")==0 )
      DoIgorMenu "Edit", "Export Graphics" // dialog instead
      handledIt= 1 // don't call other IgorMenuHook functions.
    endif
  endif
  return handledIt
End
```

To unregister CopyIsExportHook as a hook procedure:

```
SetIgorHook/K IgorMenuHook=CopyIsExportHook // unregister CopyIsExportHook
```

To discover which functions are associated with a *hookType*, use a command such as:

```
SetIgorHook IgorMenuHook // inquire about names registered for IgorMenuHook
Print S_info // list of functions
```

To remove (or “unregister”) named hooks:

```
SetIgorHook/K // removes all hook functions for all hookTypes
SetIgorHook/K IgorMenuHook // removes all IgorMenuHook functions
SetIgorHook/K IgorMenuHook=CopyIsExportHook // removes only this hook function
```

**See Also**

The **SetWindow** operation and **User-Defined Hook Functions** on page IV-272.

**Independent Modules** on page IV-231.
SetIgorMenuMode

SetIgorMenuMode MenuNameStr, MenuItemStr, Action

The SetIgorMenuMode operation allows an Igor programmer to disable or enable Igor’s built-in menus and menu items. This is useful for building applications that will be used by end-users who shouldn’t have access to all Igor’s extensive and confusing functionality.

Parameters

MenuNameStr
The name of an Igor menu, like “File”, “Graph”, or “Load Waves”.

MenuItemStr
The text of an Igor menu item, like “Copy” (in the Edit menu) or “New Graph” (in the Windows menu). For menu items in submenus, such as the “Load Waves” submenu in the “Data” menu, MenuItemStr is the name of the submenu.

Action
One of DisableItem, EnableItem, DisableAllItems, or EnableAllItems.

Details

All menu names and menu item text are in English. This ensures that code developed for a localized version of Igor will run on all versions. Note that no trailing “...” is used in MenuItemStr.

The SetIgorMenuModeProc.ipf procedure file includes procedures and commands that disable or enable every menu and item possible. It is in your Igor Pro folder, in WaveMetrics Procedures:Utilities. It is not intended to be used as-is. You should make a copy and edit the copy to include just the parts you need.

The text of some items in the File menu changes depending on the type of the active window. In these cases you must pass generic text as the MenuItemStr parameter. Use “Save Window”, “Save Window As”, “Save Window Copy”, “Adopt Window” and “Revert Window” instead of “Save Notebook” or “Save Procedure”, etc. Use “Page Setup” instead of “Page Setup For All Graphs”, etc. Use “Print” instead of “Print Graph”, etc.

The Edit→Insert File menu item was previously named Insert Text. For compatibility reasons, you can specify either “Insert File” or “Insert Text” as MenuItemStr to modify this item.

DoIgorMenu, ShowIgorMenus, HidelgorMenus

SetIgorOption

SetIgorOption [mainKeyword,] keyword= value
SetIgorOption [mainKeyword,] keyword= ?

The SetIgorOption operation makes unusual and temporary changes to Igor Pro’s behavior. This operation is not compilable and you will need to use the Execute operation to use it in a user function. The details of the syntax depend on the application and are documented where the alternate behaviors are described. In most cases the current value of a setting can be read using the keyword=? syntax. Simple numeric options are stored in V_flag and color options are stored in V_Red, V_Green, V_Blue, and V_Alpha The settings last for the life of the Igor session.

See Also

Syntax Coloring on page III-387 for some usage examples; SetIgorOption IndependentModuleDev=1 on page IV-232; Conditional Compilation on page IV-106; MarkPerfTestTime operation.

SetMarquee

SetMarquee [/W=winName] left, top, right, bottom

The SetMarquee operation creates a marquee on the target graph or layout window or the specified window or subwindow.

The left, top, right, bottom coordinates are the same as those returned by the GetMarquee operation (screen units measured in points).
SetProcessSleep

If the coordinates are all 0, the marquee, if it exists, is killed.
The optional axis modes supported by GetMarquee are not supported by SetMarquee.

Flags

/W=winName Specifies the named window or subwindow. When omitted, action will affect the active window or subwindow.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

See Also
The GetMarquee operation.

SetProcessSleep

The SetProcessSleep operation is obsolete and does nothing as of Igor Pro 7.00. It is documented here in case you come across it in old Igor procedure code. Do not use it in new code.

The SetProcessSleep operation determines how much time Igor will give to background tasks or other Macintosh applications executing in the background. This operation does nothing on Windows.

Parameters

sleepTicks is the amount of time given to background tasks in sixtieths of a second. sleepTicks values between 0 and 60 are valid.

Details

Igor starts up with sleepTicks = 1. Use 0 to give Igor maximum time, use a larger number to give other applications more time.

Background tasks are used mainly by data acquisition programs.

See Also
Background Tasks on page IV-307 and the SetBackground operation.

SetRandomSeed

The SetRandomSeed operation seeds the random number generator used for the enoise and gnoise functions. Use SetRandomSeed if you need “random” numbers that are reproducible. If you don’t use SetRandomSeed, the random number generator is initialized using the system clock when Igor starts. This almost guarantees that you will never get the same sequence twice unless you use SetRandomSeed.

Flags

/BETR[=better] If better is absent or non-zero, a better method is used for seeding the Mersenne Twister random number generator.

Parameters

seed should be a number in the interval (0, 1]. For any given seed, enoise or gnoise or any of the other random-number generator functions generates a particular sequence of pseudorandom numbers. Calling SetRandomSeed with the same seed restarts and repeats the sequence.

Details

Internally seed is scaled to a 32-bit unsigned integer. Consequently, the number of different values for the internally-scaled seed is less than the resolution of the double-precision numbers in the (0, 1] range.

You should use /BETR unless you need consistency with older versions of Igor. /BETR was introduced in Igor Pro 6.20.

The Mersenne Twister random number generator is used for most of Igor’s noise functions (and optionally for enoise and gnoise), and internally for operations that need random sequences, such as StatsSample or StatsResample.
Without the /BETR flag, SetRandomSeed maps seed to an internal 16-bit integer for seeding the Mersenne Twister random number generator. With /BETR it maps to an internal 32-bit integer seed. So using /BETR reduces the chance that two values of seed will map to the same internal integer seed.

See Also
The enoise and gnoise functions. Noise Functions on page III-372.

SetScale

SetScale [/I/P] dim, num1, num2 [, unitsStr], waveName [, , waveName]...
SetScale d, num1, num2 [, , unitsStr], waveName [, , waveName]...
The SetScale operation sets the dimension scaling or the data full scale for the named waves.

Parameters
The first parameter dim must be one of the following:

<table>
<thead>
<tr>
<th>Character</th>
<th>Signifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>Data full scale.</td>
</tr>
<tr>
<td>t</td>
<td>Scaling of the chunks dimension (t scaling).</td>
</tr>
<tr>
<td>x</td>
<td>Scaling of the rows dimension (x scaling).</td>
</tr>
<tr>
<td>y</td>
<td>Scaling of the columns dimension (y scaling).</td>
</tr>
<tr>
<td>z</td>
<td>Scaling of the layers dimension (z scaling).</td>
</tr>
</tbody>
</table>

If setting the scaling of any dimension (x, y, z, or t), num1 is the starting index value — the scaled index for the first point in the dimension. The meaning of num2 changes depending on the /I and /P flags. If you use /P, then num2 is the delta value — the difference in the scaled index from one point to the next. If you use /I, num2 is the “ending value” — the index value for the last element in the dimension. If you use neither flag, num2 is the “right value” — the index value that the element after the last element in the dimension would have.

These three methods are just three different ways to specify the two scaling values, the starting value and the delta value, that are stored for each dimension of each wave.

If setting the data full scale (d), then num1 is the nominal minimum and num2 is the nominal maximum data value for the waves. The data full scale values are not used. They serve only to document the minimum and maximum values the waves are expected to attain. No flags are used when setting the data full scale.

The unitsStr parameter is a string that identifies the natural units for the x, y, z, t, or data values of the named waves. Igor will use this to automatically label graph axes. This string must be one to 49 bytes such as “m” for meters, “g” for grams or “s” for seconds. If the waves have no natural units you can pass "" for this parameter.

Setting unitsStr to "dat" (case-sensitive) tells Igor that the wave is a date/time wave containing data in Igor date/time format (seconds since midnight on January 1, 1904). Date/time waves must be double-precision.

Flags
At most one flag is allowed, and then only if dimension scaling (not data full scale) is being set:

/ I          Inclusive scaling. num2 is the ending index — the index value for the very last element in the dimension.
/P          Per-point scaling. num2 is the delta index value — the difference in scaled index value from one element to the next.

Details
SetScale will not allow the delta scaling value to be zero. If you execute a SetScale command with a delta value of zero, it will set the delta value to 1.0.

If you do not use the /P flag, SetScale converts num1 and num2 into a starting index value and a delta index value. If you call SetScale on a dimension with fewer than two elements, it does this conversion as if the dimension had two elements.

Prior to Igor Pro 3.0, Igor supported only 1D waves. “SetScale x” was used to set the scaling for the rows dimensions and “SetScale y” was used to set the data full scale. With the addition of multidimensional
waves, “SetScale y” is now used to set the scaling of the columns dimension and “SetScale d” is used to set
the data full scale. For backward compatibility, “SetScale y” on a 1D wave sets the data full scale.

When setting the dimension scaling of a numeric wave, you can omit the unitsStr parameter. Igor will set
the wave’s scaling but not change its units. However, when setting the dimension scaling of a text wave,
you must supply a unitsStr parameter (use " " if the wave has no units). If you don’t, Igor will think that the
text wave is the start of a string expression and will attempt to treat it as the unitsStr.

See Also
See Also
CopyScales, DimDelta, DimOffset, DimSize, WaveUnits
For an explanation of waves and dimension scaling, see Changing Dimension and Data Scaling on page
II-63.

For further discussion of how Igor represents dates, see Date/Time Waves on page II-79.

SetVariable

SetVariable [/Z] ctrlName [keyword = value [, keyword = value ...]]
The SetVariable operation creates or modifies a SetVariable control in the target window.

A SetVariable control sets the value of a global numeric or string variable or a point in a wave when you
type or click in the control. A SetVariable can also hold its own value without the need for a global or wave.

For information about the state or status of the control, use the ControlInfo operation.

Parameters

ctrlName is the name of the SetVariable control to be created or changed.

The following keyword=value parameters are supported:

activate
Activates the control and selects the text that sets the value. Use ControlUpdate
to deactivate the control and deselect the text.

align=alignment
Sets the alignment mode of the control. The alignment mode controls the
interpretation of the leftOrRight parameter to the pos keyword. The align
keyword was added in Igor Pro 8.00.

If alignment=0 (default), leftOrRight specifies the position of the left end of the
control and the left end position remains fixed if the control size is changed.

If alignment=1, leftOrRight specifies the position of the right end of the control and
the right end position remains fixed if the control size is changed.

appearance={kind [, platform]}
Sets the appearance of the control. platform is optional. Both parameters are
names, not strings.

kind can be one of default, native, or os9.

platform can be one of Mac, Win, or All.

See Button and DefaultGUIControls for more appearance details.

bodyWidth=width
Specifies an explicit size for the body (nontitle) portion of a SetVariable control.
By default (bodyWidth=0), the body portion is the amount left over from the
specified control width after providing space for the current text of the title
portion. If the font, font size or text of the title changes, then the body portion may
grow or shrink. If you supply a bodyWidth>0, then the body is fixed at the size
you specify regardless of the body text. This makes it easier to keep a set of
controls right aligned when experiments are transferred between Macintosh and
Windows, or when the default font is changed.
disable=d  Sets user editability of the control.
    d=0: Normal.
    d=1: Hide.
    d=2: No user input.

fColor=(r,g,b)  Sets the initial color of the title. r, g, and b range from 0 to 65535. fColor defaults to black (0,0,0). To further change the color of the title text, use escape sequences as described for title=titleStr.

focusRing=fr  Enables or disables the drawing of a rectangle indicating keyboard focus:
    fr=0: Focus rectangle will not be drawn.
    fr=1: Focus rectangle will be drawn (default).

On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.

font="fontName"  Sets the font used to display the value of the variable, e.g., font="Helvetica".

format=formatStr  Sets the numeric format of the displayed value, e.g., format="%g". Not used with string variables. Never use leading text or the "%W" formats, because Igor reads the value back without interpreting the units. For a description of formatStr, see the printf operation.

frame=f  Sets the frame for the value readout.
    f=0: Value unframed.
    f=1: Value framed (default).

fontsize=s  Sets the size of the type used to display the variable’s value.

fstyle=fs  fs is a bitwise parameter with each bit controlling one aspect of the font style as follows:
    Bit 0: Bold
    Bit 1: Italic
    Bit 2: Underline
    Bit 4: Strikethrough

See Setting Bit Parameters on page IV-13 for details about bit settings.

help={helpStr}  Sets the help for the control. The help text is limited to a total of 255 bytes. You can insert a line break by putting “\r” in a quoted string.

labelBack=(r,g,b) or 0  Specifies the background fill color for labels. r, g, and b are integers from 0 to 65535. The default is 0, which uses the window’s background color.

limits={low,high,inc}  Sets the limits of the allowable values (low and high) for the variable. inc sets the amount by which the variable is incremented if you click the control’s up/down arrows. This applies to numeric variables, not to string variables. If inc is zero then the up/down arrows will not be drawn.

live=l  Determines when the readout is updated.
    l=0: Update only after variable changes (default).
    l=1: Update as variable changes.
noedit=\texttt{val} \hspace{1cm} noedit=1 prevents the user from clicking (or tabbing into) a SetVariable control to directly edit its value. This is useful when you want to make a string read-only or when you want to restrict a numeric setting to those available only via the control’s up or down arrow buttons.

noedit=0 reactivates user editing.

noedit=2 is deprecated as of Igor Pro 6.34 but still supported. It allows the use of formatting escape codes described under \textit{Annotation Escape Codes}. Use \texttt{styledText=1}, instead.

\texttt{noproc} \hspace{1cm} No procedure is to execute when the control’s value is changed.

\texttt{pos=\{leftOrRight,top\}} \hspace{1cm} Sets the position in pixels of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

\texttt{pos+=\{dx,dy\}} \hspace{1cm} Offsets the position of the control in pixels.

\texttt{proc=procName} \hspace{1cm} Sets the procedure to execute when the control’s value is changed.

\texttt{rename=newName} \hspace{1cm} Gives control a new name.

\texttt{styledText=val} \hspace{1cm} \texttt{styledText=1} allows the use of formatting escape codes described under \textit{Annotation Escape Codes} on page III-54. This works for string SetVariable controls only, not for numeric controls.

For example:
\begin{verbatim}
SetVariable sv0 value=_STR:"\JC\K(65535,0,0)Centered Red Text"
\end{verbatim}

\texttt{styledText=0} treats escape codes as plain text.

The \texttt{styledText} keyword was added in Igor Pro 6.34. For compatibility with earlier versions of Igor, the combination of \texttt{noedit=1} and \texttt{styledText=1} is recorded as \texttt{noedit=2} in recreation macros.

\texttt{size=\{width,height\}} \hspace{1cm} Sets width of control in pixels. \texttt{height} is ignored.

\texttt{title=titleStr} \hspace{1cm} Sets the title of the control to the specified string expression. The title is displayed to the left of the control. If \texttt{titleStr} is empty (""), the name of the controlled variable is displayed as the title. Use \texttt{title=" "} (put a space within the quotation marks) to create a “blank” title.

Using escape codes you can change the font, size, style, and color of the title. See \textit{Annotation Escape Codes} on page III-54 or details.

\texttt{userdata(UDName)=UDStr} \hspace{1cm} Sets the unnamed user data to \texttt{UDStr}. Use the optional \texttt{(UDName)} to specify a named user data to create.

\texttt{userdata(UDName)+=UDStr} \hspace{1cm} Appends \texttt{UDStr} to the current unnamed user data. Use the optional \texttt{(UDName)} to append to the named \texttt{UDStr}.

\texttt{value=varOrWaveName} \hspace{1cm} Sets the numeric or string variable or wave element to be controlled.

If \texttt{varOrWaveName} references a wave, the point is specified using standard bracket notation with either a numeric point number or a row label, for example: \texttt{value=awave[4]} or \texttt{value=awave[@alabel]}.

You may also use a \texttt{2D}, \texttt{3D}, or \texttt{4D} wave and specify a column, layer, and chunk index or dimension label in addition to the row index.

You can have the control store the value internally rather than in a global variable. In place of \texttt{varName}, use \texttt{_STR:str} or \texttt{_NUM:num}. For example:
\begin{verbatim}
NewPanel; SetVariable sv1,value=_NUM:123
\end{verbatim}
valueColor=(r,g,b)  Sets the color of the value text.  \(r\), \(g\), and \(b\) range from 0 to 65535.  valueColor defaults to black (0,0,0).
valueBackColor=(r,g,b)  Sets the background color under the value text.  \(r\), \(g\), and \(b\) range from 0 to 65535.
valueBackColor=0  Sets the background color under the value text to the default color, the standard document background color used on the current operating system, which is usually white.
win=winName  Specifies which window or subwindow contains the named control.  If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with \textit{winName}, see \textbf{Subwindow Syntax} on page III-92 for details on forming the window hierarchy.

**Flags**

/\Z  No error reporting.

**Details**
The target window must be a graph or panel.

**SetVariable Action Procedure**
The action procedure for a SetVariable control takes a predefined WMSetVariableAction structure as a parameter to the function:

Function ActionProcName(SV_Struct) : SetVariableControl
    STRUCT WMSetVariableAction &SV_Struct
    ...
    return 0
End

The “: SetVariableControl” designation tells Igor to include this procedure in the Procedure pop-up menu in the SetVariable Control dialog.

See \textbf{WMSetVariableAction} for details on the WMSetVariableAction structure.

Although the return value is not currently used, action procedures should always return zero.

You may see an old format SetVariable action procedure in old code:

Function procName(ctrlName, varNum, varStr, varName) : SetVariableControl
    String ctrlName
    Variable varNum    // value of variable as number
    String varStr      // value of variable as string
    String varName     // name of variable
    ...
    return 0
End

This old format should not be used in new code.

**Examples**

Executing the commands:
Variable/G globalVar=99
SetVariable setvar0 size={120,20}
SetVariable setvar0 font="Helvetica", value=globalVar

creates a SetVariable control that displays the value of globalVar.

**See Also**
The \texttt{printf} operation for an explanation of \textit{formatStr}, and \textbf{SetVariable} on page III-398.

The \texttt{ControlInfo} operation for information about the control. Chapter III-14, \textit{Controls and Control Panels}, for details about control panels and controls. The \texttt{GetUserData} operation for retrieving named user data.
SetVariableControl

SetVariableControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined SetVariable control. See Procedure Subtypes on page IV-199 for details. See SetVariable for details on creating a SetVariable control.

SetWaveLock

SetWaveLock lockVal, waveList
The SetWaveLock operation locks a wave or waves and protects them from modification. Such protection is not absolute, but it should prevent most common attempts to change or kill a wave.

Parameters
lockVal can be 0, to unlock, or 1, to lock the wave(s).
waveList is a list of waves or it can be allinCDF to act on all waves in the current data folder.

See Also
WaveInfo to check if a wave is locked.

SetWaveTextEncoding

SetWaveTextEncoding [flags] newTextEncoding, elements, [wave, wave, ...]
The SetWaveTextEncoding operation changes the text encoding of the specified waves and/or the text encoding of all waves in the specified data folder.

Wave text encodings are mostly an issue in dealing with pre-Igor Pro 7 experiments containing non-ASCII text. Most users will have no need to worry about or change them. You should not use this operation unless you have a thorough understanding of text encoding issues or are instructed to use it by someone who has a thorough understanding.

See Wave Text Encodings on page III-451 for essential background information.

SetWaveTextEncoding can work on a list of specific waves or on all of the waves in a data folder (/DF flag). When working on a data folder, it can work on just the data folder itself or recursively on sub-data folders as well.

If /CONV is present, SetTextWaveEncoding actually converts the text to a different text encoding. You would use this, for example, to convert text stored as Shift JIS (Japanese non-Unicode) into UTF-8 (Unicode).

If /CONV is omitted, SetTextWaveEncoding merely causes Igor to reinterpret text. You would do this to tell Igor what text encoding is used for a wave created by Igor Pro 6 if Igor gets it wrong.

Conversion does not change the characters that make up text - it merely changes the numeric codes used to represent those characters. Reinterpretation does not change the numeric codes but does change the characters by changing the interpretation of the numeric codes.

In some cases it may be necessary to fix text encoding issues in Igor Pro 6.3x before opening an experiment in later versions.

Parameters
newTextEncoding specifies the text encoding to set the wave element to. See Text Encoding Names and Codes on page III-463 for a list of codes.

newTextEncoding can be the special value 255 which marks a text wave's content as really containing binary data, not text. See Text Waves Containing Binary Data on page III-453 below for details.

elements is a bitwise parameter that specifies one or more elements of a wave, as follows:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Wave name</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Wave units</td>
</tr>
</tbody>
</table>
SetWaveTextEncoding

2 4 Wave note
3 8 Wave dimension labels
4 16 Text wave content

See Setting Bit Parameters on page IV-13 for details about bit settings.

wave, wave, ... is a list of the targeted waves. The list is optional and typically should be omitted if you use the /DF flag. However, if you specify a data folder via /DF and you also list specific waves, SetWaveTextEncoding works on all waves in the data folder as well as the specifically listed waves.

Flags

/BINA={markAsBinary, diagnosticsFlags]

If markAsBinary is 1, SetWaveTextEncoding marks the content of any text wave as binary if the data contains control characters (codes less than 32) other than carriage return (13), linefeed (10), and tab (9).

If markAsBinary is 0, SetWaveTextEncoding acts as if /BINA were omitted.

diagnosticsFlags is optional and defaults to 1. If you omit it you can also omit the braces (/BINA=1).

diagnosticsFlags is a bitwise parameter defined as follows:

Bit 0: Emit diagnostic message for each wave marked as binary.

All other bits are reserved for future use.

See Setting Bit Parameters on page IV-13 for details about bit settings.

The /BINA=1 flag works with with the content of text waves only. It skips non-text waves. It is also independent of the elements parameter. That is, it marks the text wave content and only the text wave content as binary even if elements is something other than 16.

If you pass 255 for newTextEncoding when using the /BINA flag, this tells SetWaveTextEncoding to stop processing after marking binary waves. No further conversion or reinterpretation is done.

See Text Waves Containing Binary Data on page III-453 for further discussion.

/CONV={errorMode [, defaultTextEncoding, diagnosticsFlags]}
SetWaveTextEncoding

Causes the text data to be converted to the specified text encoding. If /CONV is present, SetTextWaveEncoding actually converts the text. If it is omitted, SetTextWaveEncoding merely causes Igor to reinterpret it.

defaultTextEncoding and diagnosticsFlags are optional and are further discussed below. If you omit them you can also omit the braces (/CONV=1).

If /CONV is specified and the original text encoding is binary (255) then SetWaveTextEncoding does nothing, because all conversions involving binary are NOPs.

If /CONV is specified and newTextEncoding is binary (255) then no conversion is done, because all conversions involving binary are NOPs, but the wave is marked as binary. Thus this amounts to the same thing as reinterpreting the wave’s text data as binary.

If /CONV is specified, defaultTextEncoding is omitted or is -1, and the original text encoding is unknown (0) then SetWaveTextEncoding does nothing. That is, it does no reinterpretation or conversion.

errorMode determines how SetWaveTextEncoding behaves if the conversion can not be done because the text can not be mapped to the specified text encoding. This will occur if the text contains characters that can not be represented in the specified text encoding or if Igor’s notion of the original text encoding is wrong. In the latter case, call SetWaveTextEncoding without /CONV to correct Igor’s interpretation of the text and then call SetWaveTextEncoding with /CONV to do the conversion.

errorMode takes one of these values:
1: Generate error. SetWaveTextEncoding returns an error to Igor.
2: Use a substitute character for any unmappable characters. The substitute character for most text encodings is either control-Z or a question mark.
3: Skip unmappable input characters. Any unmappable characters will be missing in the output.
4: Use escape sequences representing any unmappable characters or invalid source text.

If the source text is valid in the source text encoding but can not be represented in the destination text encoding, unmappable characters are replaced with \uXXXX where XXXX specifies the UTF-16 code point of the unmappable character in hexadecimal.

If the conversion can not be done because the source text is not valid in the source text encoding, invalid bytes are replaced with \xXX where XX specifies the value of the invalid byte in hexadecimal.

defaultTextEncoding is optional. If it is present, not -1, and if the wave text element’s original encoding is unknown (0), then the wave text element is treated as if it were the specified defaultTextEncoding. This allows you to convert the text of Igor Pro 6 waves that are set to unknown when you know that they are really some other text encoding. For example, if you know a wave’s text data text encoding is Shift JIS, you can convert it to UTF-8 in one step, like this:

SetWaveTextEncoding /CONV={1,4} 1, 16, textWave0

Without the defaultTextEncoding, you would have to do two steps - the first to tell Igor what the real text encoding is and the second to do the conversion:

// Text encoding is Shift JIS
SetWaveTextEncoding 4, 16, textWave0

// Convert to UTF-8
SetWaveTextEncoding /CONV=1 1, 16, textWave0

Passing -1 for defaultTextEncoding acts the same as omitting it.
SetWaveTextEncoding

`diagnosticsFlags` is an optional bitwise parameter defined as follows:

- Bit 0: Emit diagnostic message if text conversion succeeds.
- Bit 1: Emit diagnostic message if text conversion fails.
- Bit 2: Emit diagnostic message if text conversion is skipped.
- Bit 3: Emit summary diagnostic message.

All other bits are reserved for future use.

See Setting Bit Parameters on page IV-13 for details about bit settings.

`diagnosticsFlags` defaults to 2 (bits 1 set) if the `/DF` flag is not present and to 10 (bits 1 and 3 set) if the `/DF` flag is present.

Text conversion may be skipped because the wave element is marked as unknown text encoding, because it is marked as binary, because of the `/ONLY` or `/SKIP` flags, or because `newTextEncoding` is the same as the wave element's original text encoding.

/DF={dfr, recurse, excludedDFR}

dfr is a reference to a data folder. `SetWaveTextEncoding` operate on all waves in the specified data folder. If `dfr` is null (""`) `SetWaveTextEncoding` acts as if `/DF` was omitted.

If `recurse` is 1, `SetWaveTextEncoding` works recursively on all sub-data folders. Otherwise it affects only the data folder referenced by `dfr`.

`excludedDFR` is an optional reference to a data folder to be skipped by `SetWaveTextEncoding`. For example, this command sets the text encoding of text wave data for all waves in all data folders except for root:Packages and its sub-data folders:

```
SetWaveTextEncoding /DF={root:,1,root:Packages} 1, 16
```

If `excludedDFR` is null ("") `SetWaveTextEncoding` acts as if `excludedDFR` was omitted and no data folders are excluded.

/ONLY=targetedTextEncoding

`SetWaveTextEncoding` changes only wave elements that are currently set to `targetedTextEncoding`. For example, this command converts the content of all waves that are currently set to unknown text encoding (0) to UTF-8 (1), treating the waves originally marked as unknown as Shift JIS (4) waves:

```
SetWaveTextEncoding /DF={root:,1} /ONLY=0 /CONV={1,4} 1, 16
```

Passing -1 for `targetedTextEncoding` acts as if you omitted `/ONLY` altogether.

/SKIP=skipTextEncoding

`SetWaveTextEncoding` skips all wave elements that are currently set to `skipTextEncoding`. For example, this command converts the content of all waves to UTF-8 (1) except those that are set to Japanese (4):

```
SetWaveTextEncoding /DF={root:,1} /SKIP=4 /CONV=1 1, 16
```

As explained under `/CONV`, binary (255) wave elements are always skipped and unknown (0) wave elements are skipped if the `/CONV` defaultTextEncoding parameter is omitted.

Passing -1 for `skipTextEncoding` acts as if you omitted `/SKIP` altogether.

/TYPE=type

`SetWaveTextEncoding` changes only waves of the specified type.

type is:

1: Text waves only
2: Non-text waves only
3: All waves (default)
SetWaveTextEncoding

/Z[=z] Prevents procedure execution from aborting if SetWaveTextEncoding generates an error. Use /Z or the equivalent, /Z=1, if you want to handle errors in your procedures rather than having execution abort.

/Z does not suppress invalid parameter errors. It suppresses only errors in doing text encoding reinterpretation or conversion.

Details
Because SetWaveTextEncoding is intended for use by experts or by users instructed by experts, it does not respect the lock state of waves. That is, it will change waves even if they are locked using SetWaveLock.

For background information on wave text encodings, see Wave Text Encodings on page III-451.

A wave's text wave content text encoding can also be set to the special value 255. This marks a text wave as really containing binary data, not text. See Text Waves Containing Binary Data on page III-453 for details.

Using SetWaveTextEncoding
One of the main uses for SetWaveTextEncoding is to set the encoding settings to some value other than 0 (unknown) so that Igor’s idea of the text encoding used for the items accurately reflects the actual text encoding. We call this “reinterpreting” the item. It does not change the numeric codes representing the text but rather just changes the setting that controls Igor’s idea of how the text is encoded. This does change the meaning of the underlying numeric codes. In other words, it changes the characters represented by the text.

You would do reinterpretation if you load an Igor 6 experiment and Igor interprets the waves using the wrong text encoding. For example, if you load an experiment that you know uses Shift JIS encoding but Igor interprets it as Windows-1252, you get garbage for Japanese text. Reinterpreting it as Shift JIS fixes this. An example is provided below.

The other use for SetWaveTextEncoding is to actually change the numeric codes representing the text - i.e., to convert the content to a different text encoding. For example, if you have text waves from Igor Pro 6 that are encoded in Japanese (Shift JIS), you may want to convert the text to UTF-8 (a form of Unicode) so that you can combine Japanese and non-Japanese characters or use other features that require Unicode. This also applies to western text containing non-ASCII characters encoded as MacRoman or Windows-1252. Converting changes the underlying numeric codes but does not change the characters represented by the text.

The main use for converting text is to convert Igor Pro 6 waves from whatever encoding they use, which typically will be MacRoman, Windows-1252, or Shift JIS, to UTF-8 (a form of Unicode) which is a more modern representation but is not backward compatible with Igor Pro 6.

If the /CONV flag is omitted SetWaveTextEncoding does reinterpretation. If the /CONV flag is present then SetWaveTextEncoding does text conversion except if the original text encoding is unknown (0) or binary (255) in which case it does nothing.

If a wave has mistakenly been marked as containing binary, use SetTextWaveEncoding without /CONV to set it to the correct text encoding.

If a wave’s text encoding is set to unknown (0) but you know that it really contains text in some specific encoding, you can use SetTextWaveEncoding without /CONV to set it to the correct text encoding and then use SetTextWaveEncoding with /CONV to convert it to the desired final text encoding. Alternately you can combine these two steps by using /CONV and providing a value for the optional defaultTextEncoding parameter.

Output Variables
The SetWaveTextEncoding operation returns information in the following variables:

- V_numConversionsSucceeded: Set only when the /CONV flag is used. Zero otherwise.
  
  V_numConversionsSucceeded is set to the number of successful text conversions.

- V_numConversionsFailed: Set only when the /CONV flag is used. Zero otherwise.
  
  V_numConversionsFailed is set to the number of unsuccessful text conversions.
**Examples**

// Keep in mind that, if /CONV is present, SetWaveTextEncoding does nothing
// for wave text elements currently set to binary (255).
// Also, if /CONV is present, SetWaveTextEncoding does nothing
// for wave text elements currently set to unknown (0) if the /CONV
// optional defaultTextEncoding parameter is omitted.
// In the following examples 1 means UTF-8, 4 means Shift JIS, and 16
// means text wave content.

// Reinterpret specific text waves as Shift JIS if they are currently set to unknown
SetWaveTextEncoding /ONLY=0 4, 16, textWave0, textWave1

// Convert specific waves' content to UTF-8
SetWaveTextEncoding /CONV=1 1, 16, textWave0, textWave1

// Reinterpret all text waves as Shift JIS if they are currently set to unknown
SetWaveTextEncoding /DF={root:,1} /ONLY=0 4, 16

// Convert all waves' content to UTF-8
SetWaveTextEncoding /DF={root:,1} /CONV=1 1, 16

// Convert all text waves' content from Shift JIS to UTF-8
// if it is currently set to unknown
SetWaveTextEncoding /DF={root:,1} /ONLY=0 /TYPE=1 /CONV={1,4} 1, 16

// Same as before but exclude the root:Packages data folder
SetWaveTextEncoding /DF={root:,1,root:Packages} /ONLY=0 /TYPE=1 /CONV={1,4} 1, 16

// Mark a text wave as really containing binary data
SetWaveTextEncoding 255, 16, textWaveContainingBinaryData

// This example illustrates how to do a conversion based on criteria
// that require inspecting each wave.

WaveTextEncoding, ConvertTextEncoding, ConvertGlobalStringTextEncoding

SetWindow

SetWindow winName [, keyword = value]...

The SetWindow operation sets the window note and user data for the named window or subwindow. SetWindow can also set hook functions for a base window or exterior subwindow (interior subwindows not supported).

Parameters

winName can be the name of any target window (graph, table, page layout, notebook, control panel, Gizmo, camera, or XOP target window). It can also be the keyword kwTopWin to specify the topmost target window.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

activeChildFrame=f Determines if the frame indicating the active subwindow in the named window or subwindow is drawn.

f=1: Default. Recursively check ancestors of this window. If one is found with a value of either 0 or 1, use that value. If the topmost window has a value of -1, then the frame is drawn.

f=0: If this subwindow or one of its descendants becomes active, then the frame is drawn.

f=-1: If this subwindow or one of its descendants becomes active, then the frame is not drawn.

graphicsTech=t Sets the graphics technology used to draw the window. This flag may be useful in rare cases to work around graphics limitations. See Graphics Technology (see page III-478) for background information.

t=0: Default: The graphics technology specified in Miscellaneous Settings dialog, Miscellaneous category. This is Qt Graphics by default.

t=1: Native: Core Graphics on Macintosh, GDI+ on Windows.

t=2: Old: Core Graphics on Macintosh, GDI on Windows.

hide=h Hides or unhides widows or subwindows.

h=0: Unhides a subwindow or base window.

h=1: Hides a subwindow or base window.

h=2: Unhides without restoring minimized windows (Windows only).

When unhiding subwindows, you should combine with needUpdate=1 if conditions require the subwindow to be redrawn since the window was hidden.
SetWindow

hook=procName
Sets the window hook function that Igor will call when certain events happen. Use SetWindow hook=\$\"\" to specify no hook function.

See Unnamed Window Hook Functions on page IV-296 for further details.

hook(hName)=procName
Defines a named window hook hName and sets the function that Igor will call when certain events happen. hName can be any legal name. Named hooks are called before any unnamed hooks.

Use $\"\" for procName to specify no hook.

See Named Window Hook Functions on page IV-286 for further details.

To hook a subwindow, see Window Hooks and Subwindows on page IV-286.

hookcursor=number
Sets the mouse cursor. This keyword is antiquated. See Setting the Mouse Cursor on page IV-292 for the preferred technique.

hookevents=flags
Bitfield of flags to enable certain events for the unnamed hook function:

Bit 0: Mouse button clicks.
Bit 1: Mouse moved events.
Bit 2: Cursor moved events.

To set bit 0 and bit 1 (mouse clicks and mouse moved), use $2^{0}+2^{1}=1+2=3$ for flags.
Use 7 to also enable cursor moved events. See Setting Bit Parameters on page IV-13 for details about bit settings.

This keyword applies to the unnamed hook function only. It does not affect named hook functions which always receive all events.

markerHook= {hookFuncName, start, end}
Specifies a user function and marker number range for custom markers. The marker range can be any positive integers less than 1000 and can overlap built-in marker numbers. See Custom Marker Hook Functions on page IV-299 for details.

Use $\"\"$ for hookFuncName to specify no hook.

needUpdate= n
Marks a window as needing an update (n=1) or takes no action (n=0).

note=noteStr
Sets the window note to noteStr, replacing any existing note.

note+=noteStr
Appends noteStr to current contents of the window note.

sizeLimit= {minWidth, minHeight, maxWidth, maxHeight}

ShowIgorMenus

Imposes limits on a window's size when resized with the mouse or by calling 
\texttt{MoveWindow}. The units of the limits are the same as those returned by 
\texttt{GetWindow wsize}.

The \texttt{sizeLimit} keyword was added in Igor Pro 7.00.

To allow the window width to grow essentially without bound, pass \texttt{INF} for \texttt{maxWidth}.

To allow the window height to grow essentially without bound, pass \texttt{INF} for \texttt{maxHeight}.

If \texttt{minWidth > maxWidth} or \texttt{minHeight > maxHeight}, the maximum dimensions are 
set to the minimum, effectively fixing the size of the window in that dimension.

For control panels, it is better to use \texttt{ModifyPanel fixedSize=1}.

Combining these limits with \texttt{ModifyGraph width} and \texttt{height} modes leads to 
unexpected results and is discouraged.

If you first use \texttt{sizeLimit} and then execute \texttt{ModifyPanel fixedSize=1} on the 
same window, the \texttt{fixedSize} command takes precedence. If you execute 
\texttt{SetWindow sizeLimit} on a control panel that has \texttt{fixedSize=1}, Igor 
generates an error.

Igor includes a \texttt{SetWindow sizeLimit} command in a window recreation macro 
if necessary. Igor6 does not support \texttt{SetWindow sizeLimit} so this causes an 
error when recreating the window in Igor6. If you never set the \texttt{sizeLimit} 
property for a window, or if the minimum dimensions are very small and 
maximum dimensions are \texttt{INF}, then no \texttt{SetWindow} command is generated.

\begin{verbatim}
userdata=UDStr
userdata(UDName)=UDStr

Sets the window or subwindow user data to \texttt{UDStr}. Use the optional \texttt{(UDName)} to 
specify a named user data to create.

userdata+=UDStr
userdata(UDName)+=UDStr

Appends \texttt{UDStr} to the current window or subwindow user data. Use the optional 
\texttt{(UDName)} to append to the named user data.
\end{verbatim}

\textbf{Details}

For details on named window hooks, see \textbf{Window Hook Functions} on page IV-285.

Unnamed window hook functions are supported for backward compatibility only. New code should use 
named window hook functions. For details on unnamed window hooks, see \textbf{Unnamed Window Hook 
Functions} on page IV-296.

For details on marker hooks, see \textbf{Custom Marker Hook Functions} on page IV-299.

\textbf{See Also}

The \texttt{GetWindow}, \texttt{SetIgorHook}, and \texttt{SetIgorMenuMode} operations and \texttt{AxisValFromPixel}, 
\texttt{NumberByKey}, \texttt{PopupContextualMenu}, and \texttt{TraceFromPixel} functions. The \texttt{GetUserData} operation for 
retrieving named user data.

\textbf{ShowIgorMenus}

\texttt{ShowIgorMenus \texttt{[MenuNameStr \[, MenuNameStr\] \ldots}}

The \texttt{ShowIgorMenus} operation shows the named built-in menus or, if none are explicitly named, shows all 
built-in menus in the menu bar.

User-defined menus attached to built-in menus are also affected by this operation.
ShowInfo

The ShowInfo operation puts an information panel on the target or named graph. The information panel contains cursors and readouts of values associated with waves in the graph.

Flags

/CP=\ num \[ /W=winName \] Selects a cursor pair to display in the info panel.

\( num=0 \): Selects cursor A and cursor B.
\( num=1 \): Selects cursor C and cursor D.
\( num=2 \): Selects cursor E and cursor F.
\( num=3 \): Selects cursor G and cursor H.
\( num=4 \): Selects cursor I and cursor J.

/CP={n1,n2,...} Allows you to select multiple cursor pairs to be displayed in the info panel. The numbers n1, n2, etc., are the same as the single-pair version of this flag.

This form of /CP was added in Igor Pro 7.00.

/W=winName Displays info panel in the named window.

See Also
Info Panel and Cursors on page II-254.
The HideInfo operation.
Programming With Cursors on page II-256.

ShowTools

The ShowTools operation puts a tool palette for drawing along the left hand side of the target or named graph or control panel, and optionally activates the named tool.

Flags

/A Sizes window automatically to make extra room for the tool palette. This preserves the proportion and size of the actual graph area.

/W=winName Shows tool palette in the named window. This must be the first flag specified when used in a Proc or Macro or on the command line.

winName must be either the name of a top-level window or a path leading to an exterior panel window (see Exterior Control Panels on page III-423).

Parameters

If you specify a toolName (which can be one of: normal, arrow, text, line, rect, rrect, oval, or poly) the named tool is activated. Specifying the “normal” tool has the same effect as issuing the GraphNormal command for a graph that has the drawing tools selected.
SinIntegral

Details
The activated tool is not highlighted until the top graph or control panel becomes the topmost (activated) window. Use DoWindow/F to bring a window to the top (or “front”).

See Also
The DoWindow, GraphNormal, GraphWaveDraw, GraphWaveEdit, and HideTools operations.

SinIntegral

SinIntegral(z)
The SinIntegral(z) function returns the sine integral of z.
If z is real, a real value is returned. If z is complex then a complex value is returned.
The SinIntegral function was added in Igor Pro 7.00.

Details
The sine integral is defined by

$$ Si(z) = \int_{0}^{z} \frac{\sin(t)}{t} \, dt. $$

IGOR computes the SinIntegral using the expression:

$$ Si(z) = z_1 F_2 \left( \frac{1}{2}; \frac{3}{2}; \frac{3}{2}; -\frac{z^2}{4} \right). $$

References

See Also
CosIntegral, ExpIntegralE1, hyperGPFQ

sign

sign(num)
The sign function returns -1 if num is negative or 1 if it is not negative.

Silent

Silent num
The Silent operation is largely obsolete. Only very specialized uses remain and most users can ignore this operation.
Prior to Igor Pro 7, Silent was used to enable or disable the display of macro commands in the command line as they were executed. It was also used to enable compatibility modes for very old experiments.

Parameters
If num is 2, commands issued by AppleEvents or ActiveX Automation are not shown in the history are of the command window. Use 3 to re-enable.
If num is 100, 101 or 102, all procedures are recompiled. For 102, the time to recompile is displayed in the history.

sin

sin(angle)
The sin function returns the sine of angle which is in radians.
In complex expressions, angle is complex, and sin(angle) returns a complex value.
\[ \text{sinc}(x + iy) = \sin(x) \cosh(y) + i \cos(x) \sinh(y). \]

See Also
asin, cos, tan, sec, csc, cot

sinc
\text{sinc}(\text{num})
The sinc function returns \( \sin(\text{num})/\text{num} \). The sinc function returns 1.0 when \( \text{num} \) is zero. \( \text{num} \) must be real.

sinh
\text{sinh}(\text{num})
The sinh function returns the hyperbolic sine of \( \text{num} \):

\[ \sinh(x) = \frac{e^x - e^{-x}}{2}. \]

In complex expressions, \( \text{num} \) is complex, and \( \sinh(\text{num}) \) returns a complex value.

See Also
cosh, tanh, coth

Sleep
\text{Sleep} [\text{flags}] \text{ timeSpec}
The Sleep operation puts Igor to sleep for a while. After the while is up, Igor continues execution.

You could use Sleep, for example, to give an instrument time to perform an action or to allow a user to admire a graph before proceeding.

More advanced programmers may prefer to use a background task as an alternative. See Background Tasks on page IV-307.

Parameters
The format of \( \text{timeSpec} \) depends on which flags, if any, are present.

If no flags are present, then \( \text{timeSpec} \) is in \text{hh:mm:ss} format and specifies the number of elapsed hours, minutes and seconds to sleep.

Flags
\begin{itemize}
\item \text{/A} \quad \text{timeSpec} \text{ is an absolute time in 24 hour format (e.g., 16:00:00).}
\item \text{/A/W} \quad \text{Wait until tomorrow if absolute time has passed.}
\item \text{/B} \quad \text{Stop sleeping if the user clicks the mouse button.}
\end{itemize}

The \text{/B} flag is ignored if you use the \text{/PROG} flag.
Details
The Sleep operation does not let the user choose menus, move cursors, run procedures, draw in graphs, or do any other interactive task.

Normally timeSpec specifies an amount of elapsed time. If the /A flag is present, then timeSpec is an absolute time when sleep is to end. If the specified absolute time has already passed, no sleep occurs unless you also use /W, which makes it wait until tomorrow.

If you specify time in hh:mm:ss format, you can also specify the time indirectly through a string variable. See the examples.

You can end sleep by pressing the User Abort Key Combinations. Normally when you do this, it aborts any procedure that is running. However, if you use the /Q flag, the procedure continues running normally.

Displaying a Progress Dialog
When you specify /C=6 or if you use the /PROG flag, Sleep displays a progress dialog with a progress bar showing how much of the sleep time has passed. The dialog displays a prompt which you can control using the /M flag.

If you use /PROG, then /Q and /B are ignored.
If you use /C=6, then /Q and /B have special meanings:

/C=6  Progress dialog with Cancel button which aborts running procedures. The Abort key combinations abort running user procedures.

/C=6/B  Progress dialog with Abort button which aborts running procedures. The Abort key combinations abort running user procedures.

/C=6/Q  Progress dialog with Continue button which terminates the current sleep operation but allows procedures to continue. Abort key combinations allow running procedures to continue.

/C=6/B/Q  Progress dialog with Continue and Abort buttons. The Continue button terminates the current sleep operation but allows procedures to continue. The Abort button aborts running procedures. Abort key combinations allow running procedures to continue.

If you use the /PROG flag, you can provide your own titles for the Cancel and Continue buttons.

Examples
These examples assume the current time is 4 PM:

Sleep 00:01:30 // sleeps for 1 minute, 30 seconds
Sleep/A 23:30:00 // sleeps until 11:30 PM
Sleep/A 03:00:00 // doesn't sleep at all because time is past
Sleep/A/W 03:00:00 // sleeps until 3 AM tomorrow
String str1= "03:00:00" // put wakeup call time in string
Sleep/A/W $str1 // sleeps until 3 AM tomorrow
Sleep/B/C=2/S/Q 60 // sleep 60 seconds, or until user clicks, and keep going (don't abort)

The following function creates a graph and then periodically updates the displayed data. By default, it sleeps for a number of seconds specified by the sleepTime parameter.

Function SleepDemo(sleepTime, displayProgressDialog)
Variable sleepTime // In seconds
Variable displayProgressDialog // 1 for progress dialog

Make/N=200/O junk
SetScale/I x 0, 2*pi, junk
junk=sin(x)
DoWindow/F SleepDemoGraph
if (V_Flag == 0)
    Display/N=SleepDemoGraph junk
doint
DoUpdate

try
Variable i
for (i = 0; i < 10; i++)
    if (displayProgressDialog)
        // Because the abortMode is 0, pressing the user abort key combinations
        // or pressing the Done button generates an abort instead of merely
        // terminating the current Sleep call.
        int abortMode = 0
        Sleep/S/PROG={"Done", "Continue", abortMode} sleepTime
    else
        // /B makes Sleep terminate if the user clicks.
        // Because the /Q flag is omitted, pressing the user abort key combinations
        // or pressing Igor's Abort button generates an abort instead of merely
        // terminating the current Sleep call.
        Sleep/S/C=2/B sleepTime
    endif
    junk = sin(x*(i+2))
    DoUpdate
endfor
catch
    Printf "An abort occurred with V_abortCode=%d\r", V_abortCode
The Slider operation creates or modifies a Slider control in the target window. A Slider control sets or displays a single numeric value. The user can adjust the value by dragging a thumb along the length of the Slider.

For information about the state or status of the control, use the ControlInfo operation.

**Parameters**

`ctrlName` is the name of the Slider control to be created or changed.

The following keyword=value parameters are supported:

- **`align=alignment`** Sets the alignment mode of the control. The alignment mode controls the interpretation of the `leftOrRight` parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.
  - If `alignment=0` (default), `leftOrRight` specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.
  - If `alignment=1`, `leftOrRight` specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

- **`appearance={kind [, platform]}`** Sets the appearance of the control. `platform` is optional. Both parameters are names, not strings.
  - `kind` can be one of default, native, or os9.
  - `platform` can be one of Mac, Win, or All.
  - **Note:** The Slider control reverts to os9 appearance on Macintosh if `thumbColor` isn’t the default blue (0,0,65535).
  - See Button and DefaultGUIControls for more appearance details.

- **`disable=d`** Sets user editability of the control.
  - `d=0`: Normal.
  - `d=1`: Hide.
  - `d=2`: Draw in gray state; disable control action.

- **`fColor=(r,g,b)`** Sets the color of the tick marks. `r`, `g`, and `b` range from 0 to 65535. fColor defaults to black (0,0,0).

- **`focusRing=fr`** Enables or disables the drawing of a rectangle indicating keyboard focus:
  - `fr=0`: Focus rectangle will not be drawn.
  - `fr=1`: Focus rectangle will be drawn (default).
  - On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.

- **`font="fontName"`** Sets the font used to display the tick labels, e.g., `font="Helvetica"`.

- **`fsize=s`** Sets the size of the type for tick mark labels.

- **`help={helpStr}`** Sets the help for the control. The help text is limited to a total of 255 bytes. You can insert a line break by putting “\r” in a quoted string.

- **`limits= {low,high,inc}`**
  - `low` sets left or bottom value, `high` sets right or top value. Use `inc=0` for continuous or use desired increment between stops.
live=l Controls updating of readout.
  l=0: Update only after mouse is released.
  l=1: Update as slider moves (default).
	noproc Specifies that no procedure is to execute when the control’s value is changed.
pos=leftOrRight,top Sets the position in pixels of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.
pos+=[dx,dy] Offsets the position of the slider in pixels.

proc=procName Specifies the action procedure for the slider.

rename=newName Gives control a new name.

repeat=[style,springback,rate,restingValue]

Set the control to call its action procedure repeatedly at timed intervals while the user clicks the thumb.

style can take one of the following values:
  0: No repeat (default). Use this to turn the repeat feature off.
  1: Slider repeats at a constant rate.
  2: Slider repeats at a rate proportional to the distance from the restingValue.

springback controls what happens to the slider value when the user releases the mouse. If springback is 1, the slider returns to the resting value. If it is 0, it remains at the last set value.

rate specifies the rate at which the action procedure is called in calls per second. The maximum rate accepted rate is 1000. If rate is 0, it sets style to 0 which turns the repeating feature off.

restingValue specifies the value to which the slider returns when the user releases the mouse. If springback is 1, the thumb automatically returns to restingValue when the mouse button is released. If springback is 0, restingValue has no effect.

side=s Controls slider thumb.
  s=0: Thumb is blunt and tick marks are suppressed.
  s=1: Thumb points right or down (default).
  s=2: Thumb points up or left.

size=[width,height] Sets width or height of control in pixels. height is ignored if vert=0 and width is ignored if vert=1.

thumbColor=(r,g,b) Sets dominant foreground color of thumb. r, g, and b are integers from 0 to 65535. Only the hue and saturation are used. Therefore (0,1000,0) is the same tint of green as (0,10000,0).

ticks=t Controls slider ticks.
  t=0: No ticks.
  t=1: Number of ticks is calculated from limits (no ticks drawn if calculated value is less than 2 or greater than 100). Default value.
  t>1: t is the number of ticks distributed between the start and stop position. Ticks are labeled using the same automatic algorithm used for graph axes. Use negative tick values to force ticks to not be labeled. Ticks are shown on the side specified by the side keyword and are not drawn if side=0.

tkLblRot=deg Rotates tick labels. deg is a value between -360 and 360.
Slider

Slider Action Procedure

The action procedure for a Slider control takes a predefined WMSliderAction structure as a parameter to the function:

```igor
Function ActionProcName(S_Struct) : SliderControl
    STRUCT WMSliderAction &S_Struct
    ...
    return 0
End
```

The ": SliderControl" designation tells Igor to include this procedure in the Procedure pop-up menu in the Slider Control dialog.

See WMSliderAction for details on the WMSliderAction structure.

Although the return value is not currently used, action procedures should always return zero.

You may see an old format Slider action procedure in old code:

```igor
Function MySliderProc(name, value, event) : SliderControl
    String name  // name of this slider control
    Variable value  // value of slider
    Variable event // bit field: bit 0: value set; 1: mouse down,
                    // 2: mouse up, 3: mouse moved
    return 0   // other return values reserved
End
```

This old format should not be used in new code.
Repeating Sliders
A repeating slider calls your action procedure periodically while the user is clicking the thumb. See Repeating Sliders on page III-399 for an overview.

When the repeat style is set to 2, the call rate is proportional to the slider value. See the Slider reference documentation in the online help for the formula.

Whereas the rate can be set as high as 1000 calls per second, if your action procedure takes more time to execute than the period of the slider repeat, you will simply lose repeats. It is unlikely that a rate of more than about 50 calls per second can realistically be achieved.

Examples

Function SliderExample()
    NewPanel /W=(150,50,501,285)
    Variable/G var1
    Execute "ModifyPanel cbRGB=(56797,56797,56797)"
    SetVariable setvar0,pos={141,18},size={122,17},limits={-Inf,Inf,1},value=var1
    Slider foo,pos={26,31},size={62,143},limits={-5,10,1},variable=var1
    Slider foo2,pos={173,161},size={150,53}
    Slider foo2,limits={-5,10,1},variable=var1,vert=0,thumbColor=(0,1000,0)
    Slider foo3,pos={80,31},size={62,143}
    Slider foo3,limits={-5,10,1},variable=var1,side=2,thumbColor=(1000,1000,0)
    Slider foo4,pos={173,59},size={150,13}
    Slider foo4,limits={-5,10,1},variable=var1,side=0,vert=0
    Slider foo5,pos={173,90},size={150,53}
    Slider foo5,limits={-5,10,1},variable=var1,side=2,vert=0
    Slider foo5,ticks=5,thumbColor=(500,1000,1000)
End

SliderControl

SliderControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined slider control. See Procedure Subtypes on page IV-199 for details. See Slider for details on creating a slider control.

Slow

Slow ticks
The Slow operation is obsolete. Prior to Igor Pro 7 it slowed down execution of macros for debugging purposes. It now does nothing.

Smooth

Smooth [flags] num, wave0 [, wave1]...
The Smooth operation smooths the named waves using binomial (Gaussian) smoothing, boxcar (sliding average) smoothing, Savitzky-Golay (polynomial) smoothing, or running-median filtering.

Parameters
num is the number of smoothing operations to be applied for binomial smoothing or the integer number of points in the smoothing window for boxcar, Savitzky-Golay, and running-median smoothing, or, if you use /BLPF, the low-pass cutoff frequency.

Each wave, which may be floating point or integer, is smoothed in-place, overwriting the values with the smoothed result.

If an input wave is complex, the real and imaginary parts are smoothed independently.
Smooth

If an input wave contains NaNs, the results are undefined. (The **Loess** and **Interpolate2** operations can fill in NaNs).
**Smooth**

**Flags**

/B [\(b\)]
Invokes boxcar smoothing algorithm. If given, \(b\) specifies the number of passes to use when smoothing the data with smoothing factor \(num\) (box width). The number of passes can be any value between 1 and 32767.

/BLPF [=roundMode]
Calculates the integer number of smoothing operations to be applied for binomial smoothing based on interpreting the \(num\) parameter as the low-pass cutoff frequency and then performs the smoothing. /BLPF was added in Igor Pro 8.00.

The calculated number of smoothing operations is returned in \(V_{\text{iterations}}\):

\[
V_{\text{iterations}} = \ln(\sqrt{2})\left(\frac{1}{(\pi f_{cn})^2} - \frac{1}{6}\right)
\]

where \(f_{cn} = num \times \text{DimDelta}(\text{wave0}, dim)\)

If \(\text{roundMode}\) is 1, \(V_{\text{iterations}}\) is rounded down to an integer value. This is the default if you use /BLPF by itself without \(\text{roundMode}\).

If \(\text{roundMode}\) is 2, \(V_{\text{iterations}}\) is rounded up to an integer value.

\(f_{cn}\) is the Nyquist-normalized cutoff frequency and should be \(\leq 0.182028\), which results in \(V_{\text{iterations}} = 1\).

The cutoff frequency, also known as the "half power point", is the frequency at which the magnitude response of the smoothing filter declines to \(1/\sqrt{2} \approx 0.707107\).

/DIM = dim
Specifies the wave dimension to smooth.

\(dim = 1\): Treats entire wave as 1D (default)
\(dim = 0\): Operates along rows
\(dim = 1\): Operates along columns
\(dim = 2\): Operates along layers
\(dim = 3\): Operates along chunks

/E = endEffect
Determines how to handle the ends of the wave (\(w\)) when fabricating missing neighbor values.

\(\text{endEffect} = 0\): Bounce method (default). Uses \(w[i]\) in place of the missing \(w[-i]\) and \(w[n+i]\) in place of the missing \(w[n-i]\).

\(\text{endEffect} = 1\): Wrap method. Uses \(w[n-i]\) in place of the missing \(w[-i]\) and vice versa.

\(\text{endEffect} = 2\): Zero method. Uses 0 for any missing value.

\(\text{endEffect} = 3\): Repeat method. Uses \(w[0]\) in place of the missing \(w[-i]\) and \(w[n]\) in place of the missing \(w[n+i]\).

/EVEN [=evenAllowed]
Specifies the smoothing increment for boxcar smoothing (/B). Values are:

0: Increments even values of \(num\) to the next odd value. Default when /EVEN omitted.

1: Uses even values of \(num\) for boxcar smoothing despite the half-sample shifting this introduces in the smoothed output (prior to version 6, this shift was prevented). Same as /EVEN alone.

/F [=f]
Selects the boxcar or multipass binomial smoothing method:

\(f = 0\): Slow, but accurate, method (default).

\(f = 1\): Fast method. Same as /F alone.
### Smooth

**/M=threshold**  
Invokes running-median smoothing and specifies an absolute numeric threshold used to optionally replace “outliers”. Points that differ from the central median by an amount exceeding *threshold* are replaced, either with the *replacement* value specified by /R, or otherwise with the median value.

Special *threshold* values are:

- **0**: Replace all values with running-median values or the *replacement* value.
- **(NaN)**: Replace only NaN input values with running-median values or the *replacement* value.

The smoothing factor *num* is the number of points in the smoothing window used to compute each median.

**/MPCT=percentile**  
Used with /M to compute a smoothed value that is a different percentile than the median. /M must be present if /MPCT is used.

*percentile* is a value from 0 to 100.

Roughly speaking, the smoothed value returned is the smallest value in the smoothing window that is greater than the smallest *percentile* % of the values. See “Median and Percentile Smoothing Details”, below.

- **percentile=0**: The smoothed value is the minimum value in the smoothing window.
- **percentile=50**: The smoothed value is the median of the values in the smoothing window. This is the default if /MPCT is omitted.
- **percentile=100**: The smoothed value is the maximum value in the smoothing window.

**/R=replacement**  
Specifies the value that replaces input values that exceed the central median by *threshold* (requires /M). *replacement* can be any value (including NaN or ±Inf if *waveName* is floating point).

**/S=sgOrder**  
Invokes Savitzky-Golay smoothing algorithm and specifies the smoothing order. *sgOrder* must be either 2 or 4.

### Binomial Smoothing Details

For binomial smoothing, use no flags other than /BLPF, /DIM, /E, and /F.

If you are not using /BLPR, *num* is the number of smoothing operations between 1 and 32767.

If you are using /BLPF, *num* is the low-pass cutoff frequency which must be less than 0.182028 times the sampling frequency of *wave0*. The computed smoothing factor is returned in *V_iterations*. Very small values of *fcn* (≈ 0.0007 or less) will fail with errors due to excessive number of smoothing operations or to insufficient range (too few wave points).

In Igor Pro 6 and later, the binomial smooth algorithm automatically switches to a nearly-equivalent but much faster multipass box smooth when *num* >= 50. You can prevent the switch to box smoothing by setting this global variable:

```
Variable/G root:V_doOrigBinomSmooth=1
```

The binomial smoothing algorithm does not detect and ignore NaNs in the input data. Use **Loess** or **Interpolate2** to fill in NaNs.

### Boxcar Smoothing Details

For boxcar smoothing, use the /B flag and a *num* value from 1 to 32767.

For *num* < 2, no smoothing is done.

If *num* is even and /EVEN is not specified, *num* is incremented to the next (odd) integer.

If *num* is even and /EVEN is specified, each smoothed output is formed from one more previous value than future values.
The fast boxcar smoothing (/F) algorithm creates small errors when the data has a large offset. For some data sets you may want to subtract the mean of the data before smoothing and add it back in afterwards.

The boxcar smoothing algorithm detects and ignores NaNs in the input data. If num is less than the number of NaNs near the output point, then the result is NaN. Otherwise the average of the non-NaN neighboring points is used to compute the smoothed result.

**Savitzky-Golay Smoothing Details**

For Savitzky-Golay smoothing, use the /S flag and an odd num value from 5 to 25. An even value for num returns an error. If sgOrder=4, then num=5 gives no smoothing at all so num should be at least 7.

The Savitzky-Golay smoothing algorithm does not detect and ignore NaNs in the input data.

**Median and Percentile Smoothing Details**

For running-median smoothing, use the /M flag and a num value from 1 to 32767. When num is 1, no smoothing is done.

If num is even, the median is the average of the two middle values.

For example, the median of 6 values around data[i] is the median of data[i-3], data[i-2], data[i-1], data[i], data[i+1], and data[i+2], and if these values were already sorted, the median would be the average of data[i-1] and data[i].

Use /M=0 to replace all values with the median over the smoothing window or use /M=threshold/R=(NaN) to replace outliers with NaNs.

Use /M=(NaN) to replace only NaN input values with the running-median values or the replacement value.

The running-median smoothing algorithm detects and ignores NaNs in the input data. If num is less than the number of NaNs near the output point, then the result is NaN. Otherwise the median of the non-NaN neighboring points is used to compute the smoothed result.

The running-median is a special case of running-percentile, with percentile=50.

The /M and /MPCT algorithm uses an interpolated rank to compute the value of percentiles other than 0 and 100.

Using Example 1 from <http://cnx.org/content/m10805/latest/> ("A Third Definition"), the 25th percentile (/MPCT=25) of the 8 values:

```
Make/O sortedData={3,5,7,8,9,11,13,15} // Already sorted, rank 1 to 8
```

The first step is to compute the rank (R) of the 25th percentile. This is done using the following formula: R=(percentile/100)*(num+1), where percentile is 25 and num is 8, so here R = 2.25.

If R were an integer, the Pth percentile would be the number with rank R; if R were 2 the result would be the 2nd value = 5.

Since R is not an integer, we compute the Pth percentile by interpolation as follows:

1. Define IR as the integer portion of R (the number to the left of the decimal point). For this example, IR=2.
2. Define FR as the fractional portion of R. For this example, FR=0.25
3. Find the values with Rank IR and with Rank IR+1. For this example, this means the values with Rank 2 and the score with Rank 3. The values are 5 and 7.
4. Interpolate by multiplying the difference between the values by FR and add the result to the lower values. For these data, this is 0.25(7-5)+5=5.5

Therefore, the 25th percentile is 5.5:

```
Smooth/M=0/MPCT=(percentile) 8, sortedData // 8-point smoothing window
Print sortedData[3] // prints 5.5, the 25th percentile of all 8 values
```

**Smoothing Window and End Effects Details**

These smoothing algorithms compute the output value for a given point using each point’s neighbors. Except for running-median smoothing, each algorithm combines neighboring points before and after the point being smoothed. At the start or end of a wave some points will not have enough neighbors so some method for fabricating neighbor values must be implemented. The /E flag specifies the method.

The running-median filter, however, ignores /E. At each end of the data fewer values are included in the median calculation, so that values “beyond” the end of data are not needed.
The first output value is the median of \[ \text{wave}_0, \text{floor}((\text{num}-1)/2) \]. For example, if \text{num} = 7, then the first output value is the median of \text{wave}[0], \text{wave}[1], \text{wave}[2], and \text{wave}[3]. Because that is an even number of points, the median is the average of the two middle values. Continuing the example, if the values were 3, 1, 7, and 5, the two middle values are 3 and 5. The computed median would be \((3+5)/2=4\).

Examples

Box smoothing example:

Make/N=100 wv; Display wv
wv=gnoise(1)
Smooth/B/E=3,wv  // output[p] = average of wv[p-1], wv[p] and wv[p+1]
   // /E=3 causes wv[0] = (wv[0]+wv[0]+wv[1])/3
   // and wv[n-1] = (wv[n-2]+wv[n-1]+wv[n-1])/3

Demonstrate the impulse response of Savitzky-Golay Smoothing:

Make/O/N=100 wv
wv= p==50  // 1 at center of wave, 0 elsewhere; an impulse
SetScale/P x, 0, 1/1000, "s", wv  // 1000 Hz sampling rate
Smooth/S=2 5,wv
Display wv
ModifyGraph mode=8,marker=19
FFT/MAG/DEST=fftMag wv
Display fftMag

Replace NaN with median:

Make/O/N=100 data= enoise(1)>.9 ? NaN : sin(x/8)  // signal with NaNs
Duplicate/O data, dataMedian
Smooth/M=(NaN) 5, dataMedian  // replace (only) NaNs with 5-point median

FilterFIR, FilterIIR, Loess, Interpolate2
Also see the “Smooth Operation Responses” example experiment.

SmoothCustom

SmoothCustom [/E=endEffect] coefsWaveName, waveName [, waveName]...

Note: SmoothCustom is obsolete. Use the FilterFIR operation instead. For multidimensional data use the MatrixConvolve or MatrixFilter operations.

The SmoothCustom operation smooths waves by convolving them with coefsWaveName.

Parameters
coopsWaveName must be single or double floating point, must not be one of the destination waveNames, must not be complex.
waveName is a numeric destination wave that is overwritten by the convolution of itself and coefsWaveName.

Flags
/E=endEffect End effect method, a value between 0 and 3. See the Smooth operation for a description of the /E flag.

Details
The convolution is in the time domain. That is, the FFT is not employed. For this reason the length of coefsWaveName should be small or small in comparison to the destination waves.

SmoothCustom presumes that the middle point of coefsWaveName corresponds to the delay = 0 point. The “middle” point number = trunc(numpnts(coefsWaveName-1)/2). coefsWaveName usually contains the two-sided impulse response of a filter, and contains an odd number of points. This is the type of wave created by FilterFIR.

SmoothCustom ignores the X scaling of all the waves.

The SmoothCustom operation is not multidimensional aware. See Analysis on Multidimensional Waves on page II-89 for details.

Sort

Sort [ /A /DIML /C /R ] sortKeyWaves, sortedWaveName [, sortedWaveName]...

The Sort operation sorts the sortedWaveNames by rearranging their Y values to put the data values of sortKeyWaves in order.

Parameters
sortKeyWaves is either the name of a single wave, to use a single sort key, or the name of multiple waves in braces, to use multiple sort keys.

All waves must be of the same length.

The sortKeyWaves must not be complex.

Flags
/A[=a] Alphanumeric sort. When sortKeyWaves includes text waves, the normal sorting places “wave1” and “wave10” before “wave9”.

The optional a parameter requires Igor Pro 7.00 or later.

Use /A or /A=1 to sort the number portion numerically, so that “wave9” is sorted before “wave10”.

Use /A=2 to ignore + and - characters in the text so that “Text-09” sorts before “Text-10”.

Note: SmoothCustom is obsolete. Use the FilterFIR operation instead. For multidimensional data use the MatrixConvolve or MatrixFilter operations.
SortColumns

/C Case-sensitive sort. When sortKeyWaves includes text waves, the sort is case-insensitive unless you use the /C flag to make it case-sensitive.

/DIML Moves the dimension labels with the values (keeps any row dimension label with the row's value).

/LOC Performs a locale-aware sort. When sortKeyWaves includes text waves, the text encoding of the text waves’ data is taken into account and sorting is done according to the sorting conventions of the current system locale. This flag is ignored if the text waves’ data encoding is unknown, binary, Symbol, or Dingbats. This flag cannot be used with the /A flag. See Details for more information.

The /LOC flag was added in Igor Pro 7.00.

/R Reversed sort; sort from largest to smallest.

Details

sortKeyWaves are not actually sorted unless they also appear in the list of destination waves. The sort algorithm does not maintain the relative position of items with the same key value.

When the /LOC flag is used, the bytes stored in the text wave at each point are converted into a Unicode string using the text encoding of the text wave data. These Unicode strings are then compared using OS specific text comparison routines based on the locale set in the operating system. This means that the order of sorted items may differ when the same sort is done with the same data under different operating systems or different system locales.

When /LOC is omitted the sort is done on the raw text without regard to the waves’ text encoding.

Examples

Sort/R myWave,myWave // sorts myWave in decreasing order
Sort xWave,xWave,yWave // sorts x wave in increasing order,
// corresponding yWave values follow.
Make/O/T myWave={"1st","2nd","3rd","4th"}
Make/O key1={2,1,1,1} // places 2nd, 3rd, 4th before 1st.
Make/O key2={0,1,3,2} // arranges 2nd, 3rd, 4th as 2nd, 4th, 3rd.
Sort {key1,key2},myWave // sorts myWave in increasing order by key1.
// For equal key1 values, sorted by key2.
// Result is myWave={"2nd","4th","3rd","1st"}
Make/O/T tw={"w1","w10","w9","w-2.1"}
Sort/A tw,tw // sorts tw in increasing number-aware order:
// Result is tw={"w-2.1","w1","w9","w10"}

FindDuplicates

SortColumns

SortColumns [flags] keyWaves={waveList}, sortWaves={waveList}

The SortColumns operation rearranges data in columns of the sortWaves using the data movements that would sort the values of the keyWaves if they were sorted.

The SortColumns operation was added in Igor Pro 7.00.

Parameters

keyWaves is a lists of 1 or more wave references in braces separated by commas. The first listed wave is the primary sort key, the second is the secondary sort key, and so on. The keyWaves list can contain a maximum of 10 waves. The key waves can be either text or real numeric waves but all key waves must be of the same type and have the same number of points. Complex waves, wave reference waves and data folder reference waves cannot be used as key waves.

sortWaves is a lists of one or more wave references in braces separated by commas. The sortWaves list can contain a maximum of 100 waves.
SortColumns

Flags

/A Alphanumeric sort.
When keyWaves includes text waves, or the /KNDX flag is used and the first wave in the sortWaves list is a text wave, the normal sorting places "wave1" and "wave10" before "wave9". Use /A to sort the number portion numerically, so that "wave9" is sorted before "wave10". /A cannot be used with the /LOC flag.

/C Case-sensitive sort. When keyWaves includes text waves, or the /KNDX flag is used and the first wave in the sortWaves list is a text wave, the sort is case-insensitive unless you use the /C flag to make it case-sensitive.

/DIML Moves the row dimension labels with the data values. Column dimension labels remain unchanged.

/KNDX=[c0, c1, ... c9]
Specifies up to 10 columns of the first wave in the sortWaves list to use as the sort keys. This flag and the keyWaves keyword are mutually exclusive. If this flag is used then the first wave in the sortWaves list must be either a real numeric or text wave.

/LOC Locale aware sort.
When keyWaves includes text waves, or the /KNDX flag is used and the first wave in the sortWaves list is a text wave, the text encoding of the text waves' data is taken into account and sorting is done according to the sorting conventions of the current system locale.

/LOC is ignored if the text waves' data encoding is unknown, binary, Symbol, or Dingbats.
/LOC can not be used with the /A flag.
See Details for more information.

/R Reverses the sort, sorting from largest to smallest.

Details
Waves in the keyWaves list are not actually sorted unless they also appear in the sortWaves list.
All waves must have the same number of rows but can have different numbers of columns, layers and chunks.
keyWaves, or the first wave in the sortWaves list when /KNDX is used, must be either numeric or text waves.
When the sortWaves list includes 3D or 4D waves, the operation sorts all columns of all layers/chunks.
The sorting algorithm used does not maintain the relative position of rows with the same key value.
When the /LOC flag is used, the bytes stored in the text wave at each point are converted into a Unicode string using the text encoding of the text wave data. These Unicode strings are then compared using OS-specific text comparison routines based on the current locale as set in the operating system. This means that the order of sorted items may differ when the same sort is done with the same data under different operating systems or different system locales.

Examples
// Define a function that creates sample data
Function CreateSampleData()
  Make/O key1={3,1,0,2}
  Make/O/T text1="Jack","Fred","Robin","Bob"
  Make/O w1={|{1,2,3,4},{11,12,13,14}}
End

// Create sample data and display in a table
CreateSampleData()
Edit key1,text1,w1

// Sort based on a numeric key
SortColumns keyWaves=key1,sortWaves=w1
SortList

SortList(listStr [, listSepStr [, options]])

The SortList function returns listStr after sorting it according to the default or listSepStr and options parameters. listStr should contain items separated by listSepStr, such as "the first item;second item;".

Use SortList to sort the items in a string containing a list of items separated by a string, such as those returned by functions like TraceNameList or WaveList, or a line of text from a delimited text file, where listSepStr can be "\r" or "\r\n".

listSepStr and options are optional; their defaults are ";" and 0 (ascending alphabetic sort), respectively.

Details
listStr is treated as if it ends with a listSepStr even if it doesn’t. The returned list will always have an ending listSepStr string.

In Igor6, SortList used only the first byte of listSepStr. As of Igor7, it uses the whole string.

options controls the sorting method, as follows:

0: Default sort (ascending case-sensitive alphabetic ASCII sort).
1: Descending sort.
2: Numeric sort.
4: Case-insensitive sort.
8: Case-sensitive alphanumeric sort.
16: Case-insensitive alphanumeric sort that sorts wave0 and wave9 before wave10.
32: Unique sort in which duplicates are removed. Added in Igor Pro 7.00.
64: Ignore + and - in the alphanumeric sort so that “Text-09” sorts before “Text-10”. Set options to 80 or 81. Added in Igor Pro 7.00.

options may also be a bitwise combination of these values with the following restriction: only one of 2, 4, 8, or 16 may be specified. Thus the legal values are thus 0, 1, 2, 3, 4, 5, 8, 9, 16, 17, 32, 33, 34, 35, 36, 40, 41, 48, 49, 80 or 81. Other values will produce undefined sorting.

In a case-insensitive, unique sort (options=4+32), if two items differ only in case, which one is retained is not specified.

Examples

// Alphabetic sorts
Print SortList("c;a;a;b") // prints "a;a;b;c;"
Print SortList("you,me,More", ",", 0) // prints "More,me,you,"
Print SortList("you,me,More", ",", 4) // prints "me,More,you,"
Print SortList("9,93,91,33,15,3", ",", 4) // prints "15,3,33,9,91,93,"
Print SortList("Zx;abc;All;", ",", 0) // prints "All;Zx;abc;"
Print SortList("Zx;abc;All;", ",", 8) // prints "abc;All;Zx;"
Print SortList("w9;w10;w02;", ",", 16) // prints "w02;w9;w10;"

// Unique sort
Print SortList("b;c;a;a;", ";", 32) // prints "a;b;c;"
SoundInRecord

The SoundInRecord operation records audio input at the sample rate obtained from the wave's X scaling and for the number of points determined by the length of the wave. The recording is done synchronously.

The number type of the wave must be one of the types reported by the SoundInStatus operation in the V_SoundInSampSize variable. On Windows this will typically be 8- or 16-bit integer while on Macintosh 16-bit integer and 32-bit floating point (the OS X native type) will be supported.

To record in stereo, provide a 2 column wave. (The software is designed to handle any number of channels but has not been tested on more than 2.)

Flags
/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

Details
SoundInRecord requires a computer with sound inputs. Several sample experiments using sound input can be found in your Igor Pro Folder in the Examples folder.

See Also
The SoundInSet, SoundInStartChart, and SoundInStatus operations.

SoundInSet

The SoundInSet operation is used to setup the input device for recording.

Parameters
SoundInSet can accept multiple keyword =value parameters on one line.

agc=a Turns automatic gain control mode on (a=1) or off (a=0). Will generate an error if device does not support setting agc. Use SoundInStatus to check or use /Z flag to make errors nonfatal.

Windows: This is not supported and V_SoundInAGC from the SoundInStatus command always returns -1.

gain=g Sets input gain, 0 is lowest gain and 1 is highest. Will generate an error if device does not support setting gain. Use SoundInStatus to check or use /Z flag to make errors nonfatal.

Windows: SoundInSet attempts to adjust the master gain of the sound input device but not all sound cards have a master gain. If V_SoundInGain from the SoundInStatus command returns -1, you will have to use your sound card software to adjust the input gain for the particular input source your are using. On some cards there are separate line-in and microphone-in sources.

Flags
/Z Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

Details
SoundInSet requires a computer with sound inputs. Several sample experiments using sound inputs are in your Igor Pro Folder in the Examples folder.
SoundInStartChart

See Also
The SoundInRecord, SoundInStartChart, and SoundInStatus operations.

**SoundInStartChart**

`SoundInStartChart [Z] buffersize, destFIFOname`

The SoundInStartChart operation starts audio data acquisition into the given FIFO.

**Parameters**

`buffersize` is the number of bytes to allocate for the interrupt time buffer which then feeds into the given Igor named FIFO `destFIFOname`. The FIFO must be set up with the correct number of channels and number type - use SoundInStatus to find legal values. The sample rate is read from the FIFO also, so that also needs to be correct.

**Flags**

`/Z` Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

**Details**

SoundInStartChart requires a computer with sound inputs. Several sample experiments using sound inputs are in your Igor Pro Folder in the Examples folder.

On systems where 32-bit floating point data is supported, you can use NewFIFOChan with no flags and a range of -1 to 1.

See Also
The SoundInRecord, SoundInSet, SoundInStatus and SoundInStopChart operations, and FIFOs and Charts on page IV-301.

SoundInStatus

**SoundInStatus**

The SoundInStatus operation creates and sets a set of variables and strings with information about the current sound input device. The variable V_flag is set to an error code and will be zero if the device is available. If not then none of the following are valid.

<table>
<thead>
<tr>
<th>Variables</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>S_SoundInName</td>
<td>String with name of device.</td>
</tr>
<tr>
<td>V_SoundInAGC</td>
<td>Automatic gain control on or off (1 or 0). This is an optional item and if</td>
</tr>
<tr>
<td></td>
<td>the current device does not support AGC then V_SoundInAGC will be set to</td>
</tr>
<tr>
<td></td>
<td>-1.</td>
</tr>
<tr>
<td>V_SoundInChansAv</td>
<td>Available number of channels (e.g., 1 for mono, 2 for stereo).</td>
</tr>
<tr>
<td>V_SoundInGain</td>
<td>Current input gain. Ranges from 0 (lowest) to 1. This is an optional item</td>
</tr>
<tr>
<td></td>
<td>and if the current device does not support gain then V_SoundInGain will</td>
</tr>
<tr>
<td></td>
<td>be set to -1.</td>
</tr>
<tr>
<td>V_SoundInSampSize</td>
<td>Bits set depending on number of bits available in a sample.</td>
</tr>
<tr>
<td></td>
<td>Bit 0: Set if can do 8 bits.</td>
</tr>
<tr>
<td></td>
<td>Bit 1: Set if can do 16 bits.</td>
</tr>
<tr>
<td></td>
<td>Bit 3: Set if 32-bit floating point is supported (range is -1 to 1).</td>
</tr>
<tr>
<td>W_SoundInRates</td>
<td>Wave containing sample rate info: if point zero contains zero then points</td>
</tr>
<tr>
<td></td>
<td>1 and 2 contain the lower and upper limits of a continuous range else</td>
</tr>
<tr>
<td></td>
<td>point zero contains the number of discrete rates which follow in the wave.</td>
</tr>
<tr>
<td></td>
<td>The usual rates are 44100 Hz and 4800 Hz.</td>
</tr>
</tbody>
</table>
See Also
The SoundInRecord, SoundInSet, and SoundInStartChart operations.

**SoundInStopChart**

**SoundInStopChart [/Z]**
The SoundInStopChart operation stops audio data acquisition started by SoundInStartChart.

**Flags**

/\_Z \hspace{1em} Errors are not fatal. V_flag is set to zero if no error, else nonzero if error.

**Details**

SoundInStopChart requires a computer equipped with sound input hardware.
Audio data acquisition also stops automatically when an experiment is closed.

See Also
The SoundInStartChart and SoundInStatus operations.

**SoundLoadWave**

**SoundLoadWave [flags] waveName [ ,fileNameStr ]**
The SoundLoadWave operation loads sound data from the named file into a wave. Mono, stereo, surround-sound, and high-resolution sound formats are supported.
The SoundLoadWave operation was added in Igor Pro 7.00.

**Parameters**

waveName is the name of the wave to load the sound into.

If fileNameStr is omitted or is "", SoundLoadWave displays an Open File dialog.

The file to be loaded is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If SoundLoadWave can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to choose the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-429 for details on forming the path.

**Flags**

/I [= filterStr] \hspace{1em} Force interactive mode. Use optional filter string to limit allowable file extensions. See Open File Dialog File Filters on page IV-143.

/O \hspace{1em} Overwrite existing waves in case of a name conflict.

/P=pathName \hspace{1em} Specifies the folder to load the file from. pathName is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd:\Folder1:" or "C:\\Folder1\". See Symbolic Paths on page II-21 for details.

/Q \hspace{1em} Quiet: Doesn’t print message to history area, and doesn’t abort, if the sound can not be loaded. V_Error is set to the returned error code, which will be zero if there was no error.

/S=(startT,endT) \hspace{1em} Load a subrange of the sound resource. startT and endT are in seconds, clipped to the duration of the loaded sound.

/TMOT= timeOut \hspace{1em} Aborts load if timeOut, in seconds, is exceeded.

**Details**

SoundLoadWave uses Core Audio on Macintosh and Qt framework calls on Windows. Note that some files can not be loaded due to digital rights managment issues even though they can be played.
SoundLoadWave

If `waveName` specifies a wave that does not exist, it is created. The wave is redimensioned to a wave type that maintains the numeric precision of the sound data. If the wave can not be created or resized to fit the loaded data then SoundLoadWave returns an error.

If `waveName` does exist, the wave is overwritten only if the /O flag is specified. Without the /O flag SoundLoadWave returns an error.

Multi-channel audio is loaded into sequential columns of the destination wave.

On Macintosh, Core Audio provides only 32-bit floating point data and that is the data type used for the wave. The BITS value in S_info, described below, may be zero for some formats.

On Windows, SoundLoadWave uses the smallest Igor wave data type that preserves the number of bits in the audio. Igor doesn't have a 24-bit data type, so these values are stored in a 32-bit integer wave.

**Output Variables**

SoundLoadWave sets these output variables:

- **V_flag**: Set to 1 if a sound is loaded and fits into available memory, 0 otherwise.
- **V_Error**: Set if /Q is specified, V_Error is set to a non-zero error code if something went wrong or to zero on success. Negative returned codes are system-dependent, positive are Igor-defined errors.
  
  V_Error = 1 means there wasn't enough memory to load the (uncompressed) sound.
- **S_path**: Set to the full file path of the loaded file, not including the file name.
- **S_fileName**: Set to the name of the loaded file.
- **S_waveNames**: Set to the name of loaded wave.
- **S_info**: Information about the loaded sound.

If the sound file exists, SoundLoadWave sets the string variable S_info to:

"FILE:nameOfFile;FORMAT:soundFileFormat;CHANNELS:numChannels;CHANNEL_LAYOUT:channelLayoutDescription;CHANNEL_ORDER:channelsList;BITS:numBits;SAMPLES:numSamples;RATE:samplesPerSec;"

The `soundFileFormat` and `channelLayoutDescription` values are text descriptions of the sound data in the file, and are written in the localized language. This information is available only on Macintosh and may or may not be present in a given sound file.

The `channelsList` value is a comma-separated list of channel names, always in English abbreviations, such as "L,R" or "L,R,C,LFE,Ls,Rs". The meaning of the abbreviations:

<table>
<thead>
<tr>
<th>channelList Abbreviation</th>
<th>Channel or Speaker Names</th>
</tr>
</thead>
<tbody>
<tr>
<td>L</td>
<td>Front Left</td>
</tr>
<tr>
<td>R</td>
<td>Front Right</td>
</tr>
<tr>
<td>C</td>
<td>Front Center</td>
</tr>
<tr>
<td>LFE</td>
<td>Low Frequency Effects</td>
</tr>
<tr>
<td>Ls</td>

<td>Rear Center Surround (Top Back Center)</td>
</tr>
<tr>
<td>Rs</td>
<td>Rear Right Surround (Top Back Right)</td>
</tr>
</tbody>
</table>

Examples

// Display an Open File dialog and load the chosen file.
// Use file's name for wave, overwrite any pre-existing wave, print information to history
SoundLoadWave/O myDestWave

// SoundLoadWave stores following in S_Info and prints it to the history area
FILE:<file name>;FORMAT:MPEG Layer 3;CHANNELS:2;BITS:0;SAMPLES:524416;RATE:44100;

// Rename the wave to a cleaned up version of the file name
Rename myDestWave, $CleanupName(S_fileName,1)

See Also
SoundSaveWave, PlaySound

SoundSaveWave

**SoundSaveWave [flags] typeStr, waveName [ , fileNameStr ]**

The SoundSaveWave operation saves the named wave on disk as an Audio Interchange File Format (AIFF-C) or Microsoft WAVE sound file. AIFF-C is primarily used on Macintosh.

The SoundSaveWave operation was added in Igor Pro 7.00.

**Parameters**

typeStr must be either "AIFC" or "WAVE".

fileNameStr contains the name of the file in which the named wave is saved. If you omit fileNameStr, SoundSaveWave uses the wave name with the appropriate extension.

The file to be written is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If SoundSaveWave can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-429 for details on forming the path.
The sound file is always an uncompressed AIFF-C or WAVE file, with as many channels as the wave contains columns.

The sound file format is determined by the wave’s data type. Signed 8-, 16- and 32-bit integers are supported as is 32-bit floating point. When writing floating point waves, the wave data should be scaled to +/- 1 as full scale.

**Output Variables**

SoundSaveWave sets these automatically created variables:

- **V_flag**: Set to 0 if the wave was successfully saved to the file or to a non-zero error code.
- **S_fileName**: Set to the name of the saved file.
- **S_path**: Set to the full path to the file’s directory.

**Examples**

```plaintext
// Create a simple sound (1000 Hz tone burst)
Make/O/N=10000 mySound // Single-precision wave, 10,000 values
SetScale/P x, 0, 1/8000, "" mySound // 8000 Hz sampling frequency (1.25 seconds)
mySound= sin(2*pi*1000*x) // 1000 Hz tone
Hanning mySound // Fade in and out

// Save it to a file, chosen from the Save File dialog
SoundSaveWave "AIFC", mySound, "my sound.aif"

// Create a floating point stereo frequency sweep
Make/O/N=(20000,2) stereoSineSoundF32 // 32-bit float data
SetScale/P x,0,1e-4,stereoSineSoundF32 // Set sample rate to 10KHz
stereoSineSoundF32= sin(2*Pi*(1000 + (1-2*q)*150*x)*x)
NewPath sound // Create a symbolic path via dialog
SoundSaveWave/P=sound/O "WAVE", stereoSineSoundF32
```

---

**SpecialCharacterInfo**

`SpecialCharacterInfo(notebookNameStr, specialCharacterNameStr, whichStr)`

The SpecialCharacterInfo function returns a string containing information about the named special character in the named notebook window.

**Parameters**

- **notebookNameStr**: If notebookNameStr is "", the top visible notebook is used. Otherwise notebookNameStr contains either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0#nb0. See Subwindow Syntax on page III-92 for details on host-child specifications.

- **specialCharacterNameStr**: If specialCharacterNameStr is "", and if exactly one special character is selected, the selected special character is used. If other than exactly one special character is selected, an error is returned.

---

**Flags**

- **/I**: Presents a Save File dialog in which you can specify the file to be saved.
- **/O**: Overwrites the file if it already exists.
- **/P=pathName**: Specifies the folder to store the file in. pathName is the name of an Igor symbolic path, created via NewPath. It is not a file system path like "hd:Folder1:" or "C:\Folder1". See Symbolic Paths on page II-21 for details.
- **/Q**: Suppresses the normal messages in the history area of the command window. At present nothing is written to the history even if /Q is omitted.

**Details**

The sound file is always an uncompressed AIFF-C or WAVE file, with as many channels as the wave contains columns.

The sound file format is determined by the wave’s data type. Signed 8-, 16- and 32-bit integers are supported as is 32-bit floating point. When writing floating point waves, the wave data should be scaled to +/- 1 as full scale.
whichStr identifies the information item you want. Because SpecialCharacterInfo can return several items that may contain semicolons, it does not return a semicolon-separated keyword-value list like other info functions. Instead it returns just one item as specified by whichStr.

Details
Here are the supported values for whichStr.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Returned Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>The name of the special character.</td>
</tr>
</tbody>
</table>
| FRAME     | 0: None
1: Single
2: Double
3: Triple
4: Shadow |
| LOC       | Paragraph and character position (e.g., 1,3). |
| SCALING   | Horizontal and vertical scaling in units of one tenth of a percent (e.g., 1000,1000). |
| TYPE      | Special character type is: Picture, Graph, Table, Layout, Action, ShortDate, LongDate, AbbreviatedDate, Time, Page, TotalPages, or WindowTitle. |
| WINTYPE   | 1 for graphs, 2 for tables, 3 for layouts. |
| OBJECTNAME| The name of the window with which the special character is associated. |
| BGRGB     | Background color in RGB format (e.g., 65535,65534,49151). |
| COMMANDS  | Command string. |
| ENABLEBGRGB| 1 if the action's background color is enabled, 0 if not. |
| HELPTEXT  | Help text string. |
| IGNOREERRORS| 0 or 1. |
| LINKSTYLE | 0 or 1. |
| PADDING   | The value of the left, right, top, bottom and internal padding properties, in that order (e.g., 4,4,4,4,8). |
| PICTURE   | 1 if the action has a picture, 0 if not. |
| PROCPICTNAME| The name of the action Proc Picture or " " if none. |
| QUIET     | 0 or 1. |
| SHOWMODE  | 1: Title only
2: Picture only
3: Picture below title
4: Picture above title
5: Picture to the left of title
6: Picture to the right of title |
| TITLE     | Title string. |

These keywords apply to Igor-object pictures only. If the specified character is not an Igor-object picture, "" is returned.

The remaining keywords apply to notebook action characters only. If the specified special character is not a notebook action character, " " is returned.
SpecialCharacterList

If `whichStr` is an unknown keyword, `SpecialCharacterInfo` returns "" but does not generate an error.

**Examples**

```
Function PrintSpecialCharacterInfo(notebookName, specialCharacterName)
    String notebookName, specialCharacterName
    String typeStr=SpecialCharacterInfo(notebookName, specialCharacterName, "TYPE")
    String locStr=SpecialCharacterInfo(notebookName, specialCharacterName, "LOC")
    Printf "TYPE: %s\r", typeStr
    Printf "LOC: %s\r", locStr
End
```

**See Also**

The Notebook and NotebookAction operations; the SpecialCharacterList function; Using Igor-Object Pictures on page III-18.

SpecialCharacterList

```SpecialCharacterList(notebookNameStr, separatorStr, mask, flags)```

The SpecialCharacterList function returns a string containing a list of names of special characters in a formatted text notebook.

**Parameters**

- `notebookNameStr`: If `notebookNameStr` is "", the top visible notebook is used. Otherwise `notebookNameStr` contains either kwTopWin for the top notebook window, the name of a notebook window or a host-child specification (an hcSpec) such as Panel0#nb0. See Subwindow Syntax on page III-92 for details on host-child specifications.
- `separatorStr`: should contain a single ASCII character, usually semicolon, to separate the names.
- `mask`: determines which types of special characters are included. `mask` is a bitwise parameter with values:
  - 1: Pictures including graphs, tables and layouts.
  - 2: Notebook actions.
  - 4: All other special characters such as dates and times.

or a bitwise combination of the above for more than one type. See Setting Bit Parameters on page IV-13 for details about bit settings.

- `flags`: is a bitwise parameter. Pass 0 to include all special characters or 1 to include only selected special characters. All other bits are reserved and should be passed as zero.

**Details**

Only formatted text notebooks have special characters. When called for a plain text notebook, `SpecialCharacterList` always returns "".

**Examples**

Print a list of all special characters in the top notebook:

```Print SpecialCharacterList("", ";", -1, 0)```

Print a list of notebook action characters in Notebook0:

```Print SpecialCharacterList("Notebook0", ";", 2, 0)```

Print a list of selected notebook action characters in Notebook0:

```Print SpecialCharacterList("Notebook0", ";", 2, 1)```

**See Also**

The Notebook and NotebookAction operations; the SpecialCharacterInfo function.

SpecialDirPath

```SpecialDirPath(dirIDStr, domain, flags, createDir)```

The SpecialDirPath function returns a full path to a file system directory specified by `dirIDStr` and `domain`. It provides a programmer with a way to access directories of special interest, such as the preferences directory and the desktop directory.
The path returned always ends with a separator character which may be a colon, backslash, or forward slash depending on the operating system and the flags parameter.

SpecialDirPath depends on operating system behavior. The exact path returned depends on the locale, the operating system, the specific installation, the current user, and possibly other factors.

**Parameters**

dirIDStr is one of the following strings:

- **"Packages"** Place for advanced programmers to put preferences for their procedure packages.
- **"Documents"** The OS-defined place for users to put documents.
- **"Preferences"** The OS-defined place for applications to put preferences.
- **"Desktop"** The desktop.
- **"Temporary"** The OS-defined place for applications to put temporary files.
- **"Igor Application"** The Igor installation folder. This is typically:

  `/Applications/Igor Pro X Folder (Macintosh)`

  or

  `C:\Program Files\WaveMetrics\Igor Pro X Folder (Windows)`

  where “X” is the major version number.

  Use only with domain = 0 (the current user).

- **"Igor Executable"** The folder containing the current Igor executable. On Macintosh, this is the path to the executable itself, not to the application bundle.

  Use only with domain = 0 (the current user).

  Requires Igor Pro 7.00 or later.

- **"Igor Preferences"** The folder in which Igor’s own preference files are stored.

- **"Igor Pro User Files"** A guaranteed-writable folder for the user to store their own Igor files, and to activate extensions, help, and procedure files by creating shortcuts or aliases in the appropriate subfolders. Use only with domain = 0 (the current user).

  This is the folder opened using the Show Igor Pro User Files menu item in the Help menu.

*domain* permits discriminating between, for example, the preferences folder for all users versus the preferences folder for the current user. It is supported only for certain *dirIDStrs*. It is one of the following:

- **0:** The current user (recommended value for most purposes).
- **1:** All users (may generate an error or return the same path as 0).
- **2:** System (may generate an error or return the same path as 1).

flags a bitwise parameter:

- **Bit 0:** If set, the returned path is a native path (Macintosh-style on Mac OS 9, Unix-style on Mac OS X, Windows-style on Windows). If cleared, the returned path is a Macintosh-style path regardless of the current platform. In most cases you should set this bit to zero since Igor accepts Macintosh-style paths on all operating systems. You must set this bit to one if you are going to pass the path to an external script.

  All other bits are reserved and must be set to zero.

See Setting Bit Parameters on page IV-13 for details about bit settings.
createDir is 1 if you want the directory to be created if it does not exist or 0 if you do not want it to be created. This flag will not work if the current user does not have sufficient privileges to create the specified directory. In almost all cases it is not needed, you can’t count on it, and you should pass 0.

Details
The domain parameter has no effect in most cases. In almost all cases you should pass 0 (current user) for this parameter. For values other than 0, SpecialDirPath might return an error which you must be prepared to handle.

In the event of an error, SpecialDirPath returns a NULL string and sets a runtime error code. You can check for an error like this:

```c
String fullPath = SpecialDirPath("Packages", 0, 0, 0)
Variable len = strlen(fullPath)    // strlen(NULL) returns NaN
if (numtype(len) == 2)    // fullPath is NULL?
    Print "SpecialDirPath returned error."
endif
```

Here is sample output from SpecialDirPath("Packages",0,0,0):

**Mac OS X**
hd:Users:<user>:Library:Preferences:WaveMetrics:Igor Pro X:Packages:

**Windows**
C:Documents and Settings:<user>:Application Data:WaveMetrics:Igor Pro X:Packages:

where <user> is the name of the current user and “X” is the major version number.

Example
For an example using SpecialDirPath, see **Saving Package Preferences** on page IV-244.

---

**sphericalBessJ**

`sphericalBessJ(n, x [, accuracy])`

The sphericalBessJ function returns the spherical Bessel function of the first kind and order \( n \).

\[
 j_n(x) = \sqrt{\frac{\pi}{2x}} J_{n+1/2}(x).
\]

For example:

\[
 j_0(x) = \frac{\sin(x)}{x}
\]

\[
 j_1(x) = \frac{\sin(x)}{x^2} - \frac{\cos(x)}{x}
\]

\[
 j_2(x) = \left(\frac{3}{x^3} - \frac{1}{x}\right)\sin(x) - \frac{3}{x^2}\cos(x).
\]

Details
See the **bessI** function for details on accuracy and speed of execution.

See Also
The **sphericalBessJD** and **sphericalBessY** functions.

---

**sphericalBessJD**

`sphericalBessJD(n, x [, accuracy])`

The sphericalBessJD function returns the derivative of the spherical Bessel function of the first kind and order \( n \).
sphericalBessY

sphericalBessY(n, x [, accuracy])
The sphericalBessY function returns the spherical Bessel function of the second kind and order \( n \).

\[
y_n(x) = \sqrt{\frac{\pi}{2x}} Y_{n+1/2}(x).
\]

\[
y_0(x) = -\frac{\cos(x)}{x}
\]

\[
y_1(x) = -\frac{\cos(x)}{x^2} - \frac{\sin(x)}{x}
\]

\[
y_2(x) = \left(\frac{1}{x} - \frac{3}{x^3}\right)\cos(x) - \frac{3}{x^2}\sin(x).
\]

References

**SphericalInterpolate**

**SphericalInterpolate** *triangulationDataWave*, *dataPointsWave*, *newLocationsWave*

The SphericalInterpolate operation works in conjunction with the SphericalTriangulate operation to calculate interpolated values on a surface of a sphere. Given a set of \( \{x_i, y_i, z_i\} \) points on the surface of a sphere with their associated values \( \{v_i\} \), the SphericalTriangulate operation performs the Delaunay triangulation and creates an output that is used by the SphericalInterpolate operation to calculate values at any other point on the surface of a sphere. The interpolation calculation uses Voronoi polygons to weigh the contribution of the nearest neighbors to any given location on the sphere.

**Parameters**
*triangulationDataWave* is a 13 column wave that was created by the SphericalTriangulate operation.
*dataPoints* is a 4 column wave. The first 3 columns are the \( \{x_i, y_i, z_i\} \) locations that were used to create the triangulation, and the last column corresponds to the \( \{v_i\} \) values at the triangulation locations.
*newLocationsWave* is a 3 column wave that specifies the x, y, z locations on the sphere at which the interpolated values are calculated. Note that internally, each triplet is normalized to a point on the unit sphere before it is used in the interpolation.

**Details**
You will always need to use the SphericalTriangulate operation first to generate the *triangulationDataWave* input for this operation.

The result of the operation are put in the wave W_SphericalInterpolation.

See Also
The SphericalTriangulate operation.

Demo
Choose File→Example Experiments→Analysis→SphericalTriangulationDemo.

**SphericalTriangulate**

**SphericalTriangulate** [/Z] *tripletWaveName*

The SphericalTriangulate operation triangulates an arbitrary XYZ triplet wave on a surface of a sphere.

It starts by normalizing the data to make sure that \( \sqrt{x^2+y^2+z^2}=1 \), and then proceeds to calculate the Delaunay triangulation.

**Flags**
/Z No error reporting.

**Details**
The result of the triangulation is the wave M_SphericalTriangulation. This 13 column wave is used in SphericalInterpolate to obtain the interpolated values.

**Example**
// Generates output waves that can be used in Gizmo to display the triangulation.
// triangulationData is the M_TriangulationData output from SphericalTriangulation.
// tripletWave is the source wave input to SphericalTriangulation.
// Output wave sphereTrianglesPath can be used to display the triangulation as a path.
// Output wave sphereTrianglesSurf can be used to display the triangulation as a surface.
Function BuildTriangleWaves(triangulationData, tripletWave)
    Wave triangulationData, tripletWave

    // Extract 3 columns from triangulationData that contain the index of the row.
    Duplicate/O/FREE/rs[] [1,3] triangulationData, triIndices
    Variable finalNumTriangles = dimSize(triIndices, 0), i, j, k

    // Initialize both waves to NaN so any unassigned point would appear as a hole.
    Make/O/N=(5*finalNumTriangles, 3) sphereTrianglesPath=NaN
    Make/O/N=(3*finalNumTriangles, 3) sphereTrianglesSurf=NaN

    // Assign the values of the vertices to the two waves:
    Variable rowIndex, rowIndex0, outRowCount = 0, outcount2 = 0
    for (i=1; i<finalNumTriangles; i+=1)
        for (j=0; j<3; j+=1)
            for (k=0; k<3; k+=1)
                sphereTrianglesPath[outRowCount][k] = tripletWave[rowIndex][k]
                sphereTrianglesSurf[outcount2][k] = tripletWave[rowIndex][k]
        endfor
        outRowCount += 1
        outcount2 += 1
    endfor

    // Close the triangle path by returning to the first vertex:
    rowIndex0 = triIndices[i][0]
    sphereTrianglesPath[outRowCount][0] = tripletWave[rowIndex0][0]
    sphereTrianglesPath[outRowCount][1] = tripletWave[rowIndex0][1]
    sphereTrianglesPath[outRowCount][2] = tripletWave[rowIndex0][2]
    outRowCount += 2 // Increment row count and skip the NaN
    endfor
End

See Also
The SphericalInterpolate operation.

Demo
Choose File→Example Experiments→Analysis→SphericalTriangulationDemo.

SplitString

SplitString /E=regExprStr str [, substring1 [, substring2,... substringN]]

The SplitString operation uses the regular expression regExprStr to split str into subpatterns. See Subpatterns on page IV-181 for details. Each matched subpattern is returned sequentially in the corresponding substring parameter.

Parameters
str is the input string to be split into subpatterns.

The substring1...substringN output parameters must be the names of existing string variables if you need to use the matched subpatterns. The first matched subpattern is returned in substring1, the second in substring2, etc.

Flags
/E=regExprStr  Specifies the Perl-compatible regular expression string containing subpattern definition(s).

Details
regExprStr is a regular expression with successive subpattern definitions, such as shown in the examples. (Subpatterns are regular expressions within parentheses.)
For unmatched subpatterns, the corresponding substring is set to "". If you specify more substring parameters than subpatterns, the extra parameters are also set to "".
The number of matched subpatterns is returned in V_flag.
The part of str that matches regExprStr (often all of str) is stored in S_value.
SplitWave

Examples

// Split the output of the date() function:
Print date()
  Mon, May 2, 2005
String expr="([[:alpha:]]+), ([[:alpha:]]+), ([[:digit:]]+), ([[:digit:]]+)"
String dayOfWeek, monthName, dayNumStr, yearStr
SplitString/E=(expr) date(), dayOfWeek, monthName, dayNumStr, yearStr
Print V_flag
4
Print dayOfWeek
  Mon
Print monthName
  May
Print dayNumStr
  2
Print yearStr
  2005
Print S_value
  Mon, May 2, 2005

// Get the part of str that matches regExprStr
SplitString/E=",.\*," "stuff in front,second value,stuff at end"
Print S_value
  ,second value,

See Also
Regular Expressions on page IV-170 and Subpatterns on page IV-181.

sscanf, Grep, strsearch, str2num, RemoveEnding, TrimString

SplitWave

SplitWave [flags] srcWave
The SplitWave operation creates new waves containing subsets of the data in srcWave which must be 2D or greater.
The newly generated waves have lower dimensionality than srcWave. The operation is ideal for splitting 2D waves into constituent columns, 3D waves into their layers, etc.
Added in Igor Pro 7.00.

Flags

/DDF=destDataFolder Specifies the data folder where the generated waves are created. If the data folder does not exist the operation creates it. If the /DDF flag is not used, output goes into the current data folder.

/FREE Generates free output waves. The /OREF flag must also be used when the /FREE flag is used. When you use this flag there is no need to use either /N or /NAME.

/N=baseName Provides the base name for all output waves. The waves will be named sequentially, i.e., baseName0, baseName1...

/NAME=strList strList is a semicolon-separated list of wave names to be used as the names of the output waves.
If strList contains fewer names than the number needed, the operation terminates and returns an error.
If the output data folder is the data folder containing srcWave then strList must not contain the name of srcWave.
Only simple names, not full paths, are allowed in strList.

/NOTE Copies the wave note, if any, from srcWave to the output waves. The /NOTE flag was added in Igor Pro 8.00.

/O Permits overwriting of existing destination waves. Overwriting srcWave is not permitted.
### Details
The SplitWave operation is in some ways the inverse of the Concatenate operation. srcWave is decomposed into waves of lower dimensionality.

Splitting a 2D 10x15 wave results in 15 waves of 10 rows each.

Splitting a 3D 10x15x4 using /SDIM=2 results in 4 2D waves of dimension 10x15.

Splitting a 3D 10x15x4 using /SDIM=1 results in 60 1D waves of 10 rows each.

The SplitWave operation works on all wave types. srcWave must be 2D or greater.

The operation creates the string variable S_waveNames which contains a semicolon separated list of the names of the output waves. However if you use /FREE then S_waveNames will be empty as free waves can not be accessed by name; use /OREF to access the created waves.

#### Examples
```plaintext
// Create sample input
Make/N=(5,4,3,2) wave1 = p + 10*q + 100*r + 1000*s

// Split chunks into 2 3D waves and store them in data folder Chunks
SplitWave/DDF=Chunks/N=chunk wave1

// Split layers into 6 2D waves and store them in data folder Layers
SplitWave/DDF=Layers/N=Layers/SDIM=2 wave1

// Split into 24 1D waves and store them in data folder Columns
SplitWave/DDF=Columns/N=Columns/SDIM=1 wave1
```

### sprintf

`sprintf stringName, formatStr [, parameter]`...

The sprintf operation is the same as printf except it prints the formatted output to the string variable `stringName` rather than to the history area.

#### Parameters
- `formatStr` See printf.
- `parameter` See printf.
- `stringName` Results are “printed” into the named string variable.

#### See Also
The printf operation for complete format and parameter descriptions and Creating Formatted Text on page IV-252.
**sqrt**

sqrt(num)

The sqrt function returns the square root of num or NaN if num is negative.

In complex expressions, num is complex, and sqrt(num) returns the complex value x + iy.

**sscanf**

sscanf scanStr, formatStr, var [, var]

The sscanf operation is useful for parsing text that contains numeric or string data. It is based on the C sscanf function and provides a subset of the features available in C.

Here is a trivial example:

Variable v1
sscanf "Value= 1.234", "Value= %f", v1

This skips the text “Value=” and the following space and then converts the text “1.234” (or whatever number appeared there) into a number and stores it in the local variable v1.

The sscanf operation sets the variable V_flag to the number of values read. You can use this as an initial check to see if the scanStr is consistent with your expectations.

**Note:** The sscanf operation is supported in user functions only. It is not available using the command line, using a macro, or using the Execute operation.

**Parameters**

scanStr contains the text to be parsed.

formatStr is a format string which describes how the parsing is to be done.

formatStr is followed by the names of one or more local numeric or string variables or NVARs (references to global numeric variables) or SVARs (references to global string variables), which are represented by var above.

sscanf can handle a maximum of 100 var parameters.

**Details**

The format string consists of the following:

- Normal text, which is anything other than a percent sign (“%”) or white space.
- White space (spaces, tabs, linefeeds, carriage returns).
- A percent (“%”) character, which is the start of a conversion specification.

The trivial example illustrates all three of these components.

Variable v1
sscanf "Value= 1.234", "Value= %f", v1

sscanf attempts to match normal text in the format string to the identical normal text in the scan string. In the example, the text “Value=” in the format string skips the identical text in the scan string.

sscanf matches a single white space character in the format string to 0 or more white space characters in the scan string. In the example, the single space skips the single space in the scan string.

When sscanf encounters a percent character in the format string, it attempts to convert the corresponding text in the scan string into a number or string, depending on the conversion character following the percent, and stores the resulting number or string in the corresponding variable in the parameter list. In the example, “%f” converts the text “1.234” into a number which it stores in the local variable v1.

A conversion specification consists of:

- A percent character (“%”).
- An optional “*”, which is a conversion suppression character.
- An optional number, which is a maximum field width.
- A conversion character, which specifies how to interpret text in the scan string.

Don’t worry about the suppression character and the maximum width specification for now. They will be explained later.
The `sscanf` operation supports a subset of the conversion characters supported by the C `sscanf` operation. The supported conversion characters, which are case-sensitive, are:

- **d** Converts text representing a decimal number into an integer numeric value.
- **i** Converts text representing a decimal, octal or hexadecimal number into an integer value. If the text starts with “0x” (zero-x), it is interpreted as hexadecimal. Otherwise, if it starts with “0” (zero), it is interpreted as octal. Otherwise it is interpreted as decimal.
- **o** Converts text representing an octal number into an integer numeric value.
- **u** Converts text representing an unsigned decimal number into an integer numeric value.
- **x** Converts text representing a hexadecimal number into an integer numeric value.
- **c** Converts a single character into an integer value which is the ASCII code representing that character.
- **e** Converts text representing a decimal number into a floating point numeric value.
- **f** Same as e.
- **g** Same as e.
- **s** Stores text up to the next white space into a string.
- **[** Stores text that matches a list of specific characters into a string. The list consists of the characters inside the brackets (“%[abc]”). If the first character is “^”, this means to match any character that is not in the list. You can specify a range of characters to match. For example “% [A-Z] ” matches all of the upper case letters and “% [A-Za-z] ” matches all of the upper and lower case letters.

Here are some simplified examples to illustrate each of these conversions.

Variable v1
String s1

**Convert text representing a decimal number to an integer value:**

```c
sscanf "1234", "%d", v1
```

**Convert text representing a decimal, octal, or hexadecimal number:**

```c
sscanf "1.234", "%i", v1 // Convert from decimal.
sscanf "01234", "%i", v1 // Convert from octal.
sscanf "0x123", "%i", v1 // Convert from hex.
```

**Convert text representing an octal number:**

```c
sscanf "1234", "%o", v1
```

**Convert text representing an unsigned decimal number:**

```c
sscanf "1234", "%u", v1
```

**Convert text representing a hexadecimal number:**

```c
sscanf "1FB9", "%x", v1
```

**Convert a single ASCII character:**

```c
sscanf "A", "%c", v1
```

**Convert text representing a decimal number to a floating point value:**

```c
sscanf "1.234", "%e", v1
sscanf "1.234", "%f", v1
sscanf "1.234", "%g", v1
```

**Copy a string of text up to the first white space:**

```c
sscanf "Hello There", "%s", s1
```

**Copy a string of text matching the specified characters:**

```c
sscanf "+4.27", "%[+-]", s1
```

In a C program, you will sometimes see the letters “l” (ell) or “h” between the percent and the conversion character. For example, you may see “%lf” or “%hd”. These extra letters are not needed or tolerated by Igor’s `sscanf` operation.
When sscanf matches the format string to the scan string, it reads from the scan string until a character that would be inappropriate for the section of the format string that sscanf is trying to match. In the following example, sscanf stops reading characters to be converted into a number when it hits the first character that is not appropriate for a number.

```c
Variable v1
String s1, s2
sscanf "1234Volts DC", "%d%s %s", v1, s1, s2
```

sscanf stops matching text for "%d" when it hits "V" and stores the converted number in v1. It stops matching text for the first "%s" when it hits white space and stores the matched text in s1. It then skips the space in the scan string because of the corresponding space in the format string. Finally, it matches the remaining text to the second "%s" and stores the text in s2.

The maximum field width must appear just before the conversion character ("d" in this case).

```c
Variable v1, v2
sscanf "12349876", "%4d%4d", v1, v2
```

The suppression character ("*") is used in a conversion specification to skip values in the scan string. It parses the value, but sscanf does not store the value in any variable. In the following example, we read one number into local variable v1, skip a colon, and read another number into local variable v2, skip a colon, and read another number into local variable v3.

```c
Variable v1, v2, v3
sscanf "12:30:45", "%d%*:d%*:d", v1, v2, v3
```

Here ("%*:d") means "read a colon character but don't store it anywhere". The "*" character must appear immediately after the percent. Note that there is nothing in the parameter list corresponding to the suppressed strings.

If the text in the scan string is not consistent with the text in the format string, sscanf may not read all of the values that you expected. You can check for this using the V_flag variable, which is set to the number of values read. This kind of inconsistency does not cause sscanf to return an error to Igor, which would cause procedure execution to abort. It is a situation that you can deal with in your procedure code.

The sscanf operation returns the following kinds of errors:

- Out-of-memory.
- The number of parameters implied by formatStr does not match the number of parameters in the var list.
- formatStr calls for a numeric variable but the parameter list expects a string variable.
- formatStr calls for a string variable but the parameter list expects a numeric variable.
- formatStr includes an unsupported, unknown or incorrectly constructed conversion specification.
- The var list references a global variable that does not exist.

**Examples**

Here is a simple example to give you the general idea:

```iog
Function SimpleExample()
    Variable v1, valuesRead
    sscanf "Value=1.234", "Value=%g", v1
    valuesRead = V_flag
    if (valuesRead != 1)
        Printf "Error: Expected 1 value, got %d values\r", valuesRead
    else
        Printf "Value read = %g\r", v1
    endif
End
```

For an example that uses sscanf to load data from a text file, choose File→Example Experiments→Programming→Load File Demo.

Stack

Stack [flags] [objectName] [, objectName]...

The Stack operation stacks the named layout objects in the top page layout.

Parameters

objectName is the name of a graph, table, picture or annotation object in the top page layout.

Flags

/A=(rows,cols) /I /O=objTypes /S
/G=grout /M /R /W=(left,top,right,bottom)

See Also

The Tile operation for details on the flags and parameters.

StackWindows

StackWindows [flags] [windowName] [, windowName]...

The StackWindows operation stacks the named windows on the desktop.

Flags

/A=(rows,cols) /G=grout /O=objTypes /P /W=(left,top,right,bottom)
/C /I /M /R

See Also

See the TileWindows operation for details on the flags and parameters.

StartMSTimer

StartMSTimer

The StartMSTimer function creates a new microsecond timer and returns a timer reference number.

Details

You can create up to ten different microsecond timers using StartMSTimer. A valid timer reference number is a number between 0 and 9. If StartMSTimer returns -1, there are no free timers available. StartMSTimer works in conjunction with StopMSTimer.

See Also

StopMSTimer, ticks, DateTime

Static

Static constant objectName = value
Static strconstant objectName = value
Static Function funcName()
Static Structure structureName
Static Picture pictName

The Static keyword specifies that a constant, user-defined function, structure, or Proc Picture is local to the procedure file in which it appears. Static objects can only be used by other functions; they cannot be accessed from macros; they cannot be accessed from other procedure files or from the command line.

See Also

Static Functions on page IV-103, Proc Pictures on page IV-57, and Constants on page IV-52.

StatsAngularDistanceTest

StatsAngularDistanceTest [flags] [srcWave1, srcWave2, srcWave3...]

The StatsAngularDistanceTest operation performs nonparametric tests on the angular distance between sample data and reference directions for two or more samples in individual waves. The angular distance is the shortest distance between two points on a circle (in radians). Specify the sample waves using /WSTR or by listing them following the flags. Set reference directions with /ANG, /ANGW, or the sample mean direction.
StatsAngularDistanceTest

Flags

/ALPH=val
Sets the significance level (default 0.05).

/ANG=[d1, d2]
Sets reference directions (in radians) for two samples; for more than two samples use /ANGW.

/ANGM
Computes the mean direction of each sample and uses it as the reference direction.

/ANGW=dWave
Sets reference directions (in radians) for more than two samples using directions in dWave, which must be single or double precision.

/APRX=m
Controls the approximation method for computing the P-value in the case of two samples (Mann-Whitney Wilcoxon). See StatsWilcoxonRankTest for more details. The default value is 0, which may require long computation times if your sample size is large. Use /APRX=1 if you have a large sample and you expect ties in the data.

/Q
No results printed in the history area.

/T=k
Displays results in a table. k specifies the table behavior when it is closed.

/TAIL=tail
tail is a bitwise parameter that specifies the tails tested.

/WSTR=waveListString
Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.

/Z
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

The inputs for StatsAngularDistanceTest are two or more waves each corresponding to individual sample. The waves must be single or double precision expressing the angles in radians. There is no restriction on the number of points or dimensionality of the waves but the data should not contain NaNs or INFs. We recommend that you use double precision waves, especially if there are ties in the data. The reference directions should also be in radians. For two samples, StatsAngularDistanceTest computes the angular distances between the input data and the reference directions and then uses the Mann-Whitney-Wilcoxon test (StatsWilcoxonRankTest). Results are stored in the W_WilcoxonTest wave and in the corresponding table. For more than two samples, StatsAngularDistanceTest uses the Kruskal-Wallis test, storing results in the wave W_KWTestResults wave in the current data folder.

References

See, in particular, Chapter 27 of:

See Also

Chapter III-12, Statistics for a function and operation overview; StatsWilcoxonRankTest and StatsKWTest.
StatsANOVA1Test

StatsANOVA1Test [flags] [wave1, wave2,... wave100]
The StatsANOVA1Test operation performs a one-way ANOVA test (fixed-effect model). The standard ANOVA test results are stored in the M_ANOVA1 wave in the current data folder.

Flags

/ALPH=val Sets the significance level (default 0.05).

/BF Performs the Brown and Forsythe test computing F'' and degrees of freedom. The W_ANOVA1BnF wave in the current data folder contains the output.

/Q No results printed in the history area.

/T=k Displays results in a table; additional tables are created with /BF and /W.

k specifies the table behavior when it is closed.

k=0: Normal with dialog (default).
k=1: Kills with no dialog.
k=2: Disables killing.

/W Performs the Welch test F' and computes degrees of freedom. The W_ANOVA1Welch wave in the current data folder contains the output.

/WSTR=waveListString Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.

/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

Inputs to StatsANOVA1Test are two or more 1D numerical waves containing (one wave for each group of samples). Use NaN for missing entries or use waves with different numbers of points. The standard ANOVA results are in the M_ANOVA1 wave with corresponding row and column labels. Use /T to display the results in a table. In each case you will get the two degrees of freedom values, the F value, the critical value Fc for the choice of alpha and the degrees of freedom, and the P-value for the result. V_flag will be set to -1 for any error and to zero otherwise.

In some cases the ANOVA test may not be appropriate. For example, if groups do not exhibit sufficient homogeneity of variances. Although this may not be fatal for the ANOVA test, you may get more insight by performing the variances test in StatsVariancesTest.

If there are only two groups this test should be equivalent to StatsTTest.

You can evaluate the power of an ANOVA test for a given set of degrees of freedom and noncentrality parameter using:

\[
power = 1 - StatsNCFCDF(StatsInvFCDF((1 - \alpha), n1, n2), n1, n2, \delta)\]

Here \(n1\) is the Groups' degrees of freedom, \(n2\) is the Error degrees of freedom, and \(\delta\) is the noncentrality parameter. For more information see ANOVA Power Calculations Panel and the associated example experiment.

References

Chapter III-12, Statistics for a function and operation overview; StatsVariancesTest, StatsTTest, StatsNCFCDF, and StatsInvFCDF.
StatsANOVA2NRTest

**StatsANOVA2NRTest [flags] srcWave**

The StatsANOVA2NRTest operation performs a two-factor analysis of variance (ANOVA) on the data that has no replication where there is only a single datum for every factor level. *srcWave* is a 2D wave of any numeric type. Output is to the M_ANOVA2NRResults wave in the current data folder or optionally to a table.

**Flags**

* /ALPH=val*  
Sets the significance level (default 0.05).

* /FOMD*  
Estimates one missing value. You will also have to use a single or double precision wave for *srcWave* and designate the single missing value as NaN. The estimated value is printed to the history as well as the bias used to correct the sum of the squares of factor A.

* /INT=val*  
Sets the degree of interactivity.

Sets the degree of interactivity.

* val=0:*  
No interaction between the factors (default).

* val=1:*  
Significant interaction effect between factors.

Combination with /MODL determines which factors to test:

<table>
<thead>
<tr>
<th>val</th>
<th>Model 1</th>
<th>Model 2</th>
<th>Model 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>A&amp;B</td>
<td>A</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>A&amp;B</td>
<td>A&amp;B</td>
<td>A&amp;B</td>
</tr>
</tbody>
</table>

As indicated in the table, factor B is not tested for significant interaction under Model 3 and neither factor A nor factor B are tested for Model 1. If you are willing to accept an increase in Type II error you can obtain the relevant values by specifying Model 2. None of the models support a test for interaction A x B.

* /MODL=m*  
Sets the model number.

* m=1:*  
Factor A and factor B are fixed.

* m=2:*  
Both factors are random.

* m=3:*  
Factor A is fixed and factor B is random (default).

* /Q*  
No results printed in the history area.

* /T=k*  
Displays results in a table. *k* specifies the table behavior when it is closed.

* k=0:*  
Normal with dialog (default).

* k=1:*  
Kills with no dialog.

* k=2:*  
Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

* /Z*  
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

**Details**

Input to StatsANOVA2NRTest is a 2D wave in which the Factor A corresponds to rows and Factor B corresponds to columns. H0 provides that there is no difference in the means of the respective populations, i.e., if H0 is rejected for Factor A but accepted for Factor B that means that there is no difference in the means of the columns but the means of the rows are different.

NaN and INF entries are not supported although you may use a single NaN value in combination with the /FOMD flag. If *srcWave* contains dimension labels they will be used to designate the two factors in the output.

The contents of the M_ANOVA2NRResults output wave columns are as follows:
The variable V_flag is set to zero if the operation succeeds or to -1 otherwise.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsANOVA1Test and StatsANOVA2Test.

StatsANOVA2RMTest

StatsANOVA2RMTest [flags] srcWave

The StatsANOVA2RMTest operation performs analysis of variance (ANOVA) on srcWave where replicates consist of multiple measurements on the same subject (repeated measures). srcWave is a 2D wave of any numeric type. Output is to the M_ANOVA2RMResults wave in the current data folder or optionally to a table.

Flags

/ALPH=val Sets the significance level (default 0.05).
/Q No results printed in the history area.
/T=k Displays results in a table. k specifies the table behavior when it is closed.
    k=0: Normal with dialog (default).
    k=1: Kills with no dialog.
    k=2: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

Input to StatsANOVA2RMTest is the 2D srcWave in which the factor A (Groups) are columns and the different subjects are rows. It does not support NaNs or INFs.

The contents of the M_ANOVA2RMResults output wave columns are: the first contains the sum of the squares (SS) values, the second contains the degrees of freedom (DF), the third contains the mean square (MS) values, the fourth contains the single F value for this test, the fifth contains the critical F value for the specified alpha and degrees of freedom, and the last column contains the conclusion with 0 to reject H0 or 1 to accept it. In each case H0 corresponds to the mean level, which is the same for all subjects.

V_flag will be set to -1 for any error and to zero otherwise.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsANOVA2RTTest and StatsANOVA2Test.

StatsANOVA2Test

StatsANOVA2Test [flags] srcWave

The StatsANOVA2Test operation performs a two-factor analysis of variance (ANOVA) on srcWave. Output is to the M_ANOVA2Results wave in the current data folder or optionally to a table.
StatsBetaCDF

Flags

/ALPH=val  Sets the significance level (default 0.05).

/FAKE=num  Specifies the number of points in srcWave obtained by “estimation”. num is subtracted from the total and error degrees of freedom.

/MODL=m  Sets the model number.

m=1:  Factor A and factor B are fixed.

m=2:  Both factors are random.

m=3:  Factor A is fixed and factor B is random (default).

/Q  No results printed in the history area.

/T=k  Displays results in a table. k specifies the table behavior when it is closed.

k=0:  Normal with dialog (default).

k=1:  Kills with no dialog.

k=2:  Disables killing.

/Z  Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

Input to StatsANOVA2Test is the single or double precision 3D srcWave in which the factor A levels are columns, the factor B levels are rows, and the replicates are layers. If srcWave contains dimension labels they will be used to designate the factors in the output.

Ideally, the number of replicates must be equal for each factor and each level. StatsANOVA2Test supports both equal replication and proportional replication. Proportional replication allows for different number of data in each cell with missing data represented as NaN and the number of points in each cell is given by

\[ N_{ij} = \frac{\text{sum of data in row } i \times \text{sum of data in column } j}{\text{number of samples}}. \]

If you have no replicates (a single datum per cell) use StatsANOVA2NRTest instead. If the number of replicates in your data does not satisfy these conditions you may be able to “estimate” additional replicates using various methods. In that case use the /FAKE flag so that the operation can account for the estimated data by reducing the total and error degrees of freedom. /FAKE only accounts for the number of estimates being used. You must provide an appropriate number of estimated values.

The contents of the M_ANOVA2Results output wave columns are: the first contains the sum of the squares (SS) values, the second the degrees of freedom (DF), the third contains the mean square (MS) values, the fourth contains the computed F value for this test, the fifth contains the critical Fc value for the specified alpha and degrees of freedom, and the last contains the conclusion with 0 to reject H0 or 1 to accept it. In each case H0 corresponds to the mean level, which is the same for all populations.

V_flag will be set to -1 for any error and to zero otherwise.

StatsBetaCDF

StatsBetaCDF(x, p, q [, a, b])

The StatsBetaCDF function returns the beta cumulative distribution function

\[ F(x,p,q,a,b) = \frac{1}{B(p,q)} \int_0^{x-a/b} t^{p-1}(1-t)^{q-1} dt, \quad p,q > 0 \]

\[ a \leq x \leq b \]

where \( B(p,q) \) is the beta function
The defaults \((a=0\) and \(b=1\)) correspond to the standard beta distribution where \(a\) is the location parameter, \((b-a)\) is the scale parameter, and \(p\) and \(q\) are shape parameters.

**References**

See Also
Chapter III-12, *Statistics* for a function and operation overview; StatsBetaPDF and StatsInvBetaCDF.

**StatsBetaPDF**

*StatsBetaPDF*(\(x,\ p,\ q\ [,\ a,\ b]\))

The StatsBetaPDF function returns the beta probability distribution function

\[
f(x; p,q,a,b) = \frac{(x-a)^{p-1} (b-x)^{q-1}}{B(p,q)(b-a)^{p+q-1}}, \quad a \leq x \leq b
\]

where \(B(p,q)\) is the beta function

\[
B(p,q) = \int_0^1 t^{p-1} (1-t)^{q-1} \, dt.
\]

The defaults \((a=0\) and \(b=1\)) correspond to the standard beta distribution where \(a\) is the location parameter, \((b-a)\) is the scale parameter, and \(p\) and \(q\) are shape parameters. When \(p<1\), \(f(x=a)\) returns \(\infty\).

**References**

See Also
Chapter III-12, *Statistics* for a function and operation overview; StatsBetaCDF and StatsInvBetaCDF.

**StatsBinomialCDF**

*StatsBinomialCDF*(\(x,\ p,\ N\))

The StatsBinomialCDF function returns the binomial cumulative distribution function

\[
F(x; p,N) = \sum_{i=1}^{x} \left( \begin{array}{c} N \\ i \end{array} \right) p^i (1-p)^{N-i}, \quad x = 1, 2, \ldots
\]

where

\[
\left( \begin{array}{c} N \\ i \end{array} \right) = \frac{N!}{i!(N-i)!}.
\]

See Also
Chapter III-12, *Statistics* for a function and operation overview; StatsBinomialCDF and StatsBinomialPDF.

**StatsBinomialPDF**

*StatsBinomialPDF*(\(x,\ p,\ N\))

The StatsBinomialPDF function returns the binomial probability distribution function
StatsCauchyCDF

\[ f(x; p, N) = \binom{N}{x} p^x (1 - p)^{N-x}, \quad x = 0, 1, 2, \ldots \]

where

\[ \binom{N}{x} = \frac{N!}{x!(N-x)!}. \]

is the probability of obtaining \( x \) good outcomes in \( N \) trials where the probability of a single successful outcome is \( p \).

Chapter III-12, Statistics for a function and operation overview; StatsBinomialCDF and StatsInvBinomialCDF.

StatsCauchyCDF

\( \text{StatsCauchyCDF} (x, \mu, \sigma) \)

The StatsCauchyCDF function returns the Cauchy-Lorentz cumulative distribution function

\[ F(x; \mu, \sigma) = \frac{1}{2} + \frac{1}{\pi} \tan^{-1} \left( \frac{x - \mu}{\sigma} \right). \]

See Also
Chapter III-12, Statistics for a function and operation overview; StatsCauchyCDF and StatsCauchyPDF.

StatsCauchyPDF

\( \text{StatsCauchyPDF} (x, \mu, \sigma) \)

The StatsCauchyPDF function returns the Cauchy-Lorentz probability distribution function

\[ f(x; \mu, \sigma) = \frac{1}{\sigma\pi} \frac{1}{1+\left( \frac{x-\mu}{\sigma} \right)^2}, \]

where \( \mu \) is the location parameter and \( \sigma \) is the scale parameter. Use \( \mu=0 \) and \( \sigma=1 \) for the standard form of the Cauchy-Lorentz distribution.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsCauchyCDF and StatsInvCauchyCDF.

StatsChiCDF

\( \text{StatsChiCDF} (x, n) \)

The StatsChiCDF function returns the chi-squared cumulative distribution function for the specified value and degrees of freedom \( n \).

\[ F(x; n) = \frac{\gamma\left( \frac{n}{2}, \frac{x}{2} \right)}{\Gamma\left( \frac{n}{2} \right)}. \]

where is \( \gamma(a,b) \) the incomplete gamma function. The distribution can also be expressed as
StatsChiPDF

StatsChiPDF(x, n)
The StatsChiPDF function returns the chi-squared probability distribution function for the specified value and degrees of freedom as

\[
F(x; n) = 1 - \operatorname{gammq}\left(\frac{n}{2}, \frac{x}{2}\right).
\]

See Also
Chapter III-12, Statistics for a function and operation overview; StatsChiCDF, StatsInvChiCDF, and gammq.

StatsChiPDF

The StatsChiPDF function returns the chi-squared probability distribution function for the specified value and degrees of freedom as

\[
f(x; n) = \frac{\exp\left(-\frac{x}{2}\right) \left(\frac{n}{2}\right)^\frac{n}{2} \Gamma\left(\frac{n}{2}\right)}{2^n \Gamma\left(\frac{n}{2}\right)}.
\]

See Also
Chapter III-12, Statistics for a function and operation overview; StatsChiCDF and StatsChiPDF.

StatsChiTest

StatsChiTest [flags] srcWave1, srcWave2
The StatsChiTest operation computes a \(\chi^2\) statistic for comparing two distributions or a \(\chi^2\) statistic for comparing a sample distribution with its expected values. In both cases the comparison is made on a bin-by-bin basis. Output is to the W_StatsChiTest wave in the current data folder or optionally to a table.

Flags

/ALZR Allows zero entries in source waves. If you are using /S zero entries in srcWave2 are skipped.

/NCON=nCon Specifies the number of constraints (0 by default), which reduces the number degrees of freedom and the critical value by nCon.

/S Sets the calculation mode to a single distribution where srcWave1 represents an array of binned measurements and srcWave2 represents the corresponding expected values.

/T=k Displays results in a table. k specifies the table behavior when it is closed.

k=0: Normal with dialog (default).

k=1: Kills with no dialog.

k=2: Disables killing.

/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details
The source waves, srcWave1 and srcWave2, must have the same number of points and can be any real numeric data type. Any nonpositive values (including NaN) in either wave removes the entry in both waves from consideration and reduces the degrees of freedom by one. The number degrees of freedom is initially the number of points in srcWave1-1-nCon. By default it is assumed that srcWave1 and srcWave2 represent two distributions of binned data.

When you specify /S, srcWave1 must consist of binned values of measured data and srcWave2 must contain the corresponding expected values. The calculation is:
StatsCircularCorrelationTest

$$\chi^2 = \sum_{i=0}^{n-1} \frac{(Y_i - V_i)^2}{V_i}.$$ 

Here $Y_i$ is the sample point from $srcWave1$, $V_i$ is the expected value of $Y_i$ based on an assumed distribution ($srcWave2$), and $n$ is the number of points in the each wave. If you do not use /S, it calculates:

$$\chi^2 = \sum_{i=0}^{n-1} \frac{(Y_{1i} - Y_{2i})^2}{Y_{1i} + Y_{2i}},$$

where $Y_{1i}$ and $Y_{2i}$ are taken from $srcWave1$ and $srcWave2$ respectively. $V_{flag}$ will be set to -1 for any error and to zero otherwise.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsContingencyTable.

StatsCircularCorrelationTest

**StatsCircularCorrelationTest [flags] waveA, waveB**

The StatsCircularTwoSampleTest operation performs a number of tests for two samples of circular data. Using the appropriate flags you can choose between parametric or nonparametric, unordered or paired tests. The input consists of two waves that contain one or two columns. The first column contains angle data expressed in radians and an optional second column contains associated vector lengths. The waves must be either single or double precision floating point. Results are stored in the W_StatsCircularCorrelationTest wave in the current data folder and optionally displayed in a table. Some flags generate additional outputs, described below.

Flags

- **/ALPH=val**
  Sets the significance level (default 0.05).

- **/NAA**
  Performs a nonparametric angular-angular correlation test.

- **/PAA**
  Performs a parametric angular-angular correlation test.

- **/PAL**
  Performs a parametric angular-linear correlation test. In this case the angle wave is $waveA$ and the linear data corresponds to $waveB$.

- **/Q**
  No results printed in the history area.

- **/T=k**
  Displays results in a table. $k$ specifies the table behavior when it is closed.
  - $k=0$: Normal with dialog (default).
  - $k=1$: Kills with no dialog.
  - $k=2$: Disables killing.

- **/Z**
  Ignores errors.

Details

The nonparametric test (/NAA) follows Fisher and Lee’s modification of Mardia’s statistic, which is an analogue of Spearman’s rank correlation. The test ranks the angles of each sample and computes the quantities $r'$ and $r''$ as follows:

$$r' = \frac{\left( \sum_{i=0}^{n-1} \cos \left( \frac{2\pi}{n} (r_{ai} - r_{bi}) \right) \right)^2 + \left( \sum_{i=0}^{n-1} \sin \left( \frac{2\pi}{n} (r_{ai} - r_{bi}) \right) \right)^2}{n^2},$$

where $r_{ai}$ and $r_{bi}$ are taken from $waveA$ and $waveB$ respectively.
The parametric test for angular-angular correlation (/PAA) involves computation of a correlation coefficient \( r_{aa} \) and then evaluating the mean \( \bar{r}_{aa} \) and variance \( s^2_{r_{aa}} \) of equivalent correlation coefficients computed from the same data but by deleting a different pair of angles each time. The mean and variance are then used to compute confidence limits \( L1 \) and \( L2 \):

\[
L1 = nr_{aa} - (n-1)\bar{r}_{aa} - Z_{\alpha(2)} \sqrt{\frac{s^2_{r_{aa}}}{n}},
\]

\[
L2 = nr_{aa} - (n-1)\bar{r}_{aa} + Z_{\alpha(2)} \sqrt{\frac{s^2_{r_{aa}}}{n}}
\]

where \( Z_{\alpha(2)} \) is the normal distribution two-tail critical value at the \( \alpha \) level of significance. \( H_0 \) (corresponding to no correlation) is rejected if zero is not contained in the interval \( [L1, L2] \).

The parametric test for angular-linear correlation (/PAL) involves computation of the correlation coefficient \( r_{al} \) which is then compared with a critical value from \( \chi^2 \) for alpha significance and two degrees of freedom.

\[
r_{al} = \sqrt{\frac{r_{xc}^2 + r_{sx}^2 - 2r_{xc}r_{sx}r_{cs}}{1 - r_{cs}^2}},
\]

where:

\[
r_{xc} = \sqrt{\frac{\sum_{i=0}^{n-1} X_i \cos(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} X_i \sum_{i=0}^{n-1} \cos(a_i)}{\sum_{i=0}^{n-1} X_i^2 - \frac{1}{n} \sum_{i=0}^{n-1} X_i} \left( \sum_{i=0}^{n-1} \cos^2(a_i) - \frac{1}{n} \left( \sum_{i=0}^{n-1} \cos(a_i) \right)^2 \right)}
\]

\[
r_{sx} = \sqrt{\frac{\sum_{i=0}^{n-1} X_i \sin(a_i) - \frac{1}{n} \sum_{i=0}^{n-1} X_i \sum_{i=0}^{n-1} \sin(a_i)}{\sum_{i=0}^{n-1} X_i^2 - \frac{1}{n} \sum_{i=0}^{n-1} X_i} \left( \sum_{i=0}^{n-1} \sin^2(a_i) - \frac{1}{n} \left( \sum_{i=0}^{n-1} \sin(a_i) \right)^2 \right)}
\]
StatsCircularMeans

The StatsCircularMeans operation calculates the mean of a number of circular means, returning the mean angle (grand mean), the length of the mean vector, and optionally confidence interval around the mean angle. Output is to the history area and to the W_CircularMeans wave in the current data folder.

**Flags**

- `/ALPH=val` Sets the significance level (default 0.05).
- `/CI` Calculates the confidence interval (labeled CI_t1 and CI_t2) around the mean angle.
- `/NSOA` Performs nonparametric second order analysis according to Moore’s version of Rayleigh’s test where H_0 corresponds to uniform distribution around the circle. Moore’s test ranks entries by the lengths of the mean radii (second column of the input) from smallest (rank 1) to largest (rank n) and then computes the statistic:

\[
R' = \sqrt{\frac{\left(\frac{1}{n} \sum_{i=0}^{n-1} (i+1) \cos(a_i)\right)^2 + \left(\frac{1}{n} \sum_{i=0}^{n-1} (i+1) \sin(a_i)\right)^2}{n}},
\]

where \(a_i\) are the mean angle entries (from column 1) corresponding to vector length rank \((i+1)\). The critical value is obtained from Moore’s distribution StatsInvMooreCDF.

- `/PSOA` Perform parametric second order analysis where H_0 corresponds to no mean population direction. It assumes that the second order quantities are from a bivariate normal distribution. If this is not the case, use /NSOA above. The test statistic is:

\[
F = \frac{k(k-2)}{2} \left[ \frac{\bar{X}^2 S_y^2 - 2 \bar{X} \bar{Y} S_{xy} + \bar{Y}^2 S_x^2}{S_x^2 S_y^2 - S_{xy}^2} \right],
\]

where
The srcWave input to StatsCircularMeans must be a single or double precision two column wave containing in each row a mean angle (radians) and the length of a mean radius (the first column contains mean angles and the second column contains mean vector lengths). srcWave must not contain any NaNs or INFs. The confidence interval calculation follows the procedure outlined by Batschelet. V_flag will be set to -1 for any error and to zero otherwise.

References

See Also
Chapter III-12, *Statistics* for a function and operation overview; StatsCircularMoments, StatsInvMooreCDF, and StatsInvFCDF.

StatsCircularMoments

The StatsCircularMoments operation computes circular statistical moments and optionally performs angular uniformity tests for the data in srcWave. The extent of the calculation is determined by the requested moment. The default results are stored in the W_CircularStats wave in the current data folder and are optionally displayed in a table. Additional results are listed under the corresponding flags.

Flags

/ALPH=alpha Sets an alpha value for computing confidence intervals (default is 0.05).
Designates the input as p-axial data. For example, if the input represents undirected lines then \( p = 2 \) and the operation multiplies the angles by a factor \( p \) (after shifting /ORGN and accounting for /CYCL). It does not back-transform the mean or median axis.

Specifies the length of the data cycle. You do not need to do so if you are using one of the built-in modes, but this is still a useful option, as for setting the length of a particular month when using /MODE=5.

Computes circular statistics for grouped data. In this case srcWave contains frequencies or the number of events that belong to a particular angle group. There are as many groups as there are elements in srcWave. The first group is centered at \( \text{start} \) radians and each consecutive group is centered \( \text{delta} \) radians away. You must set both the \( \text{start} \) and \( \text{delta} \) to sensible values. srcWave may contain NaNs but it is an error if all values are NaN. The only other flags that work in combination with this flag are /Q, /T, and /Z.

Tests the uniformity of a circular distribution of ungrouped data using the Kuiper statistic. The data are converted into a set \( \{ x_i \} \) by normalizing the input angles to the range \([0,1]\), ranking the results then using the two quantities \( D_+ \) and \( D_- \) to compute the Kuiper statistic. Use \( k=0 \) for Fisher’s version:

\[
V = \left( D_+ + D_- \right) \left( \sqrt{n} + 0.155 + 0.24 / \sqrt{n} \right),
\]

Use \( k=1 \), added in Igor Pro 8.00, for the more common definition of the Kuiper statistic:

\[
V = \left( D_+ + D_- \right).
\]

Here

\[
D_+ = \text{Max of: } \frac{1}{n} - x_0, \frac{2}{n} - x_1, \ldots, \frac{1}{n} - x_{n-1},
\]

\[
D_- = \text{Max of: } x_0, x_1, \ldots, x_{\frac{1}{n} - 1}, x_{\frac{n-1}{n}} - x_{\frac{n-1}{n}} - \frac{1}{n}, x_{\frac{n-1}{n}},
\]

and \( n \) is the number of valid points in srcWave. You can find the results in the wave W_CircularStats under row label “Kuiper V” and “Kuiper CDF(V)”. See Fisher and Press et al. for more information.

Computes Linear Order Statistics by sorting the angle values from small to large, dividing each angle by \( 2\pi \) and shifting the origin so that the output range is \([0,1]\). The results are stored in the wave W_LinearOrderStats in the current data folder. The X scaling of the wave is set so that the offset and the delta are \( 1/(n+1) \) where \( n \) is the number of non-NaN points in the input.

Computes specified moments. By default, it computes the second order moments as well as skewness, kurtosis, median, and mean deviation. Use /M=1 for the first moment. For higher moments, both the specified moment and all the default quantities are computed.
StatsCircularMoments

/MODE=mode
Handles special types of data.

<table>
<thead>
<tr>
<th>mode</th>
<th>Data in srcWave</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Angles in radians [0,2\pi]</td>
</tr>
<tr>
<td>1</td>
<td>Angles in radians [-\pi, \pi]</td>
</tr>
<tr>
<td>2</td>
<td>Angles in degrees [0,360]</td>
</tr>
<tr>
<td>3</td>
<td>Angles in degrees [-180,180]</td>
</tr>
<tr>
<td>4</td>
<td>Igor date format for one year cycles.</td>
</tr>
<tr>
<td>5</td>
<td>Igor date format for one month cycles.</td>
</tr>
<tr>
<td>6</td>
<td>Igor date format for one week cycles.</td>
</tr>
<tr>
<td>7</td>
<td>Igor date format for one day cycles.</td>
</tr>
<tr>
<td>8</td>
<td>Igor date format for one hour cycles.</td>
</tr>
</tbody>
</table>

/ORGN=origin
Specifies the origin of the data (the value corresponding to an angle of zero degrees). For example, if you are using Igor date format and you want the origin to be the first second in year YYYY, use /ORGN=(date2secs(YYYY,1,1)).

/Q
No results printed in the history area.

/RAYL=[meanDirection]
Performs the Rayleigh test for uniformity. If the “alternative” mean direction is specified (in radians), the test computes

\[ r0\bar{r} = r\bar{r} \cos(t\bar{r} - \text{meanDirection}) \]

and then computes the significance probability of \( r0\bar{r} \). The null hypothesis \( H_0 \) corresponds to uniformity. It is rejected when \( r0\bar{r} \) is too large. If the mean direction is not specified then \( r0\bar{r} \) is \( r\bar{r} \) which is always calculated as part of the first moments so the operation only computes the relevant significance probability (P-Value). The critical values for both cases are computed according to Durand and Greenwood.

/SAW
Saves the translated angle data in the wave W_AngleWave in the current data folder.

/T=k
Displays results in a table. \( k \) specifies the table behavior when it is closed.

\( k=0: \) Normal with dialog (default).
\( k=1: \) Kills with no dialog.
\( k=2: \) Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists, but does not display the output wave from the current data folder, the table is renamed and a new table is created.

/Z
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details
StatsCircularMoments is equivalent to WaveStats but it applies to circular data, which are distributed on the perimeter of a circle representing some period or cycle. If your data are not described by one of the built-in modes, you can specify the value of the origin (/ORGN), which is mapped to zero degrees and the size of a cycle or period.

When you use Igor date formats with the built-in modes for dates, the default origin is set to zero. The default cycle in the case of Mode 4 is 366. This is done in order to handle both leap and nonleap years. Similarly, Mode 5 uses a cycle of 31 days. Note that the internal conversion from Igor date to (year, month,
day) is independent of the cycle specification and is therefore not affected by this choice. You should use
the /CYCL flag if you use one of these modes with a fixed size of year or month.

The parameters listed below are computed and displayed (see row labels) in the table. Here \( N \) is the number
of valid (non-NaN) angles \( \{\theta_i\} \)

\[
C = \sum_{i=1}^{n} \cos \theta_i
\]

\[
S = \sum_{i=1}^{n} \sin \theta_i
\]

\[
R = \sqrt{C^2 + S^2}
\]

\[
cBar = \bar{C} = C/n
\]

\[
sBar = \bar{S} = S/n
\]

\[
rBar = \bar{R} = R/n
\]

\[
tBar = \bar{\theta} = \begin{cases} 
\text{atan}(S/C) & S > 0, C > 0 \\
\text{atan}(S/C) + \pi & C < 0 \\
\text{atan}(S/C) + 2\pi & S < 0, C > 0 
\end{cases}
\]

\[
V = 1 - \bar{R}
\]

\[
v = \sqrt{-2 \log (1 - V)}
\]

median is the value which minimizes

\[
d(\theta) = \pi - \frac{1}{n} \sum_{i=1}^{n} \left| \pi - |\theta_i - \bar{\theta}| \right|
\]

mean deviation = The minimum of the last equation when \( \theta \rightarrow \text{median} \).

Higher order moments are denoted with the moment number such that \( t3Bar \) is the uncentered third
moment of the angle while primed quantities are relative to mean direction \( tBar \). Using this notation

\[
\hat{\rho}^2 = \frac{1}{n} \sum_{i=1}^{n} \cos 2(\theta_i - \bar{\theta})
\]

\[
circular\ \text{dispersion} = \frac{1 - \hat{\rho}^2}{2\bar{R}^2}
\]

\[
skewness = \frac{\hat{\rho} \sin(\hat{\mu}' - 2\bar{\theta})}{(1 - \bar{R})^{3/2}}
\]
StatsCircularTwoSampleTest

\[
kurtosis = \frac{\widehat{\rho}_2 \cos(\hat{\mu}' - 2\bar{\theta}) - \bar{R}^4}{(1 - \bar{R})^2}
\]

where

\[
\hat{\mu}' = \begin{cases} 
\tan(S_p/C_p) & S_p > 0, C_p > 0 \\
\tan(S_p/C_p) + \pi & C_p < 0 \\
\tan(S_p/C_p) + 2\pi & S_p < 0, C_p > 0
\end{cases}
\]

and

\[
C_p = \frac{1}{n} \sum_{i=1}^{n} \cos p\theta_i, \quad S_p = \frac{1}{n} \sum_{i=1}^{n} \sin p\theta_i.
\]

Chapter III-12, *Statistics* for a function and operation overview.

StatsCircularTwoSampleTest

StatsCircularTwoSampleTest [flags] waveA, waveB

The StatsCircularTwoSampleTest operation performs second order analysis of angles. Using the appropriate flags you can choose between parametric or nonparametric, unordered or paired tests. The input consists of two waves that contain one or two columns. The first column contains angle data (mean angles) expressed in radians and an optional second column that contains associated vector lengths. The waves must be either single or double precision. Results are stored in the W_StatsCircularTwoSamples wave in the current data folder and optionally displayed in a table. Some of the tests may have additional outputs.

Flags

/ALPH = val \hspace{1cm} \text{Sets the significance level (default val=0.05).}
/NPR \hspace{1cm} \text{Performs nonparametric paired-sample test (Moore). The input waves must contain paired angular data so both must have single column and the same number of points.}
/NSOA \hspace{1cm} \text{Perform nonparametric second order two-sample test. Input waves must each contain two columns.}
/PPR \hspace{1cm} \text{Performs parametric paired-sample test. Input waves must contain paired data and must have the same number of points.}
/PSSOA \hspace{1cm} \text{Performs parametric second order analysis of two samples. The input waves must each contain two columns.}
/Q \hspace{1cm} \text{No information printed in the history area.}
StatsCMSSDCDF

\[ /T= k \]
\[ k=0: \] Normal with dialog (default).
\[ k=1: \] Kills with no dialog.
\[ k=2: \] Disables killing.

\[ /Z \]
Ignores any errors.

Details
The nonparametric paired-sample test (/NPR) is Moore’s test for paired angles applied in second order analysis. The input can consist of one or two column waves. When both waves contain a single column the operation proceeds as if all the vector length were identically 1. The Moore statistic (\( H_0 \rightarrow \) pair equality) is computed and compared to the critical value from the Moore distribution (see StatsInvMooreCDF).

The nonparametric second-order two-sample test (/NSOA) consists of pre-processing where the grand mean is subtracted from the two inputs followed by application of Watson’s U² test (StatsWatsonUSquaredTest) with \( H_0 \) implying that the two samples came from the same population. The results of this test are stored in the wave \( W_{\text{WatsonUtest}} \).

The parametric paired-sample test (/PPR) is due to Hotelling. In this test the input should consist of both angular and vector length data. The test statistic is compared with a critical value from the F distribution (StatsInvFCDF).

The parametric second order two-sample test (/PSOA) is an extension of Hotelling one-sample test to second order analysis where an F-like statistic is computed corresponding to \( H_0 \) of equal mean angles.

References

See Also
Chapter III-12, *Statistics* for a function and operation overview; StatsInvMooreCDF, StatsWatsonUSquaredTest, and StatsInvFCDF.

StatsCMSSDCDF

\[ \text{StatsCMSSDCDF}(C, n) \]
The StatsCMSSDCDF function returns the cumulative distribution function of the C distribution (mean square successive difference), which is

\[
f(C, n) = \frac{\Gamma(2m+2)}{a2^{2m+1}[\Gamma(m+1)]^2} \left( 1 - \frac{C^2}{a^2} \right)^m,
\]

where

\[
a^2 = \frac{(n^2 + 2n - 12)(n - 2)}{(n^3 - 13n + 24)},
\]

\[
m = \frac{(n^4 - n^2 - 13n^2 + 37n - 60)}{2(n^3 - 13n + 24)}.
\]

The distribution \((C>0)\) can then be expressed as

\[
F(C, n) = \frac{\Gamma(2m+2)}{a2^{2m+1}[\Gamma(m+1)]^2} C_2 F_1 \left( \frac{1}{2}, -m, \frac{3}{2}, \frac{C^2}{a^2} \right),
\]

where \(2F_1\) is the hypergeometric function \text{hyperG2F1}. 
StatsCochranTest

StatsCochranTest [flags] [wave1, wave2, ..., wave100]
The StatsCochranTest operation performs Cochran’s (Q) test on a randomized block or repeated measures dichotomous data. Output is to the M_CochranTestResults wave in the current data folder or optionally to a table.

Flags

/ALPH = val
Sets the significance level (default val=0.05).
/Q
No results printed in the history area.
/T=k
Displays results in a table. k specifies the table behavior when it is closed.
   k=0: Normal with dialog (default).
   k=1: Kills with no dialog.
   k=2: Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists but it does not display the output wave from the current data folder, the table is renamed and a new table is created.

/WSTR=waveListString
Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z
Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details
StatsCochranTest computes Cochran’s statistic and compares it to a critical value from a Chi-squared distribution, which depends only on the significance level and the number of groups (columns). The null hypothesis for the test is that all columns represent the same proportion of the effect represented by a non-zero data.

The Chi-square distribution is appropriate when there are at least 4 columns and at least 24 total data points.

Dichotomous data are presumed to consist of two values 0 and 1, thus StatsCochranTest distinguishes only between zero and any nonzero value, which is considered to be 1; it does not allow NaNs or INFS. Input waves can be a single 2D wave or a list of 1D numeric waves, which can also be specified in a string list with /WSTR. In the standard terminology, data rows represent blocks and data columns represent groups. H0 corresponds to the assumption that all groups have the same proportion of 1’s.

With the /T flag, it displays the results in a table that contains the number of rows, the number of columns, the Cochran statistic, the critical value, and the conclusion (1 to accept H0 and 0 to reject it). V_flag will be set to -1 for any error and to zero otherwise.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsCMSSDCDF and StatsSRTest.

StatsContingencyTable

StatsContingencyTable [flags] srcWave
The StatsContingencyTable operation performs contingency table analysis on 2D and 3D tables. Output is to the W_ContingencyTableResults wave in the current data folder or optionally to a table or the history area.
StatsContingencyTable

Flags

/ALPH = val  Sets the significance level (default val=0.05).

/COR = mode  Sets the correction type for 2x2 tables. By default there is no correction. Use mode=1 for Yates and mode=2 for Haber correction.

/FEXT = [row, col]  Computes Fisher’s Exact P-value with 2x2 contingency tables. row and col are zero-based indices of the table entry where it computes the probability of getting the results in the table or more extreme values. Without the /Q flag, it prints the probabilities of each individual table in the history.

Given the contingency table:

<table>
<thead>
<tr>
<th></th>
<th>Succeeded</th>
<th>Failed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group1</td>
<td>11</td>
<td>8</td>
</tr>
<tr>
<td>Group2</td>
<td>4</td>
<td>9</td>
</tr>
</tbody>
</table>

Example 1: When you use /FEXT = {0,0} the P-value represents the sum of the probabilities of the first group having in the Succeeded column 11 or more extreme values, i.e., 12, 13, 14, and 15. In each case the remaining table elements are adjusted so that row and column sums remain constant.

Example 2: When you needed to evaluate the sum of the probabilities of Group2 having 4 counts or less in the Succeeded column, then the appropriate flag is /FEXT = {1,1}, which effectively computes the equivalent of having 9, 10, 11, 12, and 13 Failed counts. In each case it computes the upper, the lower, and the two-tail probabilities.

/HTRG  Tests for heterogeneity between tables stored as layers of 3D wave.

/LLIK  Computes log likelihood statistic.

/Q  No results printed in the history area.

/T = k  Displays results in a table. k specifies the table behavior when it is closed.

k=0: Normal with dialog (default).

k=1: Kills with no dialog.

k=2: Disables killing.

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results unless you moved the output wave to a different data folder. If the named table exists but it does not display the output wave from the current data folder, the table is renamed and a new table is created.

/Z  Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

StatsContingencyTable supports 2D waves representing single contingency tables or 3D waves representing multiple 2D tables (where each table is a layer) or a single 3D table. Each entry in the wave must contain a frequency value and must be a positive number; it does not support 0’s, NaNs, or INFs. In the special case of 2x2 tables, use the /COR flag to compute the statistic using either the Yates or Haber corrections. Except for the heterogeneity option you can also compute the log likelihood statistic. In all the tests, H_0 corresponds to independence between the tested variables.

For 3D tables StatsContingencyTable provides Chi-squared, degrees of freedom, the critical value, and optionally the log likelihood G statistic (/LLIK flag) for each of the following cases:

- Mutual independence by testing if all three variables are independent of each other.
- Partial dependence (rows) by testing if rows independent of columns and layers.
- Partial dependence (columns) by testing if columns independent of rows and layers.
- Partial dependence (layers) by testing if layers independent of rows and columns.
In each case you should compare the statistic with the critical value and reject \( H_0 \) if the statistic exceeds or equals the critical value.

You should examine the table entries to determine if the Chi-square statistic is appropriate (if the frequency is smaller than 6 for \( \text{ALPH}=0.05 \) you should consider computing the Fisher exact test).

\( V \_\text{flag} \) will be set to -1 for any error and to zero otherwise.

**See Also**

Chapter III-12, *Statistics* for a function and operation overview; *StatsInvChiCDF*.

---

**StatsCorrelation**

\[ \text{StatsCorrelation}(\text{waveA}[, \text{waveB}]) \]

The StatsCorrelation function computes Pearson’s correlation coefficient between two real valued arrays of data of the same length. Pearson \( r \) is given by:

\[
r = \frac{\sum_{i=0}^{n-1} (\text{waveA}[i] - A)(\text{waveB}[i] - B)}{\sqrt{\sum_{i=0}^{n-1} (\text{waveA}[i] - A)^2 \sum_{i=0}^{n-1} (\text{waveB}[i] - B)^2}}
\]

Here \( A \) is the average of the elements in \( \text{waveA} \), \( B \) is the average of the elements of \( \text{waveB} \) and the sum is over all wave elements.

**Details**

If you use both \( \text{waveA} \) and \( \text{waveB} \) then the two waves must have the same number of points but they could be of different number type. If you use only the \( \text{waveA} \) parameter then \( \text{waveA} \) must be a 2D wave. In this case StatsCorrelation will return 0 and create a 2D wave \( \text{M\_Pearson} \) where the \( (i,j) \) element is Pearson’s \( r \) corresponding to columns \( i \) and \( j \).

Fisher’s \( z \) transformation converts Person’s \( r \) above to a normally distributed variable \( z \):

\[
z = \frac{1}{2} \ln \left( \frac{1+r}{1-r} \right),
\]

with a standard error

\[
\sigma_z = \frac{1}{\sqrt{n-3}}.
\]

You can convert between the two representations using the following functions:

Function `pearsonToFisher(inr)`

Variable `inr`

return 0.5*(ln(1+inr)-ln(1-inr))

End

Function `fisherToPearson(inz)`

Variable `inz`

return tanh(inz)

End

**See Also**

*Correlate*, *StatsLinearCorrelationTest*, and *StatsCircularCorrelationTest*.

---

**StatsDExpCDF**

\[ \text{StatsDExpCDF}(x, m, s) \]

The StatsDExpCDF function returns the double-exponential cumulative distribution function
StatsDExpPDF

\[
F(x;\mu,\sigma) = \begin{cases} 
\exp\left(\frac{x-\mu}{\sigma}\right) & \text{when } x < \mu \\
1 - \frac{1}{2} \exp\left(-\frac{|x-\mu|}{\sigma}\right) & \text{when } x \geq \mu 
\end{cases}
\]

for \(\sigma>0\). It returns NaN when \(\sigma=0\).

See Also
Chapter III-12, Statistics for a function and operation overview; StatsDExpPDF and StatsInvDExpCDF.

StatsDExpPDF

**StatsDExpPdf** \((x, m, s)\)

The StatsDExpPdf function returns the double-exponential probability distribution function

\[
\text{f}(x;\mu,\sigma) = \frac{1}{2\sigma} \exp\left(-\frac{|x-\mu|}{\sigma}\right),
\]

where \(\mu\) is the location parameter and \(\sigma>0\) is the scale parameter. Use \(\mu=0\) and \(\sigma=1\) for the standard form of the double exponential distribution. It returns NaN when \(\sigma=0\).

See Also
Chapter III-12, Statistics for a function and operation overview; StatsDExpCDF and StatsInvDExpCDF.

StatsDIPTest

**StatsDIPTest** [/Z] **srcWave**

The StatsDIPTest operation performs Hartigan test for unimodality.

Flags

/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details

The input to the operation srcWave is any real numeric wave. Outputs are: V_Value contains the dip statistic; V_min is the lower end of the modal interval; and V_max is the higher end of the modal interval. Percentage points or critical values for the dip statistic can be obtained from simulations using an identical sample size as in this example:

Function getCriticalValue(sampleSize, alpha)

Variable sampleSize, alpha

Make/O/N=(sampleSize) dataWave
Make/O/N=100000 dipResults
Variable i
for(i=0;i<100000;i+=1)
dataWave=enoise(100)
StatsDipTest dataWave
dipResults[i]=V_Value
dipResults[i]=W_INT
endfor
Histogram/P/B=4 dipResults          // Compute the PDF.
Wave W_Histogram
Integrate/METH=1 W_Histogram/D=W_INT   // Compute the CDF.
Findlevel/Q  W_int,(1-alpha)          // Find the critical value.
return V_LevelX
End

References

StatsDunnettTest

The StatsDunnettTest operation performs the Dunnett test by comparing multiple groups to a control group. Output is to the M_DunnettTestResults wave in the current data folder or optionally to a table. StatsDunnettTest usually follows StatsANOVA1Test.

Flags

/ALPH = val  Sets the significance level (default \( val=0.05 \)).
/CIDX=cIndex  Specifies the (zero based) index of the input wave corresponding to the control group. The default is zero (the first wave corresponds to the control group).
/Q  No results printed in the history area.
/SWN  Creates a text wave, T_DunnettDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column.
/T=k  Displays results in a table. \( k \) specifies the table behavior when it is closed.
\( k=0 \): Normal with dialog (default).
\( k=1 \): Kills with no dialog.
\( k=2 \): Disables killing.
/TAIL=tc  Specifies \( H_0 \).
\( tc=1 \): Default; one tailed test (\( \mu_c \leq \mu_a \)).
\( tc=2 \): One tailed test (\( \mu_c \geq \mu_a \)).
\( tc=4 \): Two tailed test (\( \mu_c = \mu_a \)).

Code combinations are not allowed.

/WSTR=waveListString  Specifies a string containing a semicolon-separated list of waves that contain sample data. Use \( waveListString \) instead of listing each wave after the flags.
/Z  Ignores errors. \( V_{flag} \) will be set to -1 for any error and to zero otherwise.

Details

StatsDunnettTest inputs are two or more 1D numeric waves (one wave for each group of samples). The input waves may contain different number of points, but they must contain two or more valid entries per wave.

For output to a table (using /T), each labelled row represents the results of the test for comparing the means of one group to the control group, and rows are ordered so that all comparisons are computed sequentially starting with the group having the smallest mean. The contents of the labeled columns are:

First  The difference between the group means
Second  SE (which is computed for possibly unequal number of points)
Third  The \( q \) statistic for the pair which may be positive or negative
Fourth  The critical \( q' \) value
Fifth  \( 0 \) if the conclusion is to reject \( H_0 \) or \( 1 \) to accept \( H_0 \)
Sixth  The P-value

\( V_{flag} \) will be set to -1 for any error and to zero otherwise.
StatsErlangCDF

Chapter III-12, Statistics for a function and operation overview; StatsTukeyTest, StatsANOVATest, StatsScheffeTest, and StatsNPMCTest.

StatsErlangCDF

\( \text{StatsErlangCDF}(x, b, c) \)

The StatsErlangCDF function returns the Erlang cumulative distribution function

\[
F(x; b, c) = 1 - \frac{\Gamma\left(\frac{x}{c}, \frac{b}{c}\right)}{\Gamma(c)}.
\]

where \( b > 0 \) (also as \( \lambda = 1/b \)) is the scale parameter, \( c > 0 \) the shape parameter, \( \Gamma(\alpha) \) the gamma function, and \( \Gamma(a, x) \) the incomplete gamma function \( \text{gammaInc} \).

See Also
Chapter III-12, Statistics for a function and operation overview; StatsErlangPDF.

StatsErlangPDF

\( \text{StatsErlangPDF}(x, b, c) \)

The StatsErlangPDF function returns the Erlang probability distribution function

\[
f(x; b, c) = \left(\frac{x}{b}\right)^{c-1} \exp\left(-\frac{x}{b}\right) \frac{b^c}{(c-1)!}.
\]

where \( b > 0 \) (also as \( \lambda = 1/b \)) is the scale parameter and \( c > 0 \) the shape parameter.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsErlangCDF.

StatsErrorPDF

\( \text{StatsErrorPDF}(x, a, b, c) \)

The StatsErrorPDF function returns the error probability distribution function or the exponential power distribution

\[
f(x; a, b, c) = \exp\left[-\frac{1}{2} \left(\frac{x-a}{b}\right)^2\right] \frac{b^{c^2+1}}{\Gamma\left(1 + \frac{c}{2}\right)}.
\]

where \( a \) is the location parameter, \( b > 0 \) is the scale parameter, \( c > 0 \) is the shape parameter, and \( \Gamma(\gamma) \) is the gamma function.

See Also
Chapter III-12, Statistics for a function and operation overview.

StatsEValueCDF

\( \text{StatsEValueCDF}(x, \mu, \sigma) \)

The StatsEValueCDF function returns the extreme-value (type I, Gumbel) cumulative distribution function
where \(\sigma > 0\). This is also known as the “minimum” form or distribution of the smallest extreme. To obtain the distribution of the largest extreme reverse the sign of \(\sigma\).

Chapter III-12, Statistics for a function and operation overview.

StatsE ValuePDF, StatsInvE ValueCDF, StatsGEV CDF, StatsGEVP DF

StatsE ValuePDF

**StatsE ValuePDF**

**StatsE ValuePDF** \((x, \mu, \sigma)\)

The StatsE ValuePDF function returns the extreme-value (type I, Gumbel) probability distribution function

\[
F(x; \mu, \sigma) = 1 - \exp\left(-\exp\left(-\frac{x - \mu}{\sigma}\right)\right),
\]

where \(\sigma > 0\). This is also known as the “minimum” form or the distribution of the smallest extreme. To obtain the distribution of the largest extreme reverse the sign of \(\sigma\).

See Also
Chapter III-12, Statistics for a function and operation overview.

StatsE ValueCDF, StatsInvE ValueCDF, StatsGEV CDF, StatsGEVP DF

StatsExpCDF

**StatsExpCDF** \((x, \mu, \sigma)\)

The StatsExpCDF function returns the exponential cumulative distribution function

\[
F(x; \mu, \sigma) = 1 - \exp\left(-\frac{x - \mu}{\sigma}\right),
\]

where \(x \geq \mu\) and \(\sigma > 0\). It returns NaN for \(\sigma = 0\).

See Also
Chapter III-12, Statistics for a function and operation overview; StatsExpPDF and StatsInvExpCDF.

StatsExpPDF

**StatsExpPDF** \((x, \mu, \sigma)\)

The StatsExpPDF function returns the exponential probability distribution function

\[
f(x; \mu, \sigma) = \frac{1}{\sigma} \exp\left(-\frac{x - \mu}{\sigma}\right),
\]

where \(\mu\) is the location parameter and \(\sigma \geq 0\) is the scale parameter. Use \(\mu = 0\) and \(\sigma = 1\) for the standard form of the exponential distribution. It returns NaN for \(\sigma = 0\).

See Also
Chapter III-12, Statistics for a function and operation overview; StatsExpCDF and StatsInvExpCDF.
StatsFCDF

**StatsFCDF**

\[ \text{StatsFCDF}(x, n_1, n_2) \]

The StatsFCDF function returns the cumulative distribution function for the F distribution with shape parameters \( n_1 \) and \( n_2 \)

\[
F(x; n_1, n_2) = 1 - Betai \left( \frac{n_2}{2}, \frac{n_1}{2}, \frac{n_2}{n_2 + n_1x} \right),
\]

where \( Betai \) is the incomplete beta function.

**See Also**

StatsFriedmanCDF

**StatsFriedmanCDF**

\[ \text{StatsFriedmanCDF}(x, n, m, \text{method}, \text{useTable}) \]

The StatsFriedmanCDF function returns the cumulative probability distribution of the Friedman distribution with \( m \) rows and \( n \) columns. The exact Friedman distribution is computationally intensive, taking on the order of \((nm)^m\) iterations. You may be able to use a range of precomputed exact values by passing a nonzero value for \( \text{useTable} \), which will use \( \text{method} \) only if the value is not in the table. For large \( m \), consider using the Chi-squared or the Monte-Carlo approximations. To abort execution, press the User Abort Key Combinations.

<table>

StatsFriedmanTest

**StatsFriedmanTest**

\[ \text{StatsFriedmanTest} [\text{flags}] [\text{wave1, wave2, ... wave100}] \]

The StatsFriedmanTest operation performs Friedman’s test on a randomized block of data. It is a nonparametric analysis of data contained in either individual 1D waves or in a single 2D wave. Output is to the M_FriedmanTestResults wave in the current data folder or optionally to a table.
The Friedman test ranks the input data on a row-by-row basis, sums the ranks for each column, and computes the Friedman statistic, which is proportional to the sum of the squares of the ranks.

Input waves can be a single 2D wave or a list of 1D numeric waves, which can also be specified in a string list with /WSTR. All 1D waves must have the same number of points. A 2D wave must not contain any NaNs.

The critical value for the Friedman distribution is fairly difficult to compute when the number of rows and columns is large because it requires a number of permutations on the order of \((\text{numColumns}!)^{\text{numRows}}\). A certain range of these critical values are supported by precomputed tables. When the exact critical value is not available you can use one of the two approximations that are always computed: the Chi-squared approximation or the Iman and Davenport approximation, which converts the Friedman statistic is converted to a new value \(F_f\) then compares it with critical values from the F distribution using weighted degrees of freedom.

With the /T flag, it displays the results in a table that contains the number of rows, the number of columns, the Friedman statistic, the exact critical value (if available), the Chi-squared approximation, the Iman and Davenport approximation, and the conclusion (1 to accept \(H_0\) and 0 to reject it).

V_flag will be set to -1 for any error and to zero otherwise.

**References**

Chapter III-12, *Statistics* for a function and operation overview; StatsFriedmanCDF and StatsInvFriedmanCDF.

**StatsFTest**

**StatsFTest** [flags] wave1, wave2
The StatsFTest operation performs the F-test on the two distributions in wave1 and wave2, which can be any real numeric type, must contain at least two data points each, and can have an arbitrary number of dimensions. Output is to the W_StatsFTest wave in the current data folder or optionally to a table.

**Flags**

/ALPH = val  
Sets the significance level (default val=0.05).

/Q  
No results printed in the history area.
The F statistic is the ratio of the variance of wave1 to the variance of wave2. We assume the waves have equal wave variances and that H0 is \( \sigma_1 = \sigma_2 \). For the upper one-tail test we reject H0 if F is greater than the upper critical value or if F is smaller than the lower critical value in the lower one-tail test. In the two-tailed test we reject H0 if F is either greater than the upper critical value or smaller than the lower critical value. The critical values are computed by numerically solving for the argument at which the cumulative distribution function (CDF) equals the appropriate values for the tests. The CDF is given by

\[
F(x, n_1, n_2) = 1 - betai \left( \frac{n_2}{2}, \frac{n_1}{2}, \frac{n_2}{n_1 + n_2} \right),
\]

where the degrees of freedom \( n_1 \) and \( n_2 \) equal the number of valid (non-NaN) points in each wave, and betai is the incomplete beta function. To get the critical value for the upper one-tail test we solve \( F(x) = 1 - \alpha \). For the lower one-tail test we solve \( F(x) = \alpha \). In the two-tailed test the lower critical value is a solution for \( F(x) = \alpha / 2 \) and the upper critical value is a solution for \( F(x) = 1 - \alpha / 2 \).

The F-test requires that the two samples are from normally distributed populations.

Chapter III-12, Statistics for a function and operation overview; StatsVariancesTest, StatsFCDF, and betai.

### StatsGammaCDF

\( \text{StatsGammaCDF}(x, \mu, \sigma, \gamma) \)

The StatsGammaCDF function returns the gamma cumulative distribution function

\[
F(x; \mu, \sigma, \gamma) = \frac{\Gamma_{inc} \left( \gamma, \frac{x - \mu}{\sigma} \right)}{\Gamma(\gamma)}, \quad x \geq \mu, \quad \sigma, \gamma > 0
\]

where \( \Gamma \) is the gamma function and \( \Gamma_{inc} \) is the incomplete gamma function gammaInc.

**See Also**
Chapter III-12, Statistics for a function and operation overview; StatsGammaPDF and StatsInvGammaCDF.

### StatsGammaPDF

\( \text{StatsGammaPDF}(x, \mu, \sigma, \gamma) \)

The StatsGammaPDF function returns the gamma probability distribution function
StatsGeometricCDF

StatsGeometricCDF \( x; \mu, \sigma, \gamma \) = 
\[
\frac{(x - \mu)}{\sigma} \frac{\exp\left(-\frac{x - \mu}{\sigma}\right)}{\sigma \Gamma(\gamma)}, \quad x \geq \mu
\]  
\[\sigma, \gamma > 0\]

where \( \mu \) is the location parameter, \( \sigma \) is the scale parameter, \( \gamma \) is the shape parameter, and \( \Gamma \) is the gamma function.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsGammaCDF and StatsInvGammaCDF.

StatsGeometricCDF

StatsGeometricCDF \((x, p)\)
The StatsGeometricCDF function returns the geometric cumulative distribution function

\[
F(x, p) = 1 - (1 - p)^{x+1}.
\]

where \( p \) is the probability of success in a single trial and \( x \) is the number of trials for \( x \geq 0 \).

See Also
Chapter III-12, Statistics for a function and operation overview; StatsGeometricPDF and StatsInvGeometricCDF.

StatsGeometricPDF

StatsGeometricPDF \((x, p)\)
The StatsGeometricPDF function returns the geometric probability distribution function

\[
f(x, p) = p(1 - p)^x,
\]

where the \( p \) is the probability of success in a single trial and \( x \) is the number of trials \( x \geq 0 \).

See Also
Chapter III-12, Statistics for a function and operation overview; StatsGeometricCDF and StatsInvGeometricCDF.

StatsHodgesAjneTest

StatsHodgesAjneTest \([flags]\) srcWave
The StatsHodgesAjneTest operation performs the Hodges-Ajne nonparametric test for uniform distribution around a circle. Output is to the W_HodgesAjne wave in the current data folder or optionally to a table.

Flags

/ALPH = val  Sets the significance level (default \( val=0.05 \)).
/Q            No results printed in the history area.
/SA=specAngle Uses the Batschelet modification of the Hodges-Ajne test to test for uniformity against the alternative of concentration around the specified angle. \( specAngle \) must be expressed in radians modulus 2\( \pi \).
/T=k          Displays results in a table. \( k \) specifies the table behavior when it is closed.
             \( k=0 \): Normal with dialog (default).
             \( k=1 \): Kills with no dialog.
             \( k=2 \): Disables killing.
/Z            Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.
Details
The input srcWave must contain angles in radians, can be any number of dimensions, can be single or double precision, and should not contain NaNs or INFs.

StatsHodgesAjneTest performs the standard Hodges-Ajne test, which simply tests for uniformity against the hypothesis that the population is not uniformly distributed around the circle. This test finds a diameter that divides the circle into two halves such that one contains the least number of data \( m \), the test statistic.

Use /SA to perform the modified (Batschelet) test, which tests against the alternative that the population is concentrated somehow about the specified angle. The modified test counts the number of points \( m' \) in 90-degree neighborhoods around the specified angle. The test statistic is given by \( C=n-m' \) where \( n \) is the number of points in the wave. The critical value is computed from the binomial probability density.

In both cases \( H_0 \) is rejected if the statistic is smaller than the critical value.

V_flag will be set to -1 for any error and to zero otherwise.

References

See, in particular, Chapter 27 of:

See Also
Chapter III-12, *Statistics* for a function and operation overview.

StatsGEVCDF

StatsGEVCDF(\( x, \mu, \sigma, \xi \))
The StatsGEVCDF function returns the generalized extreme value cumulative distribution function.

\[
F(x,\mu,\sigma,\xi) = \exp \left\{ - \left[ 1 + \xi \left( \frac{x - \mu}{\sigma} \right)^{-1/\xi} \right] \right\},
\]

where

\[
1 + \xi \left( \frac{x - \mu}{\sigma} \right) > 0,
\]

and \( \sigma > 0 \).

See Also
Chapter III-12, *Statistics* for a function and operation overview.

StatsGEVPDF, StatsEValuePDF, StatsEValueCDF, StatsInvEValueCDF

StatsGEVPDF

StatsGEVPDF(\( x, \mu, \sigma, \xi \))
The StatsGEVPDF function returns the generalized extreme value probability distribution function.

\[
f(x,\mu,\sigma,\xi) = \frac{1}{\sigma} \left[ 1 + \xi \left( \frac{x - \mu}{\sigma} \right)^{-1/\xi} \right]^{-1} \exp \left\{ - \left[ 1 + \xi \left( \frac{x - \mu}{\sigma} \right)^{-1/\xi} \right] \right\},
\]

where
StatsHyperGCDF

StatsHyperGCDF(x, m, n, k)
The StatsHyperGCDF function returns the hypergeometric cumulative distribution function, which is the probability of getting \( x \) marked items when drawing (without replacement) \( k \) items out of a population of \( m \) items when \( n \) out of the \( m \) are marked.

Details
The hypergeometric distribution is

\[
F(x; m, n, k) = \sum_{L=0}^{x} \frac{\binom{n}{L} \binom{m-L}{k-L}}{\binom{m}{k}},
\]

where \( \binom{a}{b} \) is the binomial function. All parameters must be positive integers and must have \( m>n \) and \( x<k \); otherwise it returns NaN.

References
Klotz, J.H., Computational Approach to Statistics.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsHyperGPDF.

StatsHyperGPDF

StatsHyperGPDF(x, m, n, k)
The StatsHyperGPDF function returns the hypergeometric probability distribution function, which is the probability of getting \( x \) marked items when drawing without replacement \( k \) items out of a population of \( m \) items where \( n \) out of the \( m \) are marked.

Details
The hypergeometric distribution is

\[
f(x; m, n, k) = \binom{n}{x} \binom{m-n}{k-x} \binom{m}{k},
\]

where \( \binom{a}{b} \) is the binomial function. All parameters must be positive integers and must have \( m>n \) and \( x<k \).

References
Klotz, J.H., Computational Approach to Statistics.
StatsInvBetaCDF

See Also
Chapter III-12, Statistics for a function and operation overview; StatsHyperGCDF.

StatsInvBetaCDF

StatsInvBetaCDF(cdf, p, q [, a, b])
The StatsInvBetaCDF function returns the inverse of the beta cumulative distribution function. There is no closed form expression for the inverse beta CDF; it is evaluated numerically.
The defaults (a=0 and b=1) correspond to the standard beta distribution.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsBetaCDF and StatsBetaPDF.

StatsInvBinomialCDF

StatsInvBinomialCDF(cdf, p, N)
The StatsInvBinomialCDF function returns the inverse of the binomial cumulative distribution function. The inverse function returns the value at which the binomial CDF with probability p and total elements N, has the value 0.95. There is no closed form expression for the inverse binomial CDF; it is evaluated numerically.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsBinomialCDF and StatsBinomialPDF.

StatsInvCauchyCDF

StatsInvCauchyCDF(cdf, μ, σ)
The StatsInvCauchyCDF function returns the inverse of the Cauchy-Lorentz cumulative distribution function

\[ x = \mu + \sigma \tan \left( \pi \left( \frac{cdf - 0.5}{1} \right) \right) \]

It returns NaN for cdf < 0 or cdf > 1.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsCauchyCDF and StatsCauchyPDF.

StatsInvChiCDF

StatsInvChiCDF(x, n)
The StatsInvChiCDF function returns the inverse of the chi-squared distribution of x and shape parameter n. The inverse of the distribution is also known as the percent point function.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsChiCDF and StatsChiPDF.

StatsInvCMSSDCDF

StatsInvCMSSDCDF(cdf, n)
The StatsInvCMSSDCDF function returns the critical values of the C distribution (mean square successive difference distribution), which is given by

\[ f(C,n) = \frac{\Gamma(2m+2)}{a^{2m+1} \left( \frac{m}{\Gamma(m+1)} \right)^2} \left( 1 - \frac{C^2}{\alpha^2} \right)^m \]

where
Critical values are computed from the integral of the probability distribution function.

References

See Also
Chapter III-12, *Statistics* for a function and operation overview; *StatsCMSSDCDF* and *StatsSRTTest*.

**StatsInvDExpCDF**

\[
\begin{align*}
a^2 &= \frac{(n^2 + 2n - 12)(n - 2)}{(n^3 - 13n + 24)}, \\
m &= \frac{(n^4 - n^3 - 13n^2 + 37n - 60)}{2(n^3 - 13n + 24)}.
\end{align*}
\]

The `StatsInvDExpCDF` function returns the inverse of the double-exponential cumulative distribution function.

\[
x = \begin{cases} 
\mu + \sigma \ln(2cdf) & \text{when } cdf < 0.5 \\
\mu - \sigma \ln\left[2 \left(1 - cdf\right)\right] & \text{when } cdf \geq 0.5
\end{cases}
\]

It returns NaN for `cdf` < 0 or `cdf` > 1.

See Also
Chapter III-12, *Statistics* for a function and operation overview; *StatsDExpCDF* and *StatsDExpPDF*.

**StatsInvEValueCDF**

\[
\begin{align*}
m &= \frac{n^4 - n^3 - 13n^2 + 37n - 60}{2(n^3 - 13n + 24)}.
\end{align*}
\]

The `StatsInvEValueCDF` function returns the inverse of the extreme-value (type I, Gumbel) cumulative distribution function.

\[
x = \begin{cases} 
\mu + \sigma \ln\left(2cdf\right) & \text{when } cdf < 0.5 \\
\mu - \sigma \ln\left[2 \left(1 - cdf\right)\right] & \text{when } cdf \geq 0.5
\end{cases}
\]

where \(\sigma > 0\). It returns NaN for `cdf` < 0 or `cdf` > 1. This inverse applies to the “minimum” form of the distribution. Reverse the sign of \(\sigma\) to obtain the inverse distribution of the maximum form.

See Also
Chapter III-12, *Statistics* for a function and operation overview.

*StatsEValueCDF, StatsEValuePDF, StatsGEVCDF, StatsGEVPDF*

**StatsInvExpCDF**

\[
\begin{align*}
m &= \frac{n^4 - n^3 - 13n^2 + 37n - 60}{2(n^3 - 13n + 24)}.
\end{align*}
\]

The `StatsInvExpCDF` function returns the inverse of the exponential cumulative distribution function.

\[
x = \begin{cases} 
\mu + \sigma \ln\left(2cdf\right) & \text{when } cdf < 0.5 \\
\mu - \sigma \ln\left[2 \left(1 - cdf\right)\right] & \text{when } cdf \geq 0.5
\end{cases}
\]

It returns NaN for `cdf` < 0 or `cdf` > 1.

See Also
Chapter III-12, *Statistics* for a function and operation overview; *StatsExpCDF* and *StatsExpPDF*. 
StatsInvFCDF

StatsInvFCDF

StatsInvFCDF\( (x, \ n1, \ n2) \)
The StatsInvFCDF function returns the inverse of the F distribution cumulative distribution function for \( x \) and shape parameters \( n1 \) and \( n2 \). The inverse is also known as the percent point function.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsFCDF and StatsFPDF.

StatsInvFriedmanCDF

StatsInvFriedmanCDF\( (cdf, \ n, \ m, \ method, \ useTable) \)
The StatsInvFriedmanCDF function returns the inverse of the Friedman distribution cumulative distribution function of \( cdf \) with \( m \) rows and \( n \) columns. Use this typically to compute the critical values of the distribution.

Print StatsInvFriedmanCDF\( (1-alpha, n, m, 0, 1) \)
where alpha is the significance level of the associated test.

The complexity of the computation of Friedman CDF is on the order of \( (n!)^m \). For nonzero values of \( useTable \), searches are limited to the built-in table for distribution values. If \( n \) and \( m \) are not in the table the calculation may still proceed according to the \( method \).

<table>
<thead>
<tr>
<th>method</th>
<th>What It Does</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Exact computation(slow, not recommended).</td>
</tr>
<tr>
<td>1</td>
<td>Chi-square approximation.</td>
</tr>
<tr>
<td>2</td>
<td>Monte-Carlo approximation (slow).</td>
</tr>
<tr>
<td>3</td>
<td>Use built-in table only and return a NaN if not in table.</td>
</tr>
</tbody>
</table>

For large \( m \) and \( n \), consider using the Chi-squared or the Iman and Davenport approximations. To abort execution, press the User Abort Key Combinations.

Note: Table values are different from computed values for both methods. Table values use more conservative criteria than computed values. Table values are more consistent with published values because the Friedman distribution is a highly irregular function with multiple steps of arbitrary sizes. The standard for published tables provides the X value of the next vertical transition to the one on which the specified P is found.

Precomputed tables use these values:

<table>
<thead>
<tr>
<th>( n )</th>
<th>( m )</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16</td>
</tr>
<tr>
<td>4</td>
<td>2, 3, 4, 5, 6, 7, 8, 9</td>
</tr>
<tr>
<td>5</td>
<td>2, 3, 4, 5, 6</td>
</tr>
<tr>
<td>6</td>
<td>2, 3, 4, 5</td>
</tr>
<tr>
<td>7</td>
<td>2, 3, 4</td>
</tr>
<tr>
<td>8</td>
<td>2, 3</td>
</tr>
<tr>
<td>9</td>
<td>2, 3</td>
</tr>
</tbody>
</table>

References

Chapter III-12, Statistics for a function and operation overview; StatsFriedmanCDF and StatsFriedmanTest.
StatsInvGammaCDF

StatsInvGammaCDF(cdf, μ, σ, γ)
The StatsInvGammaCDF function returns the inverse of the gamma cumulative distribution function. There is no closed form expression for the inverse gamma distribution; it is evaluated numerically.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsGammaCDF and StatsGammaPDF.

StatsInvGeometricCDF

StatsInvGeometricCDF(cdf, p)
The StatsInvGeometricCDF function returns the inverse of the geometric cumulative distribution function

\[ x = \frac{\ln(1 - cdf)}{\ln(1 - p)} - 1 \]

where \( p \) is the probability of success in a single trial and \( x \) is the number of trials.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsGeometricCDF and StatsGeometricPDF.

StatsInvKuiperCDF

StatsInvKuiperCDF(cdf)
The StatsInvKuiperCDF function returns the inverse of Kuiper cumulative distribution function. There is no closed form expression. It is mapped to the range of 0.4 to 4, with accuracy of 1e-10.

References
See in particular Section 14.3 of

See Also
Chapter III-12, Statistics for a function and operation overview; StatsKuiperCDF.

StatsInvLogisticCDF

StatsInvLogisticCDF(cdf, a, b)
The StatsInvLogisticCDF function returns the inverse of the logistic cumulative distribution function

\[ x = a + b \log \left( \frac{cdf}{1 - cdf} \right). \]

where the scale parameter \( b > 0 \) and the shape parameter is \( a \).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsLogisticCDF and StatsLogisticPDF functions.

StatsInvLogNormalCDF

StatsInvLogNormalCDF(cdf, sigma, theta, mu)
The StatsInvLogNormalCDF function returns the numerically evaluated inverse of the lognormal cumulative distribution function.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsLogNormalCDF and StatsLogNormalPDF functions.
StatsInvMaxwellCDF

StatsInvMaxwellCDF

$\text{StatsInvMaxwellCDF}(cdf, k)$

The StatsInvMaxwellCDF function returns the evaluated numerically inverse of the Maxwell cumulative distribution function. There is no closed form expression.

See Also

Chapter III-12, Statistics for a function and operation overview; the StatsMaxwellCDF and StatsMaxwellPDF functions.

StatsInvMooreCDF

StatsInvMooreCDF

$\text{StatsInvMooreCDF}(cdf, N)$

The StatsInvMooreCDF function returns the inverse cumulative distribution function for Moore’s $R^*$, which is used as a critical value in nonparametric version of the Rayleigh test for uniform distribution around the circle. It supports the range $3 \leq N \leq 120$ and does not change appreciably for $N > 120$.

The inverse distribution is computed from polynomial approximations derived from simulations and should be accurate to approximately three significant digits.

References

See Also

Chapter III-12, Statistics for a function and operation overview; the StatsCircularMeans function.

StatsInvNBinomialCDF

StatsInvNBinomialCDF

$\text{StatsInvNBinomialCDF}(cdf, k, p)$

The StatsInvNBinomialCDF function returns the numerically evaluated inverse of the negative binomial cumulative distribution function. There is no closed form expression.

See Also

Chapter III-12, Statistics for a function and operation overview; the StatsNBinomialCDF and StatsNBinomialPDF functions.

StatsInvNCChiCDF

StatsInvNCChiCDF

$\text{StatsInvNCChiCDF}(cdf, n, d)$

The StatsInvNCChiCDF function returns the inverse of the noncenteral chi-squared cumulative distribution function. It is computationally intensive because the inverse is computed numerically and involves multiple evaluations of the noncentral distribution, which is evaluated from a series expansion.

See Also

Chapter III-12, Statistics for a function and operation overview; the StatsNCChiCDF, StatsNCChiPDF, StatsChiCDF, and StatsChiPDF functions.

StatsInvNCFCDF

StatsInvNCFCDF

$\text{StatsInvNCFCDF}(cdf, n1, n2, d)$

The StatsInvNCFCDF function returns the numerically evaluated inverse of the cumulative distribution function of the noncentral F distribution. $n1$ and $n2$ are the shape parameters and $d$ is the noncentrality measure. There is no closed form expression for the inverse.

See Also

Chapter III-12, Statistics for a function and operation overview; the StatsNCFCDF and StatsNCPDF functions.

StatsInvNormalCDF

StatsInvNormalCDF

$\text{StatsInvNormalCDF}(cdf, m, s)$

The StatsInvNormalCDF function returns the numerically computed inverse of the normal cumulative distribution function. There is no closed form expression.
See Also
Chapter III-12, Statistics for a function and operation overview; the StatsNormalCDF and StatsNormalPDF functions.

StatsInvParetoCDF
StatsInvParetoCDF(cdf, a, c)
The StatsInvParetoCDF function returns the inverse of the Pareto cumulative distribution function

\[ x = \frac{a}{(1 - cdf)^{(1/c)}} \]

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsParetoCDF and StatsParetoPDF functions.

StatsInvPoissonCDF
StatsInvPoissonCDF(cdf, \lambda)
The StatsInvPoissonCDF function returns the numerically evaluated inverse of the Poisson cumulative distribution function. There is no closed form expression for the inverse Poisson distribution.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsPoissonCDF and StatsPoissonPDF functions.

StatsInvPowerCDF
StatsInvPowerCDF(cdf, b, c)
The StatsInvPowerCDF function returns the inverse of the Power Function cumulative distribution function

\[ x = \frac{b}{cdf^{(1/c)}} \]

where the scale parameter \( b \) and the shape parameter \( c \) satisfy \( b,c>0 \).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsPowerCDF, StatsPowerPDF and StatsPowerNoise functions.

StatsInvQCDF
StatsInvQCDF(cdf, r, c, df)
The StatsInvQCDF function returns the critical value of the Q cumulative distribution function for \( r \) the number of groups, \( c \) the number of treatments, and \( df \) the error degrees of freedom (\( df=r*c*(n-1) \) with sample size \( n \)).

Details
The Q distribution is the maximum of several Studentized range statistics. For a simple Tukey test, use \( r=1 \).

Examples
The critical value for a Tukey test comparing 5 treatments with 6 samples and 0.05 significance is:
Print StatsInvQCDF(1-0.05,1,5,5*(6-1))

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsTukeyTest function.

StatsInvQpCDF
StatsInvQpCDF(ng, nt, df, alpha, side, sSizeWave)
The StatsInvQpCDF function returns the critical value of the Q' cumulative distribution function for \( ng \) the number of groups, \( nt \) the number of treatments, and \( df \) the error degrees of freedom. \( side=1 \) for upper-tail or \( side=2 \) for two-tailed critical values.
StatsInvRayleighCDF

StatsInvRayleighCDF is a modified Q distribution typically used with Dunnett’s test, which compares the various means with the mean of the control group or treatment.

StatsInvRayleighCDF differs from other StatsInvXXX functions in that you do not specify a \( \text{cdf} \) value for the inverse (usually \( 1-\alpha \) for the critical value). Here \( \alpha \) selects one- or two-tailed critical values.

It is computationally intensive, taking longer to execute for smaller \( \alpha \) values.

Examples
The critical value for a Dunnett test comparing 4 treatments with 4 samples and (upper tail) 0.05 significance is:

```csharp
// n=4 because 12=1*4*(4-1).
Print StatsInvQpCDF(1,4,12,0.05,1,$"")
2.28734
```

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsDunnettTest and StatsInvQCDF functions.

StatsInvRayleighCDF

\[
\text{StatsInvRayleighCDF}(cdf [, s [, m]])
\]

The StatsInvRayleighCDF function returns the inverse of the Rayleigh cumulative distribution function given by

\[
x = \mu + \sigma \sqrt{-2 \ln(1 - \text{cdf})},
\]

with defaults \( s=1 \) and \( m=0 \). It returns NaN for \( s \leq 0 \) and zero for \( x \leq m \).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRayleighCDF and StatsRayleighPDF functions.

StatsInvRectangularCDF

\[
\text{StatsInvRectangularCDF}(cdf, a, b)
\]

The StatsInvRectangularCDF function returns the inverse of the rectangular (uniform) cumulative distribution function

\[
x = a + \text{cdf}(b - a), \quad a < b.
\]

where \( a < b \).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRectangularCDF and StatsRectangularPDF functions.

StatsInvSpearmanCDF

\[
\text{StatsInvSpearmanCDF}(cdf, N)
\]

The StatsInvSpearmanCDF function returns the inverse cumulative distribution function for Spearman’s \( r \), which is used as a critical value in rank correlation tests.

The inverse distribution is computed by finding the value of \( r \) for which it attains the \( \text{cdf} \) value. The result is usually lower than in published tables, which are more conservative when the first derivative of the distribution is discontinuous.
StatsInvStudentCDF

StatsInvStudentCDF(cdf, n)
The StatsInvStudentCDF function returns the numerically evaluated inverse of Student cumulative distribution function. There is no closed form expression.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsStudentCDF and StatsStudentPDF functions.

StatsInvTopDownCDF

StatsInvTopDownCDF(cdf, N)
The StatsInvTopDownCDF function returns the inverse cumulative distribution function for the top-down distribution. For $3 \leq N \leq 7$ it uses a lookup table CDF and returns the next higher value of $r$ for which the distribution value is larger than $cdf$. For $8 \leq N \leq 50$ it returns the nearest value for which the built-in distribution returns $cdf$. For $N>50$ it returns the scaled normal approximation.

Tabulated values are from Iman and Conover who pick as the critical value the very first transition of the distribution following the specified $cdf$ value. These tabulated values tend to be slightly higher than calculated values for $7<N<15$.

References

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRankCorrelationTest and StatsTopDownCDF functions.

StatsInvTriangularCDF

StatsInvTriangularCDF(cdf, a, b, c)
The StatsInvTriangularCDF function returns the inverse of the triangular cumulative distribution function

$$x = \begin{cases} a + \sqrt{cdf(b-a)(c-a)} & 0 \leq cdf \leq \frac{c-a}{b-a} \\ b - \sqrt{(1-cdf)(b-a)(b-c)} & \frac{c-a}{b-a} \leq cdf \leq 1 \end{cases}$$

where $a<c<b$.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsTriangularCDF and StatsTriangularPDF functions.

StatsInvUSquaredCDF

StatsInvUSquaredCDF(cdf, n, m, method, useTable)
The StatsInvUSquaredCDF function returns the inverse of Watson’s $U^2$ cumulative distribution function integer sample sizes $n$ and $m$. Use a nonzero value for useTable to search a built-in table of values. If $n$ and $m$ cannot be found in the table, it will proceed according to method:

For large $n$ and $m$, consider using the Tiku approximation. To abort execution, press the User Abort Key Combinations. Because $n$ and $m$ are interchangeable, $n$ should always be the smaller value. For $n>8$ the upper limit in the table matched the maximum that can be computed using the Burr algorithm. There is no point in using method 0 with $m$ values exceeding these limits.
The inverse is obtained from precomputed tables of Watson’s $U^2$ (see `StatsUSquaredCDF`).

Note: Table values are different from computed values. These values use more conservative criteria than computed values. Table values are more consistent with published values because the $U^2$ distribution is a highly irregular function with multiple steps of arbitrary sizes. The standard for published tables provides the $X$ value of the next vertical transition to the one on which the specified $P$ is found. See `StatsInvFriedmanCDF`.

### StatsInvVonMisesCDF

**StatsInvVonMisesCDF**

`StatsInvVonMisesCDF(cdf, a, b)`

The `StatsInvVonMisesCDF` function returns the numerically evaluated inverse of the von Mises cumulative distribution function where the value of the integral of the distribution matches `cdf`. Parameters are as for `StatsVonMisesCDF`.

**References**

**See Also**

Chapter III-12, *Statistics* for a function and operation overview; the `StatsVonMisesPDF` and `StatsVonMisesNoise` functions.

### StatsInvWeibullCDF

**StatsInvWeibullCDF**

`StatsInvWeibullCDF(cdf, m, s, g)`

The `StatsInvWeibullCDF` function returns the inverse of the Weibull cumulative distribution function

\[ x = \mu + \sigma \left[ -\ln(1 - cdf) \right]^{1/g}. \]

**See Also**

Chapter III-12, *Statistics* for a function and operation overview; the `StatsWeibullCDF` and `StatsWeibullPDF` functions.

### StatsJBTest

**StatsJBTest**

`StatsJBTest [flags] srcWave`

The `StatsJBTest` operation performs the Jarque-Bera test on `srcWave`. Output is to the W_JBResults wave in the current data folder.
StatsJBTest computes the Jarque-Bera statistic

\[ JB = \frac{n}{6} \left( S^2 + \frac{K^2}{4} \right), \]

where \( S \) is the skewness, \( K \) is the kurtosis, and \( n \) is the number of points in the input wave. We can express \( S \) and \( K \) terms of the \( j \)th moment of the distribution for \( n \) samples \( X_i \)

\[ \mu_j = \frac{1}{n} \sum_{i=1}^{n} (X_i - \bar{X})^j \]

as

\[ S = \frac{\mu_3}{(\mu_2)^{3/2}}, \]

and

\[ K = \frac{\mu_4}{(\mu_2)^2} - 3. \]

The Jarque-Bera statistic is asymptotically distributed as a Chi-squared with two degrees of freedom. For values of \( n \) in the range \([7,2000]\) the operation provides critical values obtained from Monte-Carlo simulations. For further details or if you would like to run your own simulation to obtain critical values for other values of \( n \), use the JarqueBeraSimulation example experiment.

StatsJBTest reports the number of finite data points, skewness, kurtosis, Jarque-Bera statistic, asymptotic critical value, and the critical value obtained from Monte-Carlo calculations as appropriate; it ignores NaNs and INFs.

StatsKDE

StatsKDE [flags] srcWave

StatsKDE can be used to estimate a PDF from original data distribution. Unlike histograms, this method produces a smooth result as it constructs the PDF from a normalized superposition of kernel functions.
The StatsKDE operation was added in Igor Pro 7.00.

**Flags**

- `/BWM=m` Sets the bandwidth selection method.
  - $m=0$: User-specified via `/H` flag
  - $m=1$: Silverman
  - $m=2$: Scott
  - $m=3$: Bowmann and Azzalini

- `/DEST=destWave` Specifies the output destination. Creates a real wave reference for the destination wave in a user function. See *Automatic Creation of WAVE References* on page IV-71 for details.

- `/FREE` Makes the destination wave (specified by `/DEST`) a free wave.

- `/H=bw` Specifies a fixed user-defined bandwidth.

- `/KT=kernel` Specifies the kernel type.
  - $kernel=1$: Epanechnikov
  - $kernel=2$: Bi-weight
  - $kernel=3$: Tri-weight
  - $kernel=4$: Triangular
  - $kernel=5$: Gaussian
  - $kernel=6$: Rectangular

- `/Q` No results printed in the history area. In the case of univariate KDE this flag suppresses the printing of the bandwidth value.

- `/S={x0, dx, xn}` Specifies the range of the output starting from $x=x_0$ to $x=x_n$ in increments of $dx$.

- `/Z` Ignores errors. V_flag is set to zero if there are no errors.

**Details**

StatsKDE estimates the PDF of a distribution of values using a smoothing kernel and a bandwidth parameter which affects the degree of smoothing.

Theory suggests that the Epanechnikov kernel is the most efficient but many expressions for the optimal bandwidth are derived for the Gaussian kernel. If `srcWave` contains N points and the requested output (`/S` flag) has M points then the computational complexity is $O(NM)$. For large problems it may be beneficial to use the Gaussian kernel via the FastGaussTransform operation.

**References**

**See Also**

*Statistics* on page III-365, *Histogram*, *FastGaussTransform*

**StatsKendallTauTest**

`StatsKendallTauTest [flags] wave1 [, wave2]`

The StatsKendallTauTest operation performs the nonparametric Mann-Kendall test, which computes a correlation coefficient $\tau$ (similar to Spearman’s correlation) from the relative order of the ranks of the data. Output is to the `W_StatsKendallTauTest` wave in the current data folder.
StatsKSTest

Flags
/Q No results printed in the history area.
/T=k Displays results in a table. k specifies the table behavior when it is closed.
   k=0: Normal with dialog (default).
   k=1: Kills with no dialog.
   k=2: Disables killing.
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details
Inputs may be a pair of XY (1D) waves of any real numeric type or a single 1D wave, which is equivalent to
using a pair of XY waves where the X wave is monotonically increasing function of the point number.
StatsKendallTauTest ignores wave scaling.
Kendall’s $\tau$ is 1 for a monotonically increasing input and -1 for monotonically decreasing input. The
significance of the test is computed from the normal approximation

$$Var(\tau) = \frac{4n + 10}{9n(n-1)},$$

where $n$ is the number of data points in each wave. The significance is expressed as a P-value for the null
hypothesis of no correlation.

References

See Also
Chapter III-12, *Statistics* for a function and operation overview; StatsRankCorrelationTest.

For small values of $n$ you can compute the exact probability using the procedure
WM_KendallSProbability().

StatsKSTest [flags] srcWave [, distWave]
The StatsKSTest operation performs the Kolmogorov-Smirnov (KS) goodness-of-fit test for two continuous
distributions. The first distribution is srcWave and the second distribution can be expressed either as the optional
wave distWave or as a user function with /CDFF. Output is to the W_KSResults wave in the current data folder.

Flags
/ALPH = val Sets the significance level (default val=0.05).
/CDFF=func Specifies a user function expressing the cumulative distribution function. See Details.
/Q No results printed in the history area.
/T=k Displays results in a table. k specifies the table behavior when it is closed.
   k=0: Normal with dialog (default).
   k=1: Kills with no dialog.
   k=2: Disables killing.
/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details
The Kolmogorov-Smirnov (KS) goodness-of-fit test applies only to continuous distributions and cases
where the compared distribution (expressed as a user function) is completely specified without estimating
parameters from the data. It compares the cumulative distribution function (CDF) of two distributions and
sets the test statistic D to the largest difference between the CDFs. Because CDFs are in the range [0,1], D is
also bound by this range.
StatsKuiperCDF

When specifying the distributions with two waves, StatsKSTest first sorts the data in the waves and then computes the CDFs and D. You can also specify one of the distributions with a user function. For example, the following function tests if the data in `srcWave` is normally distributed with zero mean and stdv=5:

```
Function GetUserCDF(inX) : CDFFunc
    Variable inX
    return StatsNormalCDF(inX, 0, 5)
End
```

The “: CDFFunc” designation, which requires Igor7 or later, tells Igor to make the function accessible from the Kolmogorov-Smirnov Test dialog.

Outputs are the number of elements, the KS statistic D, and the critical value. When both distributions are specified by waves, the number of elements is the weighted value (n1*n2)/(n1+n2).

**References**

Critical values are based on:

A statistically more powerful modification of the classic KS test can be found in:

StatsKSTest implements the original KS test. The difficulty in implementing the modified tests for all the cases defined by Stephens is in obtaining the critical values which have to be derived by time consuming Monte-Carlo simulations.

Critiques can be found in:

See Also

Chapter III-12, *Statistics* for a function and operation overview; StatsJBTest, WaveStats, and StatsCircularMoments.

**StatsKuiperCDF**

**StatsKuiperCDF (V)**

The StatsKuiperCDF function returns the Kuiper cumulative distribution function

\[
F(V) = 1 - 2 \sum_{j=1}^{\infty} \left( 4 j^2 V^2 - 1 \right) \exp \left( -2 j^2 V^2 \right).
\]

Accuracy is on the order of 1e-15. It returns 0 for values of V<0.4 or 1 for V>3.1.

**References**

See in particular Section 14.3 of

See Also

Chapter III-12, *Statistics* for a function and operation overview; StatsInvKuiperCDF.

**StatsKWTest**

**StatsKWTest [flags] [wave1, wave2,... wave100]**

The StatsKWTest operation performs the nonparametric Kruskal-Wallis test which tests variances using the ranks of the data. Output is to the W_KWTestResults wave in the current data folder.

**Flags**

/ALPH = val Sets the significance level (default val=0.05).
StatsKWTest

/E Computes the exact P-value using the Klotz and Teng algorithm, which may require long computation times for large data sets. You can stop the calculation by pressing the User Abort Key Combinations after which all remaining results remain valid and the exact P-value is set to NaN.

/Q No results printed in the history area.

/T=k Displays results in a table. k specifies the table behavior when it is closed.
   k=0: Normal with dialog (default).
   k=1: Kills with no dialog.
   k=2: Disables killing.

/WSTR=waveListString
   Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.

/Z Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

Details
Inputs are two or more 1D numerical waves (one for each group of samples). Use NaNs for missing data or use waves with different number of points.
StatsKWTest always computes the critical values using both the Chi-squared and Wallace approximations. If appropriate (small enough data set) you can also use /E to obtain the exact P value. When the calculation involves many waves or many data points the calculation of the exact critical value can be very lengthy. All the results are saved in the wave W_KWTestResults in the current data folder and are optionally displayed in a table (/T). The wave contains the following information:

<table>
<thead>
<tr>
<th>Row</th>
<th>Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Number of groups</td>
</tr>
<tr>
<td>1</td>
<td>Number of valid data points (excludes NaNs)</td>
</tr>
<tr>
<td>2</td>
<td>Alpha</td>
</tr>
<tr>
<td>3</td>
<td>Kruskal-Wallis Statistic H</td>
</tr>
<tr>
<td>4</td>
<td>Chi-squared approximation for the critical value Hc</td>
</tr>
<tr>
<td>5</td>
<td>Chi-squared approximation for the P value</td>
</tr>
<tr>
<td>6</td>
<td>Wallace approximation for the critical value Hc</td>
</tr>
<tr>
<td>7</td>
<td>Wallace approximation for the P value</td>
</tr>
<tr>
<td>8</td>
<td>Exact P value (requires /E)</td>
</tr>
</tbody>
</table>

H_0 for the Kruskal-Wallis test is that all input waves are the same. If the test fails and the input consisted of more than two waves, there is no indication for possible agreement between some of the waves. See StatsNPMCTest for further analysis.
V_flag will be set to -1 for any error and to zero otherwise.

Klotz, J.H., Computational Approach to Statistics.
StatsLinearCorrelationTest

See Also
Chapter III-12, Statistics for a function and operation overview; StatsWilcoxonRankTest, StatsNPMCTest, and StatsAngularDistanceTest.

StatsLinearCorrelationTest

StatsLinearCorrelationTest [flags] waveA, waveB

The StatsLinearCorrelationTest operation performs correlation tests on waveA and waveB, which must be real valued numeric waves and must have the same number of points. Output is to the W_STATS_LINEAR_CORRELATION wave in the current data folder or optionally to a table.

Flags

/ALPH = val  Sets the significance level (default val=0.05).
/CI  Computes confidence intervals for the correlation coefficient.
/Q  No results printed in the history area.
/RHO=rhoValue  Tests hypothesis that the correlation has a nonzero value |r| ≤ 1.
/T=k  Displays results in a table. k specifies the table behavior when it is closed.
   k=0: Normal with dialog (default).
   k=1: Kills with no dialog.
   k=2: Disables killing.
/Z  Ignores errors.

Details

The linear correlation tests start by computing the linear correlation coefficient for the n elements of both waves:

\[ r = \frac{\sum_{i=1}^{n} X_i Y_i - \frac{1}{n} \sum_{i=1}^{n} X_i \sum_{i=1}^{n} Y_i}{\sqrt{\left(\sum_{i=1}^{n} X_i^2 - \frac{1}{n} \left(\sum_{i=1}^{n} X_i\right)^2\right) \left(\sum_{i=1}^{n} Y_i^2 - \frac{1}{n} \left(\sum_{i=1}^{n} Y_i\right)^2\right)}} \]

Next it computes the standard error of the correlation coefficient

\[ sr = \sqrt{\frac{1 - r^2}{n - 2}} \]

The basic test is for hypothesis H0: the correlation coefficient is zero, in which case t and F statistics are applicable. It computes the statistics:

\[ t = \frac{r}{sr} \]

and

\[ F = \frac{1 + |r|}{1 - |r|}, \]

and then the critical values for one and two tailed hypotheses (designated by tc1, tc2,Fc1, and Fc2 respectively). Critical value for r are computed using
where \(i\) takes the values 1 or 2 for one and two tailed hypotheses. Finally, it computes the power of the test at the alpha significance level for both one and two tails (Power1 and Power2).

If you use /RHO it uses the Fisher transformation to compute

\[
\text{FisherZ} = \frac{1}{2} \ln \left( \frac{1+r}{1-r} \right)
\]

\[
\zeta = \frac{1}{2} \ln \left( \frac{1+\rho}{1-\rho} \right)
\]

the standard error approximation

\[
\sigma_\text{Z} = \sqrt{\frac{1}{n-3}}.
\]

\[
\text{Zstatistic} = \frac{\text{FisherZ} - \zeta}{\sigma_\text{Z}},
\]

and the critical values from the normal distribution \(Z_{ci}\).

The confidence intervals are calculated differently depending on the hypothesis for the value of the correlation coefficient. If /RHO is not used the confidence intervals are computed using the critical value \(F_{c2}\), otherwise they are computed using the critical \(Z_{c2}\) and \(\sigma_\text{Z}\).

**References**

**See Also**

Chapter III-12, *Statistics* for a function and operation overview; *StatsCircularCorrelationTest*, *StatsMultiCorrelationTest*, and *StatsRankCorrelationTest*.

**StatsLinearRegression**

\[\text{StatsLinearRegression} \ [\text{flags}] \ [\text{wave0}, \text{wavel}, ...]\]

The StatsLinearRegression operation performs regression analysis on the input wave(s). Output is to the W_StatsLinearRegression wave in the current data folder or optionally to a table. Additionally, the M_DunnettMCElevations, M_TukeyMCSlopes, and M_TukeyMCElevations waves may be created as specified.

**Flags**

1. **/ALPH = val**
   Sets the significance level (default \(\text{val}=0.05\)).

2. **/B = beta0**
   Tests the hypothesis that the slope \(b = beta0\) (default is 0). The results are expressed by the t-statistic, which can be compared with the \(t_c\) value for the two-tailed test. Get the critical value for a one-tailed test using StatsStudentCDF \((1 - \alpha, N - 2)\). It does not work with /MYVW.

3. **/BCIW**
   Computes two confidence interval waves for the high side and the low side of the confidence interval. The new waves are named with _CH and _CL suffixes respectively appended to the Y wave name and are created in the current data folder. For multiple runs a numeric suffix will also be appended to the names.
/BPIW=[mAdditional]
Computes prediction interval waves for the high side and the low side of the confidence interval on a single additional measurement (default). Use mAdditional to specify additional measurements. The new waves are named with _PH and _PL suffixes respectively appended to the Y wave name and are created in the current data folder. For multiple runs a numeric suffix will also be appended to the names.

/DET=controlIndex
Performs Dunnett’s multicomparison test for the elevations. The test requires more than two Y waves for regression, the test for the slopes should not reject the equal slope hypothesis, and the test for the elevations should reject the equal elevation hypothesis. controlIndex is the zero-based index of the Y wave representing the control (X waves do not count in the index specification). The test compares the elevation of every Y wave with the specified control.

Output is to the M_DunnettMCElevations wave in the current data folder or optionally to a table. For every Y wave and control Y wave combination, the results include SE, q, q’ (shown as qp), and the conclusion with 1 to accept the hypothesis of equal elevations or 0 to reject it. Use /TAIL to determine the critical value and the sense of the test. If you use /TUK you will also get the Tukey test for the set of elevations.

/MYVW={xWave, yWave}
Specifies that the input consists of multiple Y values for each X value. It ignores all other inputs and the results are appropriate only for multiple Y values at each X point.

yWave is a 2D wave of values arranged in columns. Use NaNs for padding where rows do not have the same number of entries as others. It will use the X scaling of yWave when xWave is null, /MYVW={*, yWave}.

It first tests the hypothesis (H0) that the population regression is linear in an analysis of variance calculation. It generates results 1-7 (see Details) as well as: Among Groups SS, Among Groups DF, Within Groups SS, Within Groups DF, Deviations from Linearity SS, Deviations from Linearity DF, F statistic defined by the ratio of Deviation from Linearity MS to Within Groups MS, and the critical value Fc.

Next, it tests the hypothesis that the slope beta=0. If the original H0 was accepted, the new F statistic=regressionMS/residualMS. Otherwise the with the critical F=regressionMS/WithinGroupsMS with a corresponding critical value. Finally, it reports the values of the coefficient of determination r2 and the standard error of the estimate SYX.

/PAIR
Specifies that the input waves are XY pairs, where each pair must be an X wave followed by a Y wave.

/Q
No results printed in the history area.

/RTO
Reflects the regression through the origin.

/T=k
Displays results in a table. k specifies the table behavior when it is closed.

k=0: Normal with dialog (default).
k=1: Kills with no dialog.
k=2: Disables killing.

/TAI=tCode
Sets the sense of the test when applying Dunnett’s test (see /DET). tCode is 1 or 2 for a one-tail critical value and 4 for a two-tail critical value.
/TUK Performed a Tukey-type test on multiple regressions on two or more Y waves. There are two possible Tukey-type tests: the first is performed if the hypothesis of equal slopes is rejected. It compares all combinations of two Y waves to identify if some of the waves have equal slopes. Output is to the M_TukeyMCSlopes wave in the current data folder or optionally to a table. For every Y wave pair, the results include the difference between slopes (absolute value), q, the critical value qc, and the conclusion set to 1 for accepting the equality of the pair of slopes or 0 for rejecting the hypothesis.

The second Tukey-type test is performed if all the slopes are the same but the elevations are not. The test (see /DET) compares all possible pairs of elevations to determine which satisfy the hypothesis of equality. Output is to the M_TukeyMCElevations wave in the current data folder.

/WSTR=waveListString

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.

/Z Ignores errors.

Details
Inputs may consist of Y waves or XY wave pairs. If X data are not used, the X values are inferred from the Y wave scaling. For multiple waves where only some have pairs, use the /PAIR flag and enter * in each place where the X values should be computed.

For each input StatsLinearRegression calculates:
1. Least squares regression line $y = a + bx$.
2. Mean value of X: xBar.
3. Mean value of Y: yBar.
4. Sum of the squares $(x_i - xBar)^2$.
5. Sum of the squares $(y_i - yBar)^2$.
6. Sum of the product $(x_i y_i - xyBar)$.
7. Standard error of the estimate $s_a = \frac{\sum(y_i - \hat{y}_i)^2}{n-2}$.
8. F statistic for the hypothesis $\beta = 0$.
9. Critical F value $F_{c}$.
10. Coefficient of determination $r^2$.
11. Standard error of the regression coefficient $S_b$.
12. t-statistic for the hypothesis $\beta = \beta_0$, NaN if /B is not specified.
13. Critical value $t_c$ for the t-statistic above (used to calculate L1 and L2).
14. Lower confidence interval boundary (L1) for the regression coefficient.
15. Upper confidence interval boundary (L2) for the regression coefficient.

For two Y waves with the same slope, it computes a common slope (bc) and then tests the equality of the elevations (a). In both cases it computes a t-statistic and compares it with a critical value. If the elevations are also the same then it computes the common elevation (ac) and the pooled means of X and Y in (xp) and (yp).

For more than two Y waves it computes:

$$A_c = \sum_{j=1}^{w} A_j; \quad A_j = \sum x_i^2 = \sum_{i=0}^{n_j-1} X_i^2 = \frac{1}{n_j} \left( \sum_{i=0}^{n_j-1} X_i \right)^2$$

$$B_c = \sum_{j=1}^{w} B_j; \quad B_j = \sum xy = \sum_{i=0}^{n_j-1} XY = \frac{1}{n_j} \left( \sum_{i=0}^{n_j-1} X_i \right) \left( \sum_{i=0}^{n_j-1} Y_i \right)$$
\[ C_c = \sum_{j=1}^{W} C_j; \]
\[ C_j = \sum_{i=0}^{n_j-1} Y_i^2 = \sum_{i=0}^{n_j-1} Y_i^2 - \frac{1}{n_j} \left( \sum_{i=0}^{n_j-1} Y_i \right)^2 \]

\[ SS_p = \sum_{j=1}^{W} C_j - \frac{B_j^2}{A_j} \]

\[ SS_c = C_c - \frac{B_c^2}{A_c^2} \]

\[ SS_t = \sum_{j=1}^{W} \sum_{i=0}^{n_j} Y_{ji}^2 - \frac{1}{N} \left( \sum_{j=1}^{W} \sum_{i=0}^{n_j} X_{ji}Y_{ji} \right)^2 \]
\[ \left( \sum_{j=1}^{W} \sum_{i=0}^{n_j} X_{ji}^2 - \frac{1}{N} \left( \sum_{j=1}^{W} \sum_{i=0}^{n_j} X_{ji} \right)^2 \right) \]
\[ \left( \sum_{j=1}^{W} \sum_{i=0}^{n_j} Y_{ji}^2 - \frac{1}{N} \left( \sum_{j=1}^{W} \sum_{i=0}^{n_j} Y_{ji} \right)^2 \right) \]

\[ DF_p = \sum_{j=1}^{W} (n_i - 2) \]
\[ DF_t = \sum_{j=1}^{W} n_i - 2 \]

Here \( W \) is the number of Y-waves and \( N = \sum_{j=1}^{W} n_j \) is the total number of data points in all Y-waves.

The test statistic \( F \) for equality of slopes is given by:

\[ F = \left( \frac{SS_c - SS_p}{numWaves - 1} \right) / SS_p / \frac{DF_p}{DF_t} \]

\( F_c \) is the corresponding critical value.

Output is to the W_LinearRegressionMC wave in the current data folder.

\( V \_flag \) is set to -1 for any error and to zero otherwise.

\( S \_waveNames \) is set to a semicolon-separated list of the names of the waves created by the operation.

StatsMooreCDF

\texttt{StatsMooreCDF(x, N)}

The StatsMooreCDF function returns the cumulative distribution function for Moore’s R*, which is used in a nonparametric version of the Rayleigh test for uniform distribution around the circle. It supports the range \(3 \leq N \leq 120\) and does not change appreciably for \(N>120\).

The distribution is computed from polynomial approximations derived from simulations and should be accurate to approximately three significant digits.
StatsMultiCorrelationTest

StatsMultiCorrelationTest operation performs various tests on multiple correlation coefficients. Inputs are two 1D waves: `corrWave`, containing correlation coefficients, and `sizeWave`, containing the size (number of elements) of the corresponding samples. Although you can do all the tests at the same time, it rarely makes sense to do so.

**Flags**

- **/ALPH = val**  
  Sets the significance level (default `val`=0.05).

- **/CON={controlRow, tails}**  
  Performs a multiple comparison test using the `controlRow` element of `corrWave` as a control. It is one- or two-tailed test according to the `tails` parameter. Output is to the `M_ControlCorrTestResults` wave in the current data folder.

- **/CONT=cWave**  
  Performs a multiple contrasts test on the correlation coefficients. The contrasts wave, `cWave`, contains the contrast factor, `c_i` entry for each of the `n` correlation coefficients `r_i` in `corrWave`, and satisfying the condition that the sum of the entries in `cWave` is zero. H_0 corresponds to

\[
\sum_{i=0}^{n-1} c_i r_i = 0.
\]

The test statistic `S` is

\[
S = \frac{1}{\sqrt{\sum_{i=0}^{n-1} c_i^2}} \left| \sum_{i=0}^{n-1} c_i z_i \right|, 
\]

where `z_i` is the Fisher z transform of the correlation coefficient `r_i`:

\[
z_i = \frac{1}{2} \ln \left( \frac{1 + r_i}{1 - r_i} \right).
\]

It produces the SE value, the contrast statistic `S`, and the critical value, which are labeled ContrastSE, ContrastS, and Contrast_Critical, respectively, in the `W_StatsMultiCorrelationTest` wave.

- **/Q**  
  No results printed in the history area.

- **/T=k**  
  Displays results in a table. `k` specifies the table behavior when it is closed.  
  - `k=0`: Normal with dialog (default).  
  - `k=1`: Kills with no dialog.  
  - `k=2`: Disables killing.

- **/TUK**  
  Performs a Tukey-type multi comparison testing between the correlation coefficients by comparing every possible combination of pairs of correlation coefficients, computing the difference in their z-transforms, the SE, and the q statistic.
**StatsNBinomialCDF**

\[
q = \frac{|z_j - z_i|}{\sqrt{\frac{1}{2} \left( \frac{1}{n_i - 3} + \frac{1}{n_j - 3} \right)}}.
\]

The critical value is computed from the \( q \) CDF (**StatsInvQCDF**) with degrees of freedom \( \text{numWaves} \) and infinity. Output is to the M_TukeyCorrTestResults wave in the current data folder or optionally to a table.

/Z

Ignores errors. \( \text{V\_flag} \) will be set to -1 for any error and to zero otherwise.

**Details**

Without any flags, StatsMultiCorrelationTest computes \( \chi^2 \) for the correlation coefficients and compares it with the critical value.

\[
\chi^2 = \sum_{i=0}^{n-1} z_i^2 (n_i - 3) - \frac{\left( \sum_{i=0}^{n-1} z_i (n_i - 3) \right)^2}{\sum_{i=0}^{n-1} (n_i - 3)},
\]

where \( z_i \) is the Fisher’s \( z \) transform of the correlation coefficients and \( n_i \) is the corresponding sample size. It computes the common correlation coefficient \( r_w \) and its transform \( z_w \).

\[
z_w = \frac{\sum_{i=0}^{n-1} z_i (n_i - 3)}{\sum_{i=0}^{n-1} (n_i - 3)}
\]

These values are calculated even when not appropriate, such as when \( \chi^2 \) exceeds the critical value and \( H_0 \) (all samples came from populations of identical correlation coefficients) is rejected.

The operation also computes ChiSquaredP (due to S.R. Paul), a different variant of \( \chi^2 \) that is corrected for bias and should be compared with the same critical value. Output is to the W_StatsMultiCorrelationTest wave in the current data folder or optionally to a table.

**References**

See, in particular, Chapters 19 and 11 of:

**See Also**

Chapter III-12, **Statistics** for a function and operation overview.

**StatsLinearCorrelationTest, StatsCircularCorrelationTest, StatsDunnettTest, StatsTukeyTest, StatsInvQCDF**, and **StatsScheffeTest**.

**StatsNBinomialCDF**

**StatsNBinomialCDF(\( x, k, p \))**

The StatsNBinomialCDF function returns the negative binomial cumulative distribution function

\[
F(x; k, p) = Betai(k, x + 1; p),
\]

where \( \text{betai} \) is the regularized incomplete beta function.
StatsNBinomialPDF

StatsNBinomialPDF(x, k, p)

The StatsNBinomialPDF function returns the negative binomial probability distribution function

\[ f(x;k,p) = \binom{x+k-1}{k-1} p^k (1-p)^x, \quad x = 0,1,2... \]

where \( \binom{a}{b} \) is the binomial function.

The binomial distribution expresses the probability of the \( k \)th success in the \( x+k \) trial for two mutually exclusive results (success and failure) and \( p \) the probability of success in a single trial.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsNBinomialCDF and StatsInvNBinomialCDF functions.

StatsNCChiCDF

StatsNCChiCDF(x, n, d)

The StatsNCChiCDF function returns the noncentral chi-squared cumulative distribution function

\[ F(x;n,d) = \sum_{i=1}^{\infty} \exp \left(\frac{d/2}{i!}\right) F_c(x; n+2i), \]

where \( n \geq 0 \) corresponds to degrees of freedom, \( d \geq 0 \) is the noncentrality parameter, and \( F_c \) is the central chi-squared distribution.

References

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsChiCDF, StatsNCChiPDF, and StatsChiPDF functions.

StatsNCChiPDF

StatsNCChiPDF(x, n, d)

The StatsNCChiPDF function returns the noncentral chi-squared probability distribution function

\[ f(x;n,d) = \frac{\sqrt{d} \exp \left(\frac{-x+d}{2}\right) x^{(n-1)/2}}{2^{n/4} I_{n/2-1} \left(\sqrt{dx}\right)}. \]

where \( n \geq 0 \) is the degrees of freedom, \( d \geq 0 \) is the noncentrality parameter, and \( I_n(x) \) is the modified Bessel function of the first kind, \( \text{bessI} \).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsNCChiCDF, StatsInvNCChiCDF, StatsChiCDF, and StatsChiPDF functions.
StatsNCFCDF

StatsNCFCDF(
\( x, \ n_1, \ n_2, \ d \))

The StatsNCFCDF function returns the cumulative distribution function of the noncentral F distribution. \( n_1 \) and \( n_2 \) are the shape parameters and \( d \) is the noncentrality measure. There is no closed form expression for the distribution.

References

See Also

Chapter III-12, *Statistics* for a function and operation overview; the StatsNCFPDF and StatsInvNCFCDF functions.

StatsNCFPDF

StatsNCFPDF(
\( x, \ n_1, \ n_2, \ d \))

The StatsNCFPDF function returns the probability distribution function of the noncentral F distribution

\[
f(x; n_1, n_2, d) = \frac{\exp(-d/2)}{B\left(\frac{n_1}{2}, \frac{n_2}{2}\right)} x^{n_1/2 - 1} (x n_1 + n_2)^{-\left(n_1 + n_2/2\right)} \left(\frac{n_1}{2}, \frac{n_2}{2}\right) \frac{1}{\Gamma\left(\frac{n_1 + n_2}{2}\right)} \left(\frac{xdn_1}{2}\right)
\]

where \( B() \) is the beta function and \( _1F_1() \) is the hypergeometric function hyperG1F1.

Chapter III-12, *Statistics* for a function and operation overview; the StatsNCFCDF and StatsInvNCFCDF functions.

StatsNCTCDF

StatsNCTCDF(
\( x, \ df, \ d \))

The StatsNCTCDF function returns the cumulative distribution function of the noncentral Student-T distribution. \( df \) is the degrees of freedom (positive integer) and \( d \) is the noncentrality measure. There is no closed form expression for the distribution.

References

See Also

Chapter III-12, *Statistics* for a function and operation overview; the StatsStudentCDF, StatsStudentPDF, and StatsNCTPDF functions.

StatsNCTPDF

StatsNCTPDF(
\( x, \ df, \ d \))

The StatsNCTPDF function returns the probability distribution function of the noncentral Student-T distribution. \( df \) is the degrees of freedom (positive integer) and \( d \) is the noncentrality measure.
\[ f(x; n, \delta) = \frac{n^{n/2} n!}{2^n e^{\delta^2/2} (n + x^2)^{n/2}} \cdot \frac{\sqrt{2} \delta \cdot x \cdot F_{1} \left( \frac{n + 1}{2}; \frac{3}{2} \cdot \frac{\delta^2 \cdot x^2}{2(n + x^2)} \right) + F_{1} \left( \frac{n + 1}{2}; \frac{\delta^2 \cdot x^2}{2(n + x^2)} \right)}{(n + x^2) \Gamma \left( \frac{n + 1}{2} \right) \sqrt{(n + x^2) \Gamma \left( \frac{n}{2} + 1 \right)}} \]

Chapter III-12, *Statistics* for a function and operation overview; the *StatsStudentPDF*, *StatsStudentCDF*, and *StatsNCTCDF* functions.

**StatsNormalCDF**

**StatsNormalCDF \((x, m, s)\)**
The StatsNormalCDF function returns the normal cumulative distribution function

\[ F(x; \mu, \sigma) = \frac{1}{2} + \frac{1}{2} \text{erf} \left( \frac{x - \mu}{\sigma \sqrt{2}} \right), \]

where \(\text{erf}\) is the error function.

See Also
Chapter III-12, *Statistics* for a function and operation overview; the *erf*, *StatsNormalPDF* and *StatsInvNormalCDF* functions.

**StatsNormalPDF**

**StatsNormalPDF \((x, m, s)\)**
The StatsNormalPDF function returns the normal probability distribution function

\[ f(x; \mu, \sigma) = \frac{1}{\sigma \sqrt{2\pi}} \exp \left( -\frac{(x - \mu)^2}{2\sigma^2} \right). \]

See Also
Chapter III-12, *Statistics* for a function and operation overview; the *StatsNormalCDF* and *StatsInvNormalCDF* functions.

**StatsNPMCTest**

**StatsNPMCTest \([flags]\) \([wave1, wave2, ... wave100]\)**
The StatsNPMCTest operation performs a number of nonparametric multiple comparison tests. Output waves are saved in the current data folder according to the test(s) performed. Some tests are only appropriate when you have the same number of samples in all groups. StatsNPMCTest usually follows *StatsANOVA1Test* or *StatsKWTest*.

Flags

/ALPH = \(val\) \hspace{5mm} Sets the significance level (default \(val=0.05\)).
StatsNPMCTest

/IDX controIndex
Performs nonparametric multiple comparisons on a control group specified by the zero-based controIndex wave in the input list. Output is to the M_NPCCResults wave in the current data folder or optionally to a table. The output column contents are: the first contains the difference between the rank sums of the control and each of the other waves; the second contains the standard error (SE); the third contains the statistic q, defined as the ratio of the difference in rank sums to SE; the fourth contains the critical value which also depends on the tails specification (see /TAIL); and the fifth contains the conclusion with 0 to reject H0 and 1 to accept it. One version of this test applies when all inputs contain the same number of samples. When that is not the case, it uses the Dunn-Hollander-Wolfe approach to compute an appropriate SE and to handle possible ties.

/CONW cWave
Performs a nonparametric multiple contrasts tests. cWave has one point for each input wave. The cWave value is 1 to include the corresponding (zero based) input wave in the first group, 2 to include the wave in the second group, or zero to exclude the wave. The contrast is defined as the difference between the normalized sum of the ranks of the first group and that of the second group. If cWave={0,1,1,1,2}, then the contrast is computed as

\[ \text{contrast} = \frac{1}{3} (R_{11} + R_{12} + R_{21} + R_{34} + R_{44}) \]

where \( R_{ni} \) is the normalized rank sum of the samples from the corresponding input wave. Note the significance of allowing zeros in the contrast wave because the actual ranking is performed on the pool of all the samples.

Output is to the M_NPMConResults wave in the current data folder or optionally to a table. The output column contents are: the first is the contrast value; the second is the standard error (SE); the third is the statistic S, which is the ratio of the absolute value of the contrast to SE; the fourth is the critical value (from \( \chi^2 \) the approximation); and the fifth is the conclusion with 0 to reject H0 and 1 indicating acceptance.

This test supports input waves with different number of samples and can also handle tied ranks. Note that the contrast wave used here is structured differently than for StatsMultiCorrelationTest.

/DHW
Performs the Dunn-Holland-Wolfe test, which supports unequal number of samples and accounts for ties in the rank sums. Output is to the M_NPMDHWResults wave in the current data folder or optionally to a table. The output column contents are: the first contains the difference between the means of the rank sums (rank sums divided by the number of samples in the group), the second contains the standard error (SE), the third contains the DHW statistic Q, the fourth contains the critical value, and the fifth contains the conclusion (0 to reject H0 and 1 to accept).

/Q
No results printed in the history area.

/SWN
Creates a text wave containing wave names corresponding to each row of the comparison table. Depending on your choice of tests, the following wave names are created:

/IDX test: T_NPCCResultsDescriptors
/DHW test: T_NPMDHWDescriptors
/SNK test: T_NPMCSNKResultsDescriptors
/TUK test: T_NPMCTukeyDescriptors

/T=k
Displays results in a table. k specifies the table behavior when it is closed.

k=0: Normal with dialog (default).
k=1: Kills with no dialog.
k=2: Disables killing.
StatsNPMCTest

The table is associated with the test and not with the data. If you repeat the test, it will update the table with the new results.

/TAIL=tc

Specifies $H_0$ with /CIDX.

tc=1: One tailed test ($\mu_c \leq \mu_a$).
tc=2: One tailed test ($\mu_c \geq \mu_a$).
tc=4: Default; two tailed test ($\mu_c = \mu_a$).

Code combinations are not allowed.

/SNK

Performs a nonparametric variation on the Student-Newman-Keuls test where the standard error SE is a function of $p$ (the rank difference). This test requires equal numbers of samples in all groups; use /DHW for unequal sizes.

Output is to the M_NPMCSNKResults wave in the current data folder. The output column contents are: the first contains the difference between rank sums, the second contains the standard error (SE), the third contains the $p$ value (rank difference), the fourth the statistic, the fifth contains the critical value, and the sixth contains the conclusion (0 to reject $H_0$ and 1 to accept). This test is more sensitive to differences than the Tukey test (/TUK).

/TUK

Perform a Tukey-type (Nemenyi) multiple comparison test using the difference between the rank sums. This is the default that is performed if you do not specify any of the test flags. This test requires equal numbers of points in all waves; use /DHW for unequal sizes.

Output is to the M_NPMCTukeyResults wave in the current data folder. The output column contents are: the first contains the difference between the rank sums, the second contains the SE values, the third contains the statistic $q$, the fourth contains the critical value for this specific alpha and the number of groups; and the last contains a conclusion flag with 0 indicating a rejection of $H_0$ and 1 indicating acceptance. $H_0$ postulates that the paired means are the same.

/WSTR=waveListString

Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.

/Z

Ignores errors.

Details

Inputs to StatsNPMCTest are two or more 1D numerical waves (one wave for each group of samples) containing two or more valid entries. The waves must have the same number of points for the use /SNK and /TUK tests, otherwise, for waves of differing lengths you must use the Dunn-Hollander-Wolfe test (/DHW).

$V$ flag will be set to zero for no execution errors. Individual tests may fail if, for example, there are different number of samples in the input waves for a test that requires an equal number of points. StatsNPMCTest skips failed tests and $V$ flag will be a binary combination identifying the failed test(s):

$V$ flag & 1 Tukey method failed (/TUK).
$V$ flag & 2 Student-Newman-Keuls failed (/SNK).

$V$ flag will be set to -1 for any other errors.

See Also

Chapter III-12, Statistics for a function and operation overview; StatsANOVA1Test and StatsKWTest.

For multiple comparisons in parametric tests see: StatsDunnettTest and StatsScheffeTest.
The StatsNPNominalSRTest operation performs a nonparametric serial randomness test for nominal data consisting of two types. The null hypothesis is that the data are randomly distributed. Output is to the W_StatsNPSRTest wave in the current data folder.

Flags

/ALPH = val Sets the significance level (default \( val=0.05 \)).
/Q No results printed in the history area.
/P={m,n,u} Provides a summary of the data instead of providing the nominal series. \( m \) is the number of elements of the first type, \( n \) is the number of elements of the second type, and \( u \) is the number of runs or contiguous sequences of each type. Do not use srcWave with /P.
/T=k Displays results in a table. \( k \) specifies the table behavior when it is closed.
\( k=0 \): Normal with dialog (default).
\( k=1 \): Kills with no dialog.
\( k=2 \): Disables killing.
/Z Ignores errors.

Details

The input wave to StatsNPNominalSRTest is specified with srcWave or /P. The wave must contain exactly two values. If srcWave is a text wave, then each type can be designated by a letter or by a short string (less than 200 bytes). If srcWave is numeric, you should avoid the usual floating point waves, which can give rise to internal representations of more than two distinct values. Output to W_StatsNPSRTest includes the total number of points (\( N \)), the number of occurrences (\( m \)) of the first variable, the number of occurrences (\( n \)) of the second variable, and the number of runs (\( u \)). When both \( m \) and \( n \) are less than 300, it computes the P value (probability \( P(u'<u) \)) and the critical values using the Swed and Eisenhart algorithm. When \( m \) or \( n \) are larger than 300, it computes the mean and standard deviation of an equivalent normal distribution with the corresponding critical value.

StatsParetoCDF

\[ \text{StatsParetoCDF}(x, a, c) \]

The StatsParetoCDF function returns the Pareto cumulative distribution function

\[ F(x,a,c) = 1 - \left( \frac{a}{x} \right)^c. \]

See Also

Chapter III-12, *Statistics* for a function and operation overview; the *StatsParetoPDF* and *StatsInvParetoCDF* functions.

StatsParetoPDF

\[ \text{StatsParetoPDF}(x, a, c) \]

The StatsParetoPDF function returns the Pareto probability distribution function
StatsPermute

\[ f(x; a, c) = \frac{c^a}{x^a} \left( \frac{a}{x} \right)^c, \quad a, c > 0 \]
\[ x \geq a. \]

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsParetoCDF and StatsInvParetoCDF functions.

StatsPermute

**StatsPermute(waveA, waveB, dir)**

The StatsPermute function permutes elements in `waveA` based on the lexicographic order of `waveB` and the direction `dir`. It returns 1 if a permutation is possible and returns 0 otherwise. Use `dir=1` for the next permutation and `dir=-1` for a previous permutation.

Details
Both `waveA` and `waveB` must be numeric. The lexicographic order of elements in the index wave is set so that permutations start with the index wave `waveB` in ascending order and end in descending order. Elements of `waveA` are permuted in place according to the order of the indices in `waveB` which are clipped (after permutation) to the valid range of entries in `waveA`. `waveB` is also permuted in place in order to allow you to obtain sequential permutations. If `waveA` consists of real numbers you can permute them using the lexicographic value of the entries directly. To do so pass "$\$" for `waveB`. Whenever it returns 0, neither `waveA` and `waveB` are changed.

Examples
Function AllPermutations(num)

Variable num

Variable i, nf=factorial(num)
Make/O/N=(num) wave0=p+1, waveA, waveB=p
Print wave0
for(i=0; i<nf; i+=1)
    waveA=wave0
    if(statsPermute(waveA, waveB, 1)==0)
        break
    endif
    print waveA
endfor
end

Executing AllPermutations(3) prints:

wave0[0] = {1, 2, 3}
waveA[0] = {1, 3, 2}
waveA[0] = {2, 1, 3}
waveA[0] = {2, 3, 1}
waveA[0] = {3, 1, 2}
waveA[0] = {3, 2, 1}

See Also
Chapter III-12, Statistics for a function and operation overview.

StatsPoissonCDF

**StatsPoissonCDF(x, \(\lambda\))**

The StatsPoissonCDF function returns the Poisson cumulative distribution function

\[ F(x; \lambda) = \sum_{i=0}^{x} \frac{\exp(-\lambda)\lambda^i}{i!}, \quad x = 0, 1, 2... \]

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsPoissonPDF and StatsInvPoissonCDF functions.
StatsPoissonPDF

StatsPoissonPDF

\[ \text{StatsPoissonPDF}(x, \lambda) \]

The StatsPoissonPDF function returns the Poisson probability distribution function

\[
f(x; \lambda) = \frac{e^{-\lambda} \lambda^x}{x!}, \quad x = 0, 1, 2, \ldots
\]

where \( \lambda \) is the shape parameter.

See Also

Chapter III-12, Statistics for a function and operation overview; the StatsPoissonCDF and StatsInvPoissonCDF functions.

StatsPowerCDF

StatsPowerCDF

\[ \text{StatsPowerCDF}(x, b, c) \]

The StatsPowerCDF function returns the Power Function cumulative distribution function

\[
F(x; b, c) = \left( \frac{x}{b} \right)^c
\]

where the scale parameter \( b \) and the shape parameter \( c \) satisfy \( b, c > 0 \) and \( b \geq x \geq 0 \).

See Also

Chapter III-12, Statistics for a function and operation overview; the StatsPowerPDF, StatsInvPowerCDF and StatsPowerNoise functions.

StatsPowerNoise

StatsPowerNoise

\[ \text{StatsPowerNoise}(b, c) \]

The StatsPowerNoise function returns a pseudorandom value from the power distribution function with probability distribution:

\[
f(x; b, c) = \frac{c}{x} \left( \frac{x}{b} \right)^c.
\]

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use SetRandomSeed. The algorithm uses the Mersenne Twister random number generator.

See Also

The SetRandomSeed operation.

The StatsPowerPDF StatsInvPowerCDF and StatsInvPowerCDF functions.

Noise Functions on page III-372.

Chapter III-12, Statistics for a function and operation overview.

StatsPowerPDF

StatsPowerPDF

\[ \text{StatsPowerPDF}(x, b, c) \]

The StatsPowerPDF function returns the Power Function probability distribution function

\[
f(x, b, c) = \left[ \frac{c}{x} \left( \frac{x}{b} \right) \right]^c,
\]

where \( b \) is a scale parameter and \( c \) is a shape parameter.

For \( b, c > 0 \), \( x \) is drawn from \( b \geq x \geq 0 \).
For \( b > 0, c < 0 \), \( x \) is drawn from \( x > b \).
For \( b < 0, c > 0 \), \( x \) is drawn from \( -b \leq x \leq 0 \).
For \( b < 0, c < 0 \), \( x \) is drawn from \( x < -b \).

Note that for \(-1 < c < 0\) the average diverges and the magnitude of a mean calculated from \( N \) samples will increase indefinitely with \( N \).

**See Also**
Chapter III-12, *Statistics* for a function and operation overview; the *StatsPowerCDF*, *StatsInvPowerCDF* and *StatsPowerNoise* functions.

### StatsQCDF

**StatsQCDF**\( (q, r, c, df) \)

The StatsQCDF function returns the value of the \( Q \) cumulative distribution function for \( r \) the number of groups, \( c \) the number of treatments, and \( df \) the error degrees of freedom \( (f = rc(n-1)) \) with sample size \( n \).

**Details**
The \( Q \) distribution is the maximum of several Studentized range statistics. For a simple Tukey test, use \( r = 1 \).

**References**

**See Also**
Chapter III-12, *Statistics* for a function and operation overview; the *StatsTukeyTest* function.

### StatsQPcdf

**StatsQPcdf**\( (q, nr, nt, dt, side, sSizeWave) \)

The StatsQPcdf function returns the \( Q' \) cumulative distribution function associated with Dunnett's test.

Here \( nr \) is the number of groups (should be set to 1), \( nt \) is the number of treatments, \( df \) is the error degrees of freedom.

Set \( side = 1 \) for upper-tail or \( side = 2 \) for two-tailed CDF.

\( sSizeWave \) is an integer wave of \( nt \) rows specifying the number of samples in each treatment.

**Details**
StatsQPcdf is a modified \( Q \) distribution typically used with Dunnett's test, which compares the various means with the mean of the control group or treatment.

**References**

**See Also**
Chapter III-12, *Statistics* for a function and operation overview; the *StatsDunnettTest*, *StatsInvQPcdf*, and *StatsInvQCDF* functions.

### StatsQuantiles

**StatsQuantiles** \([flags]\) \( srcWave \)

The StatsQuantiles operation computes quantiles and elementary univariate statistics for a set of data in \( srcWave \).

**Flags**

- \(/ALL\) Invokes all flags except \(/Q, /QM, and /Z.\)
- \(/BOX\) Computes parameters necessary to construct a box plot.
- \(/NaN\) Ignores NaNs, which are sorted to the end of the array by default.
StatsQuantiles

/IW  
Creates an index wave W_QuantilesIndex. W_QuantilesIndex[i] corresponds to the position of srcWave[i] when sorted from minimum to maximum.

/Q  
No information printed in the history area.

/QM=qMethod  
Specifies the method for computing quartiles. qMethod has one of these values:
0:  Tukey (default).
1:  Minitab.
2:  Moore and McCabe.
3:  Mendenhall and Sincich.

See Details for more information.

/QW  
Creates a single precision wave W_QuantileValues containing the quantile value corresponding to each entry in srcWave.

/STBL  
Uses a stable sort, which may require significant computation time for multiple entries with the same value.

/T=k  
Displays the result wave W_StatsQuantiles in a table and specifies window behavior when the user attempts to close the table.

If you use /K=2 you can still kill the window using the KillWindow operation.

/TM  
Computes the tri-mean: 0.25*(V_Q25+2*median+V_Q75).

/TRIM=tVal  
Computes the trimmed mean which is the mean value of the entries between the quantiles tVal (in %) and 100-tVal. By default tVal=25 and the trimmed mean corresponds to the midmean.

/Z  
Ignores any errors.

Details
StatsQuantiles produces quick five-number summaries or more detailed results for univariate data. Values are returned in the wave W_StatsQuantiles and in the variables:

V_min  
Minimum value.

V_max  
Maximum value.

V_Median  
Median value.

V_Q25  
Lower quartile.

V_Q75  
Upper quartile.

V_IQR  
Inter-quartile range V_Q75-VQ25, which is also known as the H-spread.

V_MAD  
Median absolute deviation.

V_mode  
The most frequent value.

If there is a tie and several values have the highest frequency then the lowest value among them is returned as the mode.

If all values in srcWave are unique or if the number of points in srcWave is less than 3, V_mode is set to NaN.

This output was added in Igor Pro 7.00.
Entries in the wave \texttt{W\_StatsQuantiles} depend on your choice of flags. Each row has a row label explicitly defining its value. If you use the /ALL flag, \texttt{W\_StatsQuantiles} will contain the following row labels:

\begin{itemize}
  \item minValue
  \item maxValue
  \item Median
  \item Q25
  \item Q75
  \item IQR
  \item \texttt{MedianAbsoluteDeviation}
  \item lowerInnerFence
  \item lowerOuterFence
  \item upperInnerFence
  \item upperOuterFence
  \item triMean
  \item trimmedMean
\end{itemize}

Otherwise, \texttt{W\_StatsQuantiles} will contain the first five entries and any additionally requested value. You should always access values using the dimension labels (see \texttt{Dimension Labels} on page II-87).

There is frequently some confusion in comparing statistical results computed by different programs because each may use a different definition of quartiles. You can specify the method of computing the quartiles as you prefer with the /QM flag. If you neglect to choose a method, \texttt{StatsQuantiles} uses Tukey’s method, which computes quartiles (also called hinges) as the lower and upper median values between the median of the data and the edges of the array. The Moore and McCabe method is similar to Tukey’s method except you do not include the median itself in computing the quartiles. Mendenhall and Sincich compute the quartiles using 1/4 and 3/4 of (numDataPoints+1) and round to the nearest integer (if the fraction part is exactly 0.5 they round up for the lower quartile and down for the upper quartile). Minitab uses the same expressions but instead of rounding it uses linear interpolation.

\texttt{StatsQuantiles} uses a stable index sorting routine so that \texttt{IndexSort W\_QuantilesIndex,srcWave} is a monotonically increasing wave.

\textbf{References}

\textbf{See Also}

Chapter III-12, \texttt{Statistics} for a function and operation overview; \texttt{WaveStats}, \texttt{StatsMedian}, \texttt{Sort}, and \texttt{MakeIndex}.

\textbf{StatsRankCorrelationTest}

\texttt{StatsRankCorrelationTest [flags] waveA, waveB}

The \texttt{StatsRankCorrelationTest} operation performs Spearman’s rank correlation test on \texttt{waveA} and \texttt{waveB}, 1D waves containing the same number of points. Output is to the \texttt{W\_StatsRankCorrelationTest} wave in the current data folder.

\textbf{Flags}

\begin{itemize}
  \item /ALPH = \texttt{val} Sets the significance level (default \texttt{val}=0.05).
  \item /Q \texttt{No results printed in the history area.}
  \item /T=\texttt{k} Displays results in a table. \texttt{k} specifies the table behavior when it is closed.
    \begin{itemize}
      \item \texttt{k=0:} Normal with dialog (default).
      \item \texttt{k=1:} Kills with no dialog.
      \item \texttt{k=2:} Disables killing.
    \end{itemize}
  \item /Z Ignores errors.
\end{itemize}
StatsRayleighCDF

Details
StatsRankCorrelationTest ranks waveA and waveB and then computes the sum of the squared differences of ranks for all rows. Ties are assigned an average rank and the corrected Spearman rank correlation coefficient is computed with ties. It reports the sum of the squared ranks (sumDi2), the sums of the ties coefficients (sumTx and sumTy respectively), the Spearman rank correlation coefficient (in the range [-1,1]), and the critical value. H0 corresponds to zero correlation against the alternative of nonzero correlation. The critical value is usually lower than the one in published tables. When the first derivative of the CDF is discontinuous, tables tend to use a more conservative value by choosing the next transition of the CDF as the critical value. StatsRankCorrelationTest is not as powerful as StatsLinearCorrelationTest.

Chapter III-12, Statistics for a function and operation overview.
StatsLinearCorrelationTest, StatsCircularCorrelationTest, StatsKendallTauTest, StatsSpearmanRhoCDF, and StatsInvSpearmanCDF.

StatsRayleighCDF

StatsRayleighCDF(x [, s [, m]])
The StatsRayleighCDF function returns the Rayleigh cumulative distribution function

\[ F(x; \sigma, \mu) = 1 - \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right), \quad \sigma > 0, x > \mu. \]

with defaults \(s=1\) and \(m=0\). It returns NaN for \(s \leq 0\) and zero for \(x \leq m\).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRayleighPDF and StatsInvRayleighCDF functions.

StatsRayleighPDF

StatsRayleighPDF(x [, s [, m]])
The StatsRayleighPDF function returns the Rayleigh probability distribution function

\[ f(x; \sigma, \mu) = \frac{x - \mu}{\sigma^2} \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right), \quad \sigma > 0, x > \mu. \]

with defaults \(s=1\) and \(m=0\). It returns NaN for \(s \leq 0\) and zero for \(x \leq m\).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRayleighCDF and StatsInvRayleighCDF functions.

StatsRectangularCDF

StatsRectangularCDF(x, a, b)
The StatsRectangularCDF function returns the rectangular (uniform) cumulative distribution function

\[
F(x,a,b) = \begin{cases} 
0 & x \leq a \\
\frac{x-a}{b-a} & a \leq x \leq b \\
1 & x \geq b 
\end{cases}
\]

where \(a < b\).
StatsRectangularPDF

StatsRectangularPDF

StatsRectangularPDF\( (x, a, b) \)

The StatsRectangularPDF function returns the rectangular (uniform) probability distribution function

\[
f(x; a, b) = \begin{cases} 
1 & \text{if } a \leq x \leq b \\
\frac{1}{b-a} & \text{otherwise}
\end{cases}
\]

where \( a < b \).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRectangularCDF and StatsInvRectangularCDF functions.

StatsResample

StatsResample \( /N=\text{numPoints} \) [flags] srcWave

The StatsResample operation resamples srcWave by drawing (with replacement) numPoints values from srcWave and storing them in the wave W_Resampled or M_Resampled if /MC is used. You can iterate the process and compute various statistics on the data samples.

Flags

/ITER=n
Repeats the resampling for \( n \) iterations, which is useful only when combined with /WS or /SQ.

/JCKN=ufunc
Performs Jack-Knife analysis. Here ufunc is a user function of the format:

Function ufunc(inWave)  
wave inWave  
... compute some statistic for inWave  
return someValue  
End

The results are stored in the wave W_JackKnifeStats in the current data folder. Use Edit W_JackKnifeStats.ld to display the wave with dimension labels.

The idea behind this method is that ufunc returns some statistic \( z \) for inWave which is a subsample of srcWave of size \( n-1 \). There are exactly \( n \) iterations and in each iteration the operation calls ufunc with one element of srcWave missing and stores the result in an internal array. At the end of iterations it uses the array to compute the various Jack-Knife estimates.

The standard estimator is defined as:

\[
Z = ufunc(srcWave).
\]

The Jack-Knife estimator is simply:

\[
\hat{z} = \frac{1}{n} \sum_{i=1}^{n} z_i.
\]
The Jack-Knife t-estimator is slightly less biased. It is given by:

\[ t = nZ - (n - 1)\hat{z}, \]

The estimate of the standard error is given by:

\[ \hat{\sigma}_z = \sqrt{\frac{n - 1}{n} \sum_{i=1}^{n} (z_i - \hat{z})^2}. \]

/K  
Kills W_Resampled after passing it to WaveStats. When /ITER is used, W_Resampled is not saved.

/MC  
Use /MC when you want to sample random (complete) rows from a multi-column 2D srcWave. The combination of /N=n with /MC results in the wave M_Resampled in the current data folder. M_Resampled will have n rows, the same number of columns and the same data type as srcWave.

/N=numPoints  
Specifies the number of points sampled from srcWave.

/Q  
No information printed in the history area.

/SQ=m  
Uses StatsQuantiles to compute the data quartiles. The methods are:

- \( m=0 \): Tukey (default).
- \( m=1 \): Minitab.
- \( m=2 \): Moore and McCabe.
- \( m=3 \): Mendenhall and Sincich.

See Details for information about how the results are stored. The default trim value is 25%.

/WS=m  
Uses WaveStats operation to calculate data statistics.

- \( m=0 \): Creates a new wave containing the samples (default).
- \( m=1 \): Creates the new wave and passes it to WaveStats/Q/M=1.
- \( m=2 \): Creates the new wave and passes it to WaveStats/Q/M=2.

See Details for information about how the results are stored.

/Z  
Ignores any errors.

Details
StatsResample can perform Bootstrap Analysis, permutations tests, and Monte-Carlo simulations. It draws the specified number of data points (with replacement) from srcWave and places them in a destination wave W_Resampled.

Specify /WS or /SQ to use the WaveStats or StatsQuantiles operations, respectively, to compute results directly from the data. StatsResample normally creates the wave W_Resampled and, optionally, the M_WaveStats and W_StatsQuantiles waves. Both options also create various V_ variables described below. If you use more than one iteration, StatsResample creates instead the waves M_WaveStatsSamples and M_StatsQuantilesSamples for the results.

M_WaveStatsSamples (with /WS) contains a column for each iteration. Each column is equivalent to the contents of M_WaveStats for that iteration. You can use the command

\text{Edit M_WaveStatsSamples.1d}

to display the results in a table using row labels, and, for example, to display a graph of the rms of the samples as a function of iteration number execute:

\text{Display M_WaveStatsSamples[5][]}

M_StatsQuantilesSamples (with /SQ) contains a column for each iteration. Each column consists of the contents of W_StatsQuantiles for the corresponding data. Here again you can execute the command
StatsSample

Edit M_StatsQuantilesSamples.1d
to display the wave in a table using row labels. To display a graph of the median as a function of iteration execute:
Display M_statsQuantilesSamples[2][]

Output Variables
StatsResample creates the following variables: V_Median, V_Q25, V_Q75, V_IQR, V_min, V_max,
V_numNaNs, V_numINFs, V_avg, V_sdev, V_rms, V_adev, V_skew, V_kurt, and V_Sum.
These unused variables are set to NaN.
If you use /SQ the operation sets V_Median, V_Q25, V_Q75, V_IQR, V_min, and V_max.
If you use /WS the operation sets V_min, V_max, V_numNaNs, V_numINFs, V_avg, V_sdev, V_rms,
V_adev, V_skew, V_kurt, and V_Sum.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsSample, WaveStats and StatsQuantiles.

StatsSample
StatsSample /N=numPoints [flags] srcWave
StatsSample creates a random, non-repeating sample from srcWave.
It samples srcWave by drawing without replacement numPoints values from srcWave and storing them in
the output wave W_Sampled or M_Sampled if /MC or /MR are used.
The /N flag is required.

Flags
/ACMB Creates a wave containing all unique combinations of numPoints values from srcWave. It is assumed that srcWave is a 1D numeric wave containing more than numPoints elements. The results are stored in the wave M_Combinations in the current data folder. Each row in the result wave corresponds to a unique combination of samples.
Added in Igor Pro 7.00.

/CMPL Stores all data elements from srcWave that were excluded from the random sample in the wave W_CompWave or M_CompWave in the current data folder. /CMPL was added in Igor Pro 8.00.

/N=numPoints Specifies the number of points sampled from srcWave. When combined with /MC, numPoints is the number of sampled rows and when combined with /MR, it is the number of sampled columns.

/MC Use /MC (multi-column) to randomly sample full rows from srcWave, i.e., the output consists of all columns of each selected row. /MC and /MR are mutually exclusive flags.

/MR Use /MR (multi-row) to randomly sample full columns from srcWave, i.e., the output consists of all rows of each of the selected columns. /MC and /MR are mutually exclusive flags.

/Z Ignores errors.

Details
If you omit /MC and /MR, the output is a 1D wave named W_Sampled where the samples are chosen from srcWave without regard to its dimensionality.
If you use either /MC or /MR the output is a 2D wave named M_Sampled which will have either the same number of columns (/MC) as srcWave or the same number of rows (/MR) as srcWave.

Chapter III-12, Statistics, StatsResample
StatsRunsCDF

StatsRunsCDF (n, r)
The StatsRunsCDF function returns the cumulative distribution function for the up and down runs
distribution for total number of runs r in a random linear arrangement of n unequal elements. There is no
closed form expression. It is computed numerically from the recursion of the probability density

\[ f(r, n) = \frac{rf(r, n-1) + 2f(r-1, n-1) + (n-r)f(r-2, n-1)}{n}, \]

with the initial condition

\[ f(1, n) = \frac{2}{n!}. \]

References
Olmstead, P.S., Distribution of sample arrangements for runs up and down, Annals of Mathematical
Statistics, 17, 24-33, 1946.

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsSRTTest function.

StatsScheffeTest

StatsScheffeTest [flags] [wave1, wave2, ... wave100]
The StatsScheffeTest operation performs Scheffe’s test for the equality of the means. It supports two basic
modes: the default tests all possible combinations of pairs of waves; the second tests a single combination
where the precise form of H0 is determined by the coefficients of a contrast wave (see /CONT). Output is to
the M_ScheffeTestResults wave in the current data folder.

Flags
/ALPH=val Sets the significance level (default 0.05).
/CONW=cWave Performs a multiple contrasts test. cWave has one point for each input wave. The
cWave value is 1 to include the corresponding (zero based) input wave in the first
group, 2 to include the wave in the second group, or zero to exclude the wave.

The contrast is defined as the difference between the normalized sum of the ranks of
the first group and that of the second group. If cWave=[0,1,1,1,2], then the contrast
hypothesis H0 corresponds to:

\[ \frac{\bar{X}_1 + \bar{X}_2 + \bar{X}_3}{3} - \bar{X}_4 = 0. \]

For each pair of waves (i, j) with i \neq j, it computes

\[ SE_{ij} = \sqrt{s^2 \left( \frac{1}{n_j} + \frac{1}{n_i} \right)}, \quad s^2 = \sum_{i=1}^{w} \sum_{j=0}^{n_i-1} X_j^2 - \sum_{i=1}^{w} \left( \sum_{j=0}^{n_i-1} X_j \right)^2 n_j, \]
StatsShapiroWilkTest

The StatsShapiroWilkTest computes Shapiro-Wilk statistic W and its associated P-value and stores them in V_statistic and V_prob respectively.

**Flags**
- **/Q**  
  No results printed in the history area.
- **/Z**  
  Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

**Details**
The Shapiro-Wilk test tests the null hypothesis that the population is normally distributed. If the P-value is less than the selected alpha then the null hypothesis, normality, is rejected.
The test is valid only for waves containing 3 to 5000 data points. The operation ignores any NaNs or INFs in srcWave.

Example

```c
// Test normally distributed data
Make/O/N=(200) ggg=gnoise(5)
StatsShapiroWilkTest ggg
W=0.995697 p=0.846139 // p>alpha so accept normality

// Test uniform distribution
Make/O/N=(200) eee=enoise(5)
StatsShapiroWilkTest eee
W=0.959616 p=1.7979e-05 // p<alpha so reject normality
```

StatsSignTest

`StatsSignTest [flags] wave1, wave2`

The StatsSignTest operation performs the sign test for paired-sample data contained in `wave1` and `wave2`.

**Flags**

- `/ALPH=val` Sets the significance level (default 0.05).
- `/Q` No results printed in the history area.
- `/T=k` Displays results in a table. `k` specifies the table behavior when it is closed.
  - `k=0`: Normal with dialog (default).
  - `k=1`: Kills with no dialog.
  - `k=2`: Disables killing.
- `/Z` Ignores errors. V_flag will be set to -1 for any error and to zero otherwise.

**Details**

The input waves must be the equal length, real numeric waves and must not contain any NaNs or INFs. Results are saved in the wave W_SignTest and are optionally displayed in a table. StatsSignTest computes the differences in each pair and counts the total number of entries with positive and negative differences, and tests the results using a binomial distribution. When the number of data pairs exceeds 1024 it uses a normal approximation to the binomials for calculating the probabilities and the power of the test.

**References**

Chapter III-12, *Statistics* for a function and operation overview.

StatsWilcoxonRankTest

StatsSpearmanRhoCDF

`StatsSpearmanRhoCDF(r, N)`

The StatsSpearmanRhoCDF function returns the cumulative distribution function for Spearman’s `r`, which is used in rank correlation test. It is valid for `N>1` and `-1 ≤ r ≤ 1`. The distribution is mostly computed using the Edgeworth series expansion.

**References**

**See Also**

Chapter III-12, *Statistics* for a function and operation overview; the StatsRankCorrelationTest, StatsInvSpearmanCDF, and StatsKendallTauTest functions.
The StatsSRTest operation performs a parametric or nonparametric serial randomness test on srcWave, which must contain finite numerical data. The null hypothesis of the test is that the data are randomly distributed. Output is to the W_StatsSRTest wave in the current data folder.

**Flags**

- **/ALPH = val** Sets the significance level (default val=0.05).
- **/GCD** Tests the output of a random number generator (RNG). srcWave consists of values between 0 and 2^{32} (converted to unsigned 32-bit integers). GCD computes the gcd for consecutive pairs of data in srcWave. The number of steps in the GCD and the distribution of the GCD's are compared with ideal distributions and corresponding P values are reported. This test is part of Marsaglia’s Die-Hard battery of tests. P-values close to either 0 or 1 indicate a nonideal RNG. You should use the reported minimum and maximum values to check that the input is indeed in the proper range. Typically srcWave consists of at least1e6 entries.
- **/NAPR** Use the normal approximation even when the number of points is below 150.
- **/NP** Performs a nonparametric serial randomness test by counting the numbers of runs up and down and computing the probability that such a value is obtained by chance.
- **/P** Performs a parametric serial randomness test.
- **/Q** No results printed in the history area.
- **/T=k** Displays results in a table. k specifies the table behavior when it is closed.
  - k=0: Normal with dialog (default).
  - k=1: Kills with no dialog.
  - k=2: Disables killing.
- **/Z** Ignores errors.

**Details**

The parametric test for serial randomness is according to Young. C is given by

\[
C = 1 - \frac{\sum_{i=0}^{n-2} (X_i - X_{i+1})^2}{2 \sum_{i=0}^{n-1} (X_i - \bar{X})^2},
\]

where \( \bar{X} \) is the mean and n is the number of points in srcWave. The critical value is obtained from mean square successive difference distribution StatsInvCMSSDCDF. For more than 150 points, StatsSRTest uses the normal approximation and provides the critical values from the normal distribution. For samples from a normal distribution, C is symmetrically distributed about 0 with positive values indicating positive correlation between successive entries and negative values corresponding to negative correlation.

The nonparametric test consists of counting the number of runs that are successive positive or successive negative differences between sequential data. If two sequential data are the same it computes two numbers of runs by considering the two possibilities where the equality is replaced with either a positive or a negative difference. The results of the operation include the number of runs up and down, the number of unchanged values (the number of places with no difference between consecutive entries), the size of the longest run and its associated probability, the number of converted equalities, and the probability that the number of runs is less than or equal to the reported number (StatsRunsCDF). When equalities are encountered the operation computes the probabilities that the computed number of runs or less can be found in an equivalent random sequence.
Converted equalities are those with the same sign on both sides so that when we replace the equality by the opposite sign we increase the number of runs. The equalities that are not converted are found between two different signs and therefore regardless of the sign that we give them they do not affect the total number of runs. We implicitly assume that the data does not contain more than one sequential equalities.

The longest run is determined without taking into account equalities or their conversions. The probability of the longest run is computed from Equation 6 of Olmstead, which is accurate within 0.001 when the number of runs is 5 or more. This probability applies to either positive or negative differences and should be divided by two if a specific sign is selected.

References

Chapter III-12, *Statistics* for a function and operation overview; *StatsNPNominalSRTest* and *StatsRunsCDF* functions.

**StatsStudentCDF**

**StatsStudentCDF***(t, n)*

The StatsStudentCDF function returns the Student (uniform) cumulative distribution function

\[ F(t,n) = \begin{cases} 
\frac{1}{2} \{ 1 + I \left( \frac{n}{2}, \frac{1}{2}; \frac{n}{n+t^2} \right) - I \left( \frac{n}{2}, \frac{1}{2}; \frac{n}{n+t^2} \right) \} & t > 0 \\
\frac{1}{2} \{ 1 + I \left( \frac{n}{2}, \frac{1}{2}; \frac{n}{n+t^2} \right) - I \left( \frac{n}{2}, \frac{1}{2}; \frac{n}{n+t^2} \right) \} & t < 0 \\
\frac{1}{2} & t = 0 
\end{cases} \]

where \( n > 0 \) is degrees of freedom and is the incomplete beta function \( \text{betal} \).

See Also
Chapter III-12, *Statistics* for a function and operation overview; the *StatsStudentPDF* and *StatsInvStudentCDF* functions.

**StatsStudentPDF**

**StatsStudentPDF***(t, n)*

The StatsStudentPDF function returns the Student (uniform) probability distribution function

\[ f(t,n) = \frac{n}{\sqrt{n}B\left( n, \frac{1}{2}, \frac{1}{2} \right)} \left( \frac{n}{n+t^2} \right)^{(n+1)/2} \]

where \( n > 0 \) is degrees of freedom and \( B() \) is the \( \text{beta} \) function.
See Also
Chapter III-12, Statistics for a function and operation overview; the StatsStudentCDF and StatsInvStudentCDF functions.

StatsTopDownCDF

StatsTopDownCDF(r, N)
The StatsTopDownCDF function returns the cumulative distribution function for the top-down correlation coefficient. It is computationally intensive because it must evaluate many permutations \([O((n!)^2)]\). It exactly calculates the distribution for \(3 \leq N \leq 7\); outside this range it uses Monte-Carlo estimation for \(8 \leq N \leq 50\) and asymptotic Normal approximation for \(N>50\). The Monte-Carlo estimate uses 1e6 random permutations fitted with two 9-order polynomials for the range \([-1,0]\) and \([0,1]\). The results are within 0.2% of exact values where known.

References

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsRankCorrelationTest and StatsInvTopDownCDF functions.

StatsTriangularCDF

StatsTriangularCDF(x, a, b, c)
The StatsTriangularCDF function returns the triangular cumulative distribution function

\[
F(x; a, b, c) = \begin{cases} 
0 & x \leq a \\
\frac{(x-a)^2}{(b-a)(c-a)} & a < x \leq c \\
1 - \frac{(b-x)^2}{(b-a)(b-c)} & c < x < b \\
1 & x \geq b 
\end{cases}
\]

where \(a < c < b\).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsTriangularPDF and StatsInvTriangularCDF functions.

StatsTriangularPDF

StatsTriangularPDF(x, a, b, c)
The StatsTriangularPDF function returns the triangular probability distribution function

\[
f(x; a, b, c) = \begin{cases} 
\frac{2(x-a)}{(b-a)(c-a)} & a \leq x < c \\
\frac{2(b-x)}{(b-a)(b-c)} & c < x \leq b \\
0 & Otherwise 
\end{cases}
\]

where \(a < c < b\).

See Also
Chapter III-12, Statistics for a function and operation overview; the StatsTriangularCDF and StatsInvTriangularCDF functions.
StatsTrimmedMean

StatsTrimmedMean\( (\text{waveName}, \ \text{trimValue}) \)

The StatsTrimmedMean function returns the mean of the wave \(\text{waveName}\) after removing \(\text{trimValue}\) fraction of the values from both tails of the distribution. \(\text{trimValue}\) is a number in the range \([0, 0.5]\). \(\text{waveName}\) can be any real numeric type.

See Also
Chapter III-12, Statistics for a function and operation overview; StatsQuantiles and mean.

StatsTTest

StatsTTest \([\text{flags}] \ \text{wave1} \ [, \ \text{wave2}]\)

The StatsTTest operation performs two kinds of T-tests: the first compares the mean of a distribution with a specified mean value (/MEAN) and the second compares the means of the two distributions contained in \(\text{wave1}\) and \(\text{wave2}\), which must contain at least two data points, can be any real numeric type, and can have an arbitrary number of dimensions. Output is to the W_StatsTTest wave in the current data folder or optionally to a table.

Flags

/ALPH = \(\text{val}\) \hspace{1em} Sets the significance level (default \(\text{val}=0.05\)).

/CI \hspace{1em} Computes the confidence intervals for the mean(s).

/DFM=\(m\) \hspace{1em} Specifies method for calculating the degrees of freedom.

\(m=0\): \hspace{1em} Default; computes equivalent degrees of freedom accounting for possibly different variances.

\(m=1\): \hspace{1em} Computes equivalent degrees of freedom but truncates to a smaller integer.

\(m=2\): \hspace{1em} Computes degrees of freedom by \(DF=n_1+n_2-2\), where \(n\) is the sum of points in the wave. Appropriate when variances are equal.

/MEAN=\(\text{meanV}\) \hspace{1em} Compares \(\text{meanV}\) with the mean of the distribution in \(\text{wave1}\). Outputs are the number of points in the wave, the degrees of freedom (accounting for any NaNs), the average, standard deviation (\(\sigma\)),

\[
S_x = \frac{\sigma}{\sqrt{DF + 1}},
\]

the statistic

\[
t = \frac{\bar{X} - \text{meanV}}{S_x},
\]

and the critical value, which depends on /TAIL.

/PAR \hspace{1em} Specifies that the input waves are pairs and computes the difference of each pair of data to get the average difference \(\bar{d}\) and the standard error of the difference \(S_{\bar{d}}\). The t statistic is the ratio of the two

\[
t = \frac{\bar{d}}{S_{\bar{d}}},
\]

In this case \(H_0\) is that the difference \(\bar{d}\) is zero.

This mode does not support /CI and /DFM.

/Q \hspace{1em} No results printed in the history area.
When comparing the mean of a single distribution with a hypothesized mean value, you should use /MEAN and only one wave (wave1). If you use two waves StatsTTest performs the T-test for the means of the corresponding distributions (which is incompatible with /MEAN).

When comparing the means of two distributions, the default t-statistic is computed from Welch’s approximate t:

\[
t' = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}},
\]

where \(s_i^2\) are variances, \(n_i\) the number of samples, and \(\bar{x}_i\) the averages of the respective waves. This expression is appropriate when the number of points and the variances of the two waves are different. If you want to compute the t-statistic using pooled variance you can use the /AEVR flag. In this case the pooled variance is given by

\[
s_p^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2},
\]

and the t-statistic is

\[
t = \frac{\bar{x}_1 - \bar{x}_2}{s_p \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}},
\]

The different test are:

/T=k
Displays results in a table. \(k\) specifies the table behavior when it is closed.

\(k=0\): Normal with dialog (default).
\(k=1\): Kills with no dialog.
\(k=2\): Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/TAIL=tailCode
Specifies \(H_0\).

\(tailCode=1\): One tailed test \((\mu_1 \leq \mu_2)\).
\(tailCode=2\): One tailed test \((\mu_1 \geq \mu_2)\).
\(tailCode=4\): Default; two tailed test \((\mu_1 = \mu_2)\).

When performing paired tests using /PAIR:

\(tailCode=1\): One tailed test \((\mu_d \leq 0)\).
\(tailCode=2\): One tailed test \((\mu_d \geq 0)\).
\(tailCode=4\): Default; two tailed test \((\mu_d = 0)\).

Here \(\mu_d\) is the mean of the difference population.

/Z
Ignores errors. \(V\_flag\) will be set to -1 for any error and to zero otherwise.

Details
When comparing the mean of a single distribution with a hypothesized mean value, you should use /MEAN and only one wave (wave1). If you use two waves StatsTTest performs the T-test for the means of the corresponding distributions (which is incompatible with /MEAN).

When comparing the means of two distributions, the default t-statistic is computed from Welch’s approximate t:
StatsTukeyTest

<table>
<thead>
<tr>
<th>$H_0$</th>
<th>Rejection Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\mu_1 = \mu_2$</td>
<td>$</td>
</tr>
<tr>
<td>$\mu_1 &gt; \mu_2$</td>
<td>$t \leq T_c(\alpha, V)$</td>
</tr>
<tr>
<td>$\mu_1 &lt; \mu_2$</td>
<td>$t \geq T_c(\alpha, V)$</td>
</tr>
</tbody>
</table>

$T_c$ is the critical value and $V$ is the effective number of degrees of freedom (see /DFM flag). When accounting for possibly unequal variances, $V$ is given by

$$V = \left( \frac{s_1^2}{n_1} + \frac{s_2^2}{n_2} \right)^2 \cdot \frac{n_1 - 1 + n_2}{n_1 n_2} \cdot \frac{1}{\left( \frac{s_1^2}{n_1} \right)^2 + \left( \frac{s_2^2}{n_2} \right)^2}.$$

The critical values ($T_c$) are computed by numerically by solving for the argument at which the cumulative distribution function (CDF) equals the appropriate values for the tests. The CDF is given by

$$F(x) = \begin{cases} \frac{1}{2} \text{betai} \left( \frac{v}{2}, \frac{1}{2}, \frac{v}{v + x^2} \right) & x < 0 \\ 1 - \frac{1}{2} \text{betai} \left( \frac{v}{2}, \frac{1}{2}, \frac{v}{v + x^2} \right) & x \geq 0. \end{cases}$$

To get the critical value for the upper one-tail test we solve $F(x) = 1 - \alpha$. For the lower one-tail test we solve for $x$ the equation $F(x) = \alpha$. In the two-tailed test the lower critical value is a solution for $F(x) = \alpha/2$ and the upper critical value is a solution for $F(x) = 1 - \alpha/2$.

The T-test assumes both samples are randomly taken from normal population distributions.

References

StatsTukeyTest

StatsTukeyTest [flags] [wave1, wave2, ... wave100]

The StatsTukeyTest operation performs multiple comparison Tukey (HSD) test and optionally the Newman-Keuls test. Output is to the M_TukeyTestResults wave in the current data folder. StatsTukeyTest usually follows StatsANOVA1Test.

Flags
/ALPH = val Sets the significance level (default val=0.05).
/NK Computes the Newman-Keuls test.
/Q No results printed in the history area.
/SWN Creates a text wave, T_TukeyDescriptors, containing wave names corresponding to each row of the comparison table (Save Wave Names). Use /T to append the text wave to the last column.
Inputs to StatsTukeyTest are two or more 1D numeric waves (one wave for each group of samples) containing any numbers of points but with at least two or more valid entries.

The contents of the M_TukeyTestResults columns are: the first contains the difference between the group means, the second contains SE (supports unequal number of points), the third contains the q statistic for the pair, and the fourth contains the critical q value, the fifth contains the conclusion with 0 to reject \( H_0 \) (\( \mu_i = \mu_j \)) or 1 to accept \( H_0 \), with \( /NK \), the sixth contains the \( p \) values, the seventh contains the critical values, and the eighth contains the Newman-Keuls conclusion (with 0 to reject and 1 to accept \( H_0 \)). The order of the rows is such that all possible comparisons are computed sequentially starting with the comparison of the group having the largest mean with the group having the smallest mean.

\( V \_\text{flag} \) will be set to -1 for any error and to zero otherwise.

Chapter III-12, Statistics for a function and operation overview; StatsANOVA1Test, StatsScheffeTest, and StatsDunnettTest.

**StatsUSquaredCDF**

\( \text{StatsUSquaredCDF}(u2, n, m, \text{method}, \text{useTable}) \)

The StatsUSquaredCDF function returns the cumulative distribution function for Watson’s \( U^2 \) with parameters \( u2 \) (\( U^2 \) statistic) and integer sample sizes \( n \) and \( m \). The calculation is computationally intensive, on the order of \( \text{binomial}(n+m, m) \). Use a nonzero value for \( \text{useTable} \) to search a built-in table of values. If \( n \) and \( m \) cannot be found in the table, it will proceed according to \( \text{method} \):

<table>
<thead>
<tr>
<th>method</th>
<th>What It Does</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Exact computation using Burr algorithm (could be slow).</td>
</tr>
<tr>
<td>1</td>
<td>Tiku approximation using chi-squared.</td>
</tr>
<tr>
<td>2</td>
<td>Use built-in table only and return a NaN if not in table.</td>
</tr>
</tbody>
</table>

For large \( n \) and \( m \), consider using the Tiku approximation. To abort execution, press the User Abort Key Combinations.

Precomputed tables, using the algorithm described by Burr, contain these values:

<table>
<thead>
<tr>
<th>( n )</th>
<th>( m )</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>4-30</td>
</tr>
<tr>
<td>5</td>
<td>5-30</td>
</tr>
<tr>
<td>6</td>
<td>6-30</td>
</tr>
<tr>
<td>7</td>
<td>7-30</td>
</tr>
</tbody>
</table>
Because \( n \) and \( m \) are interchangeable, \( n \) should always be the smaller value. For \( n>8 \) the upper limit in the table matched the maximum that can be computed using the Burr algorithm. There is no point in using method 0 with \( m \) values exceeding these limits.

**StatsVariancesTest**

The **StatsVariancesTest** operation performs Bartlett’s or Levene’s test to determine if wave variances are equal. Output is to the \( W_{StatsVariancesTest} \) wave in the current data folder or optionally to a table.

**Flags**

- **/ALPH** = \( val \)
  Sets the significance level (default \( val = 0.05 \)).

- **/METH** = \( m \)
  Specifies the test type.
  - \( m=0 \): Bartlett test (default).
  - \( m=1 \): Levene’s test using the mean.
  - \( m=2 \): Modified Levene’s test using the median.
  - \( m=3 \): Modified Levene’s test using the 10% trimmed mean.

- **/Q**
  No results printed in the history area.

- **/T** = \( k \)
  Displays results in a table. \( k \) specifies the table behavior when it is closed.
  - \( k=0 \): Normal with dialog (default).
  - \( k=1 \): Kills with no dialog.
  - \( k=2 \): Disables killing.

  The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

- **/WSTR** = \( waveListString \)
  Specifies a string containing a semicolon-separated list of waves that contain sample data. Use \( waveListString \) instead of listing each wave after the flags.

- **/Z**
  Ignores errors. \( V\_flag \) will be set to -1 for any error and to zero otherwise.

**Details**

All tests define the null hypothesis by
\[ H_0 : \quad \sigma_1^2 = \sigma_2^2 = \ldots = \sigma_k^2, \]

gainst the alternative

\[ H_a : \quad \sigma_i^2 \neq \sigma_j^2 \text{ for at least one } i \neq j. \]

Bartlett’s test computes:

\[
T = \frac{(n - k) \ln(\sigma_w^2) - \sum_{i=1}^{k} (n_i - 1) \ln(\sigma_i^2)}{1 + \frac{1}{3(k-1)} \left[ \sum_{i=1}^{k} \frac{1}{n_i - 1} - \frac{1}{N - k} \right]}.
\]

Here \( \sigma_i^2 \) is the variance of the \( i \)th wave, \( N \) is the sum of the points of all the waves, \( n_i \) is the number of points in wave \( i \), and \( k \) is the number of waves. The weighted variance is given by

\[ \sigma_w^2 = \frac{\sum_{i=1}^{k} (n_i - 1) \sigma_i^2}{N - k}. \]

\( H_0 \) is rejected if \( T \) is greater than the critical value taken from the \( \chi^2 \) distribution computed by solving for \( x \):

\[ 1 - \alpha = 1 - \text{gammq} \left( \frac{k - 1}{2}, \frac{x}{2} \right). \]

Levene’s test computes:

\[
W = \frac{(N - k) \sum_{i=1}^{k} n_i (Z_i - \overline{Z})^2}{(k - 1) \sum_{i=1}^{k} \sum_{j=1}^{k} (Z_{ij} - \overline{Z_i})^2},
\]

where

\[ Z_{ij} = |Y_{ij} - \overline{Y_i}|, \]

\[ \overline{Z_i} = \frac{1}{n_i} \sum_{j=1}^{k} Z_{ij}, \]

\[ \overline{Z} = \frac{1}{N} \sum_{i=1}^{k} \sum_{j=1}^{k} Z_{ij}. \]

\( Y_i \) depends on /METH.

\( H_0 \) is rejected if \( W \) is greater than the critical value from the F distribution computed by solving for \( x \):

\[ 1 - \alpha = 1 - \text{betai} \left( \frac{V_2}{2}, \frac{V_1}{2}, \frac{V_2}{V_2 + V_1 x} \right). \]

\textbf{StatsWatsonUSquaredTest}

\texttt{StatsWatsonUSquaredTest [flags] srcWave1, srcWave2}

The \texttt{StatsWatsonUSquaredTest} operation performs Watson’s nonparametric two-sample \( U^2 \) test for samples of circular data. Output is to the \texttt{W_WatsonUtest} wave in the current data folder or optionally to a table.

\textbf{Flags}

- \texttt{/ALPH=val} \quad \text{Sets the significance level (default \texttt{val}=0.05).}
- \texttt{/Q} \quad \text{No results printed in the history area.}
- \texttt{/T=k} \quad \text{Displays results in a table.} \( k \) specifies the table behavior when it is closed.
  - \( k=0 \): Normal with dialog (default).
  - \( k=1 \): Kills with no dialog.
  - \( k=2 \): Disables killing.
  
  The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
- \texttt{/Z} \quad \text{Ignores errors.}
Details
The input waves, srcWave1 and srcWave2, each must contain at least two angles in radians (mod 2π), can have any number of dimensions, and can be single or double precision. They must not contain any NaNs or INFs.

The Watson U2 H0 postulates that the two samples came from the same population against the different populations alternative. In the calculation, StatsWatsonUSquaredTest ranks the two inputs, accounts for possible ties, computes the test statistic U2, and compares it with the critical value. Because of the difficulty of computing the critical values, it always computes first the approximation due to Tiku and if possible it computes the exact critical value using the method outlined by Burr. You can evaluate the U2 CDF to get more information about the critical region.

V_flag will be set to -1 for any error and to zero otherwise.

References
We have found that this method leads to slightly different results depending on the compiler and the system on which it is implemented:

Chapter III-12, Statistics for a function and operation overview; StatsWatsonWilliamsTest, StatsWheelerWatsonTest, StatsUSquaredCDF, and StatsInvUSquaredCDF.

StatsWatsonWilliamsTest
StatsWatsonWilliamsTest [flags] [srcWave1, srcWave2, srcWave3, ...]
The StatsWatsonWilliamsTest operation performs the Watson-Williams test for two or more sample means. Output is to the W_WatsonWilliams wave in the current data folder or optionally to a table.

Flags
/ALPH = val Sets the significance level (default val=0.05).
/Q No results printed in the history area.
/T=k Displays results in a table. k specifies the table behavior when it is closed.
 k=0: Normal with dialog (default).
 k=1: Kills with no dialog.
 k=2: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/WSTR=waveListString Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.
/Z Ignores errors.

Details
The StatsWatsonWilliamsTest must have at least two input waves, which contain angles in radians, can be single or double precision, and can be of any dimensionality; the waves must not contain any NaNs or INFs.

The Watson-Williams H0 postulates the equality of the means from all samples against the simple inequality alternative. The test computes the sums of the sines and cosines from which it obtains a weighted r value (rw). According to Mardia, you should use different statistics depending on the size of rw: for rw>0.95 use the simple F statistic, but for 0.95>rw>0.7 you should use the F-statistic with the K correction factor. Otherwise you should use the t-statistic. StatsWatsonWilliamsTest computes both the (corrected) F-statistic and the t-statistic as well as their corresponding critical values.

V_flag will be set to -1 for any error and to zero otherwise.

*StatsInvWeibullCDF* functions.

**StatsWheelerWatsonTest**

_statswheelerwatsontest [flags] [srcWave1, srcWave2, srcWave3,...]_
The StatsWheelerWatsonTest operation performs the nonparametric Wheeler-Watson test for two or more samples. Output is to the W_WheelerWatson wave in the current data folder or optionally to a table.

**Flags**

_/ALPH = val_ Sets the significance level (default _val=0.05_).
_/Q_ No results printed in the history area.
_/T=k_ Displays results in a table. \( k \) specifies the table behavior when it is closed.

Displays results in a table. \( k \) specifies the table behavior when it is closed.

\( k=0: \) Normal with dialog (default).
\( k=1: \) Kills with no dialog.
\( k=2: \) Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.
StatsWilcoxonRankTest

/WSTR=waveListString
  Specifies a string containing a semicolon-separated list of waves that contain sample data. Use waveListString instead of listing each wave after the flags.

/Z
  Ignores errors.

Details
The StatsWatsonWilliamsTest must have at least two input waves, which contain angles in radians (mod $2\pi$), can be single or double precision, and can be of any dimensionality; the waves must not contain any NaNs or INFs.

The Wheeler-Watson $H_0$ postulates that the samples came from the same population. The extension of the test to more than two samples is due to Mardia. The Wheeler-Watson test is not valid for data with ties, in which case you should use Watson’s $U^2$ test.

V_flag will be set to -1 for any error and to zero otherwise.

References

See, in particular, Chapter 27 of:

See Also
Chapter III-12, Statistics for a function and operation overview; StatsWatsonUSquaredTest and StatsWheelerWatsonTest.

StatsWilcoxonRankTest

StatsWilcoxonRankTest [flags] waveA, waveB
The StatsWilcoxonRankTest operation performs the nonparametric Wilcoxon-Mann-Whitney two-sample rank test or the Wilcoxon Signed Rank test (for paired data) on waveA and waveB. Output is to the W_WilcoxonTest wave in the current data folder or optionally to a table.

waveA and waveB must not contain NaNs or INFs.

Flags

/ALPH = val
  Sets the significance level (default val=0.05).

/APRX=m
  Sets the approximation method. It computes an exact critical value by default.
  
m=1: Standard normal approximation with ties (Zar P. 151).
  
m=2: Improved normal approximation (Zar P. 152).

Approximations may be appropriate for large sample sizes when computation may take a long time.

/Q
  No results printed in the history area.

/T=k
  Displays results in a table. k specifies the table behavior when it is closed.
  
k=0: Normal with dialog (default).
  
k=1: Kills with no dialog.
  
k=2: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/TAIL=tail
  tail is a bitwise parameter that specifies the tails tested.
  
  Bit 0: Lower tail.
  
  Bit 1: Upper tail (default).
  
  Bit 2: Two tail.
The Wilcoxon-Mann-Whitney test combines the two samples and ranks them to compute the statistic $U$. If $waveA$ has $m$ points and $waveB$ has $n$ points, then $U$ is given by

$$U = mn + \frac{m(m + 1)}{2} - R_i,$$

with the corresponding statistic $U'$ given by

$$U' = nm + \frac{n(n + 1)}{2} - R2.$$

where $R_i$ is the ranks of data in the $i$th wave (ranked in ascending order).

The distribution of $U$ is difficult to compute, requiring the number of possible permutations of $m$ elements of $waveA$ and $n$ elements of $waveB$ that give rise to $U$ values that do not exceed the one computed. The distribution is computed according to the algorithm developed by Klotz. With increasing sample size one can avoid the time consuming distribution computation and use a normal approximation instead. Klotz recommends this approximation for $N=m+n-100$.

Use /APRX=2 for the best approximation. The two approximations are discussed by Zar.

The Wilcoxon Signed Rank Test, or Wilcoxon Paired-Sample Test, ranks the difference between pairs of values and computes the sums of the positive ranks ($Tp$) and the negative ranks ($Tm$). It calculates $Tp$ and $Tm$ and P-values for all tail combinations. The P-values are:

- $P_{\text{lower\_tail}}$ (P(Wp<=$Tp$))
- $P_{\text{upper\_tail}}$ (P(Wp>=$Tp$))
- $P_{\text{two\_tail}} = 2\times\text{Min}(P_{\text{lower\_tail}}, P_{\text{upper\_tail}})$

$Wp$ is the generic symbol for the sum of positive ranks for the given number of pairs.

$V_{\text{flag}}$ will be set to -1 for any error and to zero otherwise.

In both Wilcoxon-Mann-Whitney two-sample rank test and the Wilcoxon Signed Rank test $H0$ is that the data in the two input waves are statistically the same.

Klotz, J.H., *Computational Approach to Statistics*.

See Also

Chapter III-12, *Statistics* for a function and operation overview.
StatsWRCorrelationTest

StatsAngularDistanceTest, StatsKWTest, StatsWilcoxonRankTest

StatsWRCorrelationTest

StatsWRCorrelationTest [flags] waveA, waveB

The StatsWRCorrelationTest operation performs a Weighted Rank Correlation test on waveA and waveB, which contain the ranks of sequential factors. The waves are 1-based, integer ranks of factors in the range 1-2^31.

StatsWRCorrelationTest computes a top-down correlation coefficient using Savage sums as well as the critical and P-values. Output is to the W_StatsWRCorrelationTest wave in the current data folder or optionally to a table.

Flags

/ALPH = val  Sets the significance level (default val=0.05).
/Q        No results printed in the history area.
/T=k      Displays results in a table. k specifies the table behavior when it is closed.
          k=0: Normal with dialog (default).
          k=1: Kills with no dialog.
          k=2: Disables killing.

The table is associated with the test, not the data. If you repeat the test, it will update any existing table with the new results.

/Z        Ignores errors.

Details

The StatsWRCorrelationTest input waves must be one-dimensional and have the same length. The waves are 1-based, integer ranks of factors corresponding to the point number. Ranks may have ties in which case you should repeat the rank value. For example, if the second and third entries have the same rank you should enter [1,2,2,4].

H0 stipulates that the same factors are most important in both groups represented by waveA and waveB.

The top-down correlation is the sum of the product of Savage sums for each row:

\[ r_{TD} = \sum_{i=1}^{n} S_{IA} S_{IB} - n \]

\[ n - S_i \]

where \( n \) is the number of rows and the Savage sum \( S_i \) is

\[ S_i = \sum_{j=i}^{n} \frac{1}{j} \]

and \( S_{IA} \) corresponds to the \( S_i \) value of the rank of the data in row \((i-1)\) of waveA.

References

See, in particular, Chapter 19 of:

See Also

Chapter III-12, Statistics for a function and operation overview; StatsLinearCorrelationTest, StatsRankCorrelationTest, StatsTopDownCDF, and StatsInvTopDownCDF.
STFT

STFT [flags] srcWave
The STFT operation computes the Short-Time Fourier Transform of srcWave. STFT was added in Igor Pro 8.00.

Output is stored in the wave M_STFT in the current data folder or in a wave specified by the /DEST flag.

Flags

/DB=dbMode  
\[dbMode\] determines if output is scaled in decibels:
0:  No dB scaling (default)
1:  Scale the output to standard dB using 20*log(wave)
2:  Compute dBFS (dB relative to full scale where 0 is the maximum value)

/DEST=destWave  
Specifies the output wave created by the FFT operation.

It is an error to attempt specify the same wave as both srcWave and destWave.

The default output wave name M_STFT is used if you omit /DEST.

When used in a function, the STFT operation by default creates a real wave reference for the destination wave. See Automatic Creation of WAVE References on page IV-71 for details.

/HOPS=hopSize  
Specifies the offset in points between centers of consecutive source segments. By default this value is 1 and the transform is computed for segments that are offset by a single points from each other.

/OUT=mode  
Sets the output wave format.

\[mode\]=1: Complex output (default)
\[mode\]=2: Real output
\[mode\]=3: Magnitude
\[mode\]=4: Magnitude square
\[mode\]=5: Phase
\[mode\]=6: Scaled magnitude
\[mode\]=7: Scaled magnitude squared

The scaled quantities apply to transforms of real valued inputs where the output is normally folded in the first dimension (because of symmetry). The scaling applies a factor of 2 to the squared magnitude of all components except the DC. The scaled transforms should be used whenever Parseval’s relation is expected to hold.

/PAD=newSize  
Converts each segment of srcWave into a padded array of length newSize. The padded array contains the original data at the center of the array with zeros elements on both sides.

/RP=[startPoint, endPoint]  
Specifies the range of srcWave from which data are sampled in point numbers. startPoint is the first point at which segments are centered. Wave data from points preceding startPoint are used as needed for the left parts of beginning segments.

/RX=(startX, endX)  
Specifies the range of srcWave from which data are sampled in X values. The operation expects startX<endX. startX corresponds to the first point at which segments are centered. Data from points preceding startX are used as necessary to fill left parts of the beginning segments.

/SEGS=segSize  
Sets the length of the segment sampled from srcWave in points. The segment is optionally padded to a larger dimension (see /PAD) and multiplied by a window function prior to FFT. The default segment size is 128 when the number of points in srcWave is greater than 128. Otherwise it is set to one less than the number of points in the srcWave. The operation requires that segSize is at least 32 points.
StopMSTimer

/\WINF=windowKind

Premultiplies a data segment with the selected window function. The default window is Hanning. See Window Functions on page V-208 for details.

/Z

Ignores errors. V_flag is set to -1 for any error and to zero otherwise.

Details
The Short-Time Fourier Transform is a time-frequency representation for a 1D array. The squared magnitude of the transform is known as the "spectrogram" for time series or "sonogram" in the case of sound input. The operation comprises the following steps:

1. Sampling the data.

   A segment of size specified by /SEGS is sampled from srcWave centered about the first point in the wave or as specified by /RX or /RP flags. When the first point is at the beginning of the wave the centering implies that the first half of the segment is set to zero. If the first point is somewhere else the operation uses as many points as are available in the wave and sets the rest to zero. End effects are mitigated by scaling the result by a factor that accounts for the actual number of source data used in the segment. Subsequent segments are each centered at hopSize points from the previous center.

2. Apply windowing.

   The selected segment is multiplied by the specified window function.

3. Apply padding.

   If padding is specified the windowed data are centered onto a zero padded array. Padding may be used to simulate longer arrays for improved spectral resolution.

4. Compute the FFT.

   Initial complex transform may be further processed according to the /OUT flag.

Fourier Transforms on page III-251, FFT, CWT, WignerTransform, DSPPeriodogram, LombPeriodogram

StopMSTimer (timerRefNum)
The StopMSTimer function frees up the timer associated with the timerRefNum and returns the number of elapsed microseconds since StartMSTimer was called for this timer.

Parameters
timerRefNum is the value returned by StartMSTimer or the special values -1 or -2. If timerRefNum is not valid then StopMSTimer returns 0.

On Windows, passing -1 returns the clock frequency of the timer and. On Macintosh, it returns NaN.

Passing -2 returns the time in microseconds since the computer was started.

Details
If you want to make sure that all timers are free, call StopMSTimer ten times with timerRefNum equal to 0 through 9. It is OK to stop a timer that you never started.

The function result may exclude the time the system has spent in sleep states. As of this writing this applies to Macintosh only, but this behavior may change in the future since it is determined by the operating system.

Examples
How long does an empty loop take on your computer?

Function TestMSTimer ()
  Variable timerRefNum
  Variable microSeconds
  Variable n
timerRefNum = StartMSTimer
if (timerRefNum == -1)
    Abort "All timers are in use"
endif
n = 10000
do
    n -= 1
while (n > 0)
    microSeconds = StopMSTimer(timerRefNum)
    Print microSeconds/10000, "microseconds per iteration"
End

See Also
StartMSTimer, ticks, DateTime

str2num

str2num(str)
The str2num function returns a number represented by the string expression str.

Details
str2num returns NaN if str does not contain the text for a number.
str2num skips leading spaces and tabs and then reads up to the first non-numeric character.

See Also
The char2num, num2char and num2str functions.
The sscanf operation for more complex parsing jobs.

Strconstant

Strconstant ksName="literal string"
The Strconstant declaration defines the string literal string under the name ksName for use by other code, such as in a switch construct.

See Also
The Constant keyword for numeric types, Constants on page IV-52, and Switch Statements on page IV-45.

String

String [/G] strName[/N=name] [=strExpr] [, strName[/N=name] [=strExpr]...]
The String operation creates string variables and gives them the specified names.

Flags
/G Creates a global string. Overwrites any existing string with the same name.
/N=name Specifies a local name for the global string variable. /N was added in Igor Pro 8.00 and is available in user-defined functions only. See SVAR Creation below for details.

Details
The string variable is initialized when it is created if you supply the =strExpr initializer. However, when String is used to declare a function parameter, it is an error to attempt to initialize it.
You can create more than one string variable at a time by separating the names and optional initializers with commas.
If used in a procedure, the new string is local to that procedure unless the /G flag is used. If used on the command line, String is equivalent to String/G.
strName can optionally include a data folder path.

SVAR Creation
In a user-defined function, you need a local SVAR reference to access a global string variable. If you use a simple name rather than a path, Igor automatically creates an SVAR:

String/G sVar1 // Creates an SVAR named sVar1
If you use a path or a $ expression, Igor does not create an automatic SVAR reference. You can explicitly create SVARs like this:

```
String/G root:sVar2
SVAR sVar2 = root:sVar2 // Creates an SVAR named sVar2
String path = "root:sVar3"
String/G $path
SVAR sVar3 = $path // Creates an SVAR named sVar3
```

In Igor Pro 8.00 and later, you can explicitly create an SVAR reference in a user-defined function using the /N flag, like this:

```
String/G sVar4/N=sVar4 // Creates an SVAR named sVar4
String/G root:sVar5/N=sVar5 // Creates an SVAR named sVar5
String path = "root:sVar6"
String/G $path/N=sVar6 // Creates an SVAR named sVar6
```

The name used for the SVAR does not need to be the same as the name of the global variable:

```
String/G sVar7/N=sv7 // Creates an SVAR named sv7
String/G root:sVar8/N=sv8 // Creates an SVAR named sv8
String path = "root:sVar9"
String/G $path/N=sv9 // Creates an SVAR named sv9
```

### See Also

- String Variables on page II-99, Working With Strings on page IV-14, Accessing Global Variables and Waves on page IV-64

#### StringByKey

**StringByKey(keyStr, kwListStr [, keySepStr [, listSepStr [, matchCase]]])**

The StringByKey function returns a substring extracted from `kwListStr` based on the specified key contained in `keyStr`. `kwListStr` should contain keyword-value pairs such as "KEY=value1,KEY2=value2" or "Key:value1;KEY2:value2", depending on the values for `keySepStr` and `listSepStr`.

Use StringByKey to extract a string value from a string containing a "key1:value1;key2: value2;" style list such as those returned by functions like AxisInfo or TraceInfo.

If the key is not found or if any of the arguments is "" then a zero-length string is returned.

`keySepStr`, `listSepStr`, and `matchCase` are optional; their defaults are ",", ",", and 0 respectively.

#### Details

- `keyStr` is limited to 255 bytes.
- `kwListStr` is searched for an instance of the key string bound by `listSepStr` on the left and a `keySepStr` on the right. The text up to the next `listSepStr` is returned.
- `kwListStr` is treated as if it ends with a `listSepStr` even if it doesn’t.
- Searches for `keySepStr` and `listSepStr` are always case-sensitive. Searches for `keyStr` in `kwListStr` are usually case-insensitive. Setting the optional `matchCase` parameter to 1 makes the comparisons case sensitive.
- In Igor6, only the first byte of `keySepStr` and `listSepStr` was used. In Igor7 and later, all bytes are used.
- If `listSepStr` is specified, then `keySepStr` must also be specified. If `matchCase` is specified, `keySepStr` and `listSepStr` must be specified.

#### Examples

- `Print StringByKey("BKEY", "AKEY:hello;BKEY:nok-nok") // prints "nok-nok"
- `Print StringByKey("KY", "KX=1;ky=hello", ",") // prints "hello"
- `Print StringByKey("KY", "KX:1,KY:joey", ",", ",") // prints "joey"
- `Print StringByKey("kz", "KZ:1st,kz:2nd", ",", ",") // prints "1st"
- `Print StringByKey("kz", "KZ:1st,kz:2nd", ",", ",", 1)// prints "2nd"

#### See Also

- The NumberByKey, RemoveByKey, ReplaceNumberByKey, ReplaceStringByKey, ItemsInList, AxisInfo, IgorInfo, SetWindow, and TraceInfo functions.
StringCRC

StringCRC(inCRC, str)
The StringCRC function returns a 32-bit cyclic redundancy check value of bytes in str starting with inCRC. Pass 0 for inCRC the first time you call StringCRC for a particular stream of bytes as represented by the string data. Pass the last-returned value from StringCRC for inCRC if you are creating a CRC value for a given stream of bytes through multiple calls to StringCRC.

Details
Polynomial used is:
\[ x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^{8}+x^{7}+x^{5}+x^{4}+x^{2}+x+1 \]
See crc32.c in the public domain source code for zlib for more information.

See Also
Hash, WaveHash, WaveCRC

StringFromList

StringFromList(index, listStr [, listSepStr] [, offset])
The StringFromList function returns the indexth substring extracted from listStr starting offset bytes into listStr. listStr should contain items separated by listSepStr which typically is ";".

Use StringFromList to extract an item from a string such as those returned by functions like TraceNameList and AnnotationList.

Parameters
index is the zero-based index of the list item that you want to get. If index < 0, or index ≥ the number of items in list, or if listStr or listSepStr is "", then a zero-length string is returned.
listStr contains a series of text items separated by listSepStr. The trailing separator is optional though recommended. For example, these are both valid lists:
"First;Second;"
"First;Second"
listSepStr is optional. If omitted it defaults to ";". Prior to Igor Pro 7.00, only the first byte of listSepStr was used. Now all bytes are used.
offset is optional and requires Igor Pro 7.00 or later. If omitted it defaults to 0. The search begins offset bytes into listStr. When iterating through lists containing large numbers of items, using the offset parameter provides dramatically faster execution.

Details
For optimal performance, especially with lists larger than 100 items, provide the separatorStr and offset parameters as shown in the DemoStringFromList example below. When using this technique, the index parameter must be 0 and the offset parameter controls which list item is returned.

Examples
Print StringFromList(0, "wave0;wave1;") // Prints "wave0"
Print StringFromList(2, "wave0;wave1;") // Prints ""
Print StringFromList(1, "wave0;;wave2") // Prints ""

// Iterate quickly over a list using the offset parameter
Function DemoQuickStringFromList(list)
String list // A semicolon-separated string list
String separator = ";;"
Variable separatorLen = strlen(separator)
Variable numItems = ItemsInList(list)
Variable offset = 0
Variable i
for(i=0; i<numItems; i+=1)
    // When using offset, the index parameter is always 0
    String item = StringFromList(0, list, separator, offset)
StringList

```c
    // Do something with item
    offset += strlen(item) + separatorLen
    endfor
End
```

**StringList**

StringList(`matchStr`, `separatorStr`)

The `StringList` function returns a string containing a list of global string variables selected based on the `matchStr` parameter. The string variables listed are all in the current data folder.

**Details**

For a string variable name to appear in the output string, it must match `matchStr`. `separatorStr` is appended to each string variable name as the output string is generated.

The name of each string variable is compared to `matchStr`, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

- "*" Matches all string variable names
- "xyz" Matches name xyz only
- "*xyz" Matches names which end with xyz
- "xyz*" Matches names which begin with xyz
- "*xyz*" Matches names which contain xyz
- "abc*xyz" Matches names which begin with abc and end with xyz

The list contains names only, without data folder paths. Thus, they are not suitable for accessing string variables outside the current data folder.

`matchStr` may begin with the ! character to return windows that do not match the rest of `matchStr`. For example:

- "!*xyz" Matches variable names which do not end with xyz

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of `matchStr`.

**Examples**

- `StringList("*", ";")` Returns a list of all string variables in the current data folder.
- `StringList("S_*", ";")` Returns a list of all string variables in the current data folder whose names begin with "S_".

See Also
See the `VariableList` and `WaveList` functions.
StringMatch

StringMatch(string, matchStr)
The StringMatch function tests string for a match to matchStr. You may include asterisks in matchStr as a wildcard character.
StringMatch returns 1 to indicate a match, 0 for no match or NaN if it ran out of memory.

Details
matchStr is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

"*" Matches any string.
"xyz" Matches the string “xyz” only.
"*xyz" Matches strings ending with “xyz”, for instance “abcxyz”.
"xyz*" Matches strings beginning with xyz, for instance “xyzpqr”.
"*xyz*" Matches strings containing xyz, for instance “abcxyzpqr”.
"abc*xyz" Matches strings beginning with abc and ending with xyz, for instance “abcpqxyz”.

If matchStr begins with the ! character, a match is indicated if string does not match matchStr. For example:

"!*xyz" Matches strings which do not end with xyz.

The ! character is considered to be a normal character if it appears anywhere else.
Note that matching is case-insensitive, so “xyz” also matches “XYZ” or “Xyz”.
Also note that it is impossible to match an asterisk in string: use GrepString instead.
Among other uses, the StringMatch function can be used to build your own versions of the WaveList function, using NameOfWave and stringmatch to qualify names of waves found by WaveRefIndexedDFR.

See Also
The GrepString, CmpStr, strsearch, Demo, ListMatch, and ReplaceString functions and the sscanf operation.

strlen

strlen(str)
The strlen function returns the number of bytes in the string expression str.
strlen returns NaN if the str is NULL. A local string variable or a string field in a structure that has never been set is NULL. NULL is not the same as zero length. Use numtype to test if the result from strlen is NaN.

Examples
String zeroLength = ""
String neverSet
Print strlen(zeroLength), strlen(neverSet)
// Test if a string is null
Variable len = strlen(neverSet) // NaN if neverSet is null
if (numtype(len) == 2) // strlen returned NaN?
   Print "neverSet is null"
endif

See Also
Characters Versus Bytes on page III-461, Character-by-Character Operations on page IV-168

strsearch

strsearch(str, findThisStr, start[, options])
The strsearch function returns the byte position of the string expression findThisStr in the string expression str.
strswitch-case-endswitch

Details
strsearch performs a case-sensitive search.
strsearch returns -1 if findThisStr does not occur in str.
The search starts from the byte position in str specified by start; 0 references the start of str.
strsearch clips start to one less than the length of str in bytes, so it is useful to use Inf for start when searching backwards to ensure that the search is from the end of str.

options is an optional bitwise parameter specifying the search options:
1: Search backwards from start.
2: Ignore case.
3: Search backwards and ignore case.

Examples
String str="This is a test isn't it?"
Print strsearch(str,"test",0) // prints 10
Print strsearch(str,"TEST",0) // prints -1
Print strsearch(UpperStr(str),"TEST",0) // prints 10
Print strsearch(str,"TEST",0,2) // prints 10
Print strsearch(str,"is",0) // prints 2
Print strsearch(str,"is",3) // prints 5
Print strsearch(str,"is",Inf,1) // prints 15

See Also
sscanf, FindListItem, ReplaceString, Character-by-Character Operations
See Setting Bit Parameters on page IV-13 for details about bit settings.

strswitch-case-endswitch

strswitch(<string expression>)
  case <literal><constant>:
    <code>
    [break]
  [default:
    <code>]
endswitch

A strswitch-case-endswitch statement evaluates a string expression and compares the result to the case labels using a case-insensitive comparison. If a case label matches string expression, then execution proceeds with code following the matching case label. When none of the cases match, execution will continue at the default label, if it is present, or otherwise the strswitch will be exited with no action taken. Note that although the break statement is optional, in almost all case statements it will be required for the strswitch to work correctly.

See Also
Switch Statements on page IV-45, default and break for more usage details.

STRUCT

STRUCT structureName localName
STRUCT is a reference that creates a local reference to a Structure accessed in a user-defined function. When a Structure is passed to a user function, it can only be passed by reference, so in the declaration within the function you must use &localStructName to define the function input parameter.

See Also
Structures in Functions on page IV-96 for further information.
See the Structure keyword for creating a Structure definition.
StructFill

StructFill [ /AC=createFlags /SDFR=dfref ] structVar

StructFill is a programmer-convenience operation that initializes NVAR, SVAR and WAVE fields in a structure. At run time, it scans through the fields in the specified structure and attempts to set all null NVAR, SVAR and WAVE fields by looking up corresponding same-named globals in the current data folder or in the specified data folder.

StructFill was added in Igor Pro 8.00.

Parameters

structVar is the name of a STRUCT variable.

Flags

/AC=createFlags Enables auto-creation of globals.

Bit 0 enables creation of numeric and string global variables which are set to 0 and "" respectively. Variables are auto-created only if they do not already exist.

Bit 1 enables creation of waves which are created with zero points. Waves are auto-created only if they do not already exist.

/SDFR=dfRef Specifies a data folder. If you omit /SDFR, the current data folder used.

Output Variables

StructFill sets the following output variables:

V_Flag The number of NVAR, SVAR and WAVE fields that were successfully initialized.

V_Error The number of NVAR, SVAR and WAVE fields that could not be initialized.

If auto-creation is off, a field can not be initialized if the corresponding global variable, string variable, or wave does not exist. If auto-creation is on, a field can not be initialized if there was an error creating the global variable or wave.

When using auto-creation, errors are not reported other than via V_Error.

If you unexpectedly get non-zero for V_Error, you can print the structure to see which fields were left null.

See Also

Structures in Functions on page IV-96

StructGet

StructGet [/B=b] structVar, waveStruct[ [colNum]]

StructGet /S [/B=b] structVar, strStruct

The StructGet operation reads binary numeric data from a specified column of a wave or from a string variable and copies the data into the designated structure variable. The source wave or string will have been filled beforehand by StructPut.

Parameters

structVar is the name of an existing structure that is to be filled with new data values.

waveStruct is the name of a wave containing binary numeric data that will be used to fill structVar. Use the optional colNum parameter to specify a column from the structure wave. The contents of waveStruct are created beforehand using StructPut.

strStruct is the name of a string variable containing binary numeric data. The contents of strStruct are created beforehand using StructPut.
The data that are stored in \textit{waveStruct} and \textit{strStruct} are in binary format so you cannot directly view a meaningful representation of their contents by printing them or viewing the wave in a table. To view the contents of \textit{waveStruct} or \textit{strStruct} you must use \texttt{StructGet} to export them back into a structure and then retrieve the members.

If \texttt{colNum} is out of bounds it will be clipped to valid values and an error reported. If the row dimension does not match the structure size, as much data as possible will be copied to the structure.

By default, data are read in big-endian, high-byte order (Motorola). This allows data written on one platform to be read on the other.

\textbf{See Also}

The \texttt{StructPut} operation for writing structure data to waves or strings.

\textbf{StructPut}

\texttt{StructPut} \texttt{[/B=b] structVar, waveStruct[[colNum]]}

\texttt{StructPut /S [/B=b] structVar, strStruct}

The \texttt{StructPut} operation copies the binary numeric data in a structure variable to a specified column in a wave or to a string variable. The data in the wave or string can be read out into another structure using \texttt{StructGet}.

\textbf{Parameters}

\textit{structVar} is the name of a structure from which data will be exported.

\textit{waveStruct} is the name of an existing wave to which data will be exported. Use the optional \texttt{colNum} parameter to specify a column in \textit{waveStruct} to contain the data. The first column of \textit{waveStruct} will be filled if \texttt{colNum} is omitted.

\textit{strStruct} is the name of an existing string variable to which data will be exported.

\textbf{Flags}

\texttt{/B=b} \hspace{1cm} Sets the byte ordering for writing of structure data.

\texttt{b=0:} \hspace{1cm} Writes in native byte order.

\texttt{b=1:} \hspace{1cm} Writes bytes in reversed order.

\texttt{b=2:} \hspace{1cm} Default; writes data in big-endian, high-byte-first order (Motorola).

\texttt{b=3:} \hspace{1cm} Writes data in little-endian, low-byte-first order (Intel).

\texttt{/S} \hspace{1cm} Writes binary data to a string variable.

\textbf{Details}

The structure fields to be exported must contain only numeric data in either integer, floating point, or double precision format. If the structure contains any objects such as String, NVAR, WAVE, etc., then only the numeric data at the end of the structure is copied. If there is no suitable data at the end, an error is generated at compile time. Prior to Igor Pro 8, the presence of any illegal field would result in an error.

If needed, \texttt{StructPut} will redimension \textit{waveStruct} to unsigned byte format, will set the number of rows to equal the size of the structure, and set the column dimension large enough to accommodate the size specified by \texttt{colNum}. You can think of \textit{waveStruct} as a one-dimensional array of structure contents indexed by \texttt{colNum} although the wave is actually two-dimensional with each column containing a copy of a separate structure.
By default, data are written in big-endian, high-byte order (Motorola). This allows data written on one platform to be read on the other.

After you have exported the structure data to `waveStruct` or `strStruct` they will contain binary data that you cannot inspect directly. To view the contents of `waveStruct` or `strStruct`, you must use the original structure or use StructGet to export them into another structure.

**See Also**
The `StructGet` operation for reading structure data from waves or strings.

## Structure

```plaintext
Structure structureName
    memType memName [arraySize] [, memName [arraySize]]
... EndStructure
```

The `Structure` keyword introduces a structure definition in a user function. Within the body of the structure you declare the member type (`memType`) and the corresponding member name(s) (`memName`). Each `memName` may be declared with an optional array size.

### Details

Structure member types (`memType`) can be any of the following Igor objects: Variable, String, WAVE, NVAR, SVAR, DFREF, FUNCREF, or STRUCT.

Igor structures also support additional member types, as given in the next table, for compatibility with C programming structures and disk files.

<table>
<thead>
<tr>
<th>Igor Member Type</th>
<th>C Equivalent</th>
<th>Size</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>char</td>
<td>signed 8-bit int</td>
<td>1 byte</td>
<td></td>
</tr>
<tr>
<td>uchar</td>
<td>unsigned 8-bit int</td>
<td>1 byte</td>
<td></td>
</tr>
<tr>
<td>int16</td>
<td>signed 16-bit int</td>
<td>2 bytes</td>
<td></td>
</tr>
<tr>
<td>uint16</td>
<td>unsigned 16-bit int</td>
<td>2 bytes</td>
<td></td>
</tr>
<tr>
<td>int32</td>
<td>signed 32-bit int</td>
<td>4 bytes</td>
<td></td>
</tr>
<tr>
<td>uint32</td>
<td>unsigned 32-bit int</td>
<td>4 bytes</td>
<td></td>
</tr>
<tr>
<td>int64</td>
<td>signed 64-bit int</td>
<td>8 bytes</td>
<td>Requires Igor Pro 7.00 or later</td>
</tr>
<tr>
<td>uint64</td>
<td>unsigned 64-bit int</td>
<td>8 bytes</td>
<td>Requires Igor Pro 7.00 or later</td>
</tr>
<tr>
<td>float</td>
<td>float</td>
<td>4 bytes</td>
<td></td>
</tr>
<tr>
<td>double</td>
<td>double</td>
<td>8 bytes</td>
<td></td>
</tr>
</tbody>
</table>

The Variable and double types are identical although Variable can be also specified as complex (using the `/C` flag).

Each structure member may have an optional `arraySize` specification, which gives the number of elements contained by the structure member. The `array size` is an integer number from 1 to 400 except for members of type STRUCT for which the upper limit is 100.

**See Also**

**Structures in Functions** on page IV-96 for further information.

See the `STRUCT` declaration for creating a local reference to a Structure.
**StrVarOrDefault**

**StrVarOrDefault**(pathStr, defStrVal)

The StrVarOrDefault function checks to see if pathStr points to a string variable and if so, it returns its value. If the string variable does not exist, returns defStrVal instead.

**Details**

StrVarOrDefault initializes input values of macros so they can remember their state without needing global variables to be defined first. Numeric variables use the corresponding numeric function, **NumVarOrDefault**.

**Examples**

```plaintext
Macro foo(nval,sval)
  Variable nval=NumVarOrDefault("root:Packages:mypack:nvalSav",2)
  String sval=StrVarOrDefault("root:Packages:mypack:svalSav","Hi")

  DFREF dfSav= GetDataFolderDFR()
  NewDataFolder/O/S root:Packages
  NewDataFolder/O/S mypack
  Variable/G nvalSav= nval
  String/G svalSav= sval
  SetDataFolder dfSav
End
```

**StudentA**

**StudentA**(t, DegFree)

**Note:** This function is deprecated. New code should use the more accurate **StatsStudentCDF**.

The StudentA function returns the area from -t to t under the Student’s T distribution having DegFree degrees of freedom. That is, it returns the probability that a random sample from Student’s T is between -t and t.

Note that this is the bi-tail result. That is, it gives the area from -t to t, rather than the cumulative area from -∞ to t. It is this latter number that is commonly tabulated- StudentA returns the probability 1-α where the area from -t to t is the probability 1-α/2.

StudentA tests whether a normally-distributed statistic is significantly different from a certain value. You could use it to test whether an intercept from a line fit is significantly different from zero:

```plaintext
Make/O/N=20 Data=0.5*x+2+gnoise(1) // line with Gaussian noise
Display Data
CurveFit line Data /D
Print "Prob = ", StudentA(W_coef[0]/W_sigma[0], V_npnts-2)
```

Because the noise is random, the results will differ slightly each time this is tried. When we did it, the result was: `Prob = 0.999898`

which indicates that the intercept of the line fit was different from zero with 99.99 per cent probability.

**See Also**

**StatsStudentCDF**, **StatsStudentPDF**, **StatsInvStudentCDF**

**StudentT**

**StudentT**(Prob, DegFree)

**Note:** This function is deprecated. New code should use the more accurate **StatsInvStudentCDF**.

The StudentT function returns the t value corresponding to an area Prob under the Student’s T distribution from -t to t for DegFree degrees of freedom.

Note that this is a bi-tail result, which is what is usually desired. Tabulated values of the Student’s T distribution are commonly the one-sided result.

StudentT calculates confidence intervals from standard deviations for normally-distributed statistics. For instance, you can use it to calculate a confidence interval for the coefficients from a curve fit:

```plaintext
Make/O/N=20 Data=0.5*x+2+gnoise(1) // line with Gaussian noise
Display Data
```
CurveFit line Data /D
print "intercept = ", W_coef[0], "±", W_sigma[0]*StudentT(0.95, V_npnts-2)
print "slope = ", W_coef[1], "±", W_sigma[1]*StudentT(0.95, V_npnts-2)

See Also
StatsStudentCDF, StatsStudentPDF, StatsInvStudentCDF

Submenu

Submenu menuNameStr
The Submenu keyword introduces a submenu definition. It is used inside a Menu definition. See Chapter IV-5, User-Defined Menus for further information.

sum

\[ \text{sum}(\text{waveName} [, \ x1, \ x2]) \]

The sum function returns the sum of the wave elements for points from \( x=x1 \) to \( x=x2 \).

Details

The X scaling of the wave is used only to locate the points nearest to \( x=x1 \) and \( x=x2 \). To use point indexing, replace \( x1 \) with \( \text{pnt2x}(\text{waveName}, \text{pointNumber1}) \), and a similar expression for \( x2 \).
If \( x1 \) and \( x2 \) are not specified, they default to \(-\infty\) and \(+\infty\), respectively.
If the points nearest to \( x1 \) or \( x2 \) are not within the point range of 0 to \( \text{numpnts}(\text{waveName})-1 \), sum limits them to the nearest of point 0 or point \( \text{numpnts}(\text{waveName})-1 \).
If any values in the point range are NaN, sum returns NaN.

Examples

Make/O/N=100 data; SetScale/I x 0,Pi,data
data=sin(x)
Print sum(data,0,Pi) // the entire point range, and no more
Print sum(data) // same as -infinity to +infinity
Print sum(data,Inf,-Inf) // +infinity to -infinity

The following is printed to the history area:
Print sum(data,0,Pi) // the entire point range, and no more
  63.0201
Print sum(data) // same as -infinity to +infinity
  63.0201
Print sum(data,Inf,-Inf) // +infinity to -infinity
  63.0201

See Also
mean, area, SumSeries, SumDimension

SumDimension

\[ \text{SumDimension} [\text{flags}] \ \text{srcWave} \]

The SumDimension operation sums values in \( \text{srcWave} \) along the specified dimension.
The SumDimension operation was added in Igor Pro 7.00.

Flags

/D=dimension  Specifies a zero-based dimension number.
  \( \text{dimension}=0 \): Rows
  \( \text{dimension}=1 \): Columns
  \( \text{dimension}=2 \): Layers
  \( \text{dimension}=3 \): Chunks

If you omit /D the operation sums the highest dimension in the wave.
The operation sums one dimension of an N dimensional wave producing an output wave with N-1 dimensions except if srcWave is 1D wave in which case SumDimension produces a single point 1D output wave. For example, given a 4D wave of dimensions dim0 x dim1 x dim2 x dim3 and the command:

```
SumDimension/D=1/DEST=wout wave4d
```

creates a wave wout that satisfies

\[ w_{out}[i][k][l] = \sum_{j=0}^{\text{dim}1-1} \text{wave4d}[i][j][k][l], \]

and wout has dimensions dim0 x dim2 x dim3.

If any values in srcWave are NaN, the corresponding sum element will be NaN.

sum

MatrixOp keywords sumRows, sumCols, sumBeams

ImageTransform keywords sumAllCols, sumAllRows, sumPlane, sumPlanes

### SumSeries

**SumSeries** flags keyword=value

The SumSeries operation computes the sum of the results returned from a user-defined function for input values between two specified index limits.

SumSeries was added in Igor Pro 7.00.

**Flags**

/CCNT=nc When summing with one or two infinite limits you can use this flag to specify the minimum number of calls to the summand function which, when added to the sum, produce a change that is less than the tolerance. By default nc=10.

If you are summing a well-behaved monotonic series it is sufficient to set nc=1. In some pathological cases it is useful to check that the sum remains effectively unchanged even after many terms are added to the series.

/INAN Ignore NaNs returned from the user function. In the case of a complex valued summand, a NaN in either the real or imaginary components excludes the contribution of the term to the sum.

/Q Quiet mode; do not print in the history.

/Z=[z] /Z or /Z=1 prevents reporting any errors. If the operation encounters an error it sets V_Flag to the error code.

**Keywords**

lowerLimit=n1 Specifies the starting index at which the summand is evaluated. n1 must be either an integer -INF.
The SumSeries operation is primarily intended for use with one or two infinite limits. If both limits are finite the operation performs the straightforward sum by calling the summand function once for every index from lowerLimit to upperLimit, inclusive.

If one limit is infinite the sum is evaluated by starting from the finite limit and proceeding in the direction of the infinite limit index until convergence is reached. Convergence in this context is defined as multiple (nc) consecutive calls to the summand which do not change the value of the sum by more than the tolerance value. By default nc=10 but you can change it using the /CCNT flag.

When both limits are infinite the operation first computes the sum for indices 0 to INF and then the sum from -1 to -INF. The two calculations are independent and require that the same convergence condition is met independently in each case. When the summand function is complex the convergence condition must hold for the real and imaginary components independently.

The operation does not perform any test on the summand function to estimate its rate of convergence. If you provide a non-converging summand function the operation can run indefinitely. You can abort it by pressing the User Abort Key Combinations or by clicking the Abort button.

The result of the sum is stored in V_resultR and, if the summand function returns a complex result, V_resultI.

If the calculation completes without error V_Flag is set to 0. Otherwise it contains an error code.

Examples
A simple test case is the geometric series for powers of 1/2. The sum of \(x^i\) for \(i=0\) to \(i=\text{INF}\) where \(0<x<1\) is given by \(1/(1-x)\). For \(x=1/2\), this sum is 2.
Function s1(paramWave, index)
  Wave/Z paramWave    // Not used
  Variable index
    return 0.5^index
End

// Execute:
SumSeries series=s1, lowerLimit=0, upperLimit=INF
Print V_resultR

In the next example we use the series expansion of cosine and sine to evaluate \( \exp(i\pi) \).

Function s2(paramWave, index)
  Wave/Z paramWave    // Not used
  Variable index
    Variable n2=2*index
    Variable xx=pi^n2
    Variable sn=(-1)^index
    Variable fn=Factorial(n2)
    return cmplx(sn*xx/fn,sn*xx*pi/(fn*(n2+1)))
End

// Execute:
SumSeries series=s2, lowerLimit=0, upperLimit=INF
Print V_resultR, V_resultI

In the next example we sum 18 terms in the series for \( \exp(x) \) using a parameter wave to pass the value of \( x \).

Function fex(paramWave, index)
  Wave/Z paramWave    // Contains \( x \) value at which to evaluate \( \exp(x) \)
  Variable index
    Variable xx = paramWave[0]
    if (index == 0)
      return 1
    endif
    return (xx^index) / factorial(index)
End

// Execute:
Make/D/O exponent = {-1}    // The value of \( x \) at which to evaluate \( \exp(x) \)
SumSeries series=fex, lowerLimit=0, upperLimit=17, paramWave=exponent
Print/D V_resultR - exp(-1)    // Compare with built-in \( \exp \) function

Integrate1D, sum

SVAR

SVAR \[/Z\] localName \[=\] pathToStr \[,\] localName1 \[=\] pathToStr1\]

SVAR is a declaration that creates a local reference to a global string variable accessed in a user-defined function.

The SVAR reference is required when you access a global string variable in a function. At compile time, the SVAR statement specifies a local name referencing a global string variable. At runtime, it makes the connection between the local name and the actual global variable. For this connection to be made, the global string variable must exist when the SVAR statement is executed.

When localName is the same as the global string variable name and you want to reference a global variable in the current data folder, you can omit pathToStr.

pathToStr can be a full literal path (e.g., root:FolderA:var0), a partial literal path (e.g., :FolderA:var0) or $ followed by string variable containing a computed path (see Converting a String into a Reference Using $ on page IV-61).

You can also use a data folder reference or the /SDFR flag to specify the location of the string variable if it is not in the current data folder. See Data Folder References on page IV-77 and The /SDFR Flag on page IV-79 for details.

If the global variable may not exist at runtime, use the /Z flag and call SVAR_Exists before accessing the variable. The /Z flag prevents Igor from flagging a missing global variable as an error and dropping into the Igor debugger. For example:
SVAR/Exists

SVAR/Exists `<pathToPossiblyMissingStringVariable>`
if(SVAR/Exists(sv))
  `<do something with sv>`
endif

Note that to create a global string variable, you use the String/G operation.

**Flags**

/Z An SVAR reference to a null string variable does not cause an error or a debugger break.

**See Also**

SVAR_Exists function.

Accessing Global Variables and Waves on page IV-64.
Converting a String into a Reference Using $ on page IV-61.

SVAR_Exists

**SVAR_Exists(name)**
The SVAR_Exists function returns 1 if the specified SVAR reference is valid or 0 if not. It can be used only in user-defined functions.

For example, in a user function you can test if a global string variable exists like this:

SVAR /Z str1 = gStr1 // /Z prevents debugger from flagging bad SVAR
if(!SVAR_Exists(str1)) // No such global string variable?
  String/G gStr1 = ""
  // Create and initialize it
endif

**See Also**

WaveExists, NVAR_Exists, and Accessing Global Variables and Waves on page IV-64.

switch-case-endswitch

**switch(<numeric expression>)**
  case <literal><constant>:
    <code>
    [break]
  [default:
    <code>]
endswitch

A switch-case-endswitch statement evaluates the numeric expression and rounds the result to the nearest integer. If a case label matches `numeric expression`, then execution proceeds with `code` following the matching case label. When no cases match, execution continues at the default label, if present, or otherwise the switch exits with no action taken. Although the break statement is optional, in almost all case statements it is required for the switch to work correctly.

Literal numbers used as case labels are required by the compiler to be integers. Numeric constants used as case labels are rounded by the compiler to the nearest integers.

**See Also**

Switch Statements on page IV-45, default and break for more usage details.

`t`

**t**
The t function returns the T value for the current chunk of the destination wave when used in a multidimensional wave assignment statement. T is the scaled chunk index while s is the chunk index itself.

**Details**

Unlike x, outside of a wave assignment statement, t does not act like a normal variable.

For scaled dimension indices, the \( x, y, \) and \( z \) functions.

TabControl

TabControl \([/Z]\) \( ctrlName \) [\( keyword = value \) [, \( keyword = value \) ...]]
The TabControl operation creates tab panels for controls.
For information about the state or status of the control, use the ControlInfo operation.

Parameters
\( ctrlName \) is the name of the TabControl to be created or changed.

The following keyword=value parameters are supported:

align=\( alignment \) Sets the alignment mode of the control. The alignment mode controls the interpretation of the \( leftOrRight \) parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.
If \( alignment=0 \) (default), \( leftOrRight \) specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.
If \( alignment=1 \), \( leftOrRight \) specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

appearance={\( kind \) [, \( platform \) ]}
Sets the appearance of the control. \( platform \) is optional. Both parameters are names, not strings.
\( kind \) can be one of default, native, or os9.
\( platform \) can be one of Mac, Win, or All.
See DefaultGUIControls Default Fonts and Sizes for how enclosed controls are affected by native TabControl appearance.
See Button for more appearance details.

disable=\( d \) Sets user editability of the control.
\( d=0 \): Normal.
\( d=1 \): Hide.
\( d=2 \): Draw in gray state; disable control action.

defColor=(\( r, g, b \) ) Sets the initial color of the tab labels. \( r, g, \) and \( b \) can range from 0 to 65535.
To further change the color of the tab labels text, use escape sequences in the text specified by the tabLabel keyword.
\( fColor \) defaults to black (0,0,0).

focusRing=\( fr \) Enables or disables the drawing of a rectangle indicating keyboard focus:
\( fr=0 \): Focus rectangle will not be drawn.
\( fr=1 \): Focus rectangle will be drawn (default).
On Macintosh, regardless of this setting, the focus ring appears if you have enabled full keyboard access via the Shortcuts tab of the Keyboard system preferences.

font= "\( fontName \) " Sets the font used for tabs, e.g., font="Helvetica".

fsizes= \( s \) Sets the font size for tabs.
TabControl

flags=fs

fs is a bitwise parameter with each bit controlling one aspect of the font style as follows:

Bit 0: Bold
Bit 1: Italic
Bit 2: Underline
Bit 4: Strikethrough

See Setting Bit Parameters on page IV-13 for details about bit settings.

labelBack=(r,g,b) or 0

Sets fill color for current tab and the interior. r, g, and b are integers from 0 to 65535. If not set, then interior is transparent and the current tab is filled with the window background. Note that if you use a fill color, draw objects cannot be used because they will be covered up.

nproc

Specifies that no function is to run when clicking a tab.

pos={leftOrRight,top}

Sets the position in pixels of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

pos+=

Offsets the position of the control in pixels.

proc=procName

Specifies the function to run when the tab is pressed. Your function must hide and show other controls as desired. The TabControl does not do this automatically.

size={width,height}

Sets TabControl size in pixels.

tabLabel(n)=lbl

Sets nth tab label to lbl. Set the label of the last tab to "" to reduce the number of tabs. Using escape codes you can change the font, size, style, and color of the label. See Annotation Escape Codes on page III-54 or details.

userdata(UDName)=UDStr

Sets the unnamed user data to UDStr. Use the optional (UDName) to specify a named user data to create.

userdata(UDName)+=UDStr

Appends UDStr to the current unnamed user data. Use the optional (UDName) to append to the named UDStr.

value=v

Sets current tab number. Tabs count from 0.

win=winName

Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

TabControl Action Procedure

The action procedure for a TabControl takes a predefined WMTabControlAction structure as a parameter to the function:

Function ActionProcName(TC_Struct) : TabControl
  STRUCT WMTabControlAction &TC_Struct
    ...
  return 0
End

The ": TabControl" designation tells Igor to include this procedure in the Procedure pop-up menu in the Tab Control dialog.

See WMTabControlAction for details on the WMTabControlAction structure.
Although the return value is not currently used, action procedures should always return zero.

When clicking a TabControl with the selector arrow, click in the title region. The control is not selected if you click in the body. This is to make it easier to select controls in the body rather than the TabControl itself.

Example
Designing a TabControl with all the accompanying interior controls can be somewhat difficult. Here is a suggested technique:

First, create and set the size and label for one tab. Then create the various controls for this first tab. Before starting on the second tab, create the TabControl’s procedure so that it can be used to hide the first set of controls. Then add the second tab, click it to run your procedure and start adding controls for this new tab. When done, update your procedure so the new controls are hidden when you start on the third tab.

Here is an example:

1. Create a panel and a TabControl:
   NewPanel /W=(150,50,478,250)
   ShowTools
   TabControl MyTabControl,pos={29,38},size={241,142},tabLabel(0)="First Tab",value=0

2. Add a few controls to the interior of the TabControl:
   Button button0,pos={52,72},size={80,20},title="First"
   CheckBox check0,pos={52,105},size={102,15},title="Check first",value=0

3. Write an action procedure:
   Function TabActionProc(tc) : TabControl
   STRUCT WMTabControlAction& tc
   switch(tc.eventCode)
     case 2: // Mouse up
       Button button0, disable=(tc.tab!=0)
       CheckBox check0, disable=(tc.tab!=0)
     break
   endswitch
   End

4. Set the action procedure and add a new tab:
   TabControl MyTabControl,proc=TabActionProc,tabLabel(1)="Second Tab"

5. Click the second tab, which hides the first tab’s controls, and then add new controls like this:
   Button button1,pos={58,73},size={80,20},title="Second"
   CheckBox check1,pos={60,105},size={114,15},title="Check second",value=0

6. Finally, change the action procedure by adding these lines at the end:
   Button button1,disable=(tc.tab!=1)
   CheckBox check1,disable=(tc.tab!=1)

See Also
The ControlInfo operation for information about the control along with the ModifyControl and ModifyControlList operations. Chapter III-14, Controls and Control Panels, for details about control panels and controls. The GetUserData operation for retrieving named user data.

TabControl

TabControl is a procedure subtype keyword that identifies a macro or function as being an action procedure for a user-defined tab control. See Procedure Subtypes on page IV-199 for details. See TabControl for details on creating a tab control.

Table

Table is a procedure subtype keyword that identifies a macro as being a table recreation macro. It is automatically used when Igor creates a window recreation macro for a table. See Procedure Subtypes on page IV-199 and Killing and Recreating a Table on page II-182 for details.
TableStyle

TableStyle
TableStyle is a procedure subtype keyword that puts the name of the procedure in the Style pop-up menu of the New Table dialog and in the Table Macros menu. See Table Style Macros on page II-212 for details.

TableInfo

TableInfo(winNameStr, itemIndex)
The TableInfo function returns a string containing a semicolon-separated list of keywords and values that describe a column in a table or overall properties of the table. The main purpose of TableInfo is to allow an advanced Igor programmer to write a procedure which formats or arranges a table or which manipulates the table selection.

Parameters
winNameStr is the name of an existing table window or "" to refer to the top table.
itemIndex is one of the following:

<table>
<thead>
<tr>
<th>itemIndex Value</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>-2</td>
<td>Information about the table as a whole.</td>
</tr>
<tr>
<td>-1</td>
<td>Information about the Point column</td>
</tr>
<tr>
<td>≥0</td>
<td>Information about a column other than the Point column. 0 refers to the first column after the Point column, 1 refers to the second column after the Point column, and so on.</td>
</tr>
</tbody>
</table>

TableInfo returns "" in the following situations:
• winNameStr is "" and there are no table windows.
• winNameStr is a name but there are no table windows with that name.
• itemIndex not -2 and is out of range for an existing column.

Details
If itemIndex is -2, the returned string describes the table as a whole and contains the following keywords, with a semicolon after each keyword-value pair.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLENAME</td>
<td>The name of the table.</td>
</tr>
<tr>
<td>HOST</td>
<td>The host specification of the table’s host window if it is a subwindow or &quot;&quot; if it is a top-level table window.</td>
</tr>
<tr>
<td>ROWS</td>
<td>Number of used rows in the table.</td>
</tr>
<tr>
<td>COLUMNS</td>
<td>Number of used columns in the table including the Point column.</td>
</tr>
<tr>
<td>SELECTION</td>
<td>A description of the table selection as you would specify it when invoking the ModifyTable operation’s selection keyword.</td>
</tr>
<tr>
<td>FIRSTCELL</td>
<td>An identification of the first visible data cell in the top/left corner of the table in row-column format. The first data cell is at location 0, 0.</td>
</tr>
<tr>
<td>LASTCELL</td>
<td>An identification of the last visible data cell in the bottom/right corner of the table in row-column format.</td>
</tr>
<tr>
<td>TARGETCELL</td>
<td>An identification of the target (highlighted) data cell in row-column format.</td>
</tr>
<tr>
<td>ENTERING</td>
<td>1 if an entry has been started in the entry line, 0 if not.</td>
</tr>
</tbody>
</table>

If itemIndex is -1 up to but not including the number of used columns to the right of the Point column, the returned string describes the specified column and contains the following keywords, with a semicolon after each keyword-value pair.
### TableInfo

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLENAME</td>
<td>The name of the table.</td>
</tr>
<tr>
<td>HOST</td>
<td>The host specification of the table’s host window if it is a subwindow or &quot;&quot; if it is a top-level table window.</td>
</tr>
<tr>
<td>COLUMNNAME</td>
<td>Name of the column as you would specify it to the Edit operation if you were creating a table showing just the column of interest.</td>
</tr>
<tr>
<td>TYPE</td>
<td>Column’s type which will be one of the following: Unused, Point, Index, Label, Data, RealData, ImagData. “Index” identifies a index column such as the X values of a wave. “Label” identifies a column of dimension labels. “Data” identifies a data column of a scalar wave. RealData and ImagData identify a real or imaginary column of a complex wave.</td>
</tr>
<tr>
<td>INDEX</td>
<td>Column’s position. -1 refers to the Point column, 0 to the first data column, and so on.</td>
</tr>
<tr>
<td>DATATYPE</td>
<td>Numeric data type of the wave or zero for text waves. See WaveType for a definition of data type codes.</td>
</tr>
<tr>
<td>WAVE</td>
<td>A full data folder path to the wave displayed in the column or &quot;&quot; for the Point column.</td>
</tr>
<tr>
<td>COLUMNS</td>
<td>The total number of columns in the table from the wave for the column for which you are getting information. This can be used to skip over all of the columns of a multidimensional wave.</td>
</tr>
<tr>
<td>HDIM</td>
<td>The wave dimension displayed horizontally as you move from one column to the next. 0 means rows, 1 means columns, 2 means layers, 3 means chunks.</td>
</tr>
<tr>
<td>VDIM</td>
<td>The wave dimension displayed vertically in the column. 0 means rows, 1 means columns, 2 means layers, 3 means chunks.</td>
</tr>
<tr>
<td>TITLE</td>
<td>As specified for the ModifyTable operation’s title keyword.</td>
</tr>
<tr>
<td>WIDTH</td>
<td>Column’s width in points.</td>
</tr>
<tr>
<td>FORMAT</td>
<td>As specified for the ModifyTable operation’s format keyword.</td>
</tr>
<tr>
<td>DIGITS</td>
<td>As specified for the ModifyTable operation’s digits keyword.</td>
</tr>
<tr>
<td>SIGDIGITS</td>
<td>As specified for the ModifyTable operation’s sigDigits keyword.</td>
</tr>
<tr>
<td>TRAILINGZEROS</td>
<td>As specified for the ModifyTable operation’s trailingZeros keyword.</td>
</tr>
<tr>
<td>SHOWFRACSECONDS</td>
<td>As specified for the ModifyTable operation’s showFracSeconds keyword.</td>
</tr>
<tr>
<td>FONT</td>
<td>The name of the column’s font.</td>
</tr>
<tr>
<td>SIZE</td>
<td>Column’s font size.</td>
</tr>
<tr>
<td>STYLE</td>
<td>As specified for the ModifyTable operation’s style keyword.</td>
</tr>
<tr>
<td>ALIGNMENT</td>
<td>0=left, 1=center, 2=right.</td>
</tr>
<tr>
<td>RGB</td>
<td>The column’s color in R,G,B format.</td>
</tr>
<tr>
<td>ELEMENTS</td>
<td>As specified for the ModifyTable operation’s elements keyword.</td>
</tr>
</tbody>
</table>

### Examples

This example makes the table’s target cell advance by one position within the range of selected cells each time it is called. To try it, create a table, select a range of cells and then run the function using the Macros menu.

Menu "Macros"
   "Test/1", /Q, AdvanceTargetCell("")
End
Function AdvanceTargetCell(tableName)
    String tableName // Name of table or "" for top table.
    String info = TableInfo(tableName, -2)
    if (strlen(info) == 0)
        return -1 // No such table
    endif
    String selectionInfo
    selectionInfo = StringByKey("SELECTION", info)
    Variable fRow, fCol, lRow, lCol, tRow, tCol
    sscanf selectionInfo, "%d,%d,%d,%d,%d,%d", fRow, fCol, lRow, lCol, tRow, tCol
    tCol += 1
    if (tCol > lCol)
        tCol = fCol
        tRow += 1
        if (tRow > lRow)
            tRow = fRow
        endif
    endif
    ModifyTable selection=(-1, -1, -1, -1, tRow, tCol)
End

See Also
The ModifyTable operation.

Tag

Tag [flags] [traceOrAxisName, xAttach [, textStr]]
The Tag operation puts a tag on the target or named graph window or subwindow. A tag is an annotation that is attached to a particular point on a trace, image, waterfall plot, or axis in a graph.

Parameters
traceOrAxisName is an optional trace or axis name. A trace name can be optionally followed by the # character and an instance number in order to distinguish multiple instances of the same wave in a graph. It identifies the trace or image to which the tag is to be attached. An axis name can be one of the standard axis names (Bottom, Top, Left, or Right) or a user-defined custom axis name.

A string containing traceOrAxisName must be used with the $ operator to specify traceOrAxisName.
xAttach is the X value of the point on the trace to which the tag is to be attached. For a multidimensional image, it is the linear index into the matrix array. For an axis, xAttach can be the X or Y point depending on the particular axis to which the tag is attached; specifying NaN for xAttach will center the tag on the axis.
textStr is the text that is to appear in the tag.

Flags
/A=anchorCode Specifies position of tag anchor point. anchorCode is a literal, not a string.
LT left top
LC left center
LB left bottom
MT middle top
MC middle center (default)
MB middle bottom
RT right top
RC right center
RB right bottom

The anchor point is on the tag itself. Any line or arrow drawn from the tag to the wave starts at the tag’s anchor point. The anchor point also determines the precise spot on the tag which represents its position.
/AO=ao  Sets the text’s auto-orientation mode. A non-zero ao value overrides the /O value. /AO is for trace tags only. Setting /AO for any other kind of annotation has no effect. An auto-oriented tag’s text rotates whenever it is redrawn, usually when the underlying data changes, the graph is resized, or when the tag is attached to a new point.
The values for ao are:
ao=0: No auto-orientation. Use the /O value (default).
ao=1: Tangent to the trace line at the attachment point.
ao=2: Tangent to the trace line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal.
ao=3: Perpendicular to the trace line.
ao=4: Perpendicular to the trace line, snaps to vertical or horizontal if within 2 degrees of vertical or horizontal.
/B=(r,g,b)  Sets color of the tag’s background. r, g, and b specify the amount of red, green, and blue as an integer from 0 to 65535.
/B=b  Controls the tag background.
b=0: Opaque background.
b=1: Transparent background.
b=2: Same background as the graph plot area background.
b=3: Same background as the window background.
/C  Changes the existing tag.
/F=frame  Controls the tag frame.
frame=0: No frame.
frame=1: Underline frame.
frame=2: Box frame.
/G=(r,g,b)  Sets color of the text in the tag. r, g, and b specify the amount of red, green, and blue as an integer from 0 to 65535.
/H=legendSymbolWidth  legendSymbolWidth sets width of the legend symbol (the sample line or marker) in points. Use 0 for the default, automatic width.
/I=i  Controls the tag visibility.
i=1: Tag will be invisible if it is “off screen”. “Off screen” means that its attachment point or any part of the tag’s text is off screen. This is esthetically pleasing but gives you nothing to grab if you want to drag the tag back on screen.
i=0: Tag will always be visible. If it is “off screen”, it appears at the extreme edge of the graph.
/K  Kills existing tag.
/L=line  Controls the line attaching the tag to the tagged point.
line=0: No line from tag to attachment point.
line=1: Line connecting tag to attachment point.
line=2: Line with arrow pointing from tag to attachment point.
line=3: Line with arrow pointing from attachment point to tag.
line=4: Line with arrows at both ends.
/LS= linespace  Specifies a tweak to the normal line spacing where linespace is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line.

/M[=sameSize]  /M or /M=1 specifies that legend markers should be the same size as the marker in the graph. 
/M=0 turns same-size mode off so that the size of the marker in the legend is based on text size.

/N=name  Specifies name of the tag to create or change.

/O=rot  Sets the text’s rotation. rot is in (integer) degrees, counterclockwise and must be a number from -360 to 360.
0 is normal horizontal left-to-right text, 90 is vertical bottom-to-top text.
If the tag is attached to a trace (not an image or axis), any non-zero /AO value will overwrite this rotation value.

/P=tipOffset  Sets the offset from the tip of a tag’s line or arrow to the point on the wave that it is tagging. tipOffset is a positive number from 0 to 200 in points. If tipOffset=0 (default), it automatically chooses an appropriate offset.

/Q[=contourInstance]  Associates a tag with a particular contour level trace in a graph recreation macro. Of interest mainly to hard-core programmers.
When “=contourInstance” is present, /Q associates the tag with the contour wave. Igor will feel free to change or delete the tag, as appropriate, when it recalculates the contour (because you changed the contour data or appearance, the graph size or the axis range). contourInstance is a contour instance name, such as zWave or zWave#1 if you have the same wave contoured twice in the graph.
/Q by itself, with “=contourInstance” not present, disassociates the tag from the contour wave. Igor will no longer modify or delete the tag (unless the contour level to which it is attached is deleted). If you manually tweak a contour label, using the Modify Annotation dialog, Igor uses this flag.

/R=newName  Renames the tag.

/S=style  Controls the tag frame style.

style=0: Single frame.
style=1: Double frame.
style=2: Triple frame.
style=3: Shadow frame.

/T=tabSpec  tabSpec is a single number in points, such as /T=72, for evenly spaced tabs or a list of tab stops in points such as /T={50 , 150 , 225}.

/TL=extLineSpec  Specifies extended tag line parameters similar to the SetDrawEnv arrow settings.
extLineSpec = [keyword = value,…] or zero to turn off all extended specifications.
Valid *keyword-value* pairs are:

- **len=l** Length of arrow head in points (*l*=0 for auto).
- **fat=f** Width to length ratio of arrow head (default is 0.5 same as *f*=0).
- **style=s** Sets barb side mode (see `SetDrawEnv` `astyle` for values).
- **shar =s** Sets sharpness between -1 and 1 (default is 0; blunt).
- **frame=f** Sets frame thickness in outline mode.
- **lThick=l** Sets line thickness in points (default is 0.5 for *l*=0).
- **lineRGB=(r,g,b)** Sets color for lines. Default is all zeros (black); the same as the tag frame.
- **dash=d** Specifies dash pattern number between 0 and 17 (see `SetDashPattern` for patterns).

/W=winName Operates on the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with `winName`, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

/N=vis Controls annotation visibility.

- **vis=0**: Invisible annotation; not selectable. The annotation is still listed in `AnnotationList`.
- **vis=1**: Visible annotation (default).

/X=xOffset Distance from point to tag as percentage of graph width. For axis tags, the offsets are proportional to the size of the text used for the axis labels.

/Y=yOffset Distance from point to tag as percentage of graph height. For axis tags, the offsets are proportional to the size of the text used for the axis labels.

/Z=freeze Controls freezing of tag position.

- **freeze=1**: Freezes tag position (you can’t move it with the mouse).
- **freeze=0**: Unfreezes it.

**Details**

If the /C flag is used, it must be the first flag in the command and must be followed immediately by the /N= `name` flag.

If the /K flag is used, it must be the first flag in the command and must be followed immediately by the /N= `name` flag with no further flags or parameters.

`traceOrAxisName`, `xAttach`, and `textStr` are all optional. If `traceOrAxisName` is specified, then `xAttach` must be specified, and vice versa. `textStr` may be specified only if `traceOrAxisName` and `xAttach` are specified.

This syntax allows changes to the tag to be made through the flags parameters without needing to respecify the other parameters. Similarly, the tag’s attachment point can be changed without needing to respecify the `textStr` parameter.

`xAttach` is in terms of the wave’s X scaling. If `traceOrAxisName` is displayed as an XY pair, we recommend that you use “point scaling” for the waves, so that `xAttach` can be a point number (because `xAttach` will not be an X axis value).

A tag can have at most 100 lines.

`textStr` can contain escape codes which affect subsequent characters in the text. An escape code is introduced by a backslash character. In a literal string, you must enter two backslashes to produce one. See Backslashes in Annotation Escape Sequences on page III-59 for details.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See Annotation Escape Codes on page III-54 for details.
Some escape codes insert text based on the wave point or axis to which a tag is attached. See Tag Escape Codes on page III-56 and Axis Label Escape Codes on page III-58 for details.

The characters "<??>" in a tag indicate that you specified an invalid escape code or used a font that is not available.

Examples

Tag/C/N=t1/X=25/Y=50
moves the tag named t1 to the location defined by X=25 and Y=50.

Tag/C/N=t1 wave1, 50
moves the tag named t1 to wave1 at x=50.

Tag/N=t2 wave1, 50, "%\JC\{}\{numpnts(wave1)\}\ points\ in\ this\ wave" 
creates a new tag on wave1 that shows the number of points in the wave.

Tag w, 0, "%\%g\ is\ first,\ \%g\ is\ last\"\{rw[0],w[numpnts(w)-1]}"
creates a new tag on w that shows the value of the first and last points in the wave.

"\r" inserts a carriage-return character which starts a new line of text in the annotation.

Following is an example of various ways in which axis tags can be used:

Make/O jack=sin(x/8)
SetScale x,0,14e9,"y" jack
Display jack
Label bottom "\u#2" // turn off default axis label
ModifyGraph axOffset (bottom)=1.16667 // make room for tag (manual adjustment)
Tag/N=text0/F=0/A=MT/X=0.20/Y=-4.29/L=0 bottom, Nan, "%\JCTime (\U)\2nd\ line"
// now a few "important location" tags...
Tag/N=text1/F=0/A=LB/X=1.20/Y=3.00 bottom, 0, "Big Bang"
Tag/N=text2/F=0/A=MB/X=0.00/Y=2.86 bottom, 8000000000, "Earth formed"
Tag/N=text3/F=0/A=RB/X=-0.80/Y=4.71 bottom, 13040000000, "Dinosaurs ruled"

TagVal, TagWaveRef

Annotation Escape Codes on page III-54
Label, Axis Labels on page II-253
Trace Names on page II-222, Programming With Trace Names on page IV-86

TagVal

TagVal(code)

TagVal is a very specialized function that is only valid when called from within the text of a tag as part of a `{}` dynamic text escape sequence. It returns a number reflecting some property of the tag and helps you to display information about the tagged wave. The property is selected by the code parameter:

<table>
<thead>
<tr>
<th>code</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Similar to \OP, returns the tag attach point number.</td>
</tr>
<tr>
<td>1</td>
<td>Similar to \OX, returns the X coordinate of tag attachment in the graph. When a tag is attached to an XY pair of traces, the X coordinate will most likely be different than the tag’s X scaling attachment value specified in the Tag command.</td>
</tr>
<tr>
<td>2</td>
<td>Similar to \OY, returns the Y coordinate of tag attachment in the graph or the Y axis value in a Waterfall plot.</td>
</tr>
<tr>
<td>3</td>
<td>Similar to \OZ, returns the Z coordinate of tag attachment in a contour, image, or Waterfall plot.</td>
</tr>
<tr>
<td>4</td>
<td>Similar to \Ox, returns the trace x offset.</td>
</tr>
</tbody>
</table>
TagWaveRef

<table>
<thead>
<tr>
<th>code</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>Similar to ‘Oy, returns the trace y offset.</td>
</tr>
<tr>
<td>6</td>
<td>Returns the X muloffset (with the not set value 0 translated to 1).</td>
</tr>
<tr>
<td>7</td>
<td>Returns the Y muloffset (with the not set value 0 translated to 1).</td>
</tr>
</tbody>
</table>

Because TagVal returns a numeric value, the result can be formatted any way you wish using the printf formatting codes. In contrast, the ‘O codes insert preformatted text, and you don’t have control over the format.

TagVal is sometimes used in conjunction with the TagWaveRef function. For example, you might write a user-defined function that calculates a value as a function of a wave and a point number.

Examples

Tag wave0, 0, "Y value is \{"%g",TagVal(2)}"
Tag wave0, 0, "Y value is \{"%g",TagWaveRef(TagVal(0))}"  
Tag wave0, 0, "Y value is \Oy"

These examples all produce identical results.

See Also

The Tag operation, the TagWaveRef function.

For a discussion of wave references, see Wave Reference Functions on page IV-192.

TagWaveRef

TagWaveRef()

TagWaveRef is a very specialized function that is only valid when called from within the text of a tag as part of a \{} dynamic text escape sequence. It returns a wave reference to the wave that the tag is on and helps you to display information about the tagged wave. It is often used in conjunction with the TagVal function. You can pass the result of TagWaveRef to any function that takes a Wave parameter.

Examples

Show the name of the data folder containing the tagged wave:
Tag wave0, 0,"\ON is in \{"%s",GetWavesDataFolder(TagWaveRef(),0)}"

See Also

The Tag operation, the TagVal function

For a discussion of wave references, see Wave Reference Functions on page IV-192.

tan

tan(angle)
The tan function returns the tangent of angle which is in radians.

In complex expressions, angle is complex, and tan(angle) returns a complex value:

\[
tan(x + iy) = \frac{\sin(x + iy)}{\cos(x + iy)} = \frac{\sin(2x) + i \sinh(2y)}{\cos(2x) + \cosh(2y)}.
\]

See Also

atan, atan2, sin, cos, sec, csc, cot

tanh

tanh(num)
The tanh function returns the hyperbolic tangent of num:

\[
tanh(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}}.
\]
In complex expressions, \( num \) is complex, and \( \tanh(num) \) returns a complex value.

**See Also**

\( \sinh, \cosh, \coth \)

**TextBox**

\texttt{TextBox [flags] [textStr]}

The TextBox operation puts a textbox on the target or named graph window. A textbox is an annotation that is not associated with any particular trace.

**Parameters**

\( textStr \) is the text that is to appear in the textbox. It is optional.

**Flags**

\texttt{/A=anchorCode} Specifies position of textbox anchor point.

<table>
<thead>
<tr>
<th>anchorCode</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>LT</td>
<td>left top</td>
</tr>
<tr>
<td>LC</td>
<td>left center</td>
</tr>
<tr>
<td>LB</td>
<td>left bottom</td>
</tr>
<tr>
<td>MT</td>
<td>middle top</td>
</tr>
<tr>
<td>MC</td>
<td>middle center</td>
</tr>
<tr>
<td>MB</td>
<td>middle bottom</td>
</tr>
<tr>
<td>RT</td>
<td>right top</td>
</tr>
<tr>
<td>RC</td>
<td>right center</td>
</tr>
<tr>
<td>RB</td>
<td>right bottom</td>
</tr>
</tbody>
</table>

\( anchorCode \) is a literal, \textit{not} a string.

For interior textboxes, the anchor point is on the rectangular edge of the plot area of the graph window (where the left, bottom, right, and top axes are drawn).

For exterior textboxes, the anchor point is on the rectangular edge of the entire graph window.

\texttt{/B=(r,g,b)} Sets the color of the tag’s background. \( r, g, \) and \( b \) specify the amount of red, green, and blue as an integer from 0 to 65535.

\texttt{/B=b} Controls the textbox background.

- \( b=0 \): Opaque background.
- \( b=1 \): Transparent background.
- \( b=2 \): Same background as the graph plot area background.
- \( b=3 \): Same background as the window background.

\texttt{/C} Changes existing textbox.

\texttt{/D={thickMult [, shadowThick [, haloThick]]}}

\( thickMult \) multiplies the normal frame thickness of a textbox. The thickness may be set using just \( /D=\text{thickMult} \).

\( shadowThick \), if present, overrides Igor’s normal shadow thickness. It is in units of fractional points.

\( haloThick \) governs the annotation’s halo thickness (a surrounding band of the annotation’s background color), which can be -1 to 10 points wide.

The default \( haloThick \) value is -1, which preserves the behavior of previous versions of Igor where the halo of all annotations was set by the global variable \texttt{root:V_TBBufZone}. Any negative value of \( haloThick \) (-0.5, for example) will be overridden by \texttt{V_TBBufZone} if it exists, otherwise the absolute value of \( haloThick \) will be used. A zero or positive value overrides \texttt{V_TBBufZone}. 

V-941
Any of the parameters may be missing. To set \textit{haloThick} to 0 without changing other parameters, use /D\{, , 0\}.

\textbf{/E[=exterior]} \hspace{1cm} /E or /E=1 forces textbox (or legend) to be exterior to graph (provided \textit{anchorCode} is not MC) and pushes the graph margins away from the anchor edge(s). /E=2 also forces exterior mode but does not push the margins. /E=0 returns it to the default (an “interior textbox” which can be anywhere in the graph window).

\textbf{/F=frame} \hspace{1cm} Controls the textbox frame.

\hspace{1cm} frame=0: No frame.
\hspace{1cm} frame=1: Underline frame.
\hspace{1cm} frame=2: Box frame.

\textbf{/G=(r,g,b)} \hspace{1cm} Sets color of the text in the tag. \(r\), \(g\), and \(b\) specify the amount of red, green, and blue as an integer from 0 to 65535.

\textbf{/H=legendSymbolWidth} \hspace{1cm} \textit{legendSymbolWidth} sets width of the legend symbol (the sample line or marker) in points. Use 0 for the default, automatic width.

\textbf{/K} \hspace{1cm} Kills existing textbox.

\textbf{/LS= linespace} \hspace{1cm} Specifies a tweak to the normal line spacing where \textit{linespace} is points of extra (plus or minus) line spacing. For negative values, a blank line may be necessary to avoid clipping the bottom of the last line.

\textbf{/M[=sameSize]} \hspace{1cm} /M or /M=1 specifies that legend markers should be the same size as the marker in the graph.
\hspace{1cm} /M=0 turns same-size mode off so that the size of the marker in the legend is based on text size.

\textbf{/N=name} \hspace{1cm} Specifies the name of the textbox to change or create.

\textbf{/O=rot} \hspace{1cm} Sets the text’s rotation. \(rot\) is in (integer) degrees, counterclockwise and must be a number from -360 to 360.
\hspace{1cm} 0 is normal horizontal left-to-right text, 90 is vertical bottom-to-top text.

\textbf{/R=newName} \hspace{1cm} Renames the textbox.

\textbf{/S=style} \hspace{1cm} Controls the textbox frame style.

\hspace{1cm} style=0: Single frame.
\hspace{1cm} style=1: Double frame.
\hspace{1cm} style=2: Triple frame.
\hspace{1cm} style=3: Shadow frame.

\textbf{/T=tabSpec} \hspace{1cm} \textit{tabSpec} is a single number in points, such as /T=72, for evenly spaced tabs or a list of tab stops in points such as /T=\{50, 150, 225\}.

\textbf{/V=vis} \hspace{1cm} Controls annotation visibility.

\hspace{1cm} vis=0: Invisible annotation; not selectable. The annotation is still listed in \textit{AnnotationList}.
\hspace{1cm} vis=1: Visible annotation (default).

\textbf{/W=winName} \hspace{1cm} Operates in the named graph window or subwindow. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with \textit{winName}, see \textbf{Subwindow Syntax} on page III-92 for details on forming the window hierarchy.
Details
Use the optional /W=winName flag to specify a specific graph or layout window. When used on the command line or in a Macro, Proc, or Window procedure, /W must precede all other flags.

If the /C flag is used, it must be the first flag in the command (except that it may follow an initial /W) and must be followed immediately by the /N=name flag.

If the /K flag is used, it must be the first flag in the command (or follow an initial /W) and must be followed immediately by the /N=name flag with no further flags or parameters.

textStr is optional. If missing, the textbox text is unchanged. This allows changes to the textbox to be made through the flags without changing the text.

A textbox can have at most 100 lines.

textStr can contain escape codes which affect subsequent characters in the text. An escape code is introduced by a backslash character. In a literal string, you must enter two backslashes to produce one. See Backslashes in Annotation Escape Sequences on page III-59 for details.

Using escape codes you can change the font, size, style and color of text, create superscripts and subscripts, create dynamically-updated text, insert legend symbols, and apply other effects. See Annotation Escape Codes on page III-54 for details.

The characters "<??>" in a textbox indicate that you specified an invalid escape code or used a font that is not available.

Examples
TextBox/C/N=t1/X=25/Y=50
moves the textbox named t1 to the location defined by X=25 and Y=50.

TextBox/C/N=t1 "New Text"
changes the text for t1.

Programming with Annotations on page III-53.

Trace Names on page II-222, Programming With Trace Names on page IV-86.

TextEncoding

#pragma TextEncoding = "<text encoding name>"
#pragma TextEncoding is a compiler directive that tells Igor the text encoding used by a procedure file. Igor needs to know this in order to correctly interpret non-ASCII characters in the file. We recommend that you add a TextEncoding pragma to your procedure files.

See Text Encoding Names and Codes on page III-463 for a list of accepted text encoding names.

This statement must be flush against the left edge of the procedure file with no indentation. It is usually placed at or near the top of the file.
The TextEncoding pragma was added in Igor Pro 7.00 and is ignored by earlier versions. See The TextEncoding Pragma on page IV-56 for further explanation.

TextEncodingCode

TextEncodingCode(textEncodingNameStr)
The TextEncodingCode function returns the Igor text encoding code for the named text encoding or 0 if the text encoding is unknown.

The TextEncodingCode function was added in Igor Pro 7.00.

Parameters
textEncodingNameStr is an Igor text encoding name as listed under Text Encoding Names and Codes on page III-463.

Details
Igor ignores all non-alphanumeric characters in text encoding names so "Shift JIS", "ShiftJIS", "Shift_JIS" and "Shift-JIS" are equivalent.

It also ignores leading zeros in numbers embedded in text encoding names so "ISO-8859-1" and "ISO-8859-01" are equivalent.

TextEncodingCode does a case-insensitive comparison.

See Also
Text Encodings on page III-437, Text Encoding Names and Codes on page III-463, TextEncodingName

TextEncodingName

TextEncodingName(textEncoding, index)
The TextEncodingName function returns one or more text encoding names corresponding to the specified text encoding code. The result is returned as a string value.

If textEncoding is not a valid Igor text encoding code or if index is out of range, TextEncodingName returns "Unknown".

This function is mainly useful for providing a human-readable string corresponding to a given text encoding code for display purposes. You might use it to generate some Internet-compatible text, such as an HTML page, if you need a string to specify the charset.

The TextEncodingName function was added in Igor Pro 7.00.

Parameters
textEncoding is an Igor text encoding code as listed under Text Encoding Names and Codes on page III-463.
index specifies which text encoding name you want. A given text encoding can be identified by more than one name. Normally you will pass 0 to get the first text encoding name for the specified text encoding code. This is the preferred text encoding name. You can pass 1 for the second name, if any, 2 for the third, if any, and so on. You can pass -1 to get a semicolon-separated list of all text encoding names for the specified text encoding.

Details
Internally Igor has a table of text encoding codes and the corresponding text encoding names. For a given code there may be more than one acceptable name. For example, for the code 2 (MacRoman), the names "macintosh", "MacRoman" and "x-macroman" are accepted, with "macintosh" being preferred. The TextEncodingName function returns a text encoding name from the internal table.

The preferred name is usually the name recognized by the Internet Assigned Numbers Authority (IANA) as listed at http://www.iana.org/assignments/character-sets.

Examples

// Get the preferred name for the MacRoman text encoding (2)
String firstName = TextEncodingName(2, 0); Print firstName

// Get the second name for the MacRoman text encoding (2)
String secondName = TextEncodingName(2, 1); Print secondName
TextFile

TextFile(pathName, index [, creatorStr])

Note: TextFile is antiquated. Use IndexedFile instead.

The TextFile function returns a string containing the name of the indexth TEXT file from the folder specified by pathName.

On Macintosh, TextFile returns only files whose file type property is TEXT, regardless of the file’s extension.

On Windows, Igor considers files with “.txt” extensions to be of type TEXT.

Details

PathName is the name of an Igor symbolic path; it is not a string.

Index starts from zero.

CreatorStr is an optional string argument containing four ASCII characters such as “IGR0”. Only files of the specified Macintosh creator code are indexed. Set creatorStr to “????” to index all text files (or omit the argument altogether). This argument is ignored on Windows systems.

The order of files in a folder is determined by the operating system.

Examples

You can use TextFile in a procedure to sequence through each TEXT file in a folder, put the name of the text file into a string variable, and use this string variable as a parameter to the LoadWave or Open operations:

Function/S PrintFirstLineOfTextFiles(pathName)
    String pathName // Name of an Igor symbolic path.
    Variable refNum, index
    String str, fileName
    index = 0
    do
        fileName = TextFile($pathName, index)
        if (strlen(fileName) == 0)
            break // No more files
        endif
        Open/R/P=$pathName refNum as fileName
        FReadLine refNum, str // Read first line including CR/LF
        Print fileName +":" + str // Print file name and first line
        Close refNum
        index += 1 // Next file
    while (1)
End

See Also

See the IndexedFile function, which is similar to TextFile but works on files of any type, and also IndexedDir. Also see the LoadWave and Open the operations.

ThreadGroupCreate

ThreadGroupCreate(nt)

The ThreadGroupCreate function creates a thread group containing nt threads and returns a thread ID number. Use the number of computer processors for nt when trying to improve computation speed using parallel threads. A background worker might use just one thread regardless of the number of processors.

See Also

ThreadSafe Functions on page IV-103 and ThreadSafe Functions and Multitasking on page IV-317.
ThreadGroupGetDF

ThreadGroupGetDF
ThreadGroupGetDF(tgID, waitms)

ThreadGroupGetDFR should be used instead of ThreadGroupGetDF which causes memory leaks.
The ThreadGroupGetDF function retrieves a data folder path string from a thread group queue and removes the data folder from the queue.
When called from a preemptive thread it returns a data folder from the thread group's input queue. When called from the main thread it returns a data folder from the thread group's output queue.
gtID is a thread group ID returned by ThreadGroupCreate. You can pass 0 for gtID when calling ThreadGroupGetDF from a preemptive thread. You must pass a valid thread group ID when calling ThreadGroupGetDF from the main thread.

waitms is the maximum number of milliseconds to wait for a data folder to become available in the queue. Pass 0 to test if a data folder is available immediately. Pass INF to wait indefinitely or until a user abort.
ThreadGroupGetDFR returns "" if the timeout period specified by waitms expires and no data folder is available in the queue.

See Also
ThreadSafe Functions on page IV-103 and ThreadSafe Functions and Multitasking on page IV-317.
The ThreadGroupGetDFR function.

ThreadGroupGetDFR
ThreadGroupGetDFR(tgID, waitms)
The ThreadGroupGetDFR function retrieves a data folder reference from a thread group queue and removes the data folder from the queue. The data folder becomes a free data folder.
When called from a preemptive thread it returns a data folder from the thread group's input queue. When called from the main thread it returns a data folder from the thread group's output queue.
gtID is a thread group ID returned by ThreadGroupCreate. You can pass 0 for gtID when calling ThreadGroupGetDFR from a preemptive thread. You must pass a valid thread group ID when calling ThreadGroupGetDFR from the main thread.

waitms is the maximum number of milliseconds to wait for a data folder to become available in the queue. Pass 0 to test if a data folder is available immediately. Pass INF to wait indefinitely or until a user abort.
ThreadGroupGetDFR returns a NULL data folder reference if the timeout period specified by waitms expires and no data folder is available in the queue. You can test for NULL using DataFolderRefStatus.

See Also
ThreadSafe Functions on page IV-103, ThreadSafe Functions and Multitasking on page IV-317 and Free Data Folders on page IV-93.

ThreadGroupPutDF
ThreadGroupPutDF tgID, datafolder
The ThreadGroupPutDF operation posts data to a preemptive thread group.
Parameters
tgID is thread group ID returned by ThreadGroupCreate, datafolder is the data folder you wish to send to the thread group.
datafolder can be just the name of a child data folder in the current data folder, a partial path (relative to the current data folder) and name or an absolute path (starting from root) and name.
Details
When you call it from the main thread, ThreadGroupPutDF removes datafolder from the main thread’s data hierarchy and posts to the input queue of the thread group specified by tgID.
When you call it from a preemptive thread, use 0 for tgID and the data folder will be posted to the output queue of thread group to which thread belongs.
Input and output data folders may be retrieved from the queues by calling the string function ThreadGroupGetDF or ThreadGroupGetDFR.

**Warning:** Take care not to use any stale WAVE, NVAR, or SVAR variables that might contain references to objects in the data folder. Use WAVEClear on all WAVE reference variables that might contain references to waves that are in the data folder being posted before calling ThreadGroupPutDF. An error will occur if any waves in the data folder are in use or referenced in a WAVE variable.

**Warning:** Any DFREF variables that refer to the data folder (or any child thereof) must be cleared prior to executing this command. You can clear a DFREF using $dfr=$"".

From the standpoint of the source thread, ThreadGroupPutDF is conceptually similar to KillDataFolder and, like KillDataFolder, if the current data folder is within `datafolder`, the current data folder is set to the parent of `datafolder`. You can not pass `root:` as `datafolder`.

**See Also**
The ThreadGroupCreate function, ThreadSafe Functions on page IV-103, and ThreadSafe Functions and Multitasking on page IV-317.

### ThreadGroupRelease

**ThreadGroupRelease(tgID)**
The ThreadGroupRelease function releases thread group (and `tgID` is no longer valid). `tgID` is the thread group ID returned by ThreadGroupCreate.

If threads in the group are still running, Igor signals them to quit. If they continue to run, Igor forces them to quit. See Aborting Threads on page IV-325 for details.

Specifying `tgID=-2` kills all running threads.

ThreadGroupRelease returns zero if successful, -1 if an error occurred (probably invalid `tgID`), or -2 if a force quit was needed. In the latter case, you should restart Igor Pro.

Any data folders remaining in the group’s input or output queues will be discarded.

**See Also**
The ThreadGroupCreate function, ThreadSafe Functions on page IV-103, and ThreadSafe Functions and Multitasking on page IV-317.

### ThreadGroupWait

**ThreadGroupWait(tgID, waitms)**
The ThreadGroupWait function returns index+1 of the first thread found still running after `waitms` milliseconds or returns zero if all are done.

`tgID` is the thread group ID returned by ThreadGroupCreate and `waitms` is milliseconds to wait.

If any of the threads of the group encountered a runtime error, the first such error will be reported now. Use zero for `waitms` to just test or provide a large value to cause the main thread to sleep until the threads are finished. You can use INF to wait forever or until a user abort. If you know the maximum time the threads should take, you can use that value so you can print an error message or take other action if the threads don’t return in time.

When ThreadGroupWait is called, Igor updates certain internal variables including variables that track whether a thread has finished and what result it returned. Therefore you must call ThreadGroupWait before calling ThreadReturnValue.

ThreadGroupWait updates the internal state of all threads in the group.

**Finding a Free Thread**
If you pass -2 for `waitms`, ThreadGroupWait returns index+1 of the first free (not running) thread or 0 if all threads in the group are running.

This allows you to dispatch a thread anytime a free thread is available. See Parallel Processing - Thread-at-a-Time Method on page IV-320 for an example.
ThreadProcessorCount

See Also
The ThreadGroupCreate function, ThreadSafe Functions on page IV-103, and ThreadSafe Functions and Multitasking on page IV-317.

ThreadProcessorCount
ThreadProcessorCount
The ThreadProcessorCount function returns the number of processors in your computer. For example, on a Macintosh Core Duo, it would return 2.

ThreadReturnValue
ThreadReturnValue(tgID, index)
The ThreadReturnValue function returns the value that the specified thread function returned when it exited. Returns NAN if thread is still running. tgID is the thread group ID returned by ThreadGroupCreate and index is the thread number.

When ThreadGroupWait is called, Igor updates certain internal variables including variables that track whether a thread has finished and what result it returned. Therefore you must call ThreadGroupWait before calling ThreadReturnValue.

See Also
The ThreadGroupCreate function, ThreadSafe Functions on page IV-103, and ThreadSafe Functions and Multitasking on page IV-317.

ThreadSafe
ThreadSafe Function funcName()
The ThreadSafe keyword declaration specifies that a user function can be used for preemptive multitasking background tasks on multiprocessor computer systems.

A ThreadSafe function is one that can operate correctly during simultaneous execution by multiple threads. Such functions are generally limited to numeric or utility functions. Functions that access windows are not ThreadSafe. To determine if an operation is ThreadSafe, use the Command Help tab of the Help Browser and choose ThreadSafe from the pop-up menu.

ThreadSafe functions can call other ThreadSafe functions but may not call non-ThreadSafe functions. Non-ThreadSafe functions can call ThreadSafe functions.

See Also
ThreadSafe Functions on page IV-103 and ThreadSafe Functions and Multitasking on page IV-317.

ThreadStart
ThreadStart tgID, index, WorkerFunc(param1, param2,...)
The ThreadStart operation starts the specified function running in a preemptive thread.

Parameters
tgID is thread group ID returned by ThreadGroupCreate, index is the desired thread of the group to set up to execute the specified ThreadSafe WorkerFunc.

Details
The worker function starts running immediately.
The worker function must be defined as ThreadSafe and must return a real or complex numeric result.
The worker function’s return value can be obtained after the function finishes by calling ThreadReturnValue. Igor records the fact that a thread has terminated when you call ThreadGroupWait so you must call ThreadGroupWait before calling ThreadReturnValue.
The worker function can take variable and wave parameters. It can not take pass-by-reference parameters or data folder reference parameters.
Any waves you pass to the worker are accessible to both the main thread and to your preemptive thread. Such waves are marked as being in use by a thread and Igor will refuse to perform any manipulations that could change the size of the wave.
ticks

The ticks function returns the number of ticks (approximately 1/60 second) elapsed since the operating system was initialized.

See Also
The StopMSTimer function.

TickWavesFromAxis

TickWavesFromAxis [ /W=graphName /DEST= {textWaveName, numericWaveName} /O ]

axisName

The TickWavesFromAxis operation generates a pair of waves suitable for use as user tick waves (see User Ticks from Waves on page II-248). This allows you to programmatically determine the tick marks and tick labels that Igor would create for a given graph axis in auto mode.

TickWavesFromAxis was added in Igor Pro 8.00.

TickWavesFromAxis generates two waves: a two-column text wave containing tick labels and the names of tick types, and a numeric wave giving the positions of the ticks along the axis. The information stored in the output waves reflects the automatically generated ticks based on the current axis settings.

By default the waves are given names derived from the graph window and axis name: <graphname>_<axisname>_labels and <graphname>_<axisname>_values. Use /DEST to give the waves custom names.

Parameters

axisName is the name of the axis for which the tick waves are generated. This will usually be left, bottom, right or top, but may be the name of a free axis.

Flags

/DEST=[textWaveName, numericWaveName]

Specifies custom names for the generated waves. textWaveName is the name of the text wave containing the tick labels. numericWaveName is the name of the numeric wave containing the axis position values for the ticks. If the waves don’t already exist, they are created.

You may use data folder syntax as long as the data folders already exist.

The operation may create wave references for the destination waves if called in a user-defined function. See Automatic Creation of WAVE References on page IV-71 for details.

/O

Tells TickWavesFromAxis that it can overwrite existing waves.

Igor returns an error if you attempt to overwrite a numeric wave with a text wave or a text wave with a numeric wave.

/W=winName

Specifies the graph containing the axis. This may be a subwindow path. If you omit /W, the top graph window is used.

Details

The TickWavesFromAxis operation depends on drawing the axis to generate the list of ticks. It causes a screen refresh, equivalent to calling DoUpdate, twice during its execution.

The TickWavesFromAxis operation honors your axis format settings and manual range. It works on regular numeric axes, log axes and date/time axes. At this time it does not work on category axes.

See Also
User Ticks from Waves on page II-248 and the ModifyGraph UserTicks keyword.
**Tile**

*Tile [flags] [objectName [, objectName]...]*

The Tile operation tiles the specified objects in the top page layout.

**Parameters**

*objectName* is the name of a graph, table, picture or annotation object in the top page layout.

**Flags**

- **/A=(rows,cols)** Specifies number of rows/columns in which to tile objects.
- **/G=grout** Specifies grout, the spacing between window tiles, in prevailing coordinates (points unless preceded by /I, /M or /R).
- **/I** Specifies coordinates in inches.
- **/M** Specifies coordinates in centimeters.
- **/O=objTypes** Adds objects of type(s) specified by bitwise mask to list of objects to be tiled:
  - Bit 0: Tile graphs.
  - Bit 1: Tile tables.
  - Bit 3: Tile pictures.
  - Bit 5: Tile textboxes.

See [Setting Bit Parameters](#) for details about bit settings.

- **/R** Specifies coordinates measured in percent of the printable page.
- **/S** Adds selected objects to objects to be tiled.
- **/W=(left,top,right,bottom)** Specifies page layout area in which to tile objects. Coordinates are in points unless /I, /M or /R are specified before /W.

**Details**

If /A=(rows,cols) is not used, Tile uses an appropriate number of rows and columns. If /A=(rows,cols) is used, objects are tiled in a grid of that many rows and columns. If rows or cols is zero, it substitutes an appropriate number for the zero parameter.

Objects to be tiled are determined by the /S and /O=objTypes flags and by any *objectNames*.

If no /S or /O flags are present and there are no *objectNames*, then all objects in the layout are tiled.

Otherwise the objects to be tiled are determined as follows:

- All objects specified by *objectNames* are tiled.
- If the /S flag is present, the selected objects, if any, are also tiled.
- If the /O=objTypes flag is present then any objects specified by *objTypes* are also tiled. *objTypes* is a bitwise mask, so /O=3 tiles both graphs and tables.

**See Also**

The Stack operation.

---

**TileWindows**

*TileWindows [flags] [windowName [, windowName]...]*

The TileWindows operation tiles the specified windows on the desktop (*Macintosh*) or in the Igor frame window (*Windows*).

**Flags**

- **/A=(rows,cols)** Specifies number of rows/columns in which to tile windows.
- **/C** Adds the command window to the windows to be tiled.
/G=grout  Specifies grout, the spacing between tiles, in prevailing units (points unless /I or /M are used).
/I  Specifies coordinates in inches.
/M  Specifies coordinates in centimeters.
/O=objTypes  Adds windows of types specified by objTypes to windows to be tiled.

objTypes is a bitwise mask where:
- Bit 0: Graphs
- Bit 1: Tables
- Bit 2: Page layouts
- Bit 4: Notebooks
- Bit 6: Control panels
- Bit 7: Procedure windows
- Bit 9: Help windows
- Bit 12: XOP target windows
- Bit 14: Camera windows
- Bit 16: Gizmo windows

Other bits should always be zero. See Setting Bit Parameters on page IV-13 for details about bit settings.

/P  Adds the main procedure window to the windows to be tiled.
/R  Specifies coordinates measured as % of tiling rectangle.
/W=(left,top,right,bottom)  Specifies tiling rectangle on the screen. Coordinates are in points unless /I, /M, or /R are specified before /W.

Details
The windows to be tiled are determined by the /C, /P, and /O=objTypes flags and by the windowNames. If no /C, /P or /O flags are present and there is no windowNames then all windows are tiled.

Otherwise the windows to be tiled are determined as follows:
- All named windows are tiled.
- If the /C flag is present, the command window is also tiled.
- If the /P flag is present, the procedure window is also tiled.
- If the /O=objTypes flag is present, any windows specified by objTypes are also tiled.

Examples
To tile all the procedure windows, including the main one, use:
TileWindows/P/O=128  // 2^7=128

See Also
The StackWindows operation.

time

time()  The time function returns a string containing the current time. The empty parentheses are required.

See Also
The date, date2secs and DateTime functions.
TitleBox

TitleBox \[/Z\] \texttt{ctrlName [keyword = value [, keyword = value ...]]}

The TitleBox operation creates the named title box in the target window.

For information about the state or status of the control, use the \texttt{ControlInfo} operation.

Parameters

\texttt{ctrlName} is the name of the TitleBox control to be created or changed.

The following keyword=value parameters are supported:

- \texttt{anchor=hv}
  Specifies the anchor mode using a two letter code, \texttt{hv}. \texttt{h} may be L, M, or R for left, middle, and right. \texttt{v} may be T, C, or B for top, center and bottom. Default is LT.
  
  If \texttt{fixedSize=1}, the anchor code sets the positioning of text within the frame.

- \texttt{align=alignment}
  Sets the alignment mode of the control. The alignment mode controls the interpretation of the \texttt{leftOrRight} parameter to the pos keyword. The \texttt{align} keyword was added in Igor Pro 8.00.
  
  If \texttt{alignment=0} (default), \texttt{leftOrRight} specifies the position of the left end of the control and the position of the control depends on the anchor keyword.
  
  If \texttt{alignment=1}, \texttt{leftOrRight} specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.
  
  There is a conflict between the \texttt{align} keyword and the anchor keyword. See TitleBox Positioning on page V-953.

- \texttt{appearance={kind [, platform]}}
  Sets the appearance of the control. \texttt{platform} is optional. Both parameters are names, not strings.
  
  \texttt{kind} can be one of default, native, or os9.
  
  \texttt{platform} can be one of Mac, Win, or All.
  
  See \texttt{Button} and \texttt{DefaultGUIControls} for more appearance details.

- \texttt{disable=d}
  Sets user editability of the control.
  
  \texttt{d=0}: Normal.
  
  \texttt{d=1}: Hide.
  
  \texttt{d=2}: Draw in gray state.

- \texttt{fColor=(r,g,b)}
  Sets color of the titlebox. \texttt{r}, \texttt{g}, and \texttt{b} are integers from 0 to 65535.

- \texttt{fixedSize=f}
  Controls title box sizing:
  
  \texttt{f=0}: The titlebox automatically sizes itself to fit the title text (default).
  
  \texttt{f=1}: The size settings are honored, and the titlebox does not automatically size itself to fit the title text.

- \texttt{font="fontName"}
  Sets the font used for the control, e.g., \texttt{font="Helvetica"}.

- \texttt{frame=f}
  Sets frame style:
  
  \texttt{f=0}: No frame.
  
  \texttt{f=1}: Default (same as \texttt{f=3}).
  
  \texttt{f=2}: Simple box.
  
  \texttt{f=3}: 3D sunken frame.
  
  \texttt{f=4}: 3D raised frame.
  
  \texttt{f=5}: Text well.

- \texttt{fsize=s}
  Sets font size.
TitleBox

fsty le=fs

fs is a bitwise parameter with each bit controlling one aspect of the font style as follows:

Bit 0: Bold
Bit 1: Italic
Bit 2: Underline
Bit 4: Strikethrough

See Setting Bit Parameters on page IV-13 for details about bit settings.

labelBack=(r,g,b) or 0

Sets background color for title box. r, g, and b are integers from 0 to 65535. If not set (or labelBack=0), then background is transparent (not erased).

pos=leftOrRight,top

Sets the position in pixels of the top/left or top/right corner of the control at the time it is created. Unless fixedSize=1, a TitleBox control adjusts its size to fit the title text and the position can move in a way that depends on the anchor and align modes. See TitleBox Positioning on page V-953.

pos+=dx,dy

Offsets the position of the control in pixels.

size=w,h

Sets the width and height of the control in pixels.

If fixedSize=1, sets the width of the control in pixels. If fixedSize=0, a TitleBox control adjusts its size to the title text, resulting in confusion about what the size does. In this case, size=(0,0) is recommended. See TitleBox Positioning on page V-953.

title=titleStr

Sets the text of the title box to titleStr. titleStr is limited to 100 bytes.

Using escape codes you can change the font, size, style, and color of the title. See Annotation Escape Codes on page III-54 or details.

variable=sv ar

Specifies an optional global string variable from which to get the TitleBox text.

win=winName

Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Flags

/Z No error reporting.

Details

The text can come from either the title=titleStr or variable=sv ar method. Whichever is used last is the current method. The maximum length of text with the title=titleStr method is 100 bytes while the variable=sv ar method has no limit.

Using escape codes you can change the font, size, style and color of text, and apply other effects. See Annotation Escape Codes on page III-54 for details.

By default, the titlebox automatically resizes itself relative to the anchor point on the rectangle that encloses the text. Therefore you can specify a size of 0,0 along with a pos value in order to place the anchor point at the desired position. When fixedSize=1 is used, the titlebox does not resize itself and instead honors the values specified via the size keyword.

TitleBoxes can be used not only for titles but also as status or results readout areas, especially in conjunction with the variable=sv ar mode. When using a titlebox like this, you may find it useful to use fixedSize=1 so that the titlebox doesn’t change size as the text changes.

TitleBox Positioning

For compatibility with other controls, you can use the align=1 to maintain the position of the right end of a TitleBox control. This presents a conflict with the anchor keyword. To resolve the conflict, these rules are applied:
ToCommandLine

Applying `align=1`, which sets the alignment mode to right alignment, overrides any horizontal positioning specified using the anchor keyword.

Applying the anchor keyword resets the alignment mode to 0 and the anchor mode controls the horizontal position of the control.

If you specify `fixedSize=1`, only the align and pos keywords affect horizontal positioning; the anchor keyword has no effect.

For clarity, don’t mix the anchor and align keywords unless you are using `fixedSize=1`. Use anchor in preference to align unless you are trying to keep the right ends of various types of controls aligned, especially on high-resolution displays on Windows.

Examples

```plaintext
NewPanel /W=(94,72,459,294)
DrawLine 150,32,150,140
DrawLine 70,100,213,100 // draw crossing lines at 150,100

// illustrate a default box
TitleBox tbl, title="A title box with 2 lines", pos={150,100}

// Move center to 150,100
TitleBox tbl, pos={150,100}, size={0,0}, anchor=MC

// Set background color and therefore opaque mode
TitleBox tbl, labelBack=(55000,55000,65000)

// Now a few frame styles. Run these one at a time
TitleBox tbl, frame=0 // no frame
TitleBox tbl, frame=2 // plain frame
TitleBox tbl, frame=3 // 3D sunken
TitleBox tbl, frame=4 // 3D raised
TitleBox tbl, frame=5 // text well

// Now some fancy text...
TitleBox tbl, frame=1 // back to default (3D raised)
TitleBox tbl, title= "Z_18\[020 \log\B_{10}\M|\[1 + 2K(jwt) + (jwt)\S2\M|\S-1"

// Create a string variable and hook up to the TitleBox
String s1= "text from a string variable"
TitleBox tbl, variable=s1

// Change string variable contents & note automatic update of TitleBox
s1= "something new"

// A TitleBox with right end at X=200 because the align keyword takes precedence
TitleBox tb, pos={200,40}, size={0,0}, align=1, anchor=MT, title="Short Title"

// A TitleBox with right end at X=200 because align by itself overrides
// any preexisting anchor
TitleBox tb, pos={200,40}, size={0,0}, align=1, title="Short Title"

// A TitleBox with text centered in the frame and right end at X=200,
// with frame always 75 points wide
TitleBox tb, pos={200,40}, size={75,20}, align=1, fixedSize=1, anchor=MT, title="Short Title"
```

See Also

Annotation Escape Codes on page III-54.

ToCommandLine

**ToCommandLine** `commandsStr`

The ToCommandLine operation sends command text to the command line without executing the command(s).

The intended usage is for user-created panel windows with “To Cmd Line” buttons that are mimicking built-in Igor dialogs. You’ll usually want to use Execute, instead.
Parameters

commandsStr The text of one or more commands.

Details
To send more than one line of commands, separate the commands with “\r” characters.

Note: ToCommandLine does not work when typed on the command line; use it only in a Macro, Proc, or Function.

Examples
Macro CmdPanel()
    PauseUpdate; Silent 1
    NewPanel /W=(150,50,430,229)
    Button toCmdLine,pos={39,148},size={103,20},title="To Cmd Line"
    Button toCmdLine,proc=ToCmdLineButtonProc
End

Function ToCmdLineButtonProc(ctrlName) : ButtonControl
    String ctrlName
    String cmd="MyFunction(xin,yin,"yResult")" // line 1: generate results
    cmd +="\rDisplay yOutput vs wx as "results\"" // line 2: display results
    ToCommandLine cmd
    return 0
End

See Also
The Execute and DoIgorMenu operations.

ToolsGrid

ToolsGrid [/W=winName] keyword = value [, keyword = value ...]
The ToolsGrid operation controls the grid you can use for laying out draw or control objects.

Parameters
ToolsGrid can accept multiple keyword = value parameters on one line.

snap=n Turns snap to grid on (n=1) or off (n=0).
visible=n Turns on grid visibility (n=1) or hides it (n=0).
grid=(xy0,dxy,ndiv) Defines both X and Y grids where ndiv is the number of subdivisions between major grid lines and xy0 and dxy define the origin and spacing. Units are in points.
gridx=(x0,dx,ndiv) Defines the X grid where ndiv is the number of subdivisions between major grid lines and x0 and dx define the origin and spacing. Units are in points.
gridy=(y0,dy,ndiv) Defines the Y grid where ndiv is the number of subdivisions between major grid lines and y0 and dy define the origin and spacing. Units are in points.

Flags

/W=winName Sets the named window or subwindow for drawing. When omitted, action will affect the active window or subwindow. This must be the first flag specified when used in a Proc or Macro or on the command line.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details
The default grid is 1 inch with 8 subdivisions. The grid is visible only in draw or selector mode and appears in front of the currently active draw layer.

Note: ToCommandLine does not work when typed on the command line; use it only in a Macro, Proc, or Function.
TraceFromPixel

**TraceFromPixel(xpixel, ypixel, optionsString)**
The TraceFromPixel function returns a string based on an attempt to hit test the provided X and Y coordinates. Used to determine if the mouse was clicked on a trace in a graph.

When a trace is found, TraceFromPixel returns a string containing the following KEY:value; pairs:

```plaintext
TRACE:tracename
HITPOINT:pnt
```

`tracename` will be quoted if necessary and may contain instance notation. `pnt` is the point number index into the trace’s wave when the hit was detected. If a trace is not found near the coordinate point, a zero length string is returned.

**Parameters**
xpixel and ypixel are the X and Y pixel coordinates.

optionsString can contain the following:

```plaintext
WINDOW:winName;
PREF:traceName;
ONLY:traceName;
DELTAX:dx;DELTAY:dy;
```

Use the WINDOW option to hit test in a graph other than the top graph. Use the ONLY option to search only for a special target trace. If the PREF option is used then the search will start with the specified trace but if no hit is detected, it will go on to the others.

When identifying a subwindow with WINDOW:winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

The DELTAX and DELTAY values must both be specified to alter the region that Igor searches for traces. The `dx` and `dy` values are in pixels and the region searched is the rectangle from `xpixel-dx` to `xpixel+dx` and `ypixel-dy` to `ypixel+dy`.

If DELTAX or DELTAY are omitted, the search region depends on whether PREF or ONLY are specified. If either are specified then Igor first searches for the trace using `dx = 3` and `dy = 3`. If the trace is not identified, Igor searches again using `dx = 6` and `dy = 6`. If the trace is still not identified, Igor gives up and returns a zero-length result string.

If neither PREF nor ONLY are specified then Igor uses tries `3, 6, 12,` and `24` for `dx` and `dy` until it finds a trace or gives up and returns a zero-length result string.

**See Also**
The NumberByKey, StringByKey, AxisValFromPixel, and PixelFromAxisVal functions.

**ModifyGraph (traces)** and Instance Notation on page IV-20 for discussions of trace names and instance notation.

**Trace Names** on page II-222, Programming With Trace Names on page IV-86.

TraceInfo

**TraceInfo(graphNameStr, ywaveNameStr, instance)**
The TraceInfo function returns a string containing a semicolon-separated list of information about the trace in the named graph window or subwindow.

**Parameters**

- `graphNameStr` can be "" to refer to the top graph.

When identifying a subwindow with `graphNameStr`, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

- `yWaveNameStr` is either the name of a wave containing data displayed as a trace in the named graph, or a trace name (wave name with "#n" appended to distinguish the nth image of the wave in the graph). You might get a trace name from the TraceNameList function.

If `yWaveNameStr` contains a wave name, `instance` identifies which trace of `yWaveNameStr` you want information about. `instance` is usually 0 because there is normally only one instance of a given wave.
displayed in a graph. Set instance to 1 for information about the second trace of the wave named by yWaveNameStr, etc. If yWaveNameStr is ",", then information is returned on the instance\textsuperscript{th} trace in the graph.

If yWaveNameStr is a trace name, and instance is zero, the instance is extracted from yWaveNameStr. If instance is greater than zero, the wave name is extracted from yWaveNameStr, and information is returned concerning the instance\textsuperscript{th} instance of the wave.

Details
The string contains several groups of information. Each group is prefaced by a keyword and colon, and terminated with the semicolon. The keywords are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>AXISFLAGS</td>
<td>Flags used to specify the axes. Usually blank because /L and /B (left and bottom axes) are the defaults.</td>
</tr>
<tr>
<td>AXISZ</td>
<td>Z value of a contour level trace or NaN if the trace is not a contour trace.</td>
</tr>
<tr>
<td>ERRORBARS</td>
<td>The ErrorBars command for the trace, as it would appear in the recreation macro (without the beginning tab character).</td>
</tr>
<tr>
<td>RECREATION</td>
<td>List of keyword commands as used by ModifyGraph command. The format of these keyword commands is: keyword(x)=modifyParameters;</td>
</tr>
<tr>
<td>TYPE</td>
<td>The type of trace: 0: XY or waveform trace 1: Contour trace 2: Box plot trace 3: Violin plot trace</td>
</tr>
<tr>
<td>XAXIS</td>
<td>X axis name.</td>
</tr>
<tr>
<td>XRANGE</td>
<td>Point subrange of the trace's X data wave in &quot;[startPoint, endPoint : increment]&quot; format.</td>
</tr>
<tr>
<td>XWAVE</td>
<td>X wave name if any, else blank.</td>
</tr>
<tr>
<td>XWAVEDF</td>
<td>Full path to the data folder containing the X wave or blank if no X wave.</td>
</tr>
<tr>
<td>YAXIS</td>
<td>Y axis name.</td>
</tr>
<tr>
<td>YRANGE</td>
<td>Point subrange of the trace's Y data wave or &quot;[*]&quot;.</td>
</tr>
</tbody>
</table>

The format of the RECREATION information is designed so that you can extract a keyword command from the keyword and colon up to the ";", prepend "ModifyGraph \(x\)=modifyParameters;", replace the "\(x\)" with the name of a trace ("data\#1" for instance) and then Execute the resultant string as a command.

Note: The syntax of any subrange specifications in the RECREATION information are modified in the same way as for XRANGE and YRANGE. Currently only the zColor, zmrkSize, and zmrkNum keywords might have a subrange specification.

Examples
This example shows how to extract a string value from the keyword-value list returned by TraceInfo:

```
String yAxisName= StringByKey("YAXIS", TraceInfo("","",0))
```

This example shows how to extract a subrange and put the semicolon back:

```
```
The next example shows the trace information for the second instance of the wave “data” (which has an instance number of 1) displayed in the top graph:

```
Make/O data=x;Display/L/T data=data
Print TraceInfo("","data",1)[0,64]
Print TraceInfo("","data",1)[65,128]
```

Prints the following in the history area:

```
XWAVE:;YAXIS:;XAXIS:top;AXISFLAGS:/T;AXISZ:NaN;XWADEVDF:;YRANGE:
E:[*];XRANGE:;TYPE:0;ERRORBARS:;RECREATION:zColor(x)=0;zColorMax
```

Following is a function that returns the marker code from the given instance of a named wave in the top graph. This example uses the convenient GetNumFromModifyStr() function provided by the #include <Readback ModifyStr> procedures, which are useful for parsing strings returned by TraceInfo.

```
#include <Readback ModifyStr>
Function MarkerOfWave(wv,instance)
    Wave wv
    Variable instance
    Variable marker
    String info = TraceInfo("",NameOfWave(wv),instance)
    marker = GetNumFromModifyStr(info,"marker",","0)
    return marker
End
```

**See Also**

- Trace Names on page II-222,
- Programming With Trace Names on page IV-86.

The Execute operation.

---

**TraceNameList**

**TraceNameList(graphNameStr, separatorStr, optionsFlag)**

The TraceNameList function returns a string containing a list of trace names in the graph window or subwindow identified by `graphNameStr`.

**Parameters**

- `graphNameStr` can be "" to refer to the top graph window.

When identifying a subwindow with `graphNameStr`, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

The parameter `separatorStr` should contain a single ASCII character such as "," or ",;" to separate the names.

**Details**

The bits of `optionsFlag` have the following meanings:

<table>
<thead>
<tr>
<th>Bit Number</th>
<th>Bit Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Include normal graph traces</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Include contour traces</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Omit hidden traces (the default is to list even hidden traces)</td>
</tr>
<tr>
<td>3</td>
<td>8</td>
<td>Include box plot traces</td>
</tr>
<tr>
<td>4</td>

See **Setting Bit Parameters** on page IV-13 for details about bit settings.

A trace name is defined as the name of the Y wave that defines the trace with an optional #ddd suffix that distinguishes between two or more traces that have the same wave name. It may also be a user-defined trace name. Since the trace name has to be parsed, it is quoted if necessary.
TraceNameToWaveRef

Commands that take a trace name as a parameter or in a keyword can use a string containing a trace name with the $ operator to specify traceName. For instance, to change the display mode of a wave, you might use

```
ModifyGraph mode(myWave#1)=3
```

but

```
String myTraceName="myWave#1"
ModifyGraph mode($myTraceName)=3
```

will also work.

**Examples**

Make/O jack,'jack # 2';Display jack,jack,'jack # 2','jack # 2'
Print TraceNameList("",";",1)
Prints: jack;jack#1;'jack # 2';'jack # 2'#1;

// Generate a list of hidden traces
Make/O jack,jill,joy;Display jack,jill,joy
ModifyGraph hideTrace(joy)=1// hide joy
String allNormalTraces=TraceNameList("",";",1)// only visible normal traces
String hiddenTraces= RemoveFromList(allNormalTraces,visibleTraces)
Print hiddenTraces
// Prints: joy;

Trace Names on page II-222, Programming With Trace Names on page IV-86, User-defined Trace Names on page IV-88.

For other commands related to waves and traces: WaveRefIndexed, XWaveRefFromTrace, TraceNameToWaveRef, CsrWaveRef, and CsrXWaveRef.

For a description of traces: ModifyGraph. For a discussion of contour traces: Contour Traces on page II-301.

For commands referencing other waves in a graph: ImageNameList, ImageNameToWaveRef, ContourNameList, and ContourNameToWaveRef.

ModifyGraph (traces) and Instance Notation on page IV-20 for discussions of trace names and instance notation.

**TraceNameToWaveRef**

```
TraceNameToWaveRef(graphNameStr, traceNameStr)
```

The TraceNameToWaveRef function returns a wave reference to the Y wave corresponding to the given trace in the graph window or subwindow named by `graphNameStr`.

**Parameters**

`graphNameStr` can be "" to refer to the top graph window.

When identifying a subwindow with `graphNameStr`, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

The trace is identified by the string in `traceNameStr`, which could be a string determined using TraceNameList. Note that the same trace name can refer to different waves in different graphs.

Use Instance Notation (see page IV-20) to choose from traces in a graph that represent waves of the same name. For example, if `traceNameStr` is “myWave#2”, it refers to the third instance of wave “myWave” in the graph (“myWave#0” or just “myWave” is the first instance).

For a description of traces: ModifyGraph. For a discussion of contour traces, see Contour Traces on page II-301.

For a discussion of wave references, see Wave Reference Functions on page IV-192.
Triangulate3D

For commands referencing other waves in a graph: ImageNameList, ImageNameToWaveRef, ContourNameList, and ContourNameToWaveRef.

Triangulate3D

Triangulate3D [/OUT=format] srcWave

The Triangulate3D operation creates a Delaunay “triangulation” of a 3D scatter wave. The output is a list of tetrahedra that completely span the convex volume defined by srcWave. Triangulate3D can also generate the triangulation needed for performing 3D interpolation for the same domain. Normally srcWave is a triplet wave (a 2D wave of 3 columns), but can use any 2D wave that has more than 3 columns (the operation ignores all but the first 3 columns).

Flags

/OUT=format Specifies how to save the output triangulation data.

format=1: Default; saves the triangulation result in the wave M_3DVertexList, which contains in each row, indices to rows in srcWave that describe the X, Y, Z coordinates of a single tetrahedral vertex. Each tetrahedron is described by one row in M_3DVertexList.

format=2: Saves the triangulation result in the wave M_TetraPath, which is a triplet path wave describing the tetrahedra edges. For each tetrahedron, there are four rows (triangles) separated by row of NaNs. The total number of rows in M_TetraPath is 20 times the number of tetrahedra in the triangulation.

format=4: Saves a wave containing internal diagnostic information generated during the triangulation process.

/VOL Computes the volume of the full convex hull by summing the volumes of the tetrahedra generated in the triangulation. The result is stored in the variable V_value. This flag requires Igor Pro 7.00 or later.

Details

Triangulate3D implements Watson’s algorithm for tetrahedralization of a set of points in three dimensions. It starts by creating a very large tetrahedron which inscribes all the data points followed by a sequential insertion of one datum at a time. With each new datum the algorithm finds the tetrahedron in which the datum falls. It then proceeds to subdivide the tetrahedron so that the datum becomes a vertex of new tetrahedra.

The algorithm suffers from two known problems. First, it may, due to numerical instabilities, result in tetrahedra that are too thin. You can get around this problem by introducing a slight random perturbation in the input wave. For example:

srcWave+=enoise(amp)

Here amp is chosen so that it is much smaller than the smallest cartesian distance between two input points.

The second problem has to do with memory allocations which may exhaust available memory for some pathological spatial distributions of data points. The operation reports both problems in the history area.

Examples

Make/O/N=(10,3) ddd=gnoise(5) // create random 10 points in space
Triangulate3d/out=2 ddd

// now display the triangulation in Gizmo:
Window Gizmo0() : GizmoPlot
  PauseUpdate; Silent 1
  if(exists("NewGizmo")!=4)
    DoAlert 0, "Gizmo XOP must be installed"
    return
  endif
  NewGizmo/N=Gizmo0 /W=(309,44,642,373)
  ModifyGizmo startRecMacro
  ModifyGizmo scalingMode=2
  AppendToGizmo Scatter=root:ddd,name.scatter0
  ModifyGizmo ModifyObject=scatter0 property={scatterColorType,0}
  ModifyGizmo ModifyObject=scatter0 property={Shape,2}
  ModifyGizmo ModifyObject=scatter0 property={size,0.2}
ModifyGizmo ModifyObject=scatter0 property={ color,0,0,0,1}  
AppendToGizmo Path=root:M_TetraPath, name=path0  
ModifyGizmo ModifyObject=path0 property={ pathColor,0,0,1,1}  
ModifyGizmo setDisplayList=0, object=scatter0  
ModifyGizmo setDisplayList=1, object=path0  
ModifyGizmo autoscaling=1  
ModifyGizmo compile  
ModifyGizmo endRecMacro  
End

Further information about this algorithm can be found in:  

See Also
The Interpolate3D operation and the Interp3D function.

TrimString

TrimString(str [,, simplifyInternalSpaces])
The TrimString function returns a string identical to str except that leading and trailing whitespace characters are removed. The whitespace characters are space, tab, carriage-return and linefeed.

If the optional second parameter is non-zero, then each run of whitespace characters between words in str is "simplified" to a single space character.

TrimString was added in Igor Pro 7.00.

Examples
Print TrimString(" spaces at ends ") // Prints "spaces at ends"
Print TrimString(" spaces at ends ", 1) // Prints "spaces at ends"

See Also
SplitWave, RemoveEnding, ReplaceString

trunc
trunc(num)
The trunc function returns the integer closest to num in the direction of zero.

See Also
The round, floor, and ceil functions.

try
try
The try flow control keyword marks the beginning of the initial code block in a try-catch-endtry flow control construct.

See Also
The try-catch-endtry flow control statement for details.

try-catch-endtry
try
catch
endtry
A try-catch-endtry flow control statement provides a means for catching and responding to abort conditions in user functions. A programmatic abort is generated when the code executes Abort, AbortOnRTE or AbortOnValue. A user abort is generated when the user clicks the Abort button or presses the user abort key combination.
When code executes in the try-catch area, a programmatic abort immediately jumps to the code in the catch-endtry area rather than jumping to the end of the user function. A user abort jumps to the catch-endtry area when a flow control keyword such as for or while executes or at the end of the try code. Normal flow (no aborts) skips all code within the catch-endtry area.

Details
During execution of code in the catch-endtry area, user aborts are suppressed. This means that, if the user attempts to abort procedure execution by pressing the User Abort Key Combinations or by clicking the Abort button, this will not abort the catch code itself.

When an abort occurs, information about the cause of the abort is returned via the V_AbortCode variable as follows:

-4: Abort triggered by AbortOnRTE.
-3: Abort caused by Abort operation.
-2: Stack overflow abort.
-1: User abort.
>=1: Abort triggered by AbortOnValue.

See Also
Flow Control for Aborts on page IV-49 and try-catch-endtry Flow Control on page IV-50 for further details.

The AbortOnRTE and AbortOnValue keywords, and the Abort operation.

**UInt64**

```plaintext
uint64 localName
```
Declares a local unsigned 64-bit integer in a user-defined function or structure.

UInt64 is available in Igor Pro 7 and later. See Integer Expressions on page IV-40 for details.

See Also
Int, Int64

**UniqueName**

```plaintext
UniqueName(baseName, objectType, startSuffix [, windowNameStr])
```
The UniqueName function returns the concatenation of baseName and a number such that the result is not in conflict with any other object name.

windowNameStr is optional. If missing, it is taken to be the top graph, panel, layout, or notebook according to the value of objectType.

Details
baseName should be an unquoted name, such as you might receive from the user via a dialog or control panel.
**UniqueName**

`objectType` is one of the following:

1. Wave.
2. Reserved.
3. Numeric variable.
4. String variable.
5. XOP target window.
6. Graph window.
7. Table window.
8. Layout window.
9. Control panel window.
11. Data folder.
12. Symbolic path.
13. Picture.
14. Annotation in the named or topmost graph or layout.
15. Control in the named or topmost graph or panel.
16. Notebook action character in the named or topmost notebook.

`startSuffix` is the number used as a starting point when generating the numeric suffix that makes the name unique. Normally you should pass zero for `startSuffix`. If you know that names of the form `base0` through `baseN` are in use, you can make `UniqueName` run a bit faster by passing `N+1` as the `startSuffix`.

The `windowNameStr` argument is used only with object types 14, 15, and 16. The returned name is unique only to the window (other windows might have objects with the same name). If a named window is given but does not exist, `UniqueName` returns `baseName startSuffix: windowNameStr` is ignored for other object types.

**The Main Namespace**
Waves, numeric variables, string variables, built-in and external functions, built-in and external operations, user-defined functions, macros and reserved keywords exist in the main namespace. The names of each of those objects must be unique in that namespace.

**Window Namespace**
Values of `objectType` from 5 through 10 refer to the window namespace.

The expression

```csharp
CheckName("<name>", x) // where x is 5, 6, 7, 8, 9 or 10
```

returns 0 if the specified name is syntactically legal and unique in the window namespace.

That does not guarantee that the name is allowed as a window name because the DoWindow/C operation, which changes a window’s name, requires that the name also not conflict with objects in the main namespace. Consequently, to determine if a name is allowed as a window name, use this:

```
// Window names must be unique in both the window and main namespaces
Variable nameOK = CheckName("<name>",6)==0 && CheckName("<name>",1)==0
```

**Window Macro Names**
Window macro names are treated different from other main namespace names. DoWindow/C allows you to change the name of a window to the name of an existing window macro but not to any other name in the main namespace. Also this expression:

```csharp
CheckName("<name>", x) // where x is 1, 3, 4 (main namespace)
```

returns 0 even if the specified name is used as a window macro name.

**UniqueName Thread Safety**
As of Igor Pro 8.00, you can call `UniqueName` from an Igor preemptive thread but only if `objectType` is 1 (wave), 3 (global numeric variable), 4 (global string variable), 11 (data folder), or 12 (symbolic path). For any other value of `objectType`, `UniqueName` returns a runtime error.

**Examples**

```csharp
String uniqueWaveName = UniqueName(baseWaveName, 1, 0)
String uniqueControlName = UniqueName("ctrl", 15, 0, "Panel0")
```

**See Also**
`CheckName` and `CleanupName`.

---

1. Wave. 9. Control panel window.
2. Reserved. 10. Notebook window.
5. XOP target window. 13. Picture.
6. Graph window. 14. Annotation in the named or topmost graph or layout.
7. Table window. 15. Control in the named or topmost graph or panel.
8. Layout window. 16. Notebook action character in the named or topmost notebook.
UnPadString

UnPadString(str, padValue)
The UnPadString function undoes the action of PadString. It returns a string identical to str except that trailing bytes of padValue are removed.

See Also
PadString

UnsetEnvironmentVariable

UnsetEnvironmentVariable(varName)
The UnsetEnvironmentVariable function deletes the variable named varName from the environment of Igor's process, if it exists.
The function returns 0 if it succeeds or a nonzero value if it fails.
The UnsetEnvironmentVariable function was added in Igor Pro 7.00.

Parameters
varName The name of an environment variable which does not need to actually exist. It must not be an empty string and may not contain an equals sign (=).

Details
The environment of Igor's process is composed of a set of key=value pairs that are known as environment variables.
The environment of Igor's process is composed of a set of key=value pairs that are known as environment variables. Any child process created by calling ExecuteScriptText inherits the environment variables of Igor's process.
UnsetEnvironmentVariable changes the environment variables present in Igor's process and any future process created by ExecuteScriptText but does not affect any other processes already created.
On Windows, environment variable names are case-insensitive. On other platforms, they are case-sensitive.

Examples
Variable result
result = SetEnvironmentVariable("SOME_VARIABLE", "15") // Sets the variable
result = UnsetEnvironmentVariable("SOME_VARIABLE") // Unsets the variable

See Also
GetEnvironmentVariable, SetEnvironmentVariable

Unwrap

Unwrap modulus, waveName [, waveName]...
The Unwrap operation scans through each named wave trying to undo the effect of a modulus operation.

Parameters
modulus is the value applied to the named waves through the mod function as if the command:
waveName = mod(waveName, modulus)
had been executed. It is this calculation which Unwrap attempts to undo.

Details
The unwrap operation works with 1D waves only. See ImageUnwrapPhase for phase unwrapping in two dimensions.

Examples
If you perform an FFT on a wave, the result is a complex wave in rectangular coordinates. You can create a real wave that contains the phase of the result of the FFT with the command:
wave2 = imag(r2polar(wave1))
However, the rectangular to polar conversion leaves the phase information modulo 2π. You can restore the phase information with the command:
Unwrap 2*pi, wave2 
Because the first point of a wave that has been FFTed has no phase information, in this example you would precede the Unwrap command with the command:

```plaintext
wave2[0] = wave2[1]
```

**See Also**
The ImageUnwrapPhase operation and mod function.

### UpperStr

**UpperStr**(str)
The UpperStr function returns a string expression in which all lower-case ASCII characters in str are converted to upper-case.

**See Also**
The LowerStr function.

### URLDecode

**URLDecode**(inputStr)
The URLDecode function returns a percent-decoded copy of the percent-encoded string inputStr. It is unlikely that you will need to use this function; it is provided for completeness.

For an explanation of percent-encoding, see Percent Encoding on page IV-261.

**Example**

```plaintext
String theURL = "http://google.com?key1=35%25%20larger"
theURL = URLDecode(theURL)
Print theURL
    http://google.com?key1=35% larger
```

**See Also**
URLEncode, URLRequest, URLs on page IV-260.

### URLEncode

**URLEncode**(inputStr)
The URLEncode function returns a percent-encoded copy of inputStr.

Percent-encoding is useful when encoding the query part of a URL or when the URL contains special characters that might otherwise be misinterpreted by a web server. For an explanation of percent-encoding, see Percent Encoding on page IV-261.

**Example**

```plaintext
String baseURL = "http://google.com"
String key1 = "key1"
String value1 = URLEncode("35% larger")
String theURL = ""
sprintf theURL, "%s?%s=%s", baseURL, key1, value1
Print theURL
    http://google.com?key1=35%25%20larger
```

**See Also**
URLDecode, URLRequest, URLs on page IV-260.

### URLRequest

**URLRequest**(flags) url=urlStr [method=methodName, headers=headersStr]
The URLRequest operation connects to a URL using the specified method and optionally stores the response from the server. urlStr can point to a remote server or to a local file. The server’s response is stored in the S_serverResponse output variable or in a file if you use the /FILE flag.

The URLRequest operation was added in Igor Pro 7.00.
URLRequest

**Keywords**
The `url=urlStr` keyword is required. All others are optional.

**url=urlStr**  
A string containing the URL to retrieve. See **URLs** on page IV-260 for details.

**method=methodName**  
Specifies which method to use for the request. The get method is used by default. This table shows the valid methods for each supported scheme. Not all servers support all of the listed methods.

<table>
<thead>
<tr>
<th>Scheme</th>
<th>Supported Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>http, https</td>
<td>get, post, put, head, delete</td>
</tr>
<tr>
<td>ftp</td>
<td>get, put</td>
</tr>
<tr>
<td>file</td>
<td>get, put</td>
</tr>
</tbody>
</table>

Because `methodName` is a name, not a string, you must not enclose it in quotes.

Before using the post method, you should read The **HTTP POST Method** on page V-970 so that you know how to use the optional headers parameter.

If you use the head method, URLRequest sets the `S_serverResponse` output variable to "" because only the headers are retrieved. As with other methods, the headers are stored in the `S_headers` output variable.

**headers=headersStr**  
Specifies a string containing additional or replacement headers to use with the request. This parameter is ignored unless the scheme is http or https.

The headers parameter is provided primarily for use with the post method when making HTTP requests and is ignored for schemes other than http/https. The header consists of a colon-separated key:value pair (though see the next paragraph for an exception). Pairs must be separated by a carriage return (\r) character.

Certain standard headers (such as Content-Type and User-Agent) may automatically be set when making the request. You can override those default values by using this keyword and setting a different value. If you add a header with no content, as in "Accept:" (there is no data on the right side of the colon), the internally used header is disabled. To actually add a header with no content, use the form "MyHeader;" (note the trailing semicolon).

Any headers specified with this keyword are sent only to the http server, not to the proxy server, if one is in use.

See The **HTTP POST Method** on page V-970 for a detailed explanation and examples.

**Flags**

AUTH={username, password}

Uses the specified `username` and `password` string parameters for authentication. Values provided here override any username and/or password provided as part of the URL. To specify a username but not a password, pass "" for the `password` parameter.

**Note:** See **Safe Handling of Passwords** on page IV-262 for more information on how to use URLRequest to prevent authentication information, such as passwords, from being accidentally revealed.
/DFIL=dataFileNameStr Specifies a file name to use as a source of data. Typically this flag is used only with the put or post methods, but it is accepted with all methods. Unless dataFileNameStr is a full path, the /P flag must also be used. When using the post or put methods, one and only one of the /DFIL or /DSTR flags must be used.

When you use /DFIL and the method is anything other than put, the "Content-Type: application/x-www-form-urlencoded" header is automatically added. If necessary, you can override this behavior using the headers keyword. See The HTTP POST Method on page V-970 for more information.

/DSTR=dataStr Specifies the string to use as a source of data. Typically you use this flag only with the put or post methods, but it is accepted with all methods. When using the post or put methods, one and only one of the /DFIL or /DSTR flags must be used.

When /DSTR is used and the method is anything other than put, the "Content-Type: application/x-www-form-urlencoded" header is automatically added. If necessary, you can override this behavior using the headers keyword. See The HTTP POST Method on page V-970 for more information.

/FILE=destFileNameStr If present, URLRequest saves the server's response in a file instead of in the S_serverResponse output variable.

URLRequest ignores /FILE if you include the /IGN flag and the ignoreResponse parameter is not 0.

destFileNameStr can be a full path to the file, in which case /P=pathName is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If the file already exists, URLRequest returns an error unless you include the /O flag.

If you include /O and the file already exists, the existing file is overwritten. This happens even in the event of an empty response or transfer error.

You should consider using the /FILE flag when you are expecting the server to return a large amount of data, such as when downloading a file.

/IGN=[ignoreResponse] Ignore and do not store the server's response to the request. /IGN alone has the same effect as /IGN=1.

If ignore is turned on, URLRequest sets the S_serverResponse output variable to "", regardless of whether the server responded to the request or not. If you include the /FILE flag, URLRequest does not create the output file and sets S_fileName is set to "".

This flag is useful only when your goal is to establish a connection with a server and the server's response is not important. All error message codes and strings are still set when ignore is on.

/IGN=0: Same as no /IGN.
/IGN=1: Ignore server response completely. S_headers is set to "".
/IGN=2: Ignore server response but capture the headers of the response. S_serverResponse is set to "" but S_headers will contain the headers.

/NRED=maxNumRedirects Specifies the maximum number of redirects that are allowed. A redirect means that when a certain URL is requested, the server responds telling the client to try a different URL. Most web browsers automatically follow server redirects, up to a certain limit. For security purposes, it is sometimes useful to prevent redirects from being followed at all.

maxNumRedirects is a number between -1 and 1000. To allow infinite redirection, set maxNumRedirects to -1. If you omit the /NRED flag, a moderate value (currently 20, but subject to change in the future) is used.
/O Specifies that the file is to be overwritten when you use the /FILE flag and the output file already exists. If you omit /O and the file exists, URLRequest returns an error.

/P=pathName Specifies the folder to use for the output file, specified by the /FILE flag, and/or the source data file, specified by the /DFIL flag. pathName is the name of an existing Igor symbolic path.

The /P flag affects both the /FILE and /DFIL flags. If you use both flags and want to use different directories, you must provide a full path for one or both of the /FILE and /DFIL flag parameters.

If the /P flag is used without one or both of the /FILE and /DFIL flags, it is ignored.

/PROX[={proxyURLStr, proxyUserNameStr, proxyPassStr, proxyOptions}]

NOTE: This flag is experimental and has not been extensively tested. The behavior of this flag may change in the future, or it may be eliminated entirely.

Designates a proxy server to be used when making the connection. proxyURLStr is either the host name or IP address of the proxy server, or a full URL. If a full URL is used, the scheme specifies which kind of proxy is used. Typically the scheme for a proxy server should be either http or socks5. If no scheme is provided, http is assumed. See URLs on page IV-260 for more information.

If the proxy server does not require authentication, or if the username and password for the proxy server are specified in proxyURLStr, the optional proxyUserNameStr and proxyPassStr parameters do not need to be provided. The following two examples do the same thing:

/PROX={"http://proxy.example.com:800"}
/PROX={"http://proxy.example.com:800", "", ""}

As with other URLs, you can also provide the username and password as part of the URL itself. The following two examples do the same thing:

/PROX={"http://proxy.example.com:800", "user", "pass"}
/PROX={"http://user:pass@proxy.example.com:800"}

proxyOptions is optional and for future use. It is currently ignored. If provided, you must set it to 0.

If you use the /PROX flag without any parameters, Igor attempts to get proxy information from the operating system's proxy configuration information. If Igor cannot get any proxy server information from the system, no proxy server is used.

See Safe Handling of Passwords on page IV-262 for more information on how to use URLRequest to prevent authentication information, such as passwords, from being accidentally revealed.

/TIME=timeoutSeconds Forces the operation to time out after timeoutSeconds seconds if it has not completed by that time. If this flag is not provided, URLRequest runs until the server has finished sending and receiving data. For simple requests a value of a few seconds is appropriate. However, because uploading and/or downloading large amounts of data may take a long time, if timeoutSeconds is too small the request might be prematurely terminated. If you omit the /TIME flag, or if timeoutSeconds = 0, there is no timeout.

Regardless of whether or not you include /TIME, you can abort the operation by pressing the User Abort Key Combinations.
URLRequest

/V=diagnosticMode

This flag is useful only when your goal is to establish a connection with a server and the server's response is not important. All error message codes Controls diagnostic messages printed in the history area of the command window.

/V=0: Do not print any diagnostic messages. This is the default if you omit /V.
/V=1: Prints an error message if a run time error occurs.
/V=2: Prints full debugging information.

/Z=[z]

Suppress error generation. Use this if you want to handle errors yourself.
/Z=0: Do not suppress errors. This is the default if /Z is omitted.
/Z=1: Any errors generated by Igor do not stop execution. If there is an error the error code is stored in V_Flag.

/Z alone has the same effect as /Z=1.

Output Variables

URLRequest sets the following output variables:

V_flag

V_flag is zero if the operation succeeds without an error or a non-zero Igor error code if it fails.

Note that "succeeds without an error" does not necessarily mean that the operation performed as you intended. For example, if you attempt to connect to a server that requires a username and password for authentication but you do not provide this information, V_flag is likely to be 0, indicating no error. You need to inspect the value of V_responseCode to ensure that it is what you expect.

V_responseCode

Contains the status code provided by the server.

V_responseCode is valid only if V_flag is 0, meaning that no error occurred. If V_flag is nonzero, an error occurred and V_responseCode will be 0.

Different schemes use different sets of status codes.

A list of http/https status codes and their definitions can be found at:
http://www.w3.org/Protocols/rfc2616/rfc2616-sec10.html

A list of FTP status codes can be found at:

S_serverResponse

Contains the server's response to the request.

S_serverResponse is set to "" if you use the /FILE flag or the /IGN=1 or /IGN=2 flags.

We recommend that you use the /FILE flag when you expect the size of the server response to be large, such as when downloading a large file.

S_headers

Contains a list of all of the headers received as part of the response. Header names are separated from their value by a colon and pairs are separated by a carriage return followed by a line feed (\r\n). For schemes other than http and https, S_headers is set to "".

S_fileName

Contains the full Igor-style path to the output file if the /FILE flag was used. If there was an error saving to the specified file, or another kind of error, or if the /FILE flag was not used, S_fileName is set to "".

Basic Examples

// Retrieve the contents of the WaveMetrics home page.
// Output is stored in S_serverResponse
URLRequest url="http://www.wavemetrics.com"

// Download the Windows Igor6 installer and save it as a file on the desktop.
URLRequest

NewPath/O Desktop, SpecialDirPath("Desktop", 0, 0, 0)
String theURL = "http://www.wavemetrics.net/Downloads/Win/setupIgor6.exe"
URLRequest/FILE="setupIgor6.exe"/P=Desktop url=theURL

// Download a file to the desktop from an FTP server.
NewPath/O Desktop, SpecialDirPath("Desktop", 0, 0, 0)
String theURL = "ftp://ftp.wavemetrics.com/test/test.htm"
URLRequest/O/FILE="test.htm"/P=Desktop url=theURL

// Upload the same file to the FTP server.
theURL = "ftp://user:pass@ftp.wavemetrics.com/test.htm"
URLRequest/DFIL="test.htm"/P=Desktop method=put, url=theURL

Using the File Scheme
URLRequest supports the file scheme in URLs. You must provide the full path to the file as a native
Windows-style or UNIX-style path, depending on which platform the code is running.

You must specify the schema as "file://". Note that you must use three front slash characters (/) between
the colon and the full file path (for most URLs you would only use two slashes).

URLRequest url="file:///C:\Data\Trial1\control.ibw" // Works on Windows only
URLRequest url="file:///Users/bob/Data/Trial1/control.ibw" // Works on Macintosh only
URLRequest url="file:///C:\Data\Trial1\control.ibw" // Doesn't work
URLRequest url="file:///Users/bob/Data/Trial1/control.ibw" // Doesn't work

The following example shows how to convert a full Igor file path to a native path suitable for use as a file
URL:

String nativeFilePath
#ifdef WINDOWS
    String igorFilePath = "C:Documents:myFile.txt"
    nativeFilePath = ParseFilePath(5, igorFilePath, ":", 0, 0)
#else
    String igorFilePath = "MacintoshHD:Documents:myFile.txt"
    nativeFilePath = ParseFilePath(5, igorFilePath, ":", 0, 0)
#endif

REQUEST url="file:///" + nativeFilePath

The HTTP POST Method

Like the HTTP GET method, the HTTP POST method can be used to transmit information to a web server.
When using the GET method, all information must be contained within the URL itself. As an example,
making a GET request to the URL <http://www.google.com/search?q=Igor+Pro+WaveMetrics> searches
Google using the keywords "Igor", "Pro", and "WaveMetrics".

Unlike the GET method, the POST method allows the client to send information to the server that is not
contained within the URL itself. This is necessary in many situations, such as when uploading a file or
transferring a large amount of data. In addition, because the data contained in POST requests is typically not
stored in the log files of web servers, it is more appropriate for sending data that is secure, such as login
credentials and form submissions which might contain sensitive information.

When using the POST method, the client must encode its data using one of several methods and must tell
the server what type of data is being sent and how it is encoded. The client does this by setting the Content-
Type header that is part of the request. The most commonly used content type is "application/x-www-form-
encoded". Unless you provide your own Content-Type header using the optional headers parameter,
URLRequest will set this header for you. This is true regardless of which data source (/DSTR for string or
/DFIL for file) you use for the POST.

Here is a simple example that uses the POST method with URL encoded data (the default Content-Type).

String theURL = "http://www.example.com/process.php"
String nameData = URLEncode("name") + "=" + URLEncode("Dan P. Ikes, Jr.")
String address = "650 E. Chicago Ave."
String addressData = URLEncode("address") + "=" + URLEncode(address)
String postData = nameData + ";" + addressData
URLRequest/DSTR=postData method=post, url=theURL

There are two things to note in this example.
First, both the key name and value string are passed through **URLEncode** so that any special characters can be percent-encoded.

Second, keys and values are separated by an equal sign ("=") and key/value pairs are separated by an ampersand ("&"). These characters are not passed through **URLEncode** because doing so would cause them to lose their meaning as special characters.

For more information on using the application/x-www-form-urlencoded content type, see http://www.w3.org/TR/html401/interact/forms.html#h-17.13.4.1

It is also possible to transmit more complicated data using the POST method, such as simulating a form that contains regular text fields as well as a file upload field. To do so you must set the Content-Type header using the headers parameter. You must also build your post data using a multi-part header. Here is an example:

```java
String theURL = "http://www.example.com/process.php"
String postData = ""
    // Note: The boundary is arbitrary. It needs to be
    // unique enough that it is not contained within any
    // of the actual data being transmitted in the post.
String boundary = "AaBbCcDd0987"

    // name
    postData += "--" + boundary + "\r\n" // beginning of this part
    postData += "Content-Disposition: form-data; name="name"
    postData += "\r\n"
    postData += "Dan P. Ikes, Jr.\n"

    // address
    postData += "--" + boundary + "\r\n"
    postData += "Content-Disposition: form-data; name="address"
    postData += "\r\n"
    postData += "650 E. Chicago Ave.\r\n"

    // file
    // Open the file we plan to send and store the binary
    // contents of the file in a string.
Variable refNum
Open/R/2/P=Igor refNum as "ReadMe.ihf"
FStatus refNum
Variable fileSize = V_logEOF
String fileContents = ""
    fileContents = PadString(fileContents, fileSize, 0)
FBinRead refNum, fileContents
Close refNum
    postData += "--" + boundary + "\r\n"
    postData += "Content-Disposition: form-data; name="file"
    postData += "; filename="ReadMe.ihf"\r\n"
    postData += "Content-Type: application/octet-stream\r\n"
    postData += "Content-Transfer-Encoding: binary\r\n"
    postData += "\r\n"
    postData += fileContents + "\r\n"
    postData += "--" + boundary + "--\r\n" // end of this part

String headers = "Content-Type: multipart/form-data; boundary=" + boundary
URLRequest/DSTR=postData method=post, url=theURL, headers=headers
```

For more information on using the multipart/form-data content type, see http://www.w3.org/TR/html401/interact/forms.html#h-17.13.4.2

ValDisplay

ValDisplay [/Z] ctrlName [keyword = value [, keyword = value ...]]

The ValDisplay operation creates or modifies the named control that displays a numeric value in the target window. The appearance of the control varies; see the Examples section.

For information about the state or status of the control, use the ControlInfo operation.

Parameters

ctrlName is the name of the ValDisplay control to be created or changed.

The following keyword=value parameters are supported:

align=alignment

Sets the alignment mode of the control. The alignment mode controls the interpretation of the leftOrRight parameter to the pos keyword. The align keyword was added in Igor Pro 8.00.

If alignment=0 (default), leftOrRight specifies the position of the left end of the control and the left end position remains fixed if the control size is changed.

If alignment=1, leftOrRight specifies the position of the right end of the control and the right end position remains fixed if the control size is changed.

appearance={kind [, platform]}

Sets the appearance of the control. platform is optional. Both parameters are names, not strings.

kind can be one of default, native, or os9.

platform can be one of Mac, Win, or All.

See Button and DefaultGUIControls for more appearance details.

barBackColor=(r,g,b)

Sets the background color under the bar (if any). r, g, and b range from 0 to 65535.

barBackColor=0

Sets the background color under the bar to the default color, the standard document background color used on the current operating system, which is usually white.

barmisc={lts, valwidth}

Sets the “limits text size” and the size of the type showing the bar limits. If lts is zero, the bar limits are not displayed. Otherwise, lts must be between 5 and 100.

valwidth is the “value readout width”. It claims the amount of horizontal space for the numeric part of the display.

If valwidth equals or exceeds the control width available to it, the numeric readout uses all the room, and prevents display of any bar.

If valwidth is zero, there is no numeric readout, and only the bar is displayed.

valwidth can range from zero to 4000, and it defaults to 1000 (which usually leaves no room for the display bar).

bodyWidth=width

Specifies an explicit size for the body (nontitle) portion of a ValDisplay control. By default (bodyWidth=0), the body portion is the amount left over from the specified control width after providing space for the current text of the title portion. If the font, font size, or text of the title changes, then the body portion may grow or shrink. If you supply a bodyWidth>0, then the body is fixed at the size you specify regardless of the body text. This makes it easier to keep a set of controls right aligned when experiments are transferred between Macintosh and Windows, or when the default font is changed.
disable=$d$  Sets user editability of the control.
   $d=0$: Normal.
   $d=1$: Hide.
   $d=2$: Disable user input.
   Does not change control appearance because it is read-only.
   $d=3$: Hide and disable the control.
   This is useful to disable a control that is also hidden because it is
   in a hidden tab.

fColor=$(r,g,b)$  Sets the initial color of the title. $r$, $g$, and $b$ range from 0 to 65535. fColor defaults
   to black (0,0,0). To further change the color of the title text, use escape sequences
   as described for title=titlStr.

font="fontName"  Sets the font used to display the value of the variable, e.g.,
   font="Helvetica"

format=formatStr  Sets the numeric format of the displayed value. The default format is "%g". For a
   description of formatStr, see the printf operation.

frame=$f$  Sets frame style:
   $f=0$: Value is unframed.
   $f=1$: Default; value is framed (same as $f=3$).
   $f=2$: Simple box.
   $f=3$: 3D sunken frame.
   $f=4$: 3D raised frame.
   $f=5$: Text well.

fsize=$s$  Sets the size of the type used to display the value in the numeric readout. The
   default is 12 points.

fstyle=$fs$  $fs$ is a bitwise parameter with each bit controlling one aspect of the font style
   as follows:
   Bit 0: Bold
   Bit 1: Italic
   Bit 2: Underline
   Bit 4: Strikethrough
   See Setting Bit Parameters on page IV-13 for details about bit settings.

help={helpStr}  Sets the help for the control. The help text is limited to a total of 255 bytes. On
   Macintosh, help appears when you turn Igor Tips on. On Windows, help for the
   first 127 bytes or up to the first line break appears in the status line. If you press
   F1 while the cursor is over the control, you will see the entire help text. You can
   insert a line break by putting "\r" in a quoted string.

highColor=$(r,g,b)$  Specifies the bar color when the value is greater than base in the limits keyword.
   $r$, $g$, and $b$ are integers from 0 to 65535.

labelBack=$(r,g,b)$ or 0  Specifies the background fill color for labels. $r$, $g$, and $b$ are integers from 0 to
   65535. The default is 0, which uses the window’s background color.

limits={low,high,base}  Controls how the value is translated into a graphical representation when the display
   includes a bar (described fully in Details). Defaults are (0,0,0), which aren’t too
   useful.

limitsColor=$(r,g,b)$  Sets the color of the limits text, if any. $r$, $g$, and $b$ range from 0 to 65535. limitsColor
   defaults to black (0,0,0).

limitsBackColor=$(r,g,b)$  Sets the background color under the limits text. $r$, $g$, and $b$ range from 0 to 65535.
limitsBackColor=0  Sets the background color under the limits text to the default color, the standard document background color used on the current operating system, which is usually white.

lowColor=(r,g,b)  Specifies the bar color when the value is less than base in the limits keyword. r, g, and b are integers from 0 to 65535.

mode=m  Specifies the type of LED display to use, if any.

mode=0: Bar mode (default).
mode=1: Oval LED.
mode=2: Rectangular LED.
mode=3: Bar mode with no fractional part.
mode=4: Candy-stripe effect for the bar area to support indefinite-style progress windows. The value is taken to be the phase of the candy stripe. When using value=_NUM:n, n is taken as an increment value so you would normally just use 1. Uses the native platform appearance if the high and low colors are left as default. Note native formats may not fill vertical space. See Progress Windows on page IV-150 for an example.

pos=[leftOrRight,top]  Sets the position in pixels of the top/left corner of the control if its alignment mode is 0 or the top/right corner of the control if its alignment mode is 1. See the align keyword above for details.

pos+=[dx,dy]  Offsets the position of the display in pixels.

rename=newName  Gives the ValDisplay control a new name.

size=[width,height]  Sets width and height of display in pixels. width can range from 10 to 200 pixels, height from 5 to 200 pixels. Default width is 50, default height is determined by the numeric readout font size.

title=titleStr  Sets title of display to the specified string expression. The title appears to the left of the display. If this title is too long, it won’t leave enough room to display the bar or even the numeric readout! Defaults to “” (no title).

Using escape codes you can change the font, size, style, and color of the title. See Annotation Escape Codes on page III-54 or details.

value=valExpr  Displays the numeric expression valExpr. It is not a string.

As of version 6.1, you can use the syntax _NUM:num to specify a numeric value without using a dependency.

valueColor=(r,g,b)  Sets the color of the value readout text, if any. r, g, and b range from 0 to 65535. valueColor defaults to black (0,0,0).

valueBackColor=(r,g,b)  Sets the background color under the value readout text. r, g, and b range from 0 to 65535.

valueBackColor=0  Sets the background color under the value readout text to the default color, the standard document background color used on the current operating system, which is usually white.

win=winName  Specifies which window or subwindow contains the named control. If not given, then the top-most graph or panel window or subwindow is assumed.

When identifying a subwindow with winName, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

zeroColor=(r,g,b)  Governs the LED color (in LED mode only). r, g, and b are integers from 0 to 65535. Used in conjunction with the limits keyword such that zeroColor determines one endpoint color when base is between low and high, or LED color when the value is less than low.
ValDisplay

Flags

/Z No error reporting.

Details

The target window must be a graph or panel.

The appearance of the ValDisplay control depends primarily on the width and valwidth parameters and the width of the title. Space for the individual elements is allocated from left to right, with the title receiving first priority. If the control width hasn’t all been used by the title, then the value display gets either valwidth pixels of room, or what is left. If the control width hasn’t been used up, the bar is displayed in the remaining control width:

If you use the bodyWidth keyword, the value readout width and bar width occupy the body width. The total control width is then bodyWidth+title width, and the width from the size keyword is ignored.

The limits values low, high, and base and the value of valExpr control how the bar, if any, is drawn. The bar is drawn from a starting position corresponding to the base value to an ending position determined by the value of valExpr, low and high. low corresponds to the left side of the bar, and high corresponds to the right. The position that corresponds to the base value is linearly interpolated between low and high.

For example, with low=-10, high=10, and base=0, a valExpr value of 5 will draw from the center of the bar area (0 is centered between -10 and 10) to the right, halfway from the center to the right of the bar area (5 is halfway from 0 to 10):

The valExpr must be executable at any time. The expression is stored and executed when the ValDisplay needs to be updated. However, execution will occur outside the routine that creates the ValDisplay, so you must not use local variables in the expression.

valExpr may be enclosed in quotes and preceded with a # character (see When Dependencies are Updated on page IV-223) to defer evaluation of the validity of the numeric expression, which may be needed if the expression references as-yet-nonexistent global variables or user-defined functions:

ValDisplay valdisp0 value=notAVar*2 // "unknown name or symbol" error
ValDisplay valdisp0 value=#"notAVar*2" // still not valid, no error
Variable notAVar=3 // now valid; ValDisplay works

In a ValDisplay, the #"" syntax permits use of a string expression. Normally, the # prefix signifies that the following text must be a literal quoted string. String expressions are evaluated at runtime to obtain the final expression for the ValDisplay. In other words, there is a level of indirection.
ValDisplay

Examples
Here is a sampling of the various types of ValDisplay controls available:

You can use a ValDisplay to replace the bar mode with a solid color fill designed to look like an LED. Use the mode keyword with mode=1 to create an oval LED or mode=2 to create a rectangular LED. You can specify different frames with the rectangular LED but only a simple frame is available for the oval mode. Use mode=0 to revert to bar mode.

The color and brightness of the LED depends on the value that the ValDisplay is monitoring combined with the limits={low, high, base} setting, the two color settings used in bar mode along with a third color (zeroColor) that is used only in LED mode. When the value is between low and high, the color is a linear combination of endpoint colors. If base is between low and high, the endpoint colors are the low color and the zero color, or the zero color and the high color. For values outside the limits, the appropriate limiting color is chosen.

If base is less than the low, the endpoint colors are the low color and the high color. In this case, if the value is less than low the LED takes on the zero color.

You should use the bodyWidth setting in conjunction with LED mode to keep the LED from dramatically changing size or disappearing when the title is changed or if your experiment is moved to a different platform (Macintosh vs PC).

Try the ValDisplay Demo example experiment to see these different modes in action. Choose File→Example Experiments→Feature Demos→ValDisplay Demo.

Progress Windows on page IV-150 for an example of candy-stripe mode=4.
Variable

Variable \([flags] \) \(varName[/=name] [=numExpr] [, \ varName[/=name] [=numExpr]] \ldots\)

The Variable operation creates real or complex variables and gives them the specified name.

Flags

\(/C\) Declares a complex variable.
\(/D\) Obsolete, included only for backward compatibility (see Details).
\(/G\) Creates a variable with global scope and overwrites any existing variable.
\(/N=\) Specifies a local name for the global string variable. /N was added in Igor Pro 8.00 and is available in user-defined functions only. See NVAR Creation below for details.

Details

The variable is initialized when it is created if you supply the initial value. However, when Variable is used to declare a function parameter, it is an error to attempt to initialize it.

You can create more than one variable at a time by separating the names and optional initializers for multiple variables with a comma.

Numeric variables are double precision. In ancient times, variables could be single or double precision and the /D flag meant double precision. The /D flag is allowed for backward compatibility but is no longer needed and should not be used in new code.

If used in a macro or function the new variable is local to that macro or function unless the /G flag is used.

If used on the command line, the new variable is global.

\(varName\) can include a data folder path.

NVAR Creation

In a user-defined function, you need a local NVAR reference to access a global string variable. If you use a simple name rather than a path, Igor automatically creates an NVAR:

\[\text{Variable/G nVar1} // \text{Creates an NVAR named nVar1}\]

If you use a path or a $ expression, Igor does not create an automatic NVAR reference. You can explicitly create NVARs like this:

\[\text{Variable/G root:nVar2} \]
\[\text{NVAR nVar2 = root:nVar2} // \text{Creates an NVAR named nVar2}\]

\[\text{String path = "root:nVar3"} \]
\[\text{Variable/G $path} \]
\[\text{NVAR nVar3 = $path} // \text{Creates an NVAR named nVar3}\]

In Igor Pro 8.00 and later, you can explicitly create an NVAR reference in a user-defined function using the /N flag, like this:

\[\text{Variable/G nVar4/N=nVar4} // \text{Creates an NVAR named nVar4}\]
\[\text{Variable/G root:nVar5/N=nVar5} // \text{Creates an NVAR named nVar5}\]

\[\text{String path = "root:nVar6"} \]
\[\text{Variable/G $path/N=nVar6} // \text{Creates an NVAR named nVar6}\]

The name used for the NVAR does not need to be the same as the name of the global variable:

\[\text{Variable/G nVar7/N=nv7} // \text{Creates an NVAR named nv7}\]
\[\text{Variable/G root:nVar8/N=nv8} // \text{Creates an NVAR named nv8}\]

\[\text{String path = "root:nVar9"} \]
\[\text{Variable/G $path/N=nv9} // \text{Creates an NVAR named nv9}\]

Examples

To initialize a complex variable, use the \texttt{cmplx} function. For example:

\[\text{Variable/C cv1 = cmplx(1,2)}\]

This sets the real part of \texttt{cv1} to 1 and the imaginary part to 2.

See Also

\texttt{Numeric Variables} on page II-98, \texttt{Accessing Global Variables and Waves} on page IV-64
**Variance**

**Variance**

\[ \text{Variance}(\text{inWave} [, x1, x2 ] ) \]

Returns the variance of the real-valued \text{inWave}. The function ignores NaN and INF values in \text{inWave}.

**Parameters**

\text{inWave} is expected to be a real-valued numeric wave. If \text{inWave} is a complex or text wave, \text{Variance} returns NaN.

\( x1 \) and \( x2 \) specify a range in \text{inWave} over which the variance is to be calculated. They are used only to locate the points nearest to \( x=x1 \) and \( x=x2 \). The variance is then calculated over that range of points. The order of \( x1 \) and \( x2 \) is immaterial.

If omitted, \( x1 \) and \( x2 \) default to \(-\infty\) and \(+\infty\) respectively and the variance is calculated for the entire wave.

**Details**

The variance is defined by

\[
\text{var} = \frac{\sum_{i=1}^{n} (x_i - \overline{x})^2}{n - 1}
\]

where

\[
\overline{x} = \frac{\sum_{i=1}^{n} X_i}{n}.
\]

**Examples**

Make/O/N=5 test = p
SetScale/P x, 0, .1, test

// Print variance of entire wave
Print Variance(test)

// Print variance from x=0 to x=.2
Print Variance(test, 0, .2)

// Print variance for points 1 through 3
Variable x1=pnt2x(test, 1)
Variable x2=pnt2x(test, 3)
Print Variance(test, x1, x2)

**See Also**

mean, median, WaveStats, APMath

**VariableList**

\[ \text{VariableList(matchStr, separatorStr, variableTypeCode)} \]

The \text{VariableList} function returns a string containing a list of global variables selected based on the \text{matchStr} and \text{variableTypeCode} parameters. The variables listed are all in the current data folder.

**Details**

For a variable name to appear in the output string, it must match \text{matchStr} and also must fit the requirements of \text{variableTypeCode}. \text{separatorStr} is appended to each variable name as the output string is generated.

The name of each variable is compared to \text{matchStr}, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

"*" Matches all variable names.

"xyz" Matches variable name xyz only.
matchStr may begin with the ! character to return windows that do not match the rest of matchStr. For example:

"!*xyz" Matches variable names which do not end with xyz.

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of matchStr.

variableTypeCode is used to further qualify the variable. The variable name goes into the output string only if it passes the match test and its type is compatible with variableTypeCode. variableTypeCode is any one of:

2: System variables (K0, K1 . . .)
4: Scalar variables
5: Complex variables

Examples

VariableList("*", ";", 4) Returns a list of all scalar variables.
VariableList("!*V_*", ";", 5) Returns a list of all complex variables except those whose names begin with "V_".

See Also

See the StringList and WaveList functions.
See Setting Bit Parameters on page IV-13 for details about bit settings.

VCSR

vcsr( cursorName [, graphNameStr] )
The vcsr function returns the Y (vertical) value of the point which the specified cursor (A through J) is attached to in the top (or named) graph.

Parameters

cursorName identifies the cursor, which can be cursor A through J.

graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

The result is computed from the coordinate system of the graph’s Y axis. The Y axis used is the one used to display the wave on which the cursor is placed.

See Also

The hcsr, pcsr, qcsr, xcsr, and zcsr functions.

Programming With Cursors on page II-256.

version

#pragma version = versNum
In the File Information dialog, #pragma version=versNum provides file version information that is displayed next to the file name in the dialog. This line must not be indented and must appear in the first fifty lines of the file. See Procedure File Version Information on page IV-161.
VoigtFunc

See Also
The The version Pragma on page IV-54, Procedure File Version Information on page IV-161, the IgorInfo function, and #pragma.

VoigtFunc

VoigtFunc(X, Y)
The VoigtFunc function computes the Voigt function using an approximation that has, as described by the author, "accuracy is typically at at least 13 significant digits".

VoigtFunc returns values from a normalized Voigt peak centered at X=0 for the given value of X. The X input is a normalized distance from the peak center:

\[ X = \sqrt{\ln(2)} \frac{V - V_0}{\gamma_g} \]

where \(\gamma_g\) is the Gaussian component half-width, and \(V - V_0\) is the distance from the peak center.

The parameter Y is the shape parameter: when Y is zero, the peak is pure Gaussian. When Y approaches infinity, the shape becomes pure Lorentzian. When Y is \(\sqrt{\ln(2)}\), the mix is half-and-half.

VoigtFunc was added in Igor Pro 7.00. The approximation used to compute it was changed Igor 8.00 for greater accuracy.

Details
The VoigtFunc function returns values from a normalized peak that can be used as the basis for user-defined fitting functions. The function is used as the basis for the built-in Voigt fitting function and the VoigtPeak function.

VoigtFunc Curve Fitting Example
Here is an example of a user-defined fitting function built on VoigtFunc:

Constant sqrtln2=0.83255461157698 // sqrt(ln(2))
Constant sqrtln2pi=0.469718639349826 // sqrt(ln(2)/pi)

Function MyVoigtFit(w,xx) : FitFunc
    Wave w
    Variable xx

    //CurveFitDialog/ These comments were created by the Curve Fitting dialog.
    //CurveFitDialog/ Equation:
    //CurveFitDialog/ Variable ratio = sqrtln2/gw
    //CurveFitDialog/ Variable xprime = ratio*(xx-x0)
    //CurveFitDialog/ Variable voigtY = ratio*shape
    //CurveFitDialog/ f(xx) = y0 + area*sqrtln2pi*VoigtFunc(xprime, voigtY)
    //CurveFitDialog/ Independent Variables 1
    //CurveFitDialog/ xx
    //CurveFitDialog/ Coefficients 5
    //CurveFitDialog/ w[0] = y0
    //CurveFitDialog/ w[1] = area
    //CurveFitDialog/ w[2] = x0
    //CurveFitDialog/ w[3] = gw (FWHM)
    //CurveFitDialog/ w[4] = shape (Lw/Gw)

    Variable voigtX = 2*sqrtln2*(xx-w[2])/w[3]
    Variable voigtY = sqrtln2*pi
    return (w[0]+(w[1]/w[3]))*2*sqrtln2pi*VoigtFunc(voigtX, voigtY)
End

Parameter w[0] sets the vertical offset, w[1] sets the peak area, w[2] sets the location of the peak, w[3] gives the Gaussian component’s full width at half max and w[4] is the ratio of the Lorentzian width to the Gaussian width.

After the fit, assuming you used a coefficient wave named voigtCoefs, you can calculate the width of the full Voigt peak as follows:
VoigtPeak

VoigtPeak(\(w, x\))
The VoigtPeak function returns a value from a Voigt peak shape defined by coefficients in wave \(w\) at location \(x\). It was added in Igor Pro 8.00.

The Voigt peak shape is defined as a convolution of a Gaussian and a Lorentzian peak. We use an approximation that is described by the author as having “accuracy typically at least 13 significant digits”. This function is equivalent to the built-in Voigt fitting function. See Built-in Curve Fitting Functions on page III-188.

The coefficients are:
- \(w[0]\): Vertical offset.
- \(w[1]\): Peak area.
- \(w[2]\): Peak center location.
- \(w[3]\): Gaussian component width expressed as Full Width at Half Max (FWHM).
- \(w[4]\): Ratio of Lorentzian component width to the Gaussian component width. For \(w[4]=0\), the peak shape is purely Gaussian, as \(w[4] \to \infty\), the peak shape become purely Lorentzian. A value of 1 results in Gaussian and Lorentzian components of equal width.

References
The code used to compute VoigtPeak was written by Steven G. Johnson of MIT. You can learn more about it at http://ab-initio.mit.edu/Faddeeva.

VoigtPeak, Faddeeva, Built-in Curve Fitting Functions on page III-188.

WAVE

```
WAVE [ /C ] [ /T ] [ /WAVE ] [ /DF ] [ /Z ] localName [ =pathToWave ] [, localName1 [ =pathToWave1 ] ] ...
```

WAVE is a declaration that identifies the nature of a user-defined function parameter or creates a local reference to a wave accessed in the body of a user-defined function.

The optional parameter pathToWave is used only in the body of a function, not in a parameter declaration. The WAVE reference is required when you use a wave in an assignment statement in a function. At compile time, the WAVE statement specifies that the local name references a wave. At runtime, it makes the connection between the local name and the actual wave. For this connection to be made, the wave must exist when the WAVE statement is executed.

When localName is the same as the global wave name and you want to reference a wave in the current data folder, you can omit the pathToWave.

pathToWave can be a full literal path (e.g., root:FolderA:wave0), a partial literal path (e.g., :FolderA:wave0) or $ followed by string variable containing a computed path (see Converting a String into a Reference Using $ on page IV-61).

You can also use a data folder reference or the /SDFR flag to specify the location of the wave if it is not in the current data folder. See Data Folder References on page IV-77 and The /SDFR Flag on page IV-79 for details.
WAVEClear

If the wave may not exist at runtime, use the /Z flag and call WaveExists before accessing the wave. The /Z flag prevents Igor from flagging a missing wave as an error and dropping into the debugger. For example:

```
WAVE/Z wv=<pathToPossiblyMissingWave>
if( WaveExists(wv) )
    <do something with wv>
endif
```

Note that to create a wave, you use the Make operation.

Flags

/C Complex wave
/T Text wave
/WAVE Wave reference wave
/DF Data folder reference wave
/Z Ignores wave reference checking failures

See Also

WaveExists function.

WAVE Reference Type Flags on page IV-73 for additional wave type flags and information.

Accessing Waves in Functions on page IV-81.

Converting a String into a Reference Using $ on page IV-61.

WAVEClear

```
WAVEClear localName [, localName1 ...]
```

The WAVEClear operation clears out a WAVE reference variable. WAVEClear is equivalent to WAVE/Z localName= "$".

Details

Use WAVEClear to avoid unexpected results from certain operations such as Duplicate or Concatenate, which will reuse the contents of a WAVE reference variable and may not generate the wave in the desired data folder or with the desired name.

WAVEClear ensures that memory is deallocated after waves are killed as in this example:

```
Function foo()
    Make wave1
    FunctionThatKillsWave1()
    WAVEClear wave1
    AnotherFunction()
End
```

Although memory used for wave1 will be deallocated when foo returns, that memory will not be automatically released while the function executes because the WAVE variable still contains a reference to the wave. In this example, WAVEClear deallocates that memory before AnotherFunction executes.

You can also use WAVEClear before passing a data folder to preemptive threads using ThreadGroupPutDF.

See Also

WaveCRC

```
WaveCRC(inCRC, waveName [, checkHeader])
```

The WaveCRC function returns a 32-bit cyclic redundancy check value of the bytes in the named wave starting with inCRC.
Pass 0 for \textit{inCRC} the first time you call \texttt{WaveCRC} for a particular stream of bytes as represented by the wave data.

Pass the last-returned value from \texttt{WaveCRC} for \textit{inCRC} if you are creating a CRC value for a given stream of bytes through multiple calls to \texttt{WaveCRC}.

\textit{waveName} may be a numeric or text wave.

The optional \textit{checkHeader} parameter determines how much of the wave is checked:

<table>
<thead>
<tr>
<th>\textit{checkHeader}</th>
<th>\textit{What It Does}</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Check only the wave data (default).</td>
</tr>
<tr>
<td>1</td>
<td>Check only the internal binary header.</td>
</tr>
<tr>
<td>2</td>
<td>Check both.</td>
</tr>
</tbody>
</table>

\textbf{Details}

Polynomial used is:

\[ x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1 \]

See \texttt{crc32.c} in the public domain source code for zlib for more information.

\textbf{See Also}

\texttt{StringCRC}, Hash, \texttt{WaveHash}, \texttt{WaveModCount}

\textbf{WaveDims}

\texttt{WaveDims(wave)}

The \texttt{WaveDims} function returns the number of dimensions used by \texttt{wave}.

Returns zero if wave reference is null. See \texttt{WaveExists} for a discussion of null wave references.

Also returns zero if wave has zero rows. A matrix will return 2.

\textbf{WaveExists}

\texttt{WaveExists(wave)}

The \texttt{WaveExists} function returns one if wave reference is valid or zero if the wave reference is null. For example if, in a user function, you have:

\begin{verbatim}
Wave w= "$no such wave"
then WaveExists (w) will return zero.
\end{verbatim}

\texttt{WaveExists} should be used in functions only. In macros, use the exists function instead.

\textbf{See Also}

\texttt{exists}, \texttt{NVAR_Exists}, \texttt{SVAR_Exists}, and \texttt{Accessing Global Variables and Waves} on page IV-64.

\textbf{WaveHash}

\texttt{WaveHash(wave, method)}

The \texttt{WaveHash} function returns a cryptographic hash of the bytes of the wave's data using the specified method. All contents of the wave's header are ignored.

\textbf{Parameters}

\texttt{wave} may reference a numeric or text wave.

\textit{method} is a number indicating the hash algorithm to use:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SHA-256 (SHA-2)</td>
</tr>
<tr>
<td>2</td>
<td>MD4</td>
</tr>
<tr>
<td>3</td>
<td>MD5</td>
</tr>
<tr>
<td>4</td>
<td>SHA-1</td>
</tr>
</tbody>
</table>
The WaveInfo function returns a string containing a semicolon-separated list of information about the named wave.

The second parameter is reserved for future use and must be zero.

Details

The result string contains a list of keyword-value pairs. Each pair consists of a keyword, a colon, the value text, and a semicolon.

Here are the keywords:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Information Following Keyword</th>
</tr>
</thead>
<tbody>
<tr>
<td>DUNITS</td>
<td>The wave’s data units.</td>
</tr>
<tr>
<td>FULLSCALE</td>
<td>Three numbers indicating whether the wave has any data full scale information, and the min and max data full scale values. The format of the FULLSCALE description is: FULLSCALE: validFS, minFS, maxFS; validFS is 1 if minFS and maxFS have been set via a SetScale d command; otherwise it is 0.</td>
</tr>
<tr>
<td>LOCK</td>
<td>Reads back the value set by SetWaveLock.</td>
</tr>
<tr>
<td>MODIFIED</td>
<td>1 if the wave has been modified since the experiment was last saved, else 0.</td>
</tr>
<tr>
<td>MODTIME</td>
<td>The date and time that the wave was last modified in seconds since January 1, 1904.</td>
</tr>
<tr>
<td>NUMTYPE</td>
<td>A number denoting the data type of the wave.</td>
</tr>
<tr>
<td></td>
<td>For text waves this is 0.</td>
</tr>
<tr>
<td></td>
<td>For wave reference waves it is 16384.</td>
</tr>
<tr>
<td></td>
<td>For data folder reference waves it is 256.</td>
</tr>
<tr>
<td></td>
<td>For numeric waves it is one of the following:</td>
</tr>
<tr>
<td></td>
<td>1: Complex, added to one of the following</td>
</tr>
<tr>
<td></td>
<td>2: 32-bit (single precision) floating point</td>
</tr>
<tr>
<td></td>
<td>4: 64-bit (double precision) floating point</td>
</tr>
<tr>
<td></td>
<td>8: 8-bit signed integer</td>
</tr>
<tr>
<td></td>
<td>16: 16-bit signed integer</td>
</tr>
<tr>
<td></td>
<td>32: 32-bit signed integer</td>
</tr>
<tr>
<td></td>
<td>128: 64-bit signed integer</td>
</tr>
<tr>
<td></td>
<td>64: Unsigned, added to 8, 16, 32 or 128 if wave is unsigned</td>
</tr>
<tr>
<td></td>
<td>For example, the number denoting a complex double precision wave is 5 (i.e., 1+4).</td>
</tr>
</tbody>
</table>

See Also

WaveModCount, WaveCRC, StringCRC, Hash

V-984
Always pass 0 as the second input parameter. In future versions of Igor, this parameter may request other kinds of information to be returned.

A null wave reference returns a zero-length string. This might be encountered, for instance, when using WaveRefIndexedDFR in a loop to act on all waves in a data folder, and the loop has incremented beyond the highest valid index.

Examples

```igor
Make/O wave1; SetScale x,0,1,"dyn",wave1; SetScale y,3,20,"v",wave1
String info = WaveInfo(wave1,0)
Print NumberByKey("NUMTYPE", info) // Prints 2
Print StringByKey("DUNITS", info) // Prints "v"
```

See Also

The functions and operations listed under “About Waves” categories in the Command Help tab of the Igor Help Browser; among them are CreationDate, ModDate, WaveModCount, WaveType, note, and numpnts.

NumberByKey and StringByKey functions for parsing the returned keyword list.

WaveInfo lacks information about multidimensional waves. Individual functions are provided to return dimension-related information: DimDelta, DimOffset, DimSize, WaveUnits, and GetDimLabel.

## WaveList

**WaveList**

```igor
WaveList(matchStr, separatorStr, optionsStr)
```

The WaveList function returns a string containing a list of waves selected from the current data folder based on `matchStr` and `optionsStr` parameters. See Details for information on listing waves in graphs, and for references to newer, data folder-aware functions.

### Details

For a wave name to appear in the output string, it must match `matchStr` and also must fit the requirements of `optionsStr` and it must be in the current data folder. `separatorStr` is appended to each wave name as the output string is generated.

The name of each wave is compared to `matchStr`, which is some combination of normal characters and the asterisk wildcard character that matches anything.

For example:

```
"*" Matches all wave names in current data folder.
"xyz" Matches wave name xyz only, if xyz is in the current data folder.
"*xyz" Matches wave names which end with xyz and are in the current data folder.
"xyz*" Matches wave names which begin with xyz and are in the current data folder.
"*xyz*" Matches wave names which contain xyz and are in the current data folder.
"abc*xyz" Matches wave names which begin with abc and end with xyz and are in the current data folder.
```

`matchStr` may begin with the ! character to return windows that do not match the rest of `matchStr`. For example:

```
"!*xyz" Matches wave names which do not end with xyz.
```
WaveList

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of \textit{matchStr}.

\textit{optionsStr} is used to further qualify the wave.

Use "" to accept all waves in the current data folder that are permitted by \textit{matchStr}.

Set \textit{optionsStr} to one or more of the following comma-separated keyword-value pairs:

<table>
<thead>
<tr>
<th>\textit{optionsStr}</th>
<th>Selection Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;BYTE:0&quot; or &quot;BYTE:1&quot;</td>
<td>Waves that are not 8-bit integer (if 0) or only waves that are 8-bit integer (if 1).</td>
</tr>
<tr>
<td>&quot;CMPLX:0&quot; or &quot;CMPLX:1&quot;</td>
<td>Waves that are not complex (if 0) or only waves that are complex (if 1).</td>
</tr>
<tr>
<td>&quot;DIMS:numberOfDims&quot;</td>
<td>All waves in current data folder that have \textit{numberOfDims} dimensions. This is the number of dimensions reported by \textit{WaveDims}.</td>
</tr>
<tr>
<td></td>
<td>Use &quot;DIMS:0&quot; for all waves having no points ((\text{numpt}ees,(w) == 0)).</td>
</tr>
<tr>
<td></td>
<td>Use &quot;DIMS:1&quot; for graph traces (or one of the X, Y, and Z waves of a contour plot).</td>
</tr>
<tr>
<td></td>
<td>Use &quot;DIMS:2&quot; for false color and indexed color images (see \textbf{Indexed Color Details} on page II-330).</td>
</tr>
<tr>
<td></td>
<td>Use &quot;DIMS:3&quot; for direct color images (see \textbf{Direct Color Details} on page II-331).</td>
</tr>
<tr>
<td>&quot;DP:0&quot; or &quot;DF:1&quot;</td>
<td>Consider waves that are not data folder reference waves (if 0) or only waves that are data folder reference waves (if 1). You can create waves that contain data folder references using the \textbf{Make/DF} flag.</td>
</tr>
<tr>
<td>&quot;DP:0&quot; or &quot;DP:1&quot;</td>
<td>Waves that are not double precision floating point (if 0) or only waves that are double precision floating point (if 1).</td>
</tr>
<tr>
<td>&quot;INT64:0&quot; or &quot;INT64:1&quot;</td>
<td>Consider waves that are not 64-bit integer (if 0) or only waves that are 64-bit integer (if 1). 64-bit integer waves are supported in Igor7 and later.</td>
</tr>
<tr>
<td>&quot;INTEGER:0&quot; or &quot;INTEGER:1&quot;</td>
<td>Waves that are not 32-bit integer (if 0) or only waves that are 32-bit integer (if 1).</td>
</tr>
<tr>
<td>&quot;MAXCHUNKS:max&quot;</td>
<td>Waves having no more than \textit{max} chunks.</td>
</tr>
<tr>
<td>&quot;MAXCOLS:max&quot;</td>
<td>Waves having no more than \textit{max} columns.</td>
</tr>
<tr>
<td>&quot;MAXLAYERS:max&quot;</td>
<td>Waves having no more than \textit{max} layers.</td>
</tr>
<tr>
<td>&quot;MAXROWS:max&quot;</td>
<td>Waves having no more than \textit{max} rows.</td>
</tr>
<tr>
<td>&quot;MINCHUNKS:min&quot;</td>
<td>Waves having at least \textit{min} chunks.</td>
</tr>
<tr>
<td>&quot;MINCOLS:min&quot;</td>
<td>Waves having at least \textit{min} columns.</td>
</tr>
<tr>
<td>&quot;MINLAYERS:min&quot;</td>
<td>Waves having at least \textit{min} layers.</td>
</tr>
<tr>
<td>&quot;MINROWS:min&quot;</td>
<td>Waves having at least \textit{min} rows.</td>
</tr>
<tr>
<td>&quot;SP:0&quot; or &quot;SP:1&quot;</td>
<td>Waves that are not single precision floating point (if 0) or only waves that are single precision floating point (if 1).</td>
</tr>
<tr>
<td>&quot;TEXT:0&quot; or &quot;TEXT:1&quot;</td>
<td>Waves that are not text (if 0) or only waves that are text (if 1).</td>
</tr>
<tr>
<td>&quot;UNSIGNED:0&quot; or &quot;UNSIGNED:1&quot;</td>
<td>Waves that are not unsigned integer (if 0) or only waves that are unsigned integer (if 1).</td>
</tr>
<tr>
<td>&quot;WAVE:0&quot; or &quot;WAVE:1&quot;</td>
<td>Consider waves that do not contain wave references (if 0) or only waves that contain wave references (if 1). You can create waves that contain wave references using the \textbf{Make/WAVE} flag.</td>
</tr>
<tr>
<td>&quot;WIN:&quot;</td>
<td>All waves in the current data folder that are displayed in the top graph or table.</td>
</tr>
</tbody>
</table>
WaveList

You can specify more than one option by separating the options with a comma. See the Examples.

Note: Even when `optionsStr` is used to list waves used in a graph or table, the waves must be in the current data folder.

Note: In addition to waves displayed as normal graph traces, WaveList will list matrix waves used with `AppendImage` or `NewImage` and the X, Y, and Z waves used with `AppendXYZContour`.

Note: Individual contour traces are not listed because they have no corresponding waves. See Contour Traces on page II-301.

There are several functions that are more useful for listing waves in graphs and tables.

WaveList with `WIN:windowName` gives only the names of the waves in the graph or table and does not include the data folder for each wave. If you need to know what data folder the waves are in, use `WaveRefIndexed` to get the wave itself and then if needed use `GetWavesDataFolder` to get the path.

When identifying a subwindow with `WIN:windowName`, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

To list the actual waves used in a graph, or to distinguish two or more instances of the same named wave in a graph, use `TraceNameList`. This function can be used in conjunction with `TraceNameToWaveRef`, and `XWaveRefFromTrace`.

Use `ContourNameList` to list contour plots in a given window and `ContourNameToWaveRef` to access the waves used to generate the contour plot.

To list the contour traces (that is, the contour lines themselves) use `TraceNameList` with the appropriate option.

Use `ImageNameList` to list images in a given window and `ImageNameToWaveRef` to access the waves used to generate the images.

Processing Lists of Waves

Contrary to what you might expect, you can not use the output of WaveList directly with operations that have a list of waves as their parameters. See Processing Lists of Waves on page IV-193 for ways of dealing with this.

Examples

// Returns a list of all waves in the current data folder.
WaveList("*",",","")

// Returns a list of all waves in the current data folder and displayed in the top table or graph.
WaveList("*",",","WIN:")

// Returns a list of waves in the current data folder whose names end in ".bkg" and which are displayed in Graph0 as 1D traces.
WaveList("*_bkg",",","WIN:Graph0")

// Returns a list of waves in the current data folder whose names do not end in "X, Y, and Z waves of an AppendXYZContour plot.
WaveList("!*X",",","WIN:Graph0,DIMS:1")

See Also
Chapter II-6, Multidimensional Waves.

Execute, ContourNameList, ImageNameList, TraceNameList, and WaveRefIndexed.
WaveMax

WaveMax(waveName [, x1, x2])
The WaveMax function returns the maximum value in the wave for points between x=x1 to x=x2, inclusive.

Details
If x1 and x2 are not specified, they default to -inf and +inf, respectively.
The X scaling of the wave is used only to locate the points nearest to x=x1 and x=x2. To use point indexing, replace x1 with pnt2x(waveName, pointNumber1), and a similar expression for x2.
If the points nearest to x1 or x2 are not within the point range of 0 to numpnts(waveName)-1, WaveMax limits them to the nearest of point 0 or point numpnts(waveName)-1.
For a floating-point wave, WaveMax runs about three times faster than getting the same information using WaveStats. For an integer wave, WaveMax runs about ten times faster than WaveStats. The advantage may not hold for short waves.

See Also
The WaveMin function and WaveStats operation.

WaveMeanStdv

WaveMeanStdv srcWave binSizeWave
The WaveMeanStdv operation calculates the standard deviation of the means for the specified bin distribution saving the result in the wave W_MeanStdv.

For each entry in binSizeWave, srcWave is divided into the specified number of bins. Values in each bin are averaged and then the mean and standard deviation of the averages (among all bins) are calculated. The value of the standard deviation of the bin averages divided by the mean is then stored in W_MeanStdv corresponding to the bin size entry in binSizeWave.

All entries in binSizeWave must be positive integers.

Details
When the number of points in srcWave does not divide evenly into the bin size entry from binSizeWave, the last bin will have a smaller number of data points. In order not to skew the results the values corresponding to the last bin will be dropped. If your data set is small compared to the bin size you might want to pad srcWave with additional values (e.g., duplicate values from the beginning of the wave).

This operation does not support NaNs. If you get a NaN as an entry in the output wave then there is either a NaN in srcWave or something is wrong with the calculation for that entry.

WaveMin

WaveMin(waveName [, x1, x2])
The WaveMin function returns the minimum value in the wave for points between x=x1 to x=x2, inclusive.

Details
If x1 and x2 are not specified, they default to -inf and +inf, respectively.
The X scaling of the wave is used only to locate the points nearest to x=x1 and x=x2. To use point indexing, replace x1 with pnt2x(waveName, pointNumber1), and a similar expression for x2.
If the points nearest to x1 or x2 are not within the point range of 0 to numpnts(waveName)-1, WaveMin limits them to the nearest of point 0 or point numpnts(waveName)-1.
For a floating-point wave, WaveMin runs about three times faster than getting the same information using WaveStats. For an integer wave, WaveMin runs about ten times faster than WaveStats. The advantage may not hold for short waves.

See Also
The WaveMax function and WaveStats operation.
WaveModCount

WaveModCount (wave)
The WaveModCount function returns a value that can be used to tell if a global wave has been changed between one call to WaveModCount and another.

WaveModCount was added in Igor Pro 8.00.

The exact value returned by WaveModCount has no significance. The only use for it is to compare the values returned by two calls to WaveModCount. If they are different, the wave was changed in the interim.

The wave mod count for free and thread-local waves is undefined, so WaveModCount should only be used with global waves in the data hierarchy of the main thread.

A wave’s mod count changes when the wave’s data or properties, such as scaling, note, and dimensionality, are set. The mod count changes even if the new data or property values are the same as the old. For example, executing:

```
wave1 += 0
```
causes the mod count to change even though the data itself was not actually changed.

Examples

Make/O wave1 = 5
Variable waveModCount1, waveModCount2
waveModCount1 = WaveModCount (wave1); // Modify wave1
wave1 += 1
waveModCount2 = WaveModCount (wave1);
if (waveModCount2 != waveModCount1)
  Print "Wave has changed"
endif

See Also
WaveInfo, ModDate

WaveName

WaveName (winNameStr, index, type)
The WaveName function returns a string containing the name of the indexth wave of the specified type in the named window or subwindow.

Parameters

winNameStr can be "" to refer to the top graph or table.

When identifying a subwindow with winNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details

WaveName works on waves displayed in a graph, in a table or on the list of waves in the current data folder. If the window is a table, WaveName returns the column name (e.g., “wave0.d”), rather than the name of the wave itself (e.g., “wave0”).

For most uses, we recommend that you use WaveRefIndexed or WaveRefIndexedDFR instead of WaveName. WaveName returns a string containing the wave name only, with no data folder path qualifying it. Thus, you may get erroneous results if the wave referred to in the graph has the same name as a different wave in the current data folder. Likewise, if the named wave resides in a data folder that is not the current data folder, you will not be able to refer to the named wave. Use WaveRefIndexedDFR instead.

winNameStr is a string expression containing the name of a graph or table or an empty string (" "). If the string is empty and type is 4 then WaveName works on the list of all waves in the current data folder. If the string is empty and the type parameter is not 4 then WaveName works on the top graph or table.

index starts from zero.

type is a number from 1 to 4. When type is 4 and winNameStr is " ", WaveName works on the list of all waves in the current data folder.

For graph windows, type is 1 for y waves, 2 for x waves, 3 for either y or x waves.
WaveRefIndexed

For table windows, type is 1 for data columns, 2 for index or dimension label columns, 3 for either data or index or dimension label columns.

WaveName returns an empty string (" ") if there is no wave matching the parameters.

Examples
WaveName("",0,4)  // Returns name first wave current data folder.
WaveName("",0,1)  // Returns name of first Y wave in the top graph.
WaveName("Graph0",1,2)  // Returns name of second X wave in Graph0.
WaveName("Table0",1,3)  // Returns name of second column in Table0.

WaveRefIndexed

WaveRefIndexed(winNameStr, index, type)

The WaveRefIndexed function returns a wave reference to the indexth wave of the specified type in the named window or subwindow.

To iterate through the waves in a data folder, use WaveRefIndexedDFR instead of WaveRefIndexed.

Parameters
winNameStr can be "" to refer to the top graph or table window or the current data folder.

When identifying a subwindow with winNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details
WaveRefIndexed is analogous to WaveName but works better with data folders. We recommend that you use it instead of WaveName.

winNameStr is a string expression containing the name of a graph or table or an empty string (" "). If the string is empty and type is 4 then WaveRefIndexed works on Igor’s list of all waves in the current data folder. If the string is empty and the type parameter is not 4 then WaveRefIndexed works on the top graph or table.

index starts from zero.

type is a number from 1 to 4. When type is 4 and winNameStr is " ", WaveRefIndexed works on the list of all waves in the current data folder.

For graph windows, type is 1 for y waves, 2 for x waves, 3 for either y or x waves.

For table windows, type is 1 for data columns, 2 for index or dimension label columns, 3 for either data or index or dimension label columns.

WaveRefIndexed returns a null reference (see WaveExists) if there is no wave matching the parameters.

Examples
WaveRefIndexed("",0,1)  // Returns first Y wave in the top graph.
WaveRefIndexed("Graph0",1,2)  // Returns second X wave in Graph0.
WaveRefIndexed("Table0",1,3)  // wave in second column in Table0.

See Also
WaveRefIndexedDFR, NameOfWave, GetWavesDataFolder

For a discussion of wave references, see Wave Reference Functions on page IV-192.

WaveRefIndexedDFR

WaveRefIndexedDFR(dfr, index)

The WaveRefIndexedDFR function returns a wave reference to the indexth wave in the specified data folder.

Parameters
dfr is a data folder reference.

index is the zero-based index of the wave you want to access.

Details
WaveRefIndexedDFR returns a null reference (see WaveExists) if there is no wave corresponding to index in the specified data folder.
WaveRefsEqual

Example

// DemoWaveRefIndexedDFR can be called like this:
// DemoWaveRefIndexedDFR(root:, 0)  // Work on root
// DemoWaveRefIndexedDFR(root:SubDataFolder, 0)  // Work on root:SubDataFolder
// DemoWaveRefIndexedDFR(:, 0)  // Work on current data folder

Function DemoWaveRefIndexedDFR(dfr, recurse)
  DPREF dfr
  Variable recurse
  Variable index = 0
  do
    Wave/Z w = WaveRefIndexedDFR(dfr, index)
    if (!WaveExists(w))
      break
    endif
    String path = GetWavesDataFolder(w, 2)
    Print path
    index += 1
  while(1)
  if (recurse)
    Variable numChildDataFolders = CountObjectsDFR(dfr, 4)
    Variable i
    for(i=0; i<numChildDataFolders; i+=1)
      String childDFName = GetIndexedObjNameDFR(dfr, 4, i)
      DPREF childDFR = dfr:$childDFName
      DemoWaveRefIndexedDFR(childDFR, 1)
    endfor
  endif
  End

See Also
WaveRefIndexed, NameOfWave, GetWavesDataFolder
For a discussion of wave references, see Wave Reference Functions on page IV-192.

WaveRefsEqual

WaveRefsEqual(w1, w2)
The WaveRefsEqual function returns the truth the two wave references are the same.

See Also
Wave Reference Functions on page IV-192

WaveRefWaveToList

WaveRefWaveToList(waveRefWave, option)
The WaveRefWaveToList function returns a semicolon-separated string list containing data folder paths.
Each element of the returned string list is the full or partial path to the wave referenced by the corresponding element of waveRefWave. Entries in waveRefWave that are NULL or entries that correspond to free waves result in an empty list element.
The WaveRefWaveToList function was added in Igor Pro 7.00.

Parameters
waveRefWave is a wave reference wave each element of which contains a reference to an existing wave or NULL (0).

option determines if the returned path is a full path or a partial path relative to the current data folder:

option=0:  Full path.
option=1:  Partial path relative to the current data folder.

Other values of option are reserved for the future.
WaveStats

Example

Function Test()
    SetDataFolder root:
    Make/O/FREE aaa
    Make/O bbb
    Make/O/WAVE/N=3 wr
    Wr[0]=aaa
    // Wr[1] is null by initialization.
    wr[2]=bbb
    Print WaveRefWaveToList(wr,0)
End

// Executing Test() gives:
;;root:bbb;
The first empty string corresponds to the free wave 'aaa' and the second empty string corresponds to the
null entry in the wave reference wave.

ListToWaveRefWave, ListToTextWave, Wave References on page IV-70

WaveStats [flags] waveName

The WaveStats operation computes several statistics on the named wave.

Flags

/ALPH=val

Sets the significance level for the confidence interval of the mean (default val=0.05).

/C=method

Calculates statistics for complex waves only. Does not affect real waves.
You can use method in various combinations to process the real, imaginary,
magnitude, and phase of the wave. The result is stored in the wave M_WaveStats (see
Details for format).

method is defined as follows:

method=0: Default; ignores the imaginary part of waveName. Use /W to also
store statistics in M_WaveStats.

method=1: Calculates statistics for real part of waveName and stores it in
M_WaveStats.

method=2: Calculates statistics for imaginary part of waveName and stores the
result in M_WaveStats.

method=4: Calculates statistics for magnitude of waveName, i.e.,
sqrt(real^2 +imag^2), and stores the result in M_WaveStats.

method=8: Calculate statistics for phase of waveName using
atan2(imag,real).

If you use a single method the results are stored both in M_WaveStats and in the
standard variables (e.g., V_avg, etc.). If you specify method as a combination of more
than one binary field then the variables reflect the results for the lowest chosen field
and all results are stored in the wave M_WaveStats.

For example, if you use /C=12, the variables will be set for the statistics of the
magnitude and M_WaveStats will contain columns corresponding to the magnitude
and to the phase.

In this mode V_numInfs will always be zero.

Note: If you invoke this operation and M_WaveStats already exists in the current data
folder, it will be either overwritten or initialized to NaN.
Calculates statistical moments.

`moment` is defined as follows:

- `moment=1`: Calculates only lower moments: `V_avg`, `V_npnts`, `V_numInfs`, and `V_numNaNs`. Use it if you do not need the higher moments.
- `moment=2`: Default; calculates both lower moments and higher order quantities: `V_sdev`, `V_rms`, `V_adev`, `V_skew`, and `v_kurt`.

Prevents results from being printed in history.

Causes WaveStats to set the location output variables in terms of unscaled index values instead of the default scaled index values.

The location output variables are:

- `V_minRowLoc`, `V_maxRowLoc`, `V_minColLoc`, `V_maxColLoc`
- `V_minLayerLoc`, `V_maxLayerLoc`, `V_minChunkLoc`, `V_maxChunkLoc`

For 1D waves, `V_minRowLoc` and `V_maxRowLoc` are always unscaled.

Requires Igor Pro 8.03 or later.

Computes the statistics on a per-column basis for a real valued wave of two or more dimensions. The results are saved in the wave `M_WaveStats` which has the same number of columns, layers, and chunks as the input wave and where the rows, designated by dimension labels, contain the standard WaveStats statistics. All the `V_` variables are set to NaN. Note that this flag is not compatible with the flags `/C`, `/R`, `/RMD`.

The `/PCST` flag was added in Igor Pro 7.00.

Specifies an X range of the wave to evaluate.

Specifies a point range of the wave to evaluate.

If you specify the range as `/R=[startP]` then the end of the range is taken as the end of the wave. If `/R` is omitted, the entire wave is evaluated.

Designates a contiguous range of data in the source wave to which the operation is to be applied. This flag was added in Igor Pro 7.00.

You can include all higher dimensions by leaving off the corresponding brackets. For example:

- `/RMD=[firstRow,lastRow]` includes all available columns, layers, and chunks.
- `/RMD=[] [firstColumn,lastColumn]` means "all rows from column A to column B".
- `/RMD=[firstRow, *]` means "from firstRow through the last row".

Stores results in the wave `M_WaveStats` in addition to the various `V_` variables when `/C=0`.

No error reporting.

Computes z scores

\[ z_i = \frac{Y_i - \bar{Y}}{\sigma} \],

which are saved in `W_ZScores`. 

\[ V_{\text{minRowLoc}}, V_{\text{maxRowLoc}}, V_{\text{minColLoc}}, V_{\text{maxColLoc}} \]

\[ V_{\text{minLayerLoc}}, V_{\text{maxLayerLoc}}, V_{\text{minChunkLoc}}, V_{\text{maxChunkLoc}} \]
WaveStats uses a two-pass algorithm to produce more accurate results than obtained by computing the binomial expansions of the third and fourth order moments.

WaveStats returns the statistics in the automatically created variables:

- **V_npnts**: Number of points in range excluding points whose value is NaN or INF.
- **V_numNans**: Number of NaNs.
- **V_numINFs**: Number of INFs.
- **V_avg**: Average of data values.
- **V_sum**: Sum of data values.
- **V_sdev**: Standard deviation of data values,
  \[
  \sigma = \sqrt{\frac{\sum_{i=0}^{V_{\text{npnts}}-1} (Y_i - V_{\text{avg}})^2}{V_{\text{npnts}}-1}}
  \]
  "Variance" is V_sdev^2.
- **V_sem**: Standard error of the mean
  \[
  sem = \frac{\sigma}{\sqrt{V_{\text{npnts}}}}
  \]
- **V_rms**: RMS of Y values
  \[
  \sqrt{\frac{1}{V_{\text{npnts}}} \sum Y_i^2}
  \]
- **V_adev**: Average deviation
  \[
  \frac{1}{V_{\text{npnts}}} \sum_{i=0}^{V_{\text{npnts}}-1} |Y_i - \bar{Y}|
  \]
- **V_skew**: Skewness
  \[
  \frac{1}{V_{\text{npnts}}} \sum_{i=0}^{V_{\text{npnts}}-1} \left( \frac{Y_i - \bar{Y}}{\sigma} \right)^3
  \]
- **V_kurt**: Kurtosis
  \[
  \frac{1}{V_{\text{npnts}}} \sum_{i=0}^{V_{\text{npnts}}-1} \left( \frac{Y_i - \bar{Y}}{\sigma} \right)^4 - 3
  \]
- **V_minloc**: X location of minimum data value.
- **V_min**: Minimum data value.
- **V_maxloc**: X location of maximum data value.
- **V_max**: Maximum data value.
- **V_minRowLoc**: Row containing minimum data value. See /P above for further information.
- **V_maxRowLoc**: Row containing maximum data value. See /P above for further information.
- **V_minColLoc**: Column containing minimum data value (2D or higher waves). See /P above for further information.
- **V_maxColLoc**: Column containing maximum data value (2D or higher waves). See /P above for further information.
WaveStats

WaveStats prints the statistics in the history area unless /Q is specified. The various multidimensional min and max location variables will only print to the history area for waves having the appropriate dimensionality.

The format of the M_WaveStats wave is:

<table>
<thead>
<tr>
<th>Row</th>
<th>Statistic</th>
<th>Row</th>
<th>Statistic</th>
<th>Row</th>
<th>Statistic</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>numPoints</td>
<td>9</td>
<td>minLoc</td>
<td>18</td>
<td>maxColLoc</td>
</tr>
<tr>
<td>1</td>
<td>numNaNs</td>
<td>10</td>
<td>min</td>
<td>19</td>
<td>maxLayerLoc</td>
</tr>
<tr>
<td>2</td>
<td>numInfs</td>
<td>11</td>
<td>maxLoc</td>
<td>20</td>
<td>maxChunkLoc</td>
</tr>
<tr>
<td>3</td>
<td>avg</td>
<td>12</td>
<td>max</td>
<td>21</td>
<td>startRow</td>
</tr>
<tr>
<td>4</td>
<td>sdev</td>
<td>13</td>
<td>minRowLoc</td>
<td>22</td>

<td>25</td>
<td>meanL2</td>
</tr>
<tr>
<td>8</td>
<td>kurt</td>
<td>17</td>
<td>maxRowLoc</td>
<td>26</td>
<td>sem</td>
</tr>
</tbody>
</table>

meanL1 and meanL2 are the confidence intervals for the mean

\[
MeanL1 = V_{\text{avg}} - t_{\alpha,v} \frac{V_{\text{sdev}}}{\sqrt{V_{\text{npnts}}}}, \quad MeanL2 = V_{\text{avg}} + t_{\alpha,v} \frac{V_{\text{sdev}}}{\sqrt{V_{\text{npnts}}}}
\]

where \( t_{\alpha,v} \) is the critical value of the Student T distribution for \( \alpha \) significance and degree of freedom \( v=V_{\text{npnts}}-1 \).
Use Edit M_WaveStats.1d to display the results in a table with dimension labels identifying each of the row statistics.

WaveStats is not entirely multidimensional aware. Even so, much of the information computed by WaveStats is useful. See Analysis on Multidimensional Waves on page II-89 for details.

See Also
Chapter III-12, Statistics for details on other statistics.
See the ImageStats operation for calculating wave statistics for specified regions of interest in 2D matrix waves.
See the APMath operation if you require higher precision than provided by double-precision floating point. WaveMax, WaveMin, mean, median, Variance

WaveTextEncoding

WaveTextEncoding(wave, element, getEffectiveTextEncoding)
The WaveTextEncoding function returns the text encoding code for the specified element of a wave. See Wave Text Encodings on page III-451 for background information.
This function is used to deal with text encoding issues that sometimes arise in when you load pre-Igor Pro 7 experiments. Most users will have no need to use it.
The WaveTextEncoding function was added in Igor Pro 6.30. The getEffectiveTextEncoding parameter was added in Igor Pro 7.00.

Parameters
wave specifies the wave of interest.

element specifies a part of the wave, as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Wave name</td>
</tr>
<tr>
<td>2</td>
<td>Wave units</td>
</tr>
<tr>
<td>4</td>
<td>Wave note</td>
</tr>
<tr>
<td>8</td>
<td>Wave dimension labels</td>
</tr>
<tr>
<td>16</td>
<td>Text wave content</td>
</tr>
</tbody>
</table>

getEffectiveTextEncoding determines if WaveTextEncoding returns a raw text encoding code or an effective text encoding code as explained below.

Details
WaveTextEncoding returns a integer text encoding code. See Text Encoding Names and Codes on page III-463 for details.
As explained under Wave Text Encodings on page III-451, each of the wave elements has a corresponding text encoding setting. Because the notion of text encoding settings was added in Igor Pro 6.30, waves created by earlier versions have their text encoding settings set to unknown (0).
The text encoding setting stored for a given element is the "raw" text encoding. If it is unknown, then Igor applies some rules when the wave is accessed to determine an "effective" text encoding for the element being accessed. The rules are explained under Determining the Text Encoding for a Plain Text File on page III-446.

If getEffectiveTextEncoding is non-zero then WaveTextEncoding returns the effective text encoding. If getEffectiveTextEncoding is zero it returns the raw text encoding.

See Also
Wave Text Encodings on page III-451, Text Encoding Names and Codes on page III-463, Determining the Text Encoding for a Plain Text File on page III-446
WaveTransform

WaveTransform [flags] keyword srcWave

The WaveTransform operation transforms srcWave in various ways. If the /O flag is not specified then unless otherwise indicated the output is stored in the wave W_WaveTransform, which will be of the same data type as srcWave and saved in the current data folder.

Parameters

keyword is one of the following:

abs       Calculates the absolute value of the entries in srcWave. It stores results in W_Abs if srcWave is 1D or M_Abs otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single or double precision real wave.

acos      Calculates the inverse cosine of the entries in srcWave. It stores results in W_Acos if srcWave is 1D or M_Acos otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single or double precision real wave.

asin      Calculates the inverse sine of the entries in srcWave. It stores results in W_Asin if srcWave is 1D or M_Asin otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single or double precision real wave.

atan      Calculates the inverse tangent of the entries in srcWave. It stores results in W_Atan if srcWave is 1D or M_Atan otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single or double precision real wave.

cconjugate Calculates the complex conjugate of srcWave. Stores results in W_CConjugate or M_CConjugate, depending on wave dimensionality, or overwrites srcWave if /O is used.

cos       Calculates the cosine of the entries in srcWave. It stores results in W_Cos if srcWave is 1D or M_Cos otherwise. It will overwrite srcWave when used with the /O flag. srcWave must be single or double precision real wave.

crystalToRect Converts triplet (three column \{x,y,z\}) waves from nonorthogonal crystallographic coordinates to rectangular cartesian system. The parameters provided in the /P flag are the crystallographic definition of the coordinate system given by \{a, b, c, alpha, beta, gamma\}. The three angles are assumed to be expressed in radians unless the /D flag is specified. The transformation sets the first component parallel to the vector a and the third component parallel to c*. The output is stored in the current data folder in the wave M_CrystalToRect which has the same data type. If the /O flag is specified, the output overwrites the original data.

flip      Flips the data in srcWave about its center. If /O flag is used, srcWave is overwritten. Otherwise a new wave is created in the current data folder. The wave is named W_flipped or M_flipped according to the dimensionality of srcWave.

index     Fills srcWave as in jack=p.

if /P is specified then jack=p+param1.

The /O flag does not apply here.

inverse   Computes \(1/\text{srcWave}\) for each point in srcWave and stores it in W_Inverse or M_Inverse depending on the dimensionality of srcWave.

inverseIndex Fills srcWave as in jack=numPnts-1-p.

if /P is specified the jack=numPnts-1-p+param1.

magnitude Creates a real-valued wave that is the magnitude of srcWave. If you do not specify the /O flag, the output is stored in W_Magnitude or M_Magnitude depending on the dimensionality of srcWave; the output precision will be the same as srcWave.

magsqr    Creates a real-valued wave that is the magnitude squared of srcWave. If srcWave is a double precision complex wave, the output is also double precision, otherwise the output is a single precision wave. Stores the result in wave W_MagSqr or M_MagSqr, depending on the dimensionality of srcWave, or overwrites srcWave if /O is used.
### WaveTransform

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>max</td>
<td>Calculates the maximum of a point in <code>srcWave</code> and a fixed number specified as a single parameter with the <code>/P</code> flag. It stores results in <code>W_max</code> if <code>srcWave</code> is 1D or <code>M_max</code> otherwise. It will overwrite <code>srcWave</code> when used with the <code>/O</code> flag. See also the min keyword and the example below.</td>
</tr>
<tr>
<td>min</td>
<td>Calculates the minimum of a point in <code>srcWave</code> and a fixed number specified as a single parameter with the <code>/P</code> flag. It stores results in <code>W_min</code> if <code>srcWave</code> is 1D or <code>M_min</code> otherwise. It will overwrite <code>srcWave</code> when used with the <code>/O</code> flag. See also the max keyword and the example below.</td>
</tr>
<tr>
<td>normalizeArea</td>
<td>Calculates the area under the curve and rescales the wave so that the area is 1. Note that waves with negative areas will be rescaled to positive values. Applies to 1D real-valued waves. It does not affect wave scaling. Stores the result in the wave <code>W_normalizedArea</code> or overwrites <code>srcWave</code> if <code>/O</code> is used.</td>
</tr>
<tr>
<td>phase</td>
<td>Creates a real-valued wave containing the phase of the complex input wave. If the <code>/O</code> flag is not used, the output is stored in <code>W_Phase</code> or <code>M_Phase</code> depending on the dimensionality of <code>imageMatrix</code>. You can also use <code>/P={norm}</code> to divide the output wave by the value of <code>norm</code>.</td>
</tr>
<tr>
<td>rectToCrystal</td>
<td>Converts triplet (three column {x, y, z}) waves from cartesian coordinates to nonorthogonal crystallographic coordinate system. The parameters provided in the <code>/P</code> flag are the crystallographic definition of the coordinate system given by {a, b, c, alpha, beta, gamma}. The three angles are assumed to be expressed in radians unless the <code>/D</code> flag is specified. The transformation assumes the first component parallel to the vector a and the third component parallel to c*. The output is stored in the current data folder in the wave <code>M_RectToCrystal</code> which has the same data type. If the <code>/O</code> flag is specified, the output overwrites the original data.</td>
</tr>
<tr>
<td>setConstant</td>
<td>Sets <code>srcWave</code> points to a constant value specified by the <code>/V</code> flag. This keyword applies to real, numeric waves only. You can use <code>/R</code> with setConstant to set a subset of a wave.</td>
</tr>
<tr>
<td>setZero</td>
<td>Sets all <code>srcWave</code> points to zero. setZero was added in Igor Pro 7.00.</td>
</tr>
<tr>
<td>sgn</td>
<td>Sets the value to -1 if the entry is negative, 1 otherwise. Stores the results in <code>W_Sgn</code> or overwrites <code>srcWave</code> if <code>/O</code> is used. This operation will not work on UNSIGNED waves.</td>
</tr>
<tr>
<td>shift</td>
<td>Shifts the position of data in <code>srcWave</code> by the specified number of points. Unlike Rotate, WaveTransform Discards data points that shift outside existing wave boundaries. After the shift, vacated wave points are set to the specified <code>fillValue</code>. The shift and the <code>fillValue</code> are specified with the <code>/P</code> flag using the syntax: <code>/P={numPoints, fillValue}</code>. If you do not provide a fill value, it will be 0 for integer waves and NaN for SP and DP.</td>
</tr>
<tr>
<td>sin</td>
<td>Calculates the sine of the entries in <code>srcWave</code>. Stores results in <code>W_Sin</code> if <code>srcWave</code> is 1D or <code>M_Sin</code> otherwise. Overwrites <code>srcWave</code> when used with the <code>/O</code> flag, <code>srcWave</code> must be a real single or double precision floating point wave.</td>
</tr>
<tr>
<td>sqrt</td>
<td>Calculates the square root of the entries in <code>srcWave</code>. It stores results in <code>W_sqrt</code> if <code>srcWave</code> is 1D or <code>M_sqrt</code> otherwise. It will overwrite <code>srcWave</code> when used with the <code>/O</code> flag, <code>srcWave</code> must be single- or double-precision real wave.</td>
</tr>
<tr>
<td>tan</td>
<td>Calculates the tangent of the entries in <code>srcWave</code>. The results are stored in <code>W_tan</code> if <code>srcWave</code> is 1D or <code>M_tan</code> otherwise. It will overwrite <code>srcWave</code> when used with the <code>/O</code> flag, <code>srcWave</code> must be single- or double-precision real wave.</td>
</tr>
<tr>
<td>zapINFs</td>
<td>Deletes elements whose value is infinity or -infinity. This is relevant for 1D single-precision and double-precision floating point waves only and does nothing for other types of 1D waves. It is not suitable for multidimensional waves and returns an error if <code>srcWave</code> is multidimensional. Use <code>MatrixOp replace</code> for multidimensional waves.</td>
</tr>
</tbody>
</table>
WaveType

WaveType(waveName [, selector ])
The WaveType function returns the type of data stored in the wave.

If selector = 1, WaveType returns 0 for a null wave, 1 if numeric, 2 if text, 3 if the wave holds data folder references or 4 if the wave holds wave references.

If selector = 2, WaveType returns 0 for a null wave, 1 for a normal global wave or 2 for a free wave or a wave that is stored in a free data folder.

If selector is omitted or zero, the returned value for non-numeric waves (text waves, wave-reference waves and data folder-reference waves) is 0.

If selector is omitted or zero, the returned value for numeric waves is a combination of bit values shown in the following table:

<table>
<thead>
<tr>
<th>Type</th>
<th>Bit Number</th>
<th>Decimal Value</th>
<th>Hexadecimal Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>complex</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>32-bit float</td>
<td>1</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>64-bit float</td>
<td>2</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>8-bit integer</td>
<td>3</td>
<td>8</td>
<td>8</td>
</tr>
<tr>
<td>16-bit integer</td>
<td>4</td>
<td>16</td>
<td>10</td>
</tr>
</tbody>
</table>

Flags

/D If present, angles in wave data are interpreted as in degrees. Otherwise they are interpreted as in radians.
/O Overwrites input wave.
/P={param1…} Specifies parameters as appropriate for the keyword that you are using. The number of parameters and their order depends on the keyword.
/R=[startRow,endRow][startCol,endCol][startLayer,endLayer][startChunk,endChunk] Specifies the range of elements to set for the setConstant keyword.
You can omit parameters for dimensions that don’t exist in srcWave. For example, if srcWave is 1D, specify just /R=[startRow,endRow].
/V=value Specifies the value to use for the setConstant keyword. /V was added in Igor Pro 7.00.

Examples

// Produce output values in the range [-1,1]:
WaveTransform /P={(pi)} phase complexWave
// Faster than myWave=myWave>1 ? 1 : myWave
WaveTransform /P={1}/O min myWave

See Also
The Rotate operation.

</tbody>
</table>

The unsigned bit is used only with the integer types while the complex bit can be used with any numeric type. Set only one of bits 1-5 or bit 7 as they are mutually exclusive. See Setting Bit Parameters on page IV-13 for details about bit settings.

Examples

Variable waveIsComplex = WaveType(wave) & 0x01
Variable waveIs32BitFloat = WaveType(wave) & 0x02
Variable waveIs64BitFloat = WaveType(wave) & 0x04
Variable waveIs8BitInteger = WaveType(wave) & 0x08
Variable waveIs16BitInteger = WaveType(wave) & 0x10
Variable waveIs32BitInteger = WaveType(wave) & 0x20
Variable waveIs64BitInteger = WaveType(wave) & 0x80
Variable waveIsUnsigned = WaveType(wave) & 0x40

See Also

For concepts related to selector = 1 or 2, see Free Waves on page IV-89, Wave Reference Waves on page IV-76 and Data Folder Reference Waves on page IV-81.

WaveUnits

`WaveUnits(waveName, dimNumber)`

The WaveUnits function returns a string containing the units for the given dimension.

Use `dimNumber`=0 for rows, 1 for columns, 2 for layers, and 3 for chunks. Use -1 to get the data units. If the wave is just 1D, `dimNumber`=0 returns X units and 1 returns data units. This behavior is just like the WaveMetrics procedure WaveUnits found in the WaveMetrics Procedures folder in previous versions of Igor Pro.

See Also

DimDelta, DimOffset, DimSize, SetScale

wfprintf

`wfprintf refNumOrStr, formatStr [flags] waveName [, waveName]`

The wfprintf operation is like the printf operation except that it prints the contents of the named waves to a file whose file reference number is in `refNum`.

The Save operation also outputs wave data to a text file. Use Save unless you need the added flexibility provided by wfprintf.

Parameters

`refNumOrStr` is a numeric expression, a string variable or an SVAR pointing to a global string variable.

If a numeric expression, then it is a file reference number returned by the Open operation or an expression that evaluates to 1.

If `refNumOrStr` is 1, Igor prints to the history area instead of to a file.

If `refNumOrStr` is the name of a string variable, the wave contents are “printed” to the named string variable. `refNumOrStr` can also be the name of an SVAR to print to a global string:

```plaintext
SVAR sv = root:globalString
wfprintf sv, "", wave0
```

`refNumOrStr` can not be an element of a text wave.

The value of each named wave is printed to the file according to the conversion specified in `formatStr`.

`formatStr` contains one numeric conversion specification per column. See printf. If `formatStr` is " ", wfprintf uses a default format which gives tab-delimited columns. `formatStr` is limited to 800 bytes.
Flags

Note:  /R must follow the formatStr parameter directly without an intervening comma.

/R=(startX,endX)  Specifies an X range in the wave(s) to print.
/R=[startP,endP]  Specifies a point range in the wave(s) to print.

Details

As of Igor7, wfprintf supports 1D and 2D waves. Previously it supported 1D waves only.

The number of conversion characters in formatStr must exactly match the number of wave columns in all input waves. With real waves, the total number of columns is limited to 100. With complex waves, the real column and imaginary column each count as a column and the total number of columns is limited to 200.

The only conversion characters allowed are fFeEgdouxXcs (the floating point, integer and string conversion characters). You cannot use an asterisk to specify field width or precision. If any of these restrictions is intolerable, you can use fprintf in a loop.

With integer conversion characters d, o, u, x, and X, applied to floating point waves, wfprintf truncates the fractional part.

Examples

Function Example1()

  Make/O/N=10 wave0=sin(p*pi/10) // test numeric wave
  Make/O/N=10/T textWave= "row "+num2istr(p) // test text wave
  Variable refNum

  Open/P=home refNum as "output.txt" // open file for write
  wfprintf refNum, "%s = %g\r"/R=[0,5], textWave, wave0 // print 6 values each

  Close refNum

End

The resulting output.txt file contains:

row 0 = 0
row 1 = 0.309017
row 2 = 0.587785
row 3 = 0.809017
row 4 = 0.951057
row 5 = 1

Function/S NumericWaveToStringList(w)

  Wave w // numeric wave (if text, use /T here and %s below)
  String list

  wfprintf list, "%g;" w // semicolon-separated list
  return list

End

Print NumericWaveToStringList(wave0)

  0;0.309017;0.587785;0.809017;0.951057;1;0.951057;0.809017;0.587785;0.309017;

See Also

The printf operation for complete format and parameter descriptions and Creating Formatted Text on page IV-252. The Open operation about refNum and for another way of writing wave files.

The Save operation.

WhichListItem

WhichListItem(itemStr, listStr [, listSepStr [, startIndex [, matchCase]]])

The WhichListItem function returns the index of the first item of listStr that matches itemStr. listStr should contain items separated by listSepStr which typically is ";". If the item is not found in the list, -1 is returned.

Use WhichListItem to locate an item in a string containing a list of items separated by a string (usually a single ASCII character), such as those returned by functions like TraceNameList or AnnotationList, or a line from a delimited text file.

listSepStr, startIndex, and matchCase are optional; their defaults are ",", 0, and 1 respectively.
WignerTransform

Details
WhichListItem differs from FindListItem in that WhichListItem returns a list index, while FindListItem returns a character offset into a string.

listStr is searched for itemStr bound by listSepStr on the left and right.

listStr is treated as if it ends with a listSepStr even if it doesn’t.

Searches for listSepStr are always case-sensitive. The comparison of itemStr to the contents of listStr is usually case-sensitive. Setting the optional matchCase parameter to 0 makes the comparison case insensitive.

If itemStr is not found, if listStr is "", or if startIndex is not within the range of 0 to ItemsInList(listStr)-1, then -1 is returned.

In Igor6, only the first byte of listSepStr was used. In Igor7 and later, all bytes are used.

Items can be empty. In "abc;def;;ghi", the third item, whose zero-based index is 2, is empty. In ";def;;ghi;" the first and third items, whose zero-based indices are 0 and 2, are empty.

If startIndex is specified, then listStr must also be specified. If matchCase is specified, startIndex and listSepStr must be specified.

Examples
Print WhichListItem("wave0", "wave0;wave1;") // prints 0
Print WhichListItem("c", "a;b;") // prints -1
Print WhichListItem("", "a;;b;") // prints 1
Print WhichListItem("c", "a,b,c,x,c", ",") // prints 2
Print WhichListItem("c", "a,b,c,x,c", ",", 3) // prints 4
Print WhichListItem("C", "x;c;C;") // prints 2
Print WhichListItem("C", "x;c;C;", ";", 0, 0) // prints 1

WignerTransform

The WignerTransform operation computes the Wigner transformation of a 1D signal in srcWave, which is the name of a real or complex wave. The result of the WignerTransform is stored in destWave or in the wave M_Wigner in the current data folder.

Flags
/DEST=destWave Creates by default a real wave reference for the destination wave in a user function. See Automatic Creation of WAVE References on page IV-71 for details.

/GAUS=gWidth Computes the Gaussian Wigner Transform, which is a convolution of the Wigner Transform with a two-dimensional Gaussian (in the two parameters of the transform). The computation of the transform simplifies significantly when the product of the widths of the two Gaussians is unity (minimum uncertainty ellipse). gWidth uses the same units as the srcWave scaling.

/OUT=type Sets the output data type of the standard (not Gaussian) Wigner transform. The following data types are supported:
1: Complex
2: Real (default)
3: Magnitude
4: Squared magnitude

/OUT is not allowed with the Gaussian Wigner transform (/GAUS) in which the output is always real.

The /OUT flag was added in Igor Pro 8.00.
WignerTransform

/WIDE=wSize  Computes Wigner Transform and sets the transform width to wSize. This is the default transformation with wSize set to the size of srcWave.

/Z  No error reporting.

Details
The Wigner transform maps a time signal $U(t)$ into a 2D time-frequency representation:

$$W(t,v) = \int_{-\infty}^{\infty} U(t + \frac{x}{2}) U^*(t - \frac{x}{2}) e^{-2\pi i x v} dx.$$  

The computation of the Wigner transform evaluates the offset product

$$U(t + \frac{x}{2}) U^*(t - \frac{x}{2})$$

over a finite window and then Fourier transforms the result. The offset product can be evaluated over a finite window width, which can vary from a few elements of the input wave to the full length of the wave. You can control the width of this window using the /WIDE flag. If you do not specify the output destination, WignerTransform saves the results in the wave M_Wigner in the current data folder.

Although the Wigner transform is real, the output will be complex when srcWave is complex. By inspecting the complex wave you can gain some insight into the numerical stability of the algorithm. The X-scaling of the output wave is identical to the scaling of srcWave. The Y-scaling of the input wave is taken from the Fourier Transform of the offset product, which in turn is determined by the X-scaling of srcWave.

Specifically, if $dx = \text{DimDelta}(\text{srcWave}, 0)$ and srcWave has N points then $dy = \text{DimDelta}(\text{M_Wigner}, 1) = 1/(dx*N)$. WignerTransform does not set the units of the output wave.

The Ambiguity Function is related to the Wigner Transform by a Fourier Transform, and is defined by

$$A(\tau, v) = \int_{-\infty}^{\infty} U(t + \frac{\tau}{2}) U^*(t - \frac{\tau}{2}) e^{-2\pi i \tau v} dt.$$  

Convolving the Wigner Transform with a 2D Gaussian leads to what is sometimes called the Gaussian Wigner Transform or GWT. Formally the GWT is given by the equation:

$$\text{GWT}(t,v; \delta_t, \delta_v) = \frac{1}{\delta_t \delta_v} \int dt' dv' W(t',v') \exp \left\{ -2\pi \left[ \frac{(t-t')^2}{\delta_t^2} + \frac{(v-v')^2}{\delta_v^2} \right] \right\}.$$  

Computationally this equation simplifies if the respective widths of the two Gaussians satisfy the minimum uncertainty condition $\delta_t \delta_v = 1$. The /GAUS flag calculates the Gaussian Wigner Transform using your specified width, $\delta_v$, and it selects a $\delta_v$ such that it satisfies the minimum uncertainty condition.

CWT, FFT, and WaveTransform operations.

For further discussion and examples see Wigner Transform on page III-262.

References

Window

Window keyword introduces a macro that recreates a graph, table, layout, or control panel window. The macro appears in the appropriate submenu of the Windows menu. Window macros are automatically created when you close a graph, table, layout, control panel, or XOP target window. You should use Macro, Proc, or Function instead of Window for your own window macros. Otherwise, it works the same as Macro.

See Also

Macro Syntax on page IV-116 for further information.

WindowFunction

WindowFunction [/FFT=] /DEST=destWave windowKind, srcWave
The WindowFunction operation multiplies a one-dimensional (real or complex) srcWave by the named window function.
By default the result overwrites srcWave.

Parameters

srcWave A one-dimensional wave of any numerical type. See ImageWindow for windowing two-dimensional data.

windowKind Specifies the windowing function. Choices for windowKind are:
Bartlett, Blackman367, Blackman361, Blackman492, Blackman474, Cos1, Cos2, Cos3, Cos4, Hamming, Hanning, KaiserBessel20, KaiserBessel25, KaiserBessel30, Parzen, Poisson2, Poisson3, Poisson4, Riemann, and an assortment of flat-top windows listed under FFT.

See FFT for window equations and details. The equations assume that /FFT=1.

Flags

/DEST=destWave Creates or overwrites destWave with the result of the multiplication of srcWave and the window function.
When used in a function, the WindowFunction operation by default creates a real wave reference for the destination wave. See Automatic Creation of WAVE References on page IV-71 for details.

/FFT [=1] The window interval is 0...N=numpnts(srcWave). This sets the first value of srcWave to zero, but not the last value. This is appropriate for windowing data in preparation for Fourier Transforms, and is the same algorithm used by FFT.
The window interval is 0...N=numpnts(srcWave)-1 if /FFT is missing or /FFT=0. This sets the first and last value of srcWave to 0. This is the (only) algorithm that the Hanning operation uses.

Details

A “window function” alters the input data by decreasing values near the start and end of the data smoothly towards zero, so that when the FFT of the data is computed the effects of nonintegral-periodic signals are diminished. This improves the ability of the FFT to distinguish among closely-spaced frequencies. Each window function has advantages and disadvantages, usually trading off rejection of “leakage” against the ability to discriminate adjacent frequencies. For more details, see the References.

WindowFunction stores the window function’s normalization value (the average squared window value) in V_value. This is the value you would get from WaveStats’s V_rms*V_rms for a wave of srcWave’s length whose values were all equal to 1:

Make/O data = 1
WindowFunction Bartlet, data  // Bartlet allowed as synonym for Bartlett
Print V_value  // Prints 0.330709, mean of squared window values
WinList

WinList(matchStr, separatorStr, optionsStr)

The WinList function returns a string containing a list of windows selected based on the matchStr and optionsStr parameters.

Details

For a window name to appear in the output string, it must match matchStr and also must fit the requirements of optionsStr. separatorStr is appended to each window name as the output string is generated.

The name of each window is compared to matchStr, which is some combination of normal characters and the asterisk wildcard character that matches anything. For example:

- "*" Matches all window names
- "xyz" Matches window name xyz only
- "*xyz" Matches window names which end with xyz
- "xyz*" Matches window names which begin with xyz
- "*xyz*" Matches window names which contain xyz
- "abc*xyz" Matches window names which begin with abc and end with xyz

matchStr may begin with the ! character to return windows that do not match the rest of matchStr. For example:

- "!*xyz" Matches window names which do not end with xyz

The ! character is considered to be a normal character if it appears anywhere else, but there is no practical use for it except as the first character of matchStr.

optionsStr is used to further qualify the window. The acceptable values for optionsStr are:

- " " Consider all windows.
- "WIN:" The target window.
- "WIN:windowTypes" Consider windows that match windowTypes.
- "INCLUDE:includeTypes" Consider procedure windows that match includeTypes.

WinList

"INDEPENDENTMODULE:1"  Consider procedure windows that are part of any independent module as well as those that are not. Matching windows names are actually the window titles followed by " [independent module name] ".

"INDEPENDENTMODULE:0"  Consider procedure windows only if they are not part of any independent module. Matching windows names are actually the window titles, which for an external file includes the file extension, such as "WMMenus.ipf".

"FLT:1"  Return only panels that were created with NewPanel/FLT=1.
Specifying "FLT" also implies "WIN:64".

Omit FLT or use "FLT:0" to return windows that do not float (and most do not).

"FLT:2"  Return only panels that were created with NewPanel/FLT=2.
Specifying "FLT" also implies "WIN:64".

"VISIBLE:1"  Return only visible windows (ignore hidden windows).

windowTypes is a literal number. The window name goes into the output string only if it passes the match test and its type is compatible with windowTypes. windowTypes is a bitwise parameter:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Graphs</td>
</tr>
<tr>
<td>2</td>
<td>Tables</td>
</tr>
<tr>
<td>4</td>
<td>Layouts</td>
</tr>
<tr>
<td>16</td>
<td>Notebooks</td>
</tr>
<tr>
<td>64</td>
<td>Panels</td>
</tr>
<tr>
<td>128</td>
<td>Procedure windows</td>
</tr>
<tr>
<td>512</td>
<td>Help windows</td>
</tr>
<tr>
<td>4096</td>
<td>XOP target windows</td>
</tr>
<tr>
<td>16384</td>
<td>Camera windows in Igor Pro 7.00 or later</td>
</tr>
<tr>
<td>65536</td>
<td>Gizmo windows in Igor Pro 7.00 or later</td>
</tr>
</tbody>
</table>

See Setting Bit Parameters on page IV-13 for details about bit settings.

Procedure windows and help windows don't have names. WinList returns the window title instead.

includeTypes is also a literal number. The window name goes into the output string only if it passes the match test and its type is compatible with includeTypes. includeTypes is one of:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Procedure windows that are not #included.</td>
</tr>
<tr>
<td>2</td>
<td>Procedure windows included by #include &quot;someFileName&quot;.</td>
</tr>
<tr>
<td>4</td>
<td>Procedure windows included by #include &lt;someFileName&gt;.</td>
</tr>
</tbody>
</table>

or a bitwise combination of the above for more than one type of inclusion.

You can combine the WIN, INCLUDE and INDEPENDENTMODULE options by separating them with a comma.

When the INDEPENDENTMODULE option is used, the title of any procedure window that is part of an independent module will be followed by " [independent module name] ".

For example, if a procedure file contains:
WinName

#include <Axis Utilities>

A call to WinList like this:

String list = WinList("* [myIndependentModule]", ";", "INDEPENDENTMODULE:1")

will store "Axis Utilities.ipf [myIndependentModule];" in the list string, along with any other procedure windows that are part of that independent module.

When the INDEPENDENTMODULE option is omitted, the returned procedure window titles do not include any independent module name suffix, and the procedure files "visible" to WinList depend on the setting of SetIgorOption independentModuleDev (which must be done after opening the experiment):

SetIgorOption independentModuleDev=0 Consider procedure windows only if they are not part of any independent module and if they are not hidden (using #pragma hide, for example).

SetIgorOption independentModuleDev=1 Consider all procedure windows including those in independent modules or hidden.

Examples

<table>
<thead>
<tr>
<th>Command</th>
<th>Returned List</th>
</tr>
</thead>
<tbody>
<tr>
<td>WinList(&quot;*&quot;, &quot;;&quot;, &quot;;&quot;)</td>
<td>All existing non-floating windows.</td>
</tr>
<tr>
<td>WinList(&quot;*&quot;, &quot;;&quot;,&quot;WIN:3&quot;)</td>
<td>All graph and table windows.</td>
</tr>
<tr>
<td>WinList(&quot;Result_*&quot;, &quot;;&quot;, &quot;WIN:1&quot;)</td>
<td>Graphs whose names start with “Result_”.</td>
</tr>
<tr>
<td>WinList(&quot;*&quot;, &quot;;&quot;,&quot;WIN:64,FLT:1,FLT:2&quot;)</td>
<td>All floating panel windows.</td>
</tr>
<tr>
<td>WinList(&quot;*&quot;, &quot;;&quot;,&quot;INCLUDE:6&quot;)</td>
<td>All #included procedure windows.</td>
</tr>
<tr>
<td>WinList(&quot;*&quot;, &quot;;&quot;,&quot;WIN:1,INCLUDE:6&quot;)</td>
<td>All graphs and #included procedure windows.</td>
</tr>
</tbody>
</table>

See Also

Independent Modules on page IV-231. The ChildWindowList and WinType functions.

WinName

WinName(index, windowTypes [, visibleWindowsOnly [, floatKind]])

The WinName function returns a string containing the name of the indexth window of the specified type, or an empty string ("") if no window fits the parameters.

If the optional visibleWindowsOnly parameter is nonzero, only visible windows are considered. Otherwise both visible and hidden windows are considered.

If the optional floatKind parameter is 1, only floating windows created with NewPanel/FLT=1 are considered. If floatKind is 2, only NewPanel/FLT=2 windows are considered. windowTypes must contain at least 64 (panels).

If floatKind is omitted or is 0 only non-floating ("normal") windows are considered.

Procedure windows don’t have names. WinName returns the procedure window title instead.
WinRecreation

Details
index starts from zero, and returns the top-most window matching the parameters.
The window names are ordered in window-stacking order, as returned by WinList.
DoWindow/B moves the window to the back and changes the index needed to retrieve its name to the
greatest index that returns any name.
Hiding or showing a window (with SetWindow hide=1 or Notebook visible=0 or by manual means)
does not affect the index associated with the window.

windowTypes is a bitwise parameter:

1: Graphs.
2: Tables.
4: Layouts.
16: Notebooks.
64: Panels.
128: Procedure windows.
4096: XOP target windows.
16384: Camera windows in Igor Pro 7.00 or later
65536: Gizmo windows in Igor Pro 7.00 or later

See Setting Bit Parameters on page IV-13 for details about bit settings.

Examples
Print WinName(0,1)  // Prints the name of the top graph.
Print WinName(0,3)  // Prints the name of the top graph or table.
String win=WinName(0,1)  // The name of the top visible graph.
SetWindow $win hide=1  // Hide the graph (it may already be hidden).
Print WinName(0,1)  // Prints the name of the now-hidden graph.
Print WinName(0,1,1)  // Prints the name of the top visible graph.
Print WinName(0,64,1,1)  // Name of the top visible NewPanel/FLT=1 window.

See Also
WinList, DoWindow (F and /B flags), SetWindow (hide keyword), Notebook (Miscellaneous) (visible
keyword), NewPanel (/FLT flag).

WinRecreation

WinRecreation(winStr, options)
The WinRecreation function returns a string containing the window recreation macro (or style macro) for
the named window.

Parameters

winStr is the name of a graph, table, page layout, panel, notebook, Gizmo, camera, or XOP target window
or the title of a procedure window or help file. If winStr is "" and options is 0 or 1, information for the top
graph, table, page layout, panel, notebook, or XOP target window is returned.

As of Igor Pro 7.00, winStr may be a subwindow path. The returned recreation macro is generated as if the
subwindow were extracted from its host as a standalone window. See Subwindow Syntax on page III-92
for details on forming the subwindow path.

The meaning of options depends on the type of window as described in the following sections.

Target Window Details
Target windows include graphs, tables, page layouts, panels, notebooks, and XOP target windows.
If options is 0, WinRecreation returns the window recreation macro.
If options is 1, WinRecreation returns the style macro or an empty string if the window does not support
style macros.
**Graphs Details**
If `options` is 2, WinRecreation returns a recreation macro in which all occurrences of wave names are replaced with an ID number having the form `##<number>##` (for instance, `##25##`). These ID numbers can be found easily using the `strsearch` function. This is intended for applications that need to alter the recreation macro by replacing wave names with something else, usually other wave names. The ID numbers are the same as those returned by the `GetWindow` operation with the wavelist keyword.

**Graphs and Panels Details**
If `options` is 4, WinRecreation returns the window recreation macro without the default behavior of causing the graph to revert to “normal” mode (as if the GraphNormal operation had been called). This allows the use of WinRecreation when a graph or panel is in drawing tools mode without exiting that mode. For windows other than graphs or panels, this is equivalent to an `options` value of 0.

**Notebooks Details**
If `options` is -1, WinRecreation returns the same text that the Generate Commands menu item would generate with the Selected paragraphs radio button selected and all the checkboxes selected (includes text commands).

If `options` is 0, WinRecreation returns the same text that the Generate Commands menu item would generate with the Entire document radio button selected and all the checkboxes except “Generate text commands” selected.

If `options` is 1, WinRecreation returns the same text that the Generate Commands menu item would generate with the Entire document radio button selected and all the checkboxes selected (includes text commands).

Regardless of the value of `options` the text returned by WinRecreation for notebook always ends with 5 lines of file-related information formatted as comments:

```plaintext
// File Name: MyNotebook.txt
// Path: "Macintosh HD:Desktop Folder:"
// Symbolic Path: home
// Selection Start: paragraph 100, position 31
// Selection End: paragraph 100, position 31
```

**Help Windows Details**
WinRecreation returns the same 5 lines of file-related information as described above for notebooks.

Set `options` to -3 to ensure that `winStr` is interpreted as a help window title (help windows have only titles, not window names).

**Procedures Details**
WinRecreation returns the same 5 lines of file-related information as described above for notebooks.

Set `options` to -2 to ensure that `winStr` is interpreted as a procedure window title (procedure windows have only titles, not window names).

If `SetIgorOption IndependentModuleDev=1` is in effect, `winStr` can also be a procedure window title followed by a space and, in brackets, an independent module name. In such cases WinRecreation returns text from or information about the specified procedure file which is part of that independent module. (See Independent Modules on page IV-231 for independent module details.)

For example, in an experiment containing:

```plaintext
#pragma IndependentModule=myIM
#include <Axis Utilities>
```

code like this:

```plaintext
String text=WinRecreation("Axis Utilities.ipf [myIM]",-2)
```

will return the file-related information for the Axis Utilities.ipf procedure window, which is normally a hidden part of the myIM independent module.

To get the text content of a procedure window, use the `ProcedureText` function.

**Examples**

WinRecreation("Graph0",0)  // Returns recreation macro for Graph0.
WinRecreation("",1)        // Style macro for top window.
String win= WinName(0,16,1) // top visible notebook
String str= WinRecreation(str,-1) // Selected Text commands
Variable line= itemsInList(str,"\r")-5  // First file info line
Print StringFromList(line, str,"\r")  // Print File Name:
**WinType**

```
Print StringFromList(line+1, str,"\r")  // Print Path:
Print StringFromList(line+2, str,"\r")  // Print Symbolic Path:
Print StringFromList(line+3, str,"\r")  // Selection Start:
Print StringFromList(line+4, str,"\r")  // Selection End:
```

**See Also**

Saving a Window as a Recreation Macro on page II-43.

---

**WinType**

```
WinType(winNameStr)
```

The WinType function returns a value indicating the type of the named window.

**Details**

`winNameStr` is a string or string expression containing the name of a window or subwindow, or "" to signify the target window. When identifying a subwindow with `winNameStr`, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

WinType returns the following values:

- **0**: No window by that name.
- **1**: Graph
- **2**: Table
- **3**: Layout
- **5**: Notebook
- **7**: Panel
- **13**: XOP target window
- **15**: Camera window in Igor Pro 7.00 or later
- **17**: Gizmo window in Igor Pro 7.00 or later

Because command and procedure windows do not have names (they only have titles), WinType can not even be asked about those windows.

**See Also**

The **WinName**, **ChildWindowList**, and **WinList** functions.

---

**WMAxisHookStruct**

See NewFreeAxis for further explanation of WMAxisHookStruct.

```
Structure WMAxisHookStruct
    char win[200]  // Host window or subwindow name
    char axName[32]  // Name of axis
    char mastName[32]  // Name of controlling axis or ""
    char units[50]  // Axis units.
    Variable min  // Current axis range minimum value
    Variable max  // Current axis range maximum value
EndStructure
```

---

**WMBackgroundStruct**

See CtrlNamedBackground, Background Tasks on page IV-307, and Preemptive Background Task on page IV-323 for further explanation of WMBackgroundStruct.

```
Structure WMBackgroundStruct
    char name[32]  // Background task name
    UInt32 curRunTicks  // Tick count when task was called
    Int32 started  // TRUE when CtrlNamedBackground start is issued
    UInt32 nextRunTicks  // Precomputed value for next run  // but user functions may change this
EndStructure
```
WMButtonAction

This structure is passed to action procedures for button controls created using the **Button** operation.

Structure WMButtonAction

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>char ctrlName[32]</td>
<td>Control name</td>
</tr>
<tr>
<td>char win[200]</td>
<td>Host window or subwindow name</td>
</tr>
<tr>
<td>STRUCT Rect winRect</td>
<td>Local coordinates of host window</td>
</tr>
<tr>
<td>STRUCT Rect ctrlRect</td>
<td>Enclosing rectangle of the control</td>
</tr>
<tr>
<td>STRUCT Point mouseLoc</td>
<td>Mouse location</td>
</tr>
<tr>
<td>Int32 eventCode</td>
<td>See details below</td>
</tr>
<tr>
<td>Int32 eventMod</td>
<td>See Control Structure eventMod Field on page III-418</td>
</tr>
<tr>
<td>String userData</td>
<td>Primary unnamed user data</td>
</tr>
<tr>
<td>Int32 blockReentry</td>
<td>See Control Structure blockReentry Field on page III-418</td>
</tr>
</tbody>
</table>

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

WMButtonAction eventCode Field

Action functions should respond only to documented eventCode values. Other event codes may be added in the future.

The event code passed to the button action procedure has the following meaning:

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-2</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-1</td>
<td>Control being killed</td>
</tr>
<tr>
<td>1</td>
<td>Mouse down</td>
</tr>
<tr>
<td>2</td>
<td>Mouse up</td>
</tr>
<tr>
<td>3</td>
<td>Mouse up outside control</td>
</tr>
<tr>
<td>4</td>
<td>Mouse moved</td>
</tr>
<tr>
<td>5</td>
<td>Mouse enter</td>
</tr>
<tr>
<td>6</td>
<td>Mouse leave</td>
</tr>
<tr>
<td>7</td>
<td>Mouse dragged while outside the control</td>
</tr>
</tbody>
</table>

Events 2 and 3 happen only after event 1.

Events 4, 5, and 6 happen only when the mouse is over the control but happen regardless of the mouse button state.

Event 7 happens only when the mouse is pressed inside the control and then dragged outside.

WMCheckboxAction

This structure is passed to action procedures for checkbox controls created using the **CheckBox** operation.

Structure WMCheckboxAction

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>char ctrlName[32]</td>
<td>Control name</td>
</tr>
<tr>
<td>char win[200]</td>
<td>Host window or subwindow name</td>
</tr>
<tr>

</tr>
<tr>
<td>String userData</td>
<td>Primary unnamed user data</td>
</tr>
<tr>
<td>Int32 blockReentry</td>
<td>See Control Structure blockReentry Field on page III-418</td>
</tr>
<tr>
<td>Int32 checked</td>
<td>Checkbox state</td>
</tr>
</tbody>
</table>

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

WMCheckboxAction eventCode Field

Action functions should respond only to documented eventCode values. Other event codes may be added in the future.
The event code passed to the checkbox action procedure has the following meaning:

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-2</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-1</td>
<td>Control being killed</td>
</tr>
<tr>
<td>2</td>
<td>Mouse up</td>
</tr>
</tbody>
</table>

**WMCustomControlAction**

This structure is passed to action procedures for custom controls created using the **CustomControl** operation.

```c
struct WMCustomControlAction {
    char ctrlName[32]; // Control name
    char win[200]; // Host window or subwindow name
    STRUCT Rect winRect; // Local coordinates of host window
    STRUCT Rect ctrlRect; // Enclosing rectangle of the control
    STRUCT Point mouseLoc; // Mouse location
    int32 eventCode; // See details below
    int32 eventMod; // See Control Structure eventMod Field on page III-418
    string userData; // Primary unnamed user data
    int32 blockReentry; // See Control Structure blockReentry Field on page III-418
    int32 missedEvents; // TRUE when events occurred but the user function was not available for action
    int32 mode; // General purpose
    // Used only when eventCode==kCCE_frame
    int32 curFrame; // Input and output
    // Used when eventCode is kCCE_mousedown, kCCE_mousemove, kCCE_mouseenter or kCCE_mouseleave
    int32 needAction; // See Below for details
    // These fields are valid only with value=varName
    int32 isVariable; // TRUE if varName is a variable
    int32 isWave; // TRUE if varName referenced a wave
    int32 isString; // TRUE if varName is a String type
    SVAR sVal; // Valid if isVariable and not isString
    WAVE nWave; // Valid if isWave and not isString
    WAVE/T sWave; // Valid if isWave and isString
    int32 rowIndex; // If isWave, this is the row index
    char rowLabel[32]; // Wave row label
    // These fields are valid only when eventCode==kCCE_char
    int32 kCharCode; // Keyboard key character code
    int32 specialKeyCode; // See Keyboard Events on page IV-291 - Added in Igor Pro 7
    char keyText[16]; // UTF-8 string representing key struck - Added in Igor Pro 7
    int32 kbMods; // Keyboard key modifiers bit field. See details below.
} EndStructure
```

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

**WMCustomControlAction eventCode Field**

When determining the state of the eventCode member in the WMCustomControlAction structure, the various values you use are listed in the following table. You can define the kCCE symbolic constants by adding this to your procedure file:

```c
#include <CustomControl Definitions>
```

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kCCE_mousedown</td>
<td>Mouse down in control.</td>
</tr>
<tr>
<td>kCCE_mouseup</td>
<td>Mouse up in control.</td>
</tr>
<tr>
<td>kCCE_mousemove</td>
<td>Mouse moved (happens only when mouse is over the control).</td>
</tr>
<tr>
<td>kCCE_mousemove_out</td>
<td>Mouse moved outside control.</td>
</tr>
</tbody>
</table>
### Event Code Description

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kCCE_enter = 5</td>
<td>Mouse entered control.</td>
</tr>
<tr>
<td>kCCE_leave = 6</td>
<td>Mouse left control.</td>
</tr>
<tr>
<td>kCCE_mouseDraggedOutside = 7</td>
<td>The mouse moved while it was outside the control. This event is delivered only after the mouse is pressed inside the control and dragged outside. While the mouse is inside the control, kCCE_mousedraggedoutside is delivered whether the mouse button is up or down.</td>
</tr>
<tr>
<td>kCCE_draw = 10</td>
<td>Time to draw custom content.</td>
</tr>
<tr>
<td>kCCE_mode = 11</td>
<td>Sent when executing CustomControl name, mode=m.</td>
</tr>
<tr>
<td>kCCE_frame = 12</td>
<td>Sent before drawing a subframe of a custom picture.</td>
</tr>
<tr>
<td>kCCEDispose = 13</td>
<td>Sent as the control is killed.</td>
</tr>
<tr>
<td>kCCE_modernize = 14</td>
<td>Sent when dependency (variable or wave set by value=varName parameter) fires. It will also get draw events, which probably don’t need a response.</td>
</tr>
<tr>
<td>kCCE_tab = 15</td>
<td>Sent when user tabs into the control. If you want keystrokes (kCCE_char), then set needAction.</td>
</tr>
<tr>
<td>kCCE_char = 16</td>
<td>Sent on keyboard events. Stores the keyboard character in kbChar and modifiers bit field is stored in kbMods. Sets needAction if key event was used and requires a redraw.</td>
</tr>
<tr>
<td>kCCE_drawOSBM = 17</td>
<td>Called after drawing pict from picture parameter into an offscreen bitmap. You can draw custom content here.</td>
</tr>
<tr>
<td>kCCE_idle = 18</td>
<td>Idle event typically used to blink insertion points etc. Set needAction to force the control to redraw. Sent only when the host window is topmost.</td>
</tr>
</tbody>
</table>

### WMCustomControl needAction Field

The meaning of needAction depends on the event.

- Events kCCE_mousedraggedoutside, kCCE_enter, kCCE_leave, and kCCE_mouseDraggedOutside set needAction to TRUE to force redraw, which is normally not done for these events.
- Events kCCE_tab and kCCE_mousedown set needAction to TRUE to request keyboard focus (and get kCCE_char events).
- Event kCCE_idle sets needAction to TRUE to request redraw.

### WMCustomControl kbMods Field

- Bit 0: Command (Macintosh)
- Bit 1: Shift
- Bit 2: Alpha Lock. Not supported in Igor7 or later.
- Bit 3: Option (Macintosh) or Alt (Windows)
- Bit 4: Control (Macintosh) or Windows key (Windows).

### WMDrawUserShapeStruct

See DrawUserShape for further explanation of WMDrawUserShapeStruct.

Structure WMDrawUserShapeStruct

```c
SInt32 options   // Input: Value from /MO flag.
// Output: When action is getInfo, set bits as follows:
// Set bit 0 if the shape should behave like a simple line.
// When resizing end-points, you will get live updates.
// Set bit 1 if the shape is to act like a button;
```
WMFitInfoStruct

// You will get mouse down in normal operate mode.
// Set bit 2 to get rollover action.
// If 1, normal operate mode
// (only if options bit 1 or 2 was set during getInfo).
SInt32 operateMode // Input: If 0, the shape is being edited;
// if 1, normal operate mode
PointF mouseLoc // Input: The location of the mouse in normalized coordinates.
SInt32 doSetCursor // Output: If action is hitTest, set true
// to use the following cursor number.
// Also used for mouseMoved in rollover mode.
SInt32 cursorCode // Output: If action is hitTest and doSetCursor is set,
// then set this to the desired Igor cursor number.
double x0, y0, x1, y1 // Input: Coordinates of the enclosing rectangle of the shape.
RectF objectR // Input: Coordinates of the enclosing rectangle of the shape
// in device units.
char winName[MAX_HostChildSpec+1] // Input: Full path to host subwindow

// Information about the coordinate system
Rect drawRect // Draw rect in device coordinates
char xcName[MAX_OBJ_NAME+1] // Name of X coordinate system, may be axis name
char ycName[MAX_OBJ_NAME+1] // Name of Y coordinate system, may be axis name
double angle // Input: Rotation angle, use when displaying text
String textString // Input: Use or ignore; special output for "getInfo"
String privateString // Input and output: Maintained by Igor
// may be binary; special output for "getInfo"

EndStructure

WMFitInfoStruct

See The WMFitInfoStruct Structure on page III-242 for further explanation of WMFitInfoStruct.
Structure WMFitInfoStruct
char IterStarted // Nonzero on the first call of an iteration
char DoingDestWave // Nonzero when called to evaluate autodest wave
char StopNow // Fit function sets this to nonzero to
// indicate that a problem has occurred
// and fitting should stop
Int32 IterNumber // Number of iterations completed
Int32 ParamPerturbed // See The WMFitInfoStruct Structure on page III-242

EndStructure

WMGizmoHookStruct

See Gizmo Named Hook Functions on page II-404 for further explanation of WMGizmoHookStruct.
Structure WMGizmoHookStruct
Int32 version
char winName[MAX_HostChildSpec+1] // Full path to host window or subwindow
char eventName[32]
Int32 width
Int32 height
Int32 mouseX
Int32 mouseY
Variable xmin
Variable xmax
Variable ymin
Variable ymax
Variable zmin
Variable zmax
Variable eulerA
Variable eulerB
Variable eulerC
Variable wheelDx
WMListboxAction

This structure is passed to action procedures for listbox controls created using the ListBox operation.

Structure WMListboxAction
  char ctrlName[32] // Control name
  char win[200] // Host window or subwindow name
  STRUCT Rect winRect // Local coordinates of host window
  STRUCT Rect ctrlRect // Enclosing rectangle of the control
  STRUCT Point mouseLoc // Mouse location
  Int32 eventCode // See details below
  Int32 eventMod // See Control Structure eventMod Field on page III-418
  String userData // Primary unnamed user data
  Int32 blockReentry // See Control Structure blockReentry Field on page III-418
  Int32 row // Selection row. See ListBox for details.
  Int32 col // Selection column. See ListBox for details.
  WAVE/T listWave // List wave specified by ListBox command
  WAVE selWave // Selection wave specified by ListBox command
  WAVE colorWave // Color wave specified by ListBox command
  WAVE/T titleWave // Title wave specified by ListBox command

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

WMListboxAction eventCode Field

Action functions should respond only to documented eventCode values. Other event codes may be added in the future.

The event code passed to the listbox action procedure has the following meaning:

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-2</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-1</td>
<td>Control being killed.</td>
</tr>
<tr>
<td>1</td>
<td>Mouse down.</td>
</tr>
<tr>
<td>2</td>
<td>Mouse up.</td>
</tr>
<tr>
<td>3</td>
<td>Double click.</td>
</tr>
<tr>
<td>4</td>
<td>Cell selection (mouse or arrow keys).</td>
</tr>
<tr>
<td>5</td>
<td>Cell selection plus Shift key.</td>
</tr>
<tr>
<td>6</td>
<td>Begin edit.</td>
</tr>
<tr>
<td>7</td>
<td>Finish edit.</td>
</tr>
<tr>
<td>8</td>
<td>Vertical scroll. See Scroll Event Warnings on page V-459.</td>
</tr>
<tr>
<td>9</td>
<td>Horizontal scroll by user or by the hScroll=h keyword.</td>
</tr>
<tr>
<td>10</td>
<td>Top row set by row=r or first column set by col=c keywords.</td>
</tr>
<tr>
<td>11</td>
<td>Column divider resized.</td>
</tr>
<tr>
<td>12</td>
<td>Keystroke, character code is place in row field.</td>
</tr>
<tr>
<td>13</td>
<td>Checkbox was clicked. This event is sent after selWave is updated.</td>
</tr>
</tbody>
</table>

WMListboxAction row and col Fields

The row field is the row number of selection in interior or -1 if in title area.
The col field is the column number of the selection.

The meanings of row and col are different for eventCodes 8 through 11:

<table>
<thead>
<tr>
<th>Code</th>
<th>row</th>
<th>col</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>top visible row</td>
<td>horiz shift in pixels.</td>
</tr>
<tr>
<td>9</td>
<td>top visible row</td>
<td>horiz shift (user scroll).</td>
</tr>
<tr>
<td>-1</td>
<td>horiz shift (hScroll keyword).</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td>top visible row</td>
<td>-1 (row keyword).</td>
</tr>
<tr>
<td>-1</td>
<td>first visible col</td>
<td>(col keyword).</td>
</tr>
<tr>
<td>11</td>
<td>column shift</td>
<td>column resized by user.</td>
</tr>
</tbody>
</table>

If eventCode is 11, row is the horizontal shift in pixels of the column col that was resized, not the total horizontal shift of the list as reported in V_horizScroll by ControlInfo. If row is negative, the divider was moved to the left. col=0 corresponds to adjusting the divider on the right side of the first column. Use ControlInfo to get a list of all column widths.

**WMMarkerHookStruct**

See Custom Marker Hook Functions on page IV-299 for further explanation of WMMarkerHookStruct.

Structure WMMarkerHookStruct

```c
    int32 usage // 0= normal draw, 1= legend draw
    int32 marker // Marker number minus start
    float x, y // Location of desired center of marker
    float size // Half width/height of marker
    int32 opaque // 1 if marker should be opaque
    float penThick // Stroke width
    struct RGBColor mrkRGB // Fill color
    struct RGBColor eraseRGB // Background color
    struct RGBColor penRGB // Stroke color
    struct Rect ywave // Trace's y wave
    double ywIndex // Point number on ywave where marker is being drawn
EndStructure
```

**WMPopupAction**

This structure is passed to action procedures for popup menu controls created using the PopupMenu operation.

Structure WMPopupAction

```c
    char ctrlName[32] // Control name
    char win[200] // Host window or subwindow name
    struct Rect winRect // Local coordinates of host window
    struct Rect ctrlRect // Enclosing rectangle of the control
    struct Point mouseLoc // Mouse location
    int32 eventCode // See details below
    int32 eventMod // See Control Structure eventMod Field on page III-418
    string userData // Primary unnamed user data
    int32 blockReentry // See Control Structure blockReentry Field on page III-418
    int32 popNum // Item number currently selected or hovered over (1-based)
    char popStr[MAXCMDLEN] // Contents of current popup item or item hovered over
EndStructure
```

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

**WMPopupAction eventCode Field**

Action functions should respond only to documented eventCode values. Other event codes may be added in the future.
The event code passed to the pop-up menu action procedure has the following meaning:

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-2</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-1</td>
<td>Control being killed</td>
</tr>
<tr>
<td>2</td>
<td>Mouse up</td>
</tr>
<tr>
<td>3</td>
<td>Hovering - sent when the user highlights a menu item by moving the mouse cursor over it but hasn’t selected it</td>
</tr>
</tbody>
</table>

**WMSetVariableAction**

This structure is passed to action procedures for SetVariable controls created using the SetVariable operation.

```
Structure WMSetVariableAction
    char ctrlName[32] // Control name
    char win[200]    // Host window or subwindow name
    STRUCT Rect winRect // Local coordinates of host window
    STRUCT Rect ctrlRect // Enclosing rectangle of the control
    STRUCT Point mouseLoc // Mouse location
    Int32 eventCode // See details below
    Int32 eventMod // See Control Structure eventMod Field on page III-418
    String userData // Primary unnamed user data
    Int32 blockReentry // See Control Structure blockReentry Field on page III-418
    Int32 isStr // TRUE for a string variable
    Variable dval // Numeric value of variable
    char sval[MAXCMDLEN] // Value of variable as a string
    char vName[MAX_OBJ_NAME+2 + (MAXDIMS * (MAX_OBJ_NAME+5)) + 1] // Valid if using wave
    WAVE svWave
    Int32 rowIndex // Row index for a wave if rowLabel is empty
    char rowLabel[MAX_OBJ_NAME+1] // Wave row dimension label
    Int32 colIndex // Column index for a wave if colLabel is empty
    char colLabel[MAX_OBJ_NAME+1] // Wave column dimension label
    Int32 layerIndex // Layer index for a wave if layerLabel is empty
    char layerLabel[MAX_OBJ_NAME+1] // Wave layer label
    Int32 chunkIndex // Chunk index for a wave if chunkLabel is empty
    char chunkLabel[MAX_OBJ_NAME+1] // Wave chunk label
    Int32 mousePart // Part of the control where mouse down occurred
EndStructure
```

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

**WMSetVariableAction eventCode Field**

Action functions should respond only to documented eventCode values. Other event codes may be added in the future.

The event code passed to the SetVariable action procedure has the following meaning:

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-2</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-1</td>
<td>Control being killed</td>
</tr>
<tr>
<td>1</td>
<td>Mouse up</td>
</tr>
<tr>
<td>2</td>
<td>Enter key</td>
</tr>
<tr>
<td>3</td>
<td>Live update</td>
</tr>
<tr>
<td>4</td>
<td>Mouse scroll wheel up</td>
</tr>
<tr>
<td>5</td>
<td>Mouse scroll wheel down</td>
</tr>
<tr>
<td>6</td>
<td>Value changed by dependency update</td>
</tr>
</tbody>
</table>
Event code -1 is never sent to an old-style (non-structure parameter) action procedure.

Event code 1 is sent when the mouse is released after clicking the up-arrow or down-arrow buttons. It is also sent for value changes caused by the mouse scroll wheel for a non-live mode control.

Event codes 4 and 5 are sent only for string SetVariables or numeric SetVariables whose increment setting is zero. Otherwise the value change is signaled by event code 1.

For numeric SetVariables whose increment is non-zero, the mouse scroll wheel acts like a mouse click on the up-arrow button or down-arrow button. That is, event code 1, mouse up, is more like "value changed".

Event code 6 is by default sent to only structure-based action procedures.

Use SetIgorOption EnableSVE6=0 to disable sending this event at all and EnableSVE6=2 to send the event to both structure-based and old-style SetVariable action procedures. The default for EnableSVE6 is =1.

The mousePart field is valid for mouse down, mouse scroll wheel, live update, and Enter key events only:

<table>
<thead>
<tr>
<th>Value</th>
<th>Mouse Part</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A part other than 1, 2, or 3 - most likely the title</td>
</tr>
<tr>
<td>1</td>
<td>The up-arrow button on a numeric SetVariable via a mouse click on the button or the use of the up-arrow key</td>
</tr>
<tr>
<td>2</td>
<td>The down-arrow button on a numeric SetVariable via a mouse click on the button or the use of the down-arrow key</td>
</tr>
<tr>
<td>3</td>
<td>The value field</td>
</tr>
</tbody>
</table>

WMSliderAction

This structure is passed to action procedures for slider controls created using the \texttt{Slider} operation.

```plaintext
Structure WMSliderAction
    char ctrlName[32] // Control name
    char win[200] // Host window or subwindow name
    STRUCT Rect winRect // Local coordinates of host window
    STRUCT Rect ctrlRect // Enclosing rectangle of the control
    STRUCT Point mouseLoc // Mouse location
    Int32 eventCode // See details below
    Int32 eventMod // See Control Structure eventMod Field on page III-418
    String userData // Primary unnamed user data
    Int32 blockReentry // See Control Structure blockReentry Field on page III-418
    Variable curval // Value of slider
EndStructure
```

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

WMSliderAction eventCode Field

Action functions should respond only to documented eventCode values. Other event codes may be added in the future.

The event code passed to slider action procedure has the following meaning:

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-2</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-1</td>
<td>Control being killed</td>
</tr>
<tr>
<td>2</td>
<td>Mouse down but value was not set</td>
</tr>
<tr>
<td>3</td>
<td>Value set by mouse down</td>
</tr>
</tbody>
</table>
This function shows how to detect when the slider value has been set:

```plaintext
Function SliderProc(sa) : SliderControl
    STRUCT WMSliderAction &sa
    switch(sa.eventCode)
        case 3: // Value set by mouse down
            Variable curval = sa.curval
            Printf "Value set: eventCode=%d, value=%g\r", sa.eventCode, curval
            break
        case 9: // Value set by dragging mouse or arrow key
            Variable curval = sa.curval
            Printf "Value set: eventCode=%d, value=%g\r", sa.eventCode, curval
            break
        default:
            Printf "Other event: eventCode=%d\r", sa.eventCode
            break
    endswitch
    return 0
End
```

This structure is passed to action procedures for tab controls created using the `TabControl` operation.

**Structure WMTabControlAction**

- `char ctrlName[32]` // Control name
- `char win[200]` // Host window or subwindow name
- `STRUCT Rect winRect` // Local coordinates of host window
- `STRUCT Rect ctrlRect` // Enclosing rectangle of the control
- `Int32 eventCode` // See details below
- `Int32 eventMod` // See **Control Structure eventMod Field** on page III-418
- `String userData` // Primary unnamed user data
- `Int32 blockReentry` // See **Control Structure blockReentry Field** on page III-418
- `Int32 tab` // Tab number

EndStructure

The constants used to specify the size of structure char arrays are internal to Igor Pro and may change.

**WMTabControlAction eventCode Field**

Action functions should respond only to documented eventCode values. Other event codes may be added in the future.

The event code passed to tab control action procedure has the following meaning:

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-2</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-1</td>
<td>Control being killed</td>
</tr>
<tr>
<td>2</td>
<td>Mouse up</td>
</tr>
</tbody>
</table>

**WMWinHookStruct**

See **Named Window Hook Functions** on page IV-286 for further explanation of WMWinHookStruct.

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>-3</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-2</td>
<td>Control received keyboard focus (Igor8 or later)</td>
</tr>
<tr>
<td>-1</td>
<td>Control being killed</td>
</tr>
<tr>
<td>2</td>
<td>Mouse up</td>
</tr>
</tbody>
</table>

```plaintext
Structure WMWinHookStruct
    char winName[200] // Host window or subwindow name
    STRUCT Rect winRect // Local coordinates of the affected (sub)window
    STRUCT Point mouseLoc // Mouse location
    Variable ticks // Tick count when event happened
    Int32 eventCode // See **Named Window Hook Events** on page IV-286
    char eventName[32] // See **Named Window Hook Events** on page IV-286
    Int32 eventMod // See **Control Structure eventMod Field** on page III-418
    char menuName[256] // Name of the menu item as for SetIgorMenuMode
```
wnoise

wnoise(shape, scale)

The wnoise function returns a pseudo-random value from the two-parameter Weibull distribution characterized by the shape and scale, the respective gamma and alpha parameters. The two-parameter Weibull probability distribution function is

\[ f(x;\alpha,\gamma) = \frac{\gamma}{\alpha x^{\gamma-1}} \exp\left(-\frac{1}{\alpha} x^\gamma\right) \quad \alpha > 0 \]
\[ \gamma > 0 \]

The mean of the Weibull distribution is

\[ \frac{1}{\alpha^\gamma} \Gamma\left(1 + \frac{1}{\gamma}\right) \]

and the variance is

\[ \frac{2}{\alpha^\gamma} \Gamma\left(1 + \frac{2}{\gamma}\right) - \alpha^\gamma \left[ \frac{1}{\Gamma\left(1 + \frac{1}{\gamma}\right)} \right]^2. \]

Note that this definition of the PDF uses different scaling than the one used in StatsWeibullPDF. To match the scaling of StatsWeibullPDF multiply the result from Wnoise by the factor scale^(1-1/shape).

The random number generator initializes using the system clock when Igor Pro starts. This almost guarantees that you will never repeat a sequence. For repeatable “random” numbers, use SetRandomSeed. The algorithm uses the Mersenne Twister random number generator.

See Also
The SetRandomSeed operation.

Noise Functions on page III-372.
Chapter III-12, Statistics for a function and operation overview.

x

x

The x function returns the scaled row index for the current point of the destination wave in a wave assignment statement. This is the same as the X value if the destination wave is a vector (1D wave).

Details
Outside of a wave assignment statement, x acts like a normal variable. That is, you can assign a value to it and use it in an expression.
See Also
The function and Waveform Arithmetic and Assignments on page II-69.

x2pnt

\[ x2pnt(waveName, x1) \]
The x2pnt function returns the integer point number on the wave whose X value is closest to \( x1 \).
For higher dimensions, use ScaleToIndex.

See Also
DimDelta, DimOffset, pnt2x, ScaleToIndex
For an explanation of waves and X scaling, see Changing Dimension and Data Scaling on page II-63.

xcsr

\[ xcsr(cursorName[, graphNameStr]) \]
The xcsr function returns the X value of the point which the named cursor (A through J) is on in the top or named graph.

Parameters
cursorName identifies the cursor, which can be cursor A through J.
graphNameStr specifies the graph window or subwindow.

When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on forming the window hierarchy.

Details
The result is derived from the wave that the cursor is on, not from the X axis of the graph. If the wave is displayed as an XY pair, the X axis and the wave’s X scaling will usually be different.

See Also
The hcsr, pcsr, qcsr, vcsr, and zcsr
tions.

Programming With Cursors on page II-256.

XLLoadWave

\[ XLLoadWave[flags][fileNameStr] \]
The XLLoadWave operation loads data from the named Excel .xls, .xlsx or .xlsm file into waves.
XLLoadWave does not support .xslb files and can not load password-protected Excel files.

Parameters
The file to be loaded is specified by fileNameStr and /P=pathName where pathName is the name of an Igor symbolic path. fileNameStr can be a full path to the file, in which case /P is not needed, a partial path relative to the folder associated with pathName, or the name of a file in the folder associated with pathName. If XLLoadWave can not determine the location of the file from fileNameStr and pathName, it displays a dialog allowing you to specify the file.

If you use a full or partial path for fileNameStr, see Path Separators on page III-429 for details on forming the path.

If fileNameStr is omitted or is "", or if the /I flag is used, XLLoadWave presents an Open File dialog from which you can choose the file to load.

Flags

/A Automatically assigns arbitrary wave names using "wave" as the base name. Skips names already in use.

/A=baseName Same as /A but it automatically assigns wave names of the form baseName0, baseName1.
### XLLoadWave

**/C=columnName**

XLLoadWave will use the Deduce from Row method of determining the type of the Excel file columns, using the row specified by `columnName` to deduce column types. See Deduce from Row on page II-145.

**/COLT=columnNameStr**

`columnNameStr` specifies how XLLoadWave should treat each column. For example, "IT3N" means 1 text column followed by 3 numeric columns. See Determining Wave Types on page V-1023.

**/D**

Creates double-precision floating point waves. If omitted, XLLoadWave creates single-precision floating point waves.

**/F=f**

New programming should use the `/I` flag instead of the `/D`, `/L` and `/F` flags.

`f` specifies the data format of the file:

- `f=1`: Signed integer (8, 16, 32 bits allowed)
- `f=2`: Creates double-precision waves
- `f=3`: Floating point (default, 32, 64 bits allowed)

**/I**

Forces XLLoadWave to display an Open File dialog even if the file is fully specified via `/P` and `fileNameStr`.

**/J=infoMode**

If `infoMode` is 1, 2 or 3, XLLoadWave does not load the file but instead returns information about the worksheets within the workbook via the string variable `S_value`. See Getting Information About the Excel File on page V-1024.

**/K=k**

Discards waves with fewer than `k` points. For historical reasons, `k` defaults to 2.

**/N**

Same as `/A` except that, instead of choosing names that are not in use, it overwrites existing waves.

**/N=baseName**

Same as `/N` except that it automatically assigns wave names of the form `baseName0`, `baseName1`.

**/NAME=nameList**

`nameList` is a semicolon-separated list of wave names to be used for the loaded waves. See Wave Names on page V-1023 for details.

**/O**

Overwrites existing waves in case of a name conflict.

**/P=pathName**

Specifies the folder to look in for `fileNameStr`. `pathName` is the name of an existing symbolic path.

**/Q**

 Suppresses the normal messages in the history area.

**/R=(cell1,cell2)**

Restricts loading to the specified cells, e.g. `/R=(A3,D21)`. Row and column numbers start from 1.

The `/R` flag supports an optional extra parameter that should be used only in very rare cases. XLLoadWave reads the range of defined cells from the file itself and clips `cell1` and `cell2` to that range.

In very rare cases the file does not accurately identify the range of defined cells so the clipping prevents loading cells that exist in the file. In this rare case, use `/R=(cell1, cell2,1)`. The last parameter tells XLLoadWave to skip the clipping. If you specify incorrect values for `cell1` or `cell2` you may get errors or garbage results.

**/S=fileNameStr**

Specifies which worksheet to load from a workbook file. If you omit `/S=fileNameStr`, or if `fileNameStr` is "", XLLoadWave loads the first worksheet in the workbook.

**/T**

Automatically creates a table of loaded waves.
The names of the loaded waves are determined by the /A, /N, /W and /NAME flags. If all of the flags are omitted, default names, like ColumnA and ColumnB, are used.

If /W=w is present, names are loaded from row \( w \) of the worksheet and then converted to standard Igor names by replacing spaces and punctuation characters with underscores.

If /NAME=nameList is present, the wave names come from nameList, a semicolon-separated list of names. For example:

/NAME="StartTime;UnitA;UnitB;"

The names in nameList can be standard or liberal names. For example, this specifies names two standard names and one liberal name which contains a space:

/NAME="Signal;Ambient Temp;Response;"

If a name in the list is _skip_, the corresponding Excel column is skipped. For example, this would load the first and third columns and skip the second:

/NAME="Signal;_skip_;Response;"

If a name in the list is empty, the name used for the corresponding wave is as it would be if /NAME were omitted. This can be used to skip columns while taking wave names from the spreadsheet for loaded columns. In this example, the names of the first and third waves would be determined by row 1 of the spreadsheet while the second column would be skipped:

/W=1 /NAME=";_skip_;;"

The /N flag instructs Igor to automatically name new waves "wave", or baseName if /N=baseName is used, plus a number. The number starts from zero and increments by one for each wave loaded from the file. If the resulting name conflicts with an existing wave, the existing wave is overwritten.

The /A flag is like /N except that it skips names already in use.

/NAME overrides /W, /A or /N overrides both /NAME and /W.

No matter how the wave names are generated, if there is a name conflict and overwrite is off (/O is omitted), a unique name is generated. See XLLoadWave and Wave Names on page II-146 for further details.

Determining Wave Types
The /C or /COLT flag tells XLLoadWave how to decide what kind of wave, numeric, text, or date/time, to make for each Excel column.

Using /C=columnType causes XLLoadWave to use the Deduce from Row method of determining the type of the Excel file columns. columnType is the Excel row number that XLLoadWave should use to make the deduction.

Using /COLT=columnTypeStr causes XLLoadWave treat the columns based on the columnTypeStr parameter. If columnTypeStr is "N", XLLoadWave uses the Treat all Columns as Numeric method. If columnTypeStr is "T", XLLoadWave uses the Treat all Columns as Text method. If columnTypeStr is "D", XLLoadWave uses the Treat all Columns as Date method.

For any other value of columnTypeStr, XLLoadWave uses the Use Column Type String method. For example, "1T5N" tells XLLoadWave to create a text wave for the first column and numeric waves for the next 5 or more columns.

If you omit /C and /COLT, XLLoadWave uses the Treat all Columns as Numeric method.

See What XLLoadWave Loads on page II-144 for further details.
Output Variables
XLLoadWave sets the following output variables:

- **V_flag**  
  Number of waves loaded.

- **S_fileName**  
  Name of the file being loaded.

- **S_path**  
  File system path to the folder containing the file.

- **S_waveNames**  
  Semicolon-separated list of the names of loaded waves.

- **S_worksheetName**  
  Name of the loaded worksheet within the workbook file.

- **S_value**  
  Set only if you use the /J flag. See Getting Information About the Excel File below.

S_path uses Macintosh path syntax (e.g., "hd:FolderA:FolderB:"), even on Windows. It includes a trailing colon.

When XLLoadWave presents an Open File dialog and the user cancels, V_flag is set to 0 and S_fileName is set to ""

Getting Information About the Excel File
The /J flag allows you to get information about an Excel file without actually loading it.

If **infoMode** is 1, XLLoadWave does not load the file but instead returns a semicolon-separated list of the names of the worksheets within the workbook via the string variable S_value.

If **infoMode** is 2, XLLoadWave does not load the file but instead returns information about the first worksheet or the worksheet specified by /S via the string variable S_value. The format of the returned information is:

```
NAME:<worksheet name>;FIRSTROW:<first row>;FIRSTCOL:<first col>;LASTROW:<last row>;LASTCOL:<last col>
```

<first row> and <last row> are 1-based row numbers. <first col> and <last col> are 1-based column numbers; 1 refers to Column A. These refer to the defined rows and columns in the worksheet even if some or all cells are blank. If <last col> is zero, this means that there are no defined cells in the worksheet.

If **infoMode** is 3, XLLoadWave does not load the file but instead returns information about the first worksheet or the worksheet specified by /S via the string variable S_value. The format of the returned information is:

```
NAME:<worksheet name>;FIRST:<first cell>;LAST:<last cell>
```

<first cell> and <last cell> are expressed in standard Excel notation (A1, B24, etc.). These refer to the defined rows and columns in the worksheet even if some or all cells are blank. If <last cell> is "@0", this means that there are no defined cells in the worksheet.

Use the **StringByKey**, **NumberByKey** functions to extract the information from S_value. If you use these functions, your code won't break if we later add a keyword/value pair to the returned information.

Examples
Old versions of Excel came with a number of sample files. One of them was called “Instrument Data”. The following procedure loads an area of this file, makes a table and then makes a graph of the loaded waves.

This example assumes that you have the "Instrument Data.xls" file and a symbolic path named Science that points to the folder containing the file.

Function InstrumentData()
```
// Load Instrument Data file from the Scientific Analysis folder
XLLoadWave/O/T/R=(C9,M27)/W=8/C=9/P=Science "Instrument Data.xls"

// Make graph.
Display M1, M2, M3 vs X_Time
Label bottom, "Time"; Label left, "Mass"
ModifyGraph dateInfo(bottom)={1,0,0}
End
```

See also Loading Excel Data Into a 2D Wave on page II-147.
XWaveName

XWaveName(graphNameStr, traceNameStr)
The XWaveName function returns a string containing the name of the wave supplying the X coordinates
for the named trace in the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on
forming the window hierarchy.
traceNameStr is the name of the trace in question.

Details
XWaveName returns an empty string ("") if the trace is not plotted versus an X wave.
For most uses, we recommend that you use XWaveRefFromTrace instead of WaveName. XWaveName
returns a string containing the wave name only, with no data folder path qualifying it. Thus, you may get
erroneous results if the X wave referred to in the graph has the same name as a different wave in the current
data folder. Likewise, if the named wave resides in a folder that is not the current data folder, you will not
be able to refer to the named wave.

graphNameStr and traceNameStr are strings, not names.

Examples
Display ywave vs xwave // XY graph
Print XWaveName("",ywave") // prints xwave

See also
Trace Names on page II-222, Programming With Trace Names on page IV-86.

XWaveRefFromTrace

XWaveRefFromTrace(graphNameStr, traceNameStr)
The XWaveRefFromTrace function returns a wave reference to the wave supplying the X coordinates
against which the named trace is displayed in the named graph window or subwindow.

Parameters

graphNameStr can be "" to refer to the top graph window.
When identifying a subwindow with graphNameStr, see Subwindow Syntax on page III-92 for details on
forming the window hierarchy.

Details
XWaveRefFromTrace returns a null reference (see WaveExists) if the wave is not plotted versus an X wave.

graphNameStr and traceNameStr are strings, not names.

Examples
Display ywave vs xwave // XY graph
Print XWaveRefFromTrace("",ywave")[50] // prints value of xwave at point 50

Trace Names on page II-222, Programming With Trace Names on page IV-86.
The \( y \) function returns the Y value for the current column of the destination wave when used in a multidimensional wave assignment statement. \( y \) is the scaled column index whereas \( q \) is the column index itself.

**Details**
Unlike \( x \), outside of a wave assignment statement, \( y \) does not act like a normal variable.

**See Also**
\( x, z, \) and \( t \) functions for other dimensions.
\( p, q, r, \) and \( s \) functions for the scaled indices.

### \( Z \)

The \( z \) function returns the Z value for the current layer of the destination wave when used in a multidimensional wave assignment statement. \( z \) is the scaled layer index whereas \( r \) is the layer index itself.

**Details**
Unlike \( x \), outside of a wave assignment statement, \( z \) does not act like a normal variable.

**See Also**
\( x, y, \) and \( t \) functions for other dimensions.
\( p, q, r, \) and \( s \) functions for the scaled indices.

### \( \texttt{zcsr} \)

\[
\texttt{zcsr(cursorName [, graphNameStr])}
\]

The \texttt{zcsr} function returns a Z value when the specified cursor is on a contour, image, or waterfall plot. Otherwise, it returns NaN.

**Parameters**
- \texttt{cursorName} identifies the cursor, which can be cursor A through J.
- \texttt{graphNameStr} specifies the graph window or subwindow.

When identifying a subwindow with \texttt{graphNameStr}, see **Subwindow Syntax** on page III-92 for details on forming the window hierarchy.

**Examples**
- \texttt{Print zcsr("A")} // not zcsr("A")
- \texttt{Print zcsr("A", "Graph0")} // specifies the graph

**See Also**
The \texttt{hcsr}, \texttt{pcsr}, \texttt{qcsr}, \texttt{vcsr}, and \texttt{xcsr} functions.

**Programming With Cursors** on page II-256.

### \( \texttt{zeta} \)

\[
\texttt{zeta(a, b [, terms ])}
\]

The \texttt{zeta} function returns the Hurwitz Zeta function for real or complex arguments \( a \) and \( b \)

\[
\zeta(a,b) = \sum_{k=0}^{\infty} \frac{1}{(k+b)^a},
\]

\( \Re(a) > 1, \)

\( b \neq 0, -1, -2, ... \)

The Riemann \texttt{zeta} function is the special case:
\[ \zeta(a) = \zeta(a,1). \]

The zeta function was added in Igor Pro 7.00.

**Parameters**
The `terms` parameter defaults to 40. In practice evaluation may terminate before the specified number of terms when convergence is achieved.

**References**

**See Also**
Dilogarithm

**ZernikeR**

\[ \text{ZernikeR}(n, m, r) \]

The `ZernikeR` function returns the Zernike radial polynomials of degree \( n \) that contains no power of \( r \) that is less than \( m \). Here \( m \) is even or odd according to whether \( n \) is even or odd, and \( r \) is in the range 0 to 1.

Note that the full circle polynomials are complex. For any angle \( t \) (theta), they are given by:

\[ \text{ZernikeR}(n, m, r) \ast \exp(imt). \]
